If you don't specify the audit server connection string, the session player attempts to bind to an appropriate audit management database. The session player can replay sessions from only one audit store, but the audit store ID is optional because sessions usually reside in a single audit store. An individual session can span multiple audit store databases within a single audit store. If a session spans multiple audit stores, that is, different subnets or sites, you should specify which audit store to play it from.

The timestamp option is a 32-bit integer that tells the session player to jump to the point where the event of interest occurred.

Using the Uniform Resource Identifier (URI)

The Uniform Resource Identifier identifies the session player, the installation name, and the session GUID for each session. This format is especially useful when used with the **Copy Session URI** menu item. The URI link can then be pasted into an email or instant messenger message. On a computer where Audit Analyzer is installed, the recipient can simply click on the URI link and the session player starts automatically.

Playing Back a Session from a Web Browser

On computers that have Audit Analyzer installed, you can also play back sessions from a web browser. Because the cda:// protocol is automatically registered on the computer with Audit Analyzer, you can use a web browser to replay a specific session. If you want to play back a session from a web browser, you can extract the installation and session identifier from the session URI.

To get the installation and session identifier:

1. Select a session and right-click or open the session in the session player, then select **File > Copy Session URI**.

2. Open a text editor and paste the session URI into the file.
3. Delete the portion of the URI that identifies the player, so that only the installation and the object GUID remain.

   For example, if the URI looks like this:

   rep://myInstallation/b62bc280-678c-439a-aec3-09a9b7ee4395

   Remove the first part of the URI so that you only have the installation name and session identifier:

   //myInstallation/b62bc280-678c-439a-aec3-09a9b7ee4395

To play back a specific session from a web browser:

1. Open a web browser.
2. Type the installation name and session ID in the address bar of the web browser:

   cda://‹*installationName*›/‹*session_id*›

   For example:

   cda://myInstallation/b62bc280-678c-439a-aec3-09a9b7ee4395

   The session player opens and plays the specified session.

Exporting Sessions

Depending on whether you have selected the **Enable video capture auditing option** for an installation, you might have different options for exporting session data to a file. The options available also depend on whether the session activity was captured on an audited Windows computer or an audited UNIX computer.

To view your export options, select the session and right-click or open the session in the session player, then click the File menu. Depending on the session type or installation settings, you might see the following export options:

Export to Command List

Exports the time stamp and UNIX shell commands as comma separated values (csv) in a text file. The file contains the same information as displayed in the Indexed Command List for UNIX sessions.

Export to Event List

Exports the time stamp, application name, and other details as separated values (csv) in a text file. The file contains the same information as displayed in the Indexed Event List for Windows sessions.

Copy Session URI

Copies the URI of the selected session to the clipboard. You can then paste the URI into a web browser to open the session.

Check Session Data Integrity

Checks the session for any possible data tampering. If the session is fine, a message displays that the data integrity check passed. If the session has been tampered with, a message displays with details of what data was affected.

Export to TXT

Saves the selected UNIX session(s) or UNIX session(s) and user input (stdin) as a plain text file.

If you selected multiple sessions, a message displays that asks you if you want to export the multiple sessions to a single file. Click **Yes** to save the sessions in a single file or **No** to save the sessions in separate files.

If you select the Export Session with User Inputs option, user input is noted with a line number of K or "keyboard" input.

Export Detailed Executions

Saves the session in HTML, PDF, CSV, or XML format if you have enabled advanced monitoring and the session includes any detailed executions.

Export to CDF

Saves the selected Windows session in Computable Document Format. You can then open the CDF file with the session player (daplayer *filename*.cdf). Because the session player reads the session information directly from the CDF file, you don't need to specify an installation name or connect to a database to replay the session.

Export to WMV

Saves the selected session in Microsoft Windows Media Video format. You can use Windows Media Player or other media players to play back sessions in this format. However, sessions exported to WMV files do not include the summary information such as the user name, the computer name, start and end times, or the list of events captured.

Deleting Sessions

Auditing allows you collect detailed information about activity in your organization. In some cases, however, you might have sessions that collect information that you are not interested in capturing or include information that you don't want to store or make available to other auditors. For example, you might find there are sessions with very little activity or sessions that have been reviewed and are no longer needed. You might also notice that there are sessions that captured personally-identifying or medical data that other auditors should not be allowed to see. To handle these cases, you can selectively delete sessions from the audit store database.

In most cases, if you are the Master Auditor or have been granted permission to change the status of a session, you can mark sessions for deletion in Audit Analyzer. As noted in Reviewing and deleting your own sessions, however, you might be prevented from deleting your own sessions if the installation-level setting prevents users from deleting their own sessions.

To delete a specific session:

1. Open Audit Analyzer console, then use a predefined or custom query to find the sessions that you want to delete.
2. Select the sessions that you want to delete.
3. Right-click, then select **Delete**.

   Audit Analyzer displays a confirmation message indicating that the deletion cannot be reversed.
4. Click **Yes** to continue.

To delete all sessions in a query:

1. Open Audit Analyzer, right-click a query node, then select **Delete All Sessions**.

   Audit Analyzer prompts you to confirm the deletion of all sessions returned by the query.
2. Click **Yes** to continue.

   Audit Analyzer prompts you to confirm the deletion of sessions with a review status of To be Reviewed or Pending for Action.
3. Click **Yes** to delete those sessions, or click **No** to continue the deletion of other sessions but preserve the sessions marked for retention.

   While the delete operations runs, you can click Stop Delete if needed. Sessions are partially deleted up until the point where the delete operation was cancelled.

Viewing Sessions Outside of Audit Analyzer

You can view audited sessions while working in other Centrify management consoles. For example, on computers that have Audit Analyzer and Access Manager installed, you can start the session player from Access Manager or from Active Directory Users and Computers. You can also launch the session player by itself or from a web page or a software program.

Viewing Sessions from Access Manager

On computers where both the Access Manager console and the Audit Analyzer console are installed, you can search for and view sessions directly from the Access Manager console.

To view audited sessions in Access Manager:

1. Navigate to a computer, user, or role assignments node in the left pane of Access Manager.
2. In the right pane, right-click the object and select **View DirectAudit Sessions**.
3. Specify any additional criteria, then click **Find**.

Viewing Sessions in Active Directory Users and Computers

On computers where you have Active Directory Users and Computers with Access Manager properties and Audit Analyzer, you can view audited sessions directly from Active Directory Users and Computers.

To view audited sessions from Active Directory Users and Computers:

1. Navigate to the Users node in the left pane of the Active Directory Users and Computers.
2. In the right pane, right-click the user and select **All Tasks > View DirectAuditSessions**.
3. Specify any additional criteria, then click **Find**.

Using Find Sessions

Find Sessions is a separate executable file, installed in the same directory as Audit Analyzer, that you can use to find and open audited sessions. The program provides a graphical user interface and a command line interface for specifying the search criteria. You can use either interface to find sessions of interest. From the Find Sessions graphical user interface, you can also replay, update the review status, view the desktops used for any sessions found, display the list of indexed commands or events, and copy the session URI.

To start Find Sessions from the Windows command line, you can type the following in a Command prompt window:

findsessions /ia

Specifying the Sessions to Find

You can use the Common or Advanced search criteria to find sessions of interest. The Find Sessions dialog box then displays the results that match the criteria you specify. In most cases, you can find the sessions you are interested in through some combination of user name, computer name, and session time displayed on the Common tab. If you want to specify additional criteria, such as review status or auditor name, you can click the Advanced tab.

Using the Command Line Interface

You can run Find Sessions as a command line utility on computers where Audit Analyzer is installed. The command line interface can be useful, for example, if you may want to find, export, or delete sessions as part of a script. You can view usage information for the command line interface using the /help option. Specify search criteria for finding sessions using the following format:

findsessions /i="*InstallationName*" /u="*username*" /m="*computerName*" /t="*yyyyMM-dd*"

Using a web browser to access sessions

On computers that have Audit Analyzer installed, you can also find and play back sessions from a web browser. Because the cda:// protocol is automatically registered on the computer with Audit Analyzer, you can use a web browser to open Find Sessions or to replay a specific session. For example, you can embed a cda:// link in a web page to automatically generate a list of sessions, or you might want to embed a link to a session or set of sessions in a web-based report or event notification.

You must be able to specify a query using AQL syntax to open Find Sessions from a web browser. If you want to start playing back a session from a web

browser, you must know the session identifier. You can extract the session identifier from the session URI.

To start Find Sessions from a web browser:

1. Open a web browser.
2. Type the installation name and a search string using AQL syntax in the address bar of the web browser.

   For example, if you want to search an installation named MyInstallation5 for sessions that involved the Administrator user, you would type the following in the address bar:

   cda://DefaultInstallation5/?search=\"1 user=\"Administrator*\"\"
3. Click **Allow** to open the Find Sessions with the Advanced tab displayed and "user=Administrator*" listed for the Define Criteria.
4. Click **Find Now** to find sessions matching the criteria you specified.

For more information about using Find Sessions, see the Find Sessions help.

Using Tags with Sessions

Tags can be a helpful way to quickly find sessions that meet particular criteria, such as sessions that contain PII (Personally Identifiable Information). You can add one or more keywords to sessions and then use those keywords in your session queries to find those specific audited sessions.

Assigning Tags to Sessions

You can assign tags to sessions or remove tags from sessions if you're assigned to an audit role with "Update Status" permission. To apply multiple tags, separate each tag by a space.

You can use assign one or more keywords to sessions in the following ways:

- In the Audit Analyzer query results pane, right-click a session > select **Add Tags**.

  In this way, you tag the session itself and not a specific point in time of the session.

- In a session's Indexed Command List, select a command and select **Add Tags**.

  When adding a tag this way, the tag is associated with a specific timestamp in the session.

- While replaying a session, select **Session** > **Add Tags**.

  When adding a tag this way, the tag is associated with a specific timestamp in the session if you have paused the session. If you are playing the session when you add a tag, the tag isn't associated with a timestamp.

- Use the PowerShell cmdlets to tag sessions. For details, please see the PowerShell command help for the following cmdlets:

  - New-CdaAuditSessionTag
  - Get-CdaAuditSessionTag
  - Remove-CdaAuditSessionTag
  - Get-CdaAuditSession

When you add tags, each tag is a single word; to add multiple tags, just separate them with a space. Each tag needs to be at least 3 characters long.

Viewing Tags Associated with a Session

You can view tags that are associated with a session if you're assigned to an audit role with "Read" permission. You can also remove the tag after reviewing the session, if you also have the "Update Status" permission.

To view tags associated with a session

1. In Audit Analyzer, navigate to a list of sessions.
2. Right-click a session and select **Properties**.

   The Session Properties dialog box opens.
3. Click the **Tags** tab.

   The Tags tab lists all tags and related information that are associated with the selected session. In addition to tags, you can also see who added the tag to the session and when they added the tag.
4. If desired, you can click **Remove** to remove the associated tag or **Replay** to replay the session.
5. Click **OK** to save your changes and return to the Audit Analyzer window.

Searching for Sessions Associated with Tags

You can enter tags as search criteria for either quick queries, private, or shared queries. For a quick query, enter the tag name as the search term.

For a private or shared query, when you add criteria for the query you can select Tag as an attribute to use in the query.

Advanced Monitoring

The Centrify Audit & Monitoring Service captures input and output for audited users and commands and then uses this information to provide a history of executed commands.

However, you may want to gather additional information about which users and what programs are accessing or modifying production systems. For example, you may want to know when any user runs a highly privileged program, even if the user runs it from a script or by modifying system configuration files. You can use advanced monitoring to capture these kinds of activities.

One of the big differences in advanced monitoring is that you can track when *any* user performs a particular activity, not just an audited user.

Advanced monitoring uses the Linux system auditing tools to capture the following user and program activity:

When *any* user executes a particular program, not just audited users.	Audit Analyzer Linux agent syslog Monitored Execution report Monitored Execution List	yes
When *any* user (not just audited users) attempts to modify system configuration files in monitored directories specified by an administrator.	Audit Analyzer Linux agent syslog File Monitor report	yes
Which programs are executed in an audited session, *regardless of how the program is invoked*-- whether it's run by way of a script, the use of a command alias, and so forth.	Audit Analyzer Detailed Execution report	no - there would be too many events for the information to be useful.

Set up Advanced Monitoring

To configure advanced monitoring, make sure that your computer meets the requirements, make some configuration changes in the centrifyda.conf file, and then enable advanced monitoring either by using the dacontrol command or the "Enable Advanced Monitoring" group policy.

Advanced Monitoring Requirements

- Currently, Centrify supports only 64-bit Linux distributions from RedHat (RHEL, Fedora, CentOS). For more information about supported platforms and versions, please refer to the current Audit & Monitoring Service release notes.
- Verify that you have the Linux audit package running. For example, run this command:

  ```
  rpm -qa audit
  ```

- Ensure that the Linux audit package that you have is supported for use with Centrify Audit & Monitoring Service. Version 1.2.8 or later of Linux audit package is required. However, the Audit & Monitoring Service prefers the Linux audit package version 2.4.5 or later because earlier versions may have issues with startup.
- Ensure that your collector and audit store database are running Server Suite 2017 or 2017.1, or Infrastructure Services 2017.2 or later.

Configuring Advanced Monitoring

You have some options and choices as to how you configure advanced monitoring. To use any of these parameters, you must also enable advanced monitoring (by using the dareload -m command or the "Enable Advanced Monitoring" group policy). Here's a list of the configuration parameters that you can edit in the centrifyda.conf file:

- **event.file.monitor**

  Use the event.file.monitor parameter to enable advanced monitoring for configuration files.

- **event.file.monitor.process.skiplist**

  For any areas that you've specified to monitor (using event.file.monitor), use the event.file.monitor.process.skiplistparameter to ignore any specific

processes in those areas.

- **event.file.monitor.user.skiplist**

  Use the event.file.monitor.user.skiplist parameter to specify a list of users to exclude from advanced monitoring for files. For these users, the auditing service does not record any write access to directories specified in event.file.monitor.

- **event.execution.monitor**

  Use the event.execution.monitor parameter to monitor all programs that users run in an audited session.

- **event.monitor.commands**

  Use the event.monitor.commands parameter to specify a list of commands to monitor. Be sure to list each command using the full path name of the command. The auditing service generates an audit trail event when a user runs any of these monitored commands, unless the user is listed in the event.monitor.commands.user.skiplist parameter.

- **event.monitor.commands.user.skiplist**

  Use the event.execution.monitor.user.skiplist parameter to specify a list of users to exclude from advanced monitoring for program execution. For these users, the auditing service does not record any programs that they run, even when the parameter event.execution.monitor is set to true.

After you make the configuration changes in the centrifyda.conf file, run the dareload -m command to apply the changes.

Enabling Advanced Monitoring

After you've made your configuration changes in the centrifyda.conf file, the next step is to enable advanced monitoring.

To enable advanced monitoring:

- Run the following command:

  dacontrol -m

- Or, use the Enable Advanced Monitoring group policy.

To disable advanced monitoring:

- Run the following command:

  dacontrol -n

- Or, discontinue using the Enable Advanced Monitoring group policy.

Using the Advanced Monitoring Reports

These reports provide details on what your advanced monitoring configuration has tracked:

- **Monitored execution report**

  If you have configured your auditing installation for advanced monitoring, then this Monitored Execution Report provides a detailed record of the sessions where a user ran one of the commands that you've configured to monitor. This report shows who ran one of the monitored commands even if that person is not an audited user. Also, this report includes information on commands that are run individually or as part of scripts.

- **Detailed execution report**

  If you have configured your auditing installation to perform advanced monitoring, then this Detailed Execution report shows all of the commands being executed on the audited machines—including commands that are run as part of scripts or other commands.

- **File monitor report**

  The File Monitor report shows the sensitive files being modified by users on the audited machines. The File Monitor report includes any activity by any user (except root) in the following protected areas on audited computers:

  - /etc/

- /var/centrifydc/
- /var/centrifyda/
- /var/centrify/

Troubleshooting and Common Questions

This chapter describes how to view and manage log files and diagnostics for components of the auditing infrastructure on UNIX computers. This chapter also describes how to identify and resolve common problems you might encounter when auditing user activity or managing the auditing infrastructure.

Checking the Status of the UNIX Agent

After you install and enable auditing for a UNIX computer, you can check the status of the agent using the dainfo command to verify the connection to the correct installation. For example, the agent might not automatically connect to the installation if you use an installation name other than DefaultInstallation.

To check the status of the agent and the auditing infrastructure, run the following command as a user with root privileges:

```
dainfo --diag
```

The `--diag` option returns detailed information about the local computer and about the installations, audit stores, trusted collectors, trusted agents, and the active audit store database that the agent is sending its data to. The diagnostic output also includes details about the Active Directory location and object identifier for each installation.

Configuring the Installation for an Agent

If the command indicates that the status is offline or the installation is not configured, use dacontrol to explicitly identify the correct installation. For example:

```
dacontrol -i installation_name
```

You can then rerun `dainfo --diag` to verify the installation is configured correctly. Note that you cannot use `dacontrol` to connect to a different installation name if the installation is configured using the Installation group policy. In a secure installation, the Installation group policy identifies the Active Directory location that contains the service connection point object for the installation. If you are not using group policy to identify the installation, you can manually configure agents and collectors to use a specific installation name.

Checking for Disconnected Agents using Audit Manager

You can also use Audit Manager to see the status of all agents in the installation. I any agent is listed as Disconnected, you should check whether the audited computer is shut down, If the audited computer is not shut down, the agent might be outside the scope of any audit store or unable to find a collector. Use the diagnostic services to check communication between components.

Starting and Stopping the UNIX Agent

In most cases, the UNIX agent is automatically started when an audited computer is first powered on and remains running until the audited computer is shut down. Starting the agent when a computer starts up ensures the agent can capture activity for all shell sessions.

Although you typically start and stop the dad process as part of a computer's startup and shutdown scripts, you can also start the agent directly from the command line on a local computer.

If the agent is not running, run the following command to start it:

```
/usr/share/centrifydc/bin/centrifyda start
```

Detecting the Server Suite Installation Status

If you're encountering any issues with your Server Suite installation, you can run the `dacheck` program on your UNIX computers. The `dacheck` command detects the following errors in your Server Suite installation:

- Auditing binaries linkage problems
- Disk space
- DNS, collector, dad, adclient health
- Logging status
- Auditing file permissions/ownership
- Auditing installation configuration
- If ActiveDirectory joined
- Auditing database integrity
- If root in user.ignore and other criteria that affect root login

- var/centrifyda, /tmp write permission
- nsswitch.conf (or method.cfg, user.cfg for AIX)
- Selinux status
- Nscd (pwgrd) status
- User's cdax/real shell existence, permission, ownership.
- DNS Reverse lookup for collector's hostname
- Report Domain Controller

To check the status of the agent and the auditing infrastructure, run the following command as a user with root privileges:

- dacheck

The dacheck command is available in the same location as the adcheck command: /usr/share/centrifydc/bin.

Viewing and Changing Log File Settings

Log files are text files that record information about operations performed by auditing components on a local computer. If you have administrative privileges on a computer, you can open log files with any text editor.

You can view log files, change the location of the log file, and change the level of detail recorded in the log file from the Log Settings dialog box. Depending on the computer you are using, there are different ways to open the Log Settings.

Enabling Detailed Logging for Linux and UNIX Computers

In most cases, troubleshooting auditing-related issues requires information about the operation of the agent, the collector service, and database activity. For performance reasons, you should only enable agent logging when you need to capture detailed information about agent operations. For troubleshooting purposes, however, you can use the dadebug command to turn on detailed logging.

To enable audit-related logging on audited Linux or UNIX computers

1. Switch to the root user.
2. Run the dadebug clear command to remove any existing detailed logging from previous operations.

   ```
   dadebug clear
   ```

3. Run the dadebug on command to enable detailed logging on for audit-related agent operations.

   ```
   dadebug on
   ```

   Detailed messages are recorded in the /var/log/centrifydc.log file. You can view the contents of the log file with a text editor. In most cases, however, you should collect additional information and send all of the logged information to Delinea Support.

4. Restart the auditing service.

   ```
   /usr/share/centrifydc/bin/centrifyda restart
   ```

5. Run the dainfo diagnostic command and save the output to a text file.

   ```
   dainfo --diag > /tmp/dainfo.txt
   ```

6. Run the adinfo diagnostic command and save the output to a text file.

   ```
   adinfo --diag > /tmp/adinfo.txt
   ```

7. Stop detailed logging of audit-related activity.

   ```
   dadebug off
   ```

8. Send an email to Delinea Support with the log files and the agent configuration file as an attachment.

   /var/log/centrifydc.log /tmp/dainfo.txt /tmp/adinfo.txt /etc/centrifyda/centrifyda.conf

To check whether detailed logging is enabled:

1. Run dadebug without parameters to see if detailed logging is currently enabled.

```
dadebug
```

Centrify DirectAudit debug logging is on.

2. Run addebug without parameters to see if detailed logging is currently enabled.

```
addebug
```

3. Run addebug off to disable logging, if needed.

Enabling Detailed Logging for the Collector Service

If you are troubleshooting an auditing-related issue, you should enable detailed logging for the collector service on the computers where the collector service runs.

To enable detailed logging on a collector:

1. Log on to a computer with a collector service.
2. Click **Start > All Programs > Centrify Server Suite 2021.1 > Centrify Audit & Monitoring Service > Audit Collector Control Panel** to open the Collector Control Panel.
3. Click the **Troubleshooting** tab.
4. Click **Options**, change the logging level to **Trace messages**, then click **Apply**.
5. Note the log folder location or click **Browse** to specify a different location for the log file, then click **OK**.
6. Click **View Log** to view the current log file.

   From the log file window, you can also click File > Save As to save the log file.
7. Click **Close** to close the Collector Control Panel.
8. Send an email to Centrify Support with the log file from the location specified in Step 5 as an attachment.
9. Open the Collector Control Panel, click the **Troubleshooting** tab, click **Options**, change the logging level back to its default setting of **Informational messages**, then click **OK**.

Enabling Detailed Logging for Auditing Consoles

In most cases, troubleshooting auditing-related issues requires information about the operation of the agent and the collector or database activity. However, in some cases, it might be necessary to capture detailed information about the operation of Audit Manager or Audit Analyzer.

To capture detailed information for Audit Manager:

1. Log on to a computer with the Audit Manager console.
2. Click **Start > All Programs > Centrify Server Suite 2021.1 > Audit Manager** to open the Audit Manager console.
3. Select the Audit Manager node, right-click, then click **Log Settings**.
4. Change the logging level to **Trace messages**, then click **Apply**.
5. Note the log folder location or click **Browse** to specify a different location for the log file, then click **OK**.
6. Send an email to Centrify Support with the log file from the location specified in Enabling detailed logging for the collector service as an attachment.
7. Right-click Audit Manager, click **Log Settings**, change the logging level back to its default setting of **Warning messages**, then click **OK**.

To capture detailed information for Audit Analyzer:

1. Log on to a computer with the Audit Analyzer console.
2. Click **Start** > **All Programs** > **Start > All Programs > Centrify Server Suite 2021.1 > Audit Analyzer**> to open the Audit Analyzer console.
3. Select the Audit Analyzer node, right-click, then click **Options**.
4. Change the logging level to **Trace messages**, then click **Apply**.
5. Note the log folder location or click **Browse** to specify a different location for the log file, then click **OK**.
6. Send an email to Centrify Support with the log file from the location specified in Enabling detailed logging for the collector service as an attachment.
7. Right-click Audit Analyzer, click **Options**, change the logging level back to its default setting of **Warning messages**, then click **OK**.

Tracing Database Operations

Database traces are used to help diagnose problems in the management database or audit store databases. For example, database traces can help to identify inconsistencies caused by hardware errors or network interruptions. After you enable database tracing, Audit Manager tracks all of the SQL statements and debug messages from the audit management database or audit store, and records the information in the database server.

> **Note**: Tracing database operations affects database performance. You should only activate a database trace if you require this information for troubleshooting. Before you start a database trace, try to reduce the load on the database instance as much as possible, then only perform the actions needed to reproduce the issue you are troubleshooting. Turn off database tracing as soon as you have logged the activity you need for the analysis of database operations. The trace for each database can take up to 800MB of server disk space. After you turn off database tracing, restart the SQL Server instance to reset the disk space.

Starting a Database Trace

You can start a database trace for a management database or an audit store database.

To start database tracing:

1. Open Audit Manager.
2. Select an installation name, right-click, then click **Properties**.
3. Click the **Database Trace** tab.

   This tab displays basic information about the management databases and audit store databases for the selected installation. In the Trace Status column, you can see whether tracing is enabled or disabled for each database.
4. Select a management or audit store database in the list, then click **Enable** to start tracing on the database selected.
5. Click **OK**, then perform the database actions for which you want to capture information.

Stopping the Database Trace

You should turn off database tracing immediately after you have logged the activity you need for the analysis of database operations.

To stop database tracing:

1. Open Audit Manager.
2. Select the installation name, right-click, then click **Properties**.
3. Click the **Database Trace** tab.
4. Select the management or audit store database that has tracing enabled, then click **Disable** to stop tracing on the database selected.
5. Click **Export** to save the database trace from the selected databases to a file with comma-separated values (.csv).
6. Follow the prompts displayed in the Export Database Trace wizard to save the information to a file.

Exporting the Database Trace for a Management Database

The Export Database Trace wizard prompts you for different information depending on whether the database trace is for a management database or an audit store database. For example, if you generate a database trace for a management database then click **Export**, the Export Database Trace wizard prompts you for user accounts.

To export the database trace:

1. Select a start date and time for the **From** filter and an end date and time for the **To** filter, then click **Next**.
2. Click **Add** to search for and select users, then click **Next**.

   By default, you can search for users in the entire directory, you can click **Object Types** or **Locations** to change the scope of the search scope, or click **Advanced** specify other criteria.
3. Accept the default folder location or click **Browse** to select a different location, then click **Next**.
4. Review your selections, then click **Next**.

By default, the wizard save the file as *installation_name*.csv and opens the file location.

5. Click **Finish**, then click **OK** to close the installation properties.

Exporting the database trace for audit store databases

When you select an audit store from the lower area of the **Database Trace** tab on the **Properties** page and click the lower **Export** button, the wizard opens with a date/time **Export Criteria** page. On the second page, the wizard asks you to pick the domain and computer.

To export the database trace:

1. Select a start date and time for the **From** filter and an end date and time for the **To** filter, then click **Next**.
2. Click **Add** to search for and select collectors, then click **Next**.

   By default, you can search for computers in the entire directory, you can click **Object Types** or **Locations** to change the scope of the search scope, or click **Advanced** specify other criteria.
3. Click **Add** to search for and select management database computers, then click **Next**.
4. Accept the default folder location or click **Browse** to select a different location, then click **Next**.
5. Review your selections, then click **Next**.

   By default, the wizard save the file as *audit_store_name*.csv and opens the file location.
6. Click **Finish**, then click **OK** to close the installation properties.

Delegating Database Trace Management

You can delegate the authority to manage database tracing by granting the Manage Database Trace permission to other users for a management database or an audit store database.

Stopping Auditing on a Computer

Several actions can directly or indirectly stop auditing on a computer. For example:

- Someone powers down the audited computer.
- Someone logs in on the audited computer and stops the agent.
- The audited computer is moved to a different audit store, causing the initial audit store to consider the audited computer disconnected.
- The administrator checks the **Define trusted audited computer** list on the Advanced tab of an Audit Store Properties page, and does not include the audited computer on that list.

Resuming Auditing if the Agent Stops

If the dad service stops running for any reason, audited shell sessions will stop working and you will be prompted to resume or quit auditing. If you resume auditing, the cdawatch process attempts to start dad and connect to the installation. However, if you have manually stopped the dad process, for example by running /usr/share/centrifydc/bin/centrifyda stop, you must manually restart the agent.

If you decide to quit auditing when the dad service has stopped running, you are prompted to confirm that you want to terminate the session before the session ends.

Allowing Users to Log in when Auditing is Stopped

If auditing is required but the agent is not running, users might be prevented from logging in. You can log in as a user with root privileges and either restart the agent or temporarily disable auditing using `dacontrol -d` to allow users to log in.

You can also run `dainfo --diag` or check the log file to get more information. For example, if the adclient process is not running, you might be unable to restart auditing.

If you cannot immediately correct the problem, you can temporarily disable all auditing.

Determining Collector Status and Connectivity

You can use the Collector Control Panel to generate a complete diagnostic check of the collector. The diagnostic report includes detailed information about the current status of the collector and the installation and audit store to which the collector sends data.

To generate diagnostics on a collector:

1. Log on to a computer with a collector service.
2. Click **Start > All Programs > Centrify Server Suite 2021.1 > Centrify Audit & Monitoring Service > Audit Collector Control Panel** to open the Collector Control Panel.
3. Click the **Troubleshooting** tab.
4. Click **Diagnostics**.

The results display in a Diagnostic Information window. If connections are successful and components are configured correctly, you should see results similar to this:

```
Establishing connection with Collector: Success
 Getting collector's current status: Running
 Getting Collector's current Installation: DefaultInstallation (locally configured)
 Getting Collector's current Audit Store: Data Source=pysql.py.dev\\CENTRIFYSUITE;Initial Catalog=AuditStoreWindows-2018-11-02
 Machine IP address(es): 10.140.16.59
 Machine is joined to: py.dev
 Forest: py.dev
 Using Domain Controller: pydc.py.dev
 Is Global Catalog Available: True
 Using Global Catalog: pydc.py.dev
 Machine is in site: Default-First-Site-Name@py.dev
 Installations:
 DefaultInstallation
 AD Object: py.dev/Program Data/Centrify/DirectAudit/Vegas-Installation-d97d8fc9-7876-4f5b-b161-4a7b3736b8ec
 Object GUID: 1563b2e1-1ea3-4307-ac51-7c92fdf5cb8a
 Installation ID: f7b36b73-0384-4283-b6f7-63a1cdb77b17
 Audit Stores:
 AuditStoreUNIX
 Site(s): (Default-First-Site-Name@py.dev)
 Subnet(s): None configured
 Affinity: UNIX
 Trusted Agents: None configured
 Trusted Collectors: None configured
 Audit Store Active Database:

 Initial Catalog=AuditStoreWindows-2018-11-02
 Additional Connection Parameters=\<none\>
 Machine's Installation: DefaultInstallation (locally configured)
 This machine's Audit Store is 'AuditStoreWindows' based on preferred Audit Store (locally configured)
 Attempting to connect to Audit Store:
 Data Source=pysql.py.dev\\CENTRIFYSUITE
 Initial Catalog=AuditStoreWindows-2018-11-02
 Integrated Security=TRUE
 Pooling=True
 Max Pool Size=1000
 Encrypt=True
 TrustServerCertificate=True
 Additional Connection Parameters=\<none\>
 Connected to Audit Store successfully

 Done.
```

You can copy the results to a file and send them to Centrify Support for help.

Resolving Connectivity Issues between a Collector and an Audit Store

If the diagnostic report or the Collector Configuration wizard indicates that the collector cannot connect to an audit store database, check the following:

- Verify the account you logged in with has permission to add a collector.

- Verify the collector service has permission to connect to the active audit store database. You can grant this permission from Audit Manager.
- Check whether the SQL Server instance needs to be restarted. For example, make sure the SQL Server instance is not waiting for a restart to complete ASP.NET registration changes.
- Check whether there is a firewall between the collector and the SQL Server instance blocking access.
- Check whether SQL Server is configured to allow named pipes and TCP/IP connections.
- Check whether SQL Server is configured to allow remote connections.
- Compare the site or subnet that the collector is configured to use with the scope of the audit store. For example, make sure the audit store site or subnet matches the site or subnet in the audit store properties.

  AuditStore
  Site(s): (Default-First-Site-Name@pistolas.org)
  Subnet(s): None configured

Resolving Authentication Issues

If you configure the collector service to use an Active Directory account instead of the local system account, you might encounter problems with Kerberos authentication when the collector attempts to connect to the audit store database. Kerberos authentication uses the service principal names (SPN) registered for the SQL Server account to authenticate a service. When the collector (client) wants to connect to SQL Server, it locates an instance of the service, composes an SPN for that instance, connects to the service, and presents the SPN for the service to authenticate. If the collector service account does not have any SPNs, the Kerberos authentication request fails.

To resolve this problem, go to KB-1311 in the Centrify Knowledge Base, select **Attachments**, and click **View > Open > Run** to run the checkspn.vbs script on a computer that is joined to Active Directory.

> **Note**: The user who is running this command must have permission to register the SPN on the service account.

By default, this script runs in report-only mode. It checks whether the required SPNs are present on the service account in question and issues a prompt to fix it, if not. This script registers the SPN in the service account servicePrincipalName attribute in the format:

MSSQLSvc/<FQDN>:<tcpport>

Monitoring Collector Performance Counters

If you have enabled auditing and installed the collector service on a local Windows computer, you can add audit-specific performance counters to Performance Monitor to help you analyze and resolve audit-related issues. When you install the collector, the performance counters are added automatically, if you uninstall the collector, the counters are also automatically removed from Performance Monitor.

To add Server Suite performance counters:

1. Log on to a computer with a collector service.
2. Click **Start > Administrative Tools > Performance Monitor**.
3. Expand Monitoring Tools and select **Performance Monitor**.
4. Click the green plus (+) icon in the toolbar.
5. Find the Audit Collector from the list, and expand it to show the list of available performance counters.

   The performance counters generally fall into one of three categories; agent information, packet volume, and data loads. For example, if you add the counter # Connected Agent, you will be able to view the number of agents currently connected. If you add the counter # Unix Meta Message Packet, you will be able to view the number of Unix meta message packets. If you add the counter, Bytes Unix Command, you will be able to view Unix command data in bytes.
6. Choose the performance counter you would like to add and click **Add**.
7. Repeat Step 6 until you have added the counters you want to monitor.
8. Click **OK**.

Managing Microsoft SQL Server Databases

Managing an audit installation requires permission to create new SQL Server databases on a SQL Server instance. In a production environment, this is an ongoing process to keep databases small and efficient. Because the management of the audit databases is not a onetime setup operation, Delinea recommends that you have at least one dedicated SQL Server instance for the audit administrator to use. The audit administrator should also be a member of the SQL Server system administrator role to ensure full control over the databases created and archived.

Selecting SQL Server or Windows Authentication

When you configure the Microsoft SQL Server instance to use for auditing, you must specify the type of authentication to use. The appropriate type of authentication depends on how your production environment is configured. For example, if you have a firewall between components or one-way trust relationship between forests, you must allow SQL Server authentications.

To support the auditing infrastructure, you can use the following types of authentication:

- Windows authentication for creating new databases.
- Windows authentication or both SQL Server authentication and Windows authentication for connections between collectors and audit stores.
- Windows authentication or both SQL Server authentication and Windows authentication for connections between audit stores and the audit management database.
- SQL Server authentication for collectors in an untrusted forest and an audit store in a trusted forest.
- SQL Server authentication for audit store databases in a trusted forest and audit management database in an untrusted forest.

If you choose Windows authentication, you can perform actions with your own logon account or using another Windows account name and password.

Connecting to an Installation or Database

If you unable to connect to the SQL Server database, the problem might be caused by one of the following issues:

- A firewall blocking access to the SQL Server instance.
- TCP/IP has not been enabled for the SQL Server instance of SQL Server
- Remote connections have not been enabled for the SQL Server instance.

For information about areas to check, see the following article:

https://blog.sqlauthority.com/2009/05/21/sql-server-fix-error-provider-named-pipes-provider-error-40-could-not-open-a-connection-to-sql-server-microsoft-sql-server-error/

Assigning the Service Principal name for SQL Server

If you get error messages when performing database operations, such as creating a new audit management database using Audit Manager, the problem is likely because the service principal name (SPN) for the SQL Server instance is assigned to the wrong Active Directory container.

- If the SQL Server startup account is a local system account, the appropriate container is the computer name.
- If it is any other account, the appropriate container is the SQL Server startup account.

Because authentication tries to use the first SPN it finds, make sure that no SPNs are assigned to inappropriate containers. Usually this error occurs when the administrator does not remove a manually added SPN from the Active Directory container after changing the SQL Server service account.

For help troubleshooting this problem, read the following article:

https://support.microsoft.com/en-us/help/811889/how-to-troubleshoot-the-cannot-generate-sspi-context-error-message

Publishing Installation Information in Active Directory

The default location for publishing audit installation information in Active Directory is:

domain/Program Data/Centrify/DirectAudit

In most cases, this location is accessible to any administrative user. If you cannot access the publication location, check the following:

- Make sure you have permission to publish information to Active Directory.

- Verify that the publication location exists in Active Directory.
- Check the network for problems.

Moving a service connection point from its published location can result in connection problems. If you delete the default publication location and add a new publication location, you might not have permissions on the new location. If you do not have the appropriate permissions on the new location, ask the Active Directory administrator to grant you such permissions before running any of the wizards to reconfigure agents and collectors.

> **Note**: A new location might not be reflected immediately in the list current published locations. However, this has no any adverse effects apart from not being able to see the published location.

Monitoring File System Disk Space Usage

Like most software applications, Centrify Agents require adequate disk space to be available to operate properly. For example, agents read and write temporary files to authenticate processes and ensure data integrity. If your operating system does not have enough disk space to accommodate these temporary files, the agent might be unable to run and prevent users from logging on or activity from being audited.

To prevent problems with disk space allocation, you should monitor key directories, such as the /tmp and /var directories, to ensure free space is available. The disk space required by different directories depends on the configuration and operating systems of the computer and the Active Directory environment. However, if any directory approaches 100% of its allocation, you should allocate more disk or remove older files to free up space for continued operation.

Command Line Programs for Managing Audited Sessions

This chapter provides an overview of the command line interface that you can use to manage audited computers. For complete reference information about the required and optional parameters for each command, see the man page provided locally on the Centrify-managed computer.

How to Use Command Line Programs

Command-line programs allow you to perform administrative tasks directly from a UNIX shell or by using a shell script. These programs are installed when you install the Centrify Agent for *NIX, and are installed by default in the following directories:

- /usr/sbin
- /usr/bin

You can use the UNIX command-line programs to take action directly on a local UNIX computer, for example to enable or disable auditing manually on a local computer. You can also use these programs to perform administrative or diagnostic tasks when it is more convenient to run them on the UNIX computer than through Audit Manager. For example, you might find it more convenient to view details about the agent configuration or diagnostic information directly on a local computer rather than through Audit Manager or the Agent Control Panel.

Displaying Usage Information and Man Pages

You can display a summary of usage information for any UNIX command-line program by typing the command plus the --help or -h option. For example, to see the usage information for the dacontrol command:

```
dacontrol --help
```

For more complete information about any command, read the command's man page. For example, to see the man page for the dacontrol command, type:

```
man dacontrol
```

Using Commands for Administrative Tasks

The command-line programs allow you to perform administrative tasks—such as enable or disable shell auditing on UNIX computers or generate diagnostic information—directly on an audited computer. The following table provides a summary of the auditing-related programs installed with the Centrify Agent for *NIX and the Centrify Client for Linux audit package. For complete information about the syntax and options for any command, see the man page for that command.

dacheck	The dacheck command performs operating system, network, and Active Directory tests to verify a computer meets the system requirements for a successful installation. For example, the install.sh script runs the dacheck program. The dacheck command is located in the same place as the adcheck command: /usr/share/centrify/dc/bin.
dacontrol	Enable or disable session or individual command auditing on a computer. You can also use this command to manually configure the audit installation to use for a local computer if you are not identifying the installation by group policy. Only users with root privileges can run the dacontrol command. Note: {/b}If the audited system is not joined to Active Directory and it is audited by way of the Centrify Client for Linux, you cannot change the audit installation with the dacontrol command.
dad	Start the dad process manually. The dad process records terminal activity on the UNIX computer and transfers the data to a collector. In most cases, it is automatically started when the computer is first booted. However, you can run this command to manually start the audit process on a local computer. Only users with root privileges can run the dad command.
dadebug	Enable or disable logging for the dad process on an audited computer. If you enable logging, the dad process writes messages to the /var/log/centrifydc.log file. If you run dadebug without specifying an option, the command returns a status message that indicates whether logging is currently enabled or disabled. Only users with root privileges can run the dadebug command.
dadiag	Display detailed information about the configuration and current auditing status for a local computer. This command displays the same information as dainfo --diag.
	Clear the auditing service in-memory cache of name service queries and installation information. If you run this command without any

daflush	arguments, it removes both auditing-related name service query results and audit installation information from the in-memory cache. If you run this command with no arguments or specify the nameservice option, the command also automatically clears the cache for common name services—such as nscd and pwgrd—if those services are running on the local computer. Clearing the cache of name service query results is useful if you make changes that would affect the results of a name service query, and want to ensure you get updated information. For example, if you remove the UNIX Login role for an Active Directory user, some information for that user might remain in the auditing service cache and be returned when you run a command such as getent passwd for that user. You can run daflush to ensure the user is removed completely from the local computer cache, including the auditing service cache. Only users with root privileges can run the daflush command.
dainfo	Display detailed information about the status and configuration of an audited computer.
dareload	Force the dad process to reload configuration properties from the /etc/centrifyda/centrifyda.conf file or the advanced monitoring properties from /etc/centrifyda/libaudit.conf. This command enables you to apply configuration changes without restarting the agent. Only users with root privileges can run the dareload command.
dashellfix.sh	Reset shells to their source shell on computers that are not being audited in an audited zone. On audited computers, the cdash shell is used to capture and forward audit data instead of the original shell. This script enables you to restore the user's original shell choice if the auditing service and wrapper shell are removed.
daspool	Display information about the size and content of the auditing-related offline cache (spool) files. If an audited computer cannot contact a collector service, it caches session, audit trail, and other information locally until a collector becomes available. This command enables you to review information about these offline cache files. Only users with root privileges can run the daspool command.

Configuring Duplicate Audit Session Cleanup

Sometimes the auditing service records duplicate sessions if your auditing installation includes one or more UNIX computers where both of the following situations occur:

- The DirectAudit agent is installed.
- A user can log in to the computer from the Admin Portal and the cloud tenant is enabled for auditing.

To avoid this situation, add the following environment variable to your /etc/centrifydc/ssh/sshd_config file:

```
AcceptEnv centrify_cip_da_data
```

Note that the above /etc/centrifydc/ssh/ path applies if you're using the Centrify OpenSSH server. If you're using a different SSH server, the file path may be different-- so be sure to update the appropriate SSH daemon configuration file for your system.

With the environment variable set, the agent uses that to verify the SSH public key of the associated tenant. That way the auditing service can determine which sessions are duplicated and remove them. Also, the agent on the UNIX computer will no longer record sessions that originate from the Admin Portal on the same computer.

Downloading the Tenant SSH Public Key

There's a script called dadownloadsshpublickey.tcl that downloads the tenant's SSH public key. With the public key and the centrify_cip_da_data environment variable, the auditing service can determine which audit sessions are duplicates and remove them.

The agent installer puts this tcl script into /usr/bin, except for CoreOS systems where the installer puts the script into /opt/centrify/bin. This script requires root privilege to run. The output file specified by dad for the script is /var/centrifyda/tenant_rsa.pub.

If da fails to download the public key or if you need to change the public key after da has started, you can manually run this tcl script.

/usr/bin/dadownloadsshpublickey.tcl --output-file /var/centrifyda/tenant_rsa.pub

Use the following options when you run this script:

- --cip, --i *‹cloud tenant URL›*

This option is optional.

If the computer is not joined to the domain currently, use this option to specify the cloud tenant URL. If you don't use this option, the script finds the URL automatically if the computer is joined to the domain.

- --output-file, -o *<file>*

  This option is required.

  Use this option to specify the output filename for the tenant's SSH public key. This file must be in a parent directory that is writable by root only and the directory cannot be a symlink.

Installing the UNIX Agent on Remote Computers

In most cases, you install the UNIX agent locally on a computer using the install.sh script interactively. You can install the UNIX agent on remote computers using the install.sh script and a configuration file or using virtually any software distribution or package installer program. This chapter provides an overview of these alternatives for installing the agent on UNIX or Linux computers.

Installing the Agent Silently using a Configuration File

You can automate agent installation by running the install.sh script in non-interactive mode:

```
install.sh -n
```

In this mode, the script uses configuration details specified in the centrifyda-install.cfg file. If this file is not found, the install.sh script uses its built-in default values.

To specify configuration values, edit the sample centrifyda-install.cfg file in its default location, or create a new text file with the same name, and then run the install.sh script.

In the file, INSTALL=Y installs the agent, and INSTALL=U upgrades the agent.

By default, the script returns an exit code of 0 if the operation is successful. To return exit codes that provide more detailed information about the result, use:

install.sh -n --custom_rc

CODE_SIN=0	Successful install
CODE_SUP=0	Successful upgrade
CODE_SUN=0	Successful uninstall
CODE_NIN=24	Did nothing during install
CODE_NUN=25	Did nothing during uninstall
CODE_EIN=26	Error during install
CODE_EUP=27	Error during upgrade
CODE_EUN=28	Error during uninstall
CODE_ESU=29	Error during setup; for example, unsupported operating environment or invalid arguments

Using Other Programs to Install the UNIX Agent

Auditing-related files are bundled with the core Centrify Agent files into a platform-specific software package. You must install the Centrify Agent on the audited computer before you enable the auditing service.

To install auditing using a native installation mechanism:

1. Log on as a user with root privileges.
2. If you want to install from a CD and the drive is not mounted automatically, use the OS-specific command to mount the cdrom device.
3. Copy the appropriate package to a local directory.

   For Solaris 10:

   cp /cdrom/cdrom0/Unix/centrifyda-*n.n.n*-sol10-sparc-local.tgz .

For Red Hat Enterprise Linux:

cp /mnt/cdrom/Unix/centrifyda-*n.n.n*-rhel5-x86_64.rpm .

For SuSE Linux:

cp /mnt/cdrom/Unix/centrifyda-*n.n.n*-suse11-x86_64.rpm .

4. If the software package is a compressed file, unzip and extract the contents. For example, on Solaris:

   gunzip -d centrifyda-*n.n.n*-sol10-local.tgz
   tar -xf centrifyda-*n.n.n*-sol10-sparc-local.tar

5. Run the installation command appropriate to the operating environment.

   For Red Hat Linux, you can use:

   rpm –ivh centrifyda-*n.n.n*-rhel5-x86_64.rpm

   For SuSE Linux, you can use:

   rpm –ivh centrifyda-*n.n.n*-suse11-x86_64.rpm

   For Solaris, you can use:

   pkgadd –d CentrifyDA -a admin

   Note: You can also use other programs, such as SMIT or YAST, to install the agent package.

6. If you are using an installation with a name other than DefaultInstallation, you need to configure it with dacontrol or using group policy.

   If there is an installation with the name DefaultInstallation the UNIX agent uses it by default. For more information about specifying the installation, see Configuring the installation for an agent.

7. After installing the package, use dainfo to verify that auditing is installed and running. You should see output similar to the following:

```
Pinging adclient: adclient is available
    Daemon status: Online
    Current collector: DC2008r2-LG.pistolas.org:
    5063:HOST/dc2008r2-lg@PISTOLAS.ORG
     Session offline store size: 0.00 Bytes
     Session despool rate: 0.00 Bytes/second
     Audit trail offline store size: 0.00 Bytes
     Audit trail despool rate: 0.00 Bytes/second
     Getting offline database information:
     Size on disk: 52.00 KB
     Database filesystem use: 3.06 GB used,
     15.52 GB total, 12.45 GB free
     DirectAudit NSS module: Active
     User (root) audited status: Yes
     DirectAudit is not configured for per-command auditing.
```

Permissions Required to Perform Administrative and Auditing Tasks

This section describes the permissions required to perform various auditing-related activities.

Setting and Synchronizing Audit-related Permissions

As a Master Auditor, you can set the permissions that control what all other administrators and auditors can do. In most cases, you set these permissions by making selections in Audit Manager. Your selections are saved in the management database for each installation, then published in Active Directory whenever you synchronize the management database with the service connection point for the installation.

The permissions you can set consist of a specific action that can be taken, a scope to which the action applies, and the specific Active Directory user or group to which you are granting the permission.

For example, a permission might specify an action, such as ability to modify a name or detach a database with a scope such as a specific installation or audit store database. For each action and scope, you select the Active Directory user or group to be granted that permission. After users or groups are granted a permission, they are called a trustee for that action and scope.

To view the existing permissions, right-click an installation or an audit store and select Properties, then click the Security tab.

Component by Component Permissions

The table below lists the permissions needed to create or add to an installation one component at a time.

Create an audit installation	
Create an audit console	
Create a SQL Server instance	
Check a SQL Server service account	
Add a service connection point	
Add a publication location	Audit server administrator or Manage Publication Locations (Installation)
Add a UNIX agent to an audited machine	
Add a Windows agent to an audited machine	
Enable trusted audited machine list for an audit store	Audit server administrator or Manage Collectors (Installation)
Add an audited machine to the trusted list for an audit store	Audit server administrator or Manage Collectors (Installation)
Add a collector	[does not require any special permissions to install]
Enable trusted collector list for an audit store	Audit server administrator or Manage Collectors (Installation)
Add a collector to the trusted list for an audit store	Audit server administrator or Manage Collectors (Installation)
Add an audit store	Audit server administrator or Manage Audit Store List (Installation)
Add an audit store database	SQL: Database owner (dbo) or a delegated member of the db_owner role or Audit store administrator (Installation) or Audit server administrator (Installation) or Manage Databases (Installation)

Attach an audit store database Change which DB is active Attach DA version 1 database	Audit Store administrator (Installation) or Audit server administrator (Installation) or Manage Databases (Installation)
Change which DB is active	Audit Store administrator or Audit server administrator or Manage Databases
Add a subnet or AD site to the audit store	Audit Store administrator or Audit server administrator or Manage Sites (Audit store)
Add an audit server	Manage Audit Server List (Installation)
Add an audit role; change its definition, menbership or permissions	Creator of installation (Installation) or Audit server administrator (Installation) or Manage Audit Roles (Installation)

Installation Permissions

Installation permissions allow users or groups to modify different aspects of an installation's properties. By default, the Master Auditor and the management database administrator have Full Control over the installation and can assign the following permissions to other users and groups:

Full Control	Perform all administrative tasks on the selected installation and assign permissions to other users and groups.
Change Permissions	Add, modify, or remove Active Directory users and groups that have specific permissions. A user or group granted this permission can display the properties for the installation, then click the **Security** tab to select permissions for other users and groups.
Modify Name	Modify the name of the selected installation. A user or group granted this permission can display the properties for the installation, then click the **General** tab to change the installation name.
Manage Management Database List	Add or remove a management database for the selected installation. A user or group granted this permission can right-click the installation name in Audit Manager and select **Management Databases** to add or remove a management database. Deleting the management database from Microsoft SQL Server requires additional SQL Server permissions.
Manage Audit Store List	Add, modify, or remove audit stores and audit store databases for the selected installation. A user or group granted this permission can use the Add Audit Store wizard or right-click the installation name in Audit Manager, select **Management Databases**, then click **Properties** to add or remove sites or subnets associated with the installation.
Manage Collectors	Add, modify, or remove collectors for the selected installation.
Manage Audited Systems	Add, modify, or remove audited computers for the selected installation.
Manage Audit Roles	Add, modify, or remove audit roles for the selected installation.
Manage Queries	Add, modify, or remove queries for the selected installation.
Manage Publications	Add, modify, or remove publication locations in Active Directory for the service connection point associated with the selected installation. A user or group granted this permission can display the properties for the installation, then click the **Publication** tab to change the publication location in Active Directory for the installation. A user or group granted this permission can also update the information stored in Active Directory to keep the information in Active Directory synchronized with the information stored in the management database. However, users or groups with this permission must have sufficient Windows rights to be able to update objects in Active Directory.

Manage License	Add or remove license keys for an installation. A user or group granted this permission can display the properties for the installation, click the **General** tab, then click **Details** to manage licenses for the installation.
Modify Notification	Enable or disable the audit notification message for the selected installation. A user or group granted this permission can display the properties for the installation, then click the **Notification** tab to manage the notification message and image for the installation.
Modify Audit Options	Enable or disable video capture auditing for the selected installation. Control whether users are allowed to update the review status of their own sessions. Control whether users are allowed to delete their own sessions. A user or group granted this permission can display the properties for the installation, then click the **Audit Options** tab to manage installation-wide auditing options.
View	Enable read-only permission for the selected installation. If a user has only View permission, they can see all the auditing components in the Audit Manager console, but they do not have access to audited sessions nor can they change any installation details.

Setting Installation Permissions

You can set installation permissions for a specific installation, by selecting the installation name in Audit Manager.

To set permissions on an installation:

1. Open Audit Manager and select the installation name.
2. Right-click, then click **Properties**.
3. Click the **Security** tab.
4. Click **Add** to open Select Users and Groups.
5. Type the user or group name who should be granted installation permissions, then click **OK**.

   You can add multiple users or groups from the Select Users or Groups dialog box. You can also type part of the name, then click **Check Names** to look up user and group names.
6. Select the specific permissions you want to grant to the selected user or group.

Management Database Permissions

Management database permissions allow users or groups to modify different aspects of an installation's management database. By default, the Master Auditor and the management database administrator have Full Control over the management database and can assign the following permissions to other users and groups:

Full Control	Perform all administrative tasks on the selected management database and assign permissions to other users and groups.
Change Permissions	Add, modify, or remove Active Directory users and groups that have specific permissions. A user or group granted this permission can display the properties for the management database, then click the **Security** tab to select permissions for other users and groups.
Modify Name	Modify the name displayed for the selected management database. A user or group granted this permission can display the properties for the management database, then click the **General** tab to change the management database name.
Manage Scopes	Add, modify, or remove sites or subnets for a management database. A user or group granted this permission can display the properties for the management database, then click the **Scope** tab to add or remove sites and subnets.
Remove Database	Remove a management database from an installation. Deleting the management database from Microsoft SQL Server requires additional SQL Server permissions.

Manage SQL Logins	Add or remove the Allowed incoming users for the selected management database. A user or group granted this permission can display properties for the management database, then click the **Advanced** tab to add or remove allowed accounts, or to change the outgoing account or authentication type.
Manage Database Trace	Enable, disable, or export database traces for the selected management database.

Setting Management Database Permissions

You can set management database permissions for a specific installation, by selecting the installation name in Audit Manager.

To set permissions on an management database:

1. Open Audit Manager and select the installation name.
2. Right-click, then click **Management Databases**.
3. Select the management database, click **Properties**, then click the **Security** tab.
4. Click **Add**, type the user or group name who should be granted permissions, then click **OK**.
5. Select the specific permissions you want to grant to the selected user or group.

Audit Store and Audit Store Database Permissions

Audit store permissions allow users or groups to modify different aspects of an audit store or audit store database. By default, the Master Auditor and the audit store database administrator have Full Control over the audit store and its database and can assign the following permissions to other users and groups:

Full Control	Perform all administrative tasks on the selected audit store database and assign permissions to other users and groups.
Change Permissions	Add, modify, or remove Active Directory users and groups that have specific permissions. A user or group granted this permission can display the properties for the audit store, then click the **Security** tab to select permissions for other users and groups.
Modify Name	Modify the name displayed for the selected audit store. A user or group granted this permission can display the properties for the audit store, then click the **General** tab to change the audit store name.
Manage Scopes	Add, modify, or remove sites or subnets for the audit store. A user or group granted this permission can display the properties for the audit store, then click the **Scope** tab to add or remove sites and subnets.
Manage SQL Logins	Add or remove the allowed incoming collectors and management database logins for the selected audit store database. A user or group granted this permission can display properties for the audit store database, then click the **Advanced** tab to add or remove accounts for collectors and management databases.
Manage Collectors	Add, modify, or remove trusted collectors for the audit store. A user or group granted this permission can display properties for the audit store, then click the **Advanced** tab to add or remove accounts trusted collectors.
Manage Audited Systems	Add, modify, or remove trusted audited computers for the audit store. A user or group granted this permission can display properties for the audit store, then click the **Advanced** tab to add or remove accounts trusted audited computers.
Manage Databases	Add, attach, detach, or delete audit store databases for the selected audit store.
Manage Database	Enable, disable, or export database traces for the selected audit store.

Trace

Audit Role Permissions

Audit role permissions allow users or groups to modify different aspects of an audit role. By default, the Master Auditor has Full Control over the audit roles and can assign the following permissions to other users and groups:

Full Control	Perform all administrative tasks on the selected audit role and assign permissions to other users and groups.
Change Permissions	Add, modify, or remove Active Directory users and groups that have specific permissions. A user or group granted this permission can display the properties for the audit role, then click the **Security** tab to select permissions for other users and groups.
Change Role Membership	Add, modify, or remove Active Directory users and groups that are assigned to the selected role. A user or group granted this permission can use the Add Audit Role wizard to assign users and groups to an audit role or select an audit role name, right-click, then select **Assign Users and Groups** to modify the role membership.
Change Role Definition	Modify the name, description, access, or privileges for the selected audit role. A user or group granted this permission can display the properties for the audit role, then: Click the **General** tab to modify the role name or description. Click the **Access** tab to modify the type of session and other criteria. Click the **Privileges** tab to modify hat users and groups assigned to the role can do.

Auditor Permissions

Auditor permissions allow users or groups to view, create, share, and delete queries. For an installation, the Master Auditor can control access to Audit Analyzer and queries using the Manage Queries permission and the assignment of audit roles. The privileges associated with an audit role also control whether auditor can update the review status or replay sessions. By default, the Master Auditor has Full Control over the auditor permissions and audit roles and can assign the following permissions to other users and groups:

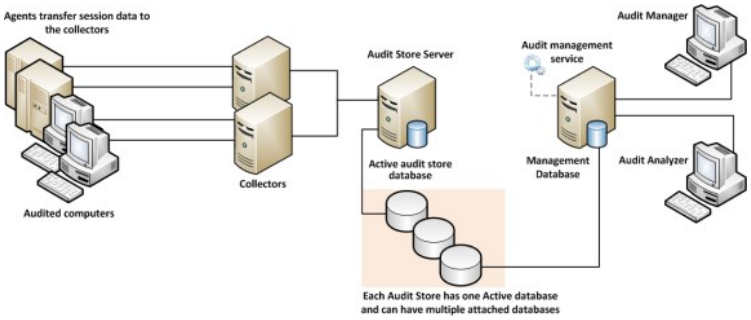
Full Control	Perform all administrative tasks on the selected query and assign permissions to other users and groups.
Change Permissions	Add, modify, or remove Active Directory users and groups that have specific permissions. A user or group granted this permission can display the properties for the query, then click the **Security** tab to select permissions for other users and groups.
Read	Read the selected query definition, session results, and indexed commands.
Delete	Delete the selected query definition, session results, and indexed commands.
Modify	Modify the selected query definition, session results, and indexed commands.

Sizing Recommendations for Audit Installations

A typical deployment of Centrify Audit & Monitoring Serviceconsists of a number of components such as one or more audited Systems (UNIX/Linux or Windows), one or more collectors, audit management server, management database, one or more audit store databases and consoles (the Audit Manager and the Audit Analyzer consoles) which all communicate with each other. Given the complexity of this communication and number of components involved, good planning is important for a successful deployment of the product. When planning a deployment, some of the most common questions that we asked are below:

- Will just one installation of Centrify Audit & Monitoring Service suffice? Or are multiple installations needed or recommended?
- How many audit stores need to be provisioned in each of the installations and how should their scope be configured?
- How many collectors will be needed and what kind of hardware is recommended for each of them?
- What is the recommended version/edition of SQL Server and what kind of hardware is recommended to host this SQL Server?

You must take into consideration a number of factors when deciding how to plan and configure the audit and monitoring servicedeployment and what kind of hardware will be needed to deploy the key components. This section will help you understand these factors in detail and come up with answers to such questions.



Planning an Audit and Monitoring Service Deployment

System Integrators often rely on the number of audited systems to estimate the hardware requirements and to come up with the overall strategy of audit and monitoring service deployment. For example, an environment with 100 audited systems may look like a small setup and one may incorrectly conclude that it's a small scale deployment that won't require a powerful hardware to support it. Once setup however, such assumptions may turn it into a deployment that seldom scales and often produces poor performance, both when capturing the audit activity and when querying the already captured audit data.

Below are a few factors that you must consider before making any deployment decisions,

SQL Server

Out of all the components in the audit and monitoring service ecosystem, SQL is the most heavyweight and will share most of the burden when it comes to workload. Using a properly equipped and optimally configured SQL Server is very important. The version and edition of SQL Server being used (such as Express or Standard or Enterprise) or the type of machine being used to host the SQL Server (such as a virtual or physical machine) can noticeably improve the overall performance. On the contrary, a poorly configured SQL Server may produce a very poor performance no matter how powerful the underlying hardware is.

Number of Concurrently Audited Users

Relying on the number of audited systems is not always a good assumption. For example, an environment may have just a handful of systems but may have a large number of users logging into these systems on a daily basis. A jumpbox scenario such as Citrix XenApp Server is a perfect example. When planning, you should plan for the number of concurrently audited users, not just the total number of audited systems. User activity patterns and behaviors also play an important role in overall performance and storage requirements. For example, the audited data will be much smaller in an environment where no logins are expected most of the time as compared to a network control systems wherein audited users are logging on and logging out throughout the day. The sizing guidelines specified in the later section of this whitepaper have all been based on workload simulations for the exact same reason.

What Needs to be Captured

What's being captured controls the overall workload on various components. Capturing video is more expensive than not doing so in terms of disk usage and load on collectors and SQL Server. Similarly, capturing interactive sessions is always going to produce more audited data when compared to capturing a

handful of commands thus putting system under more pressure. Capturing large quantities of data has another side effect; it slows down database backups and other maintenance processes which is not always liked by the database administrators.

Who Needs to be Audited

Who is being audited is equally important. Under default settings, the audit and monitoring service audits everything and everybody and this may not be a practical solution in many large environments. In production environments, it's very common to see processes or scheduled tasks that periodically monitor UNIX/Linux or Windows systems for their health by remotely executing certain commands (System Monitoring and Management software, such as BMC Patrol that periodically runs vmstat or iostat command on each of the UNIX/Linux systems is a good example). Activities like these needlessly generate thousands of Audited sessions on a daily basis and in many cases create tremendous load on an entire audit and monitoring service system.

UNIX/Linux and Windows

The type of system being audited influences the amount of data that will be captured from that system and the overall CPU load on collectors. For example, a Windows audited system almost always generates more data per day compared to a UNIX audited system with comparable number of concurrent users. This also means that an environment with Windows audited systems will most likely be more demanding (in terms of hardware resources) compared to an environment with same number of UNIX/Linux audited systems.

Query Performance

Query performance is one factor that often gets ignored. Capturing user activity and storing it in the database in a reasonable time is important. What's also important is to be able to search these records in a predictable time frame irrespective of the combined size and number of all the databases in the Centrify Audit & Monitoring Service system.

Audit Data Retention Policy

Audit data retention policy dictates how many days of data should be online and readily available for querying purpose and this number varies from one enterprise to another. Pay special attention to data retention policy requirements in the target environment. A longer retention policy typically results in large databases which also suffer from poor query performance if databases are not well maintained. On the contrary, too frequent rotation will also result in poor query performance if you keep too many inactive databases attached to the audit store.

System Overheads

Keep in mind the overhead that is caused by the Centrify Audit & Monitoring Service system itself; there are a number of background jobs carried out by various components of the audit and monitoring service system, including the audited systems themselves, collectors, and the Audit Management Server. This includes activities such as sending the audited system's heartbeat to the database (by way of collector), sending the collector's heartbeat to the database, processing active sessions list, processing and synchronizing information of audit roles with Active Directory Group criteria, calculating effective size of audited sessions, storing license usage information in Active Directory, and many more.

Latency

Geography/Network topology play an important role as it introduces latency. For example, an environment may well have just a handful of audited systems but if they're not geographically co-located, you may see delays in getting the audited user activity to its final destination (the database server); the same may happen if audited systems are not connected to collectors by a network link with reasonable bandwidth. A general rule of thumb is to group together audited systems, collectors and databases that are connected by a high speed network using the concept of audit store.

Best Practices for an Audit Installation

The previous section listed out a number of factors that may affect how a audit and monitoring service system will be deployed. Below is a set of best practices that are derived from these factors. Follow these practices for planning any audit and monitoring service deployment (large or small). You can also refer to the last section of this whitepaper that discusses how to tweak settings in an existing environment to improve performance.

Plan Based on Concurrently Audited Users

When planning, always focus on the number of concurrently audited users, not just the total number of audited systems. Take into consideration user sessions that might be generated as a result of automated monitoring activity from System Monitoring and Management software, such as BMC Patrol etc.

Avoid Single Box Deployment

Always avoid installing key components such as SQL Server, collectors and Audit Management Server on the same system, especially in environments with heavy workload. Keep in mind that a collector's workload is CPU intensive and SQL Server's workload is CPU, IO, and memory intensive. If both a collector and SQL Server are installed on the same system, they'll slow each other down.

Control the Amount of Data

It's always a good practice to establish rules to avoid capturing unnecessary data. This typically includes blacklisting commands such as top or tail (which generate large outputs and seldom contain any meaningful user activity) or enable per-command auditing instead of session auditing. Also, compile a list of users that do not really need to be audited and add them to the non-audited user's list. This often includes user accounts that are used to run automated jobs from System Monitoring and Management software, such as BMC Patrol and so forth.

Scope the Audit Stores Efficiently

Always visualize the flow of traffic, not just when audited activity is being captured but also when it's being searched and replayed. It's better to avoid traffic over slow links by splitting the audited systems into multiple audit stores based on their geographic location, even if it may mean that you'll be deploying more collectors and SQL Servers. In certain cases, splitting audited systems into multiple audit stores may not be sufficient enough and you may even need to consider provisioning multiple audit and monitoring service installations. When audited data is being queried, all calls are routed to the audit store databases by way of the Management database. If the Management database is not connected to the console or to the audit store databases by way of a fast network link, the queries will always return the results slowly no matter how good the performance of SQL Server is.

Estimate Storage Requirement based on Pilot Data

No two customers are the same and you can never accurately predict how much data will be collected over a period of time in each environment. Hence, it's important to analyze existing data in a customer's environment (from pilot project) to predict the future data growth. A pilot testing is an effective way to help you understand a number of things such as the following factors:

- Understand workload patterns and come up with an overall configuration strategy that determines how the audit stores will be scoped, which users should or should not be audited, which commands should be blacklisted and so forth.
- Database storage requirement – Roughly, how much data will be collected over the retention policy period? This will also help you establish the active audit store database rotation policy.
- What kind of hardware will be needed for the SQL Server to serve the production workload?
- How many collectors will be needed in each audit store (this number is especially important when auditing Windows systems)?

The Centrify Audit & Monitoring Service Data Analysis tool (see KB-4496) can be very helpful to understand data trends. If the Centrify Audit & Monitoring Service Data Analysis tool reveals that more than anticipated amount of data is being captured, you can always use the database rotation to keep the active audit store database's size in control thus controlling the storage requirements for all attached databases.

Maintain Databases Periodically

Apart from taking regular backups, it's also important to keep the databases healthy by maintaining them periodically. This includes activities such as reorganizing or rebuilding indexes; these tasks must be done by a customer's DBA periodically. Centrify recommends reorganizing indexes if they are 5% to 30% fragmented and rebuilding indexes if they are more than 30% fragmented.

Control the Size of Active Databases

A large active audit store database often results in poor performance as a result of fragmented indexes, lengthy backups, and out of date database statistics, especially when the databases are not maintained periodically. Centrify recommends keeping the active audit store database size between 250GB-500GB (as of Suite 2016). Consider rotating databases whenever the size exceeds the recommended thresholds. You can rotate databases programmatically by using either the Centrify DirectManage SDK or the Centrify Audit PowerShell Module, or manually using the Audit Manager console). It's also a good practice not to keep too many audit store databases attached to an audit store, because doing so affects query performance.

Plan Database Rotation based on Retention Policy

Always try to align the audit data retention policy with the active audit store database rotation. For example, if the audit data retention policy requires last 90 days of data to be online, try to rotate the active audit store database every 90 days. This strategy makes it easy to find achieved data if it's ever needed for reviewing purpose in the future. One exception to this strategy is an environment where the audit data retention policy is so long that the active audit store database is guaranteed to exceed the recommended maximum size of the active audit store database (as mentioned in the previous section). In such cases, you can divide the entire retention policy period into small periods (for example, one database for each month) and continue to rotate the active audit store database at the recommended intervals. Irrespective of which strategy you choose and implement, it's always recommended to detach all audit store

databases that contain data outside of the retention policy period. This not only improves the query performance but also reduces the disk usage on the database server.

Configure SQL Server Optimally

Centrify recommends setting the SQL Server machine's power plan settings (Control Panel > Power Options) to High Performance.

SQL Server has a setting called Max Server Memory that controls the maximum amount of physical memory that can be consumed by the SQL Server's buffer pool. An incorrectly configured Max Server Memory may either result in the SQL engine causing high IO or OS/other programs starving for more memory. It's critical to configure the Max Server memory correctly based on the amount of total physical memory available. Always configure this value as recommended before deployment begins.

Centrify recommends storing the transaction logs and data files that are associated with any SQL Server database on two separate volumes. For more information, see the Microsoft Knowledge base article https://support.microsoft.com/en-us/kb/2033523.

Other Recommendations

Centrify recommends deploying at least two collectors per audit store for redundancy purpose.

Understand that any Hardware has its Limits

It's entirely possible that even after following all the best practices, the Centrify Audit & Monitoring Service system continues to perform poorly. In such cases, you must consider splitting the workload by deploying additional SQL Servers or collectors, depending on where the bottleneck is. Deploying an additional SQL Server will almost always result in reconfiguring scope of the audit stores (in order to redirect some traffic to the new SQL Server) and it must be done with careful planning.

Creating an initial estimate of your database storage needs

Here's a way that you can do an initial but rough guess of your recommended storage needs. For a more detailed estimate, please refer to Guidelines for determining hardware configuration.

- 1 MB per minute per Windows or Linux Desktop session with nominal activity

  You could need considerably more storage than this if sessions will include flash animation, video replay, and so forth.

- Use a ratio of users to number of systems
  - For example, you could have 50 users for 1000 systems, which would be a 5% ratio; you would then multiply the number of users with the above estimates.
  - 50 Windows users would require 50 MB/minute, or 120 GB/week, or 1.5TB/quarter.

Guidelines for determining hardware configuration

The overall performance of the audit and monitoring service ecosystem ultimately depends on the performance of SQL Server and the collectors. To come up with guidelines for hardware, we have created a test environment wherein the SQL Server hardware configuration has been categorized into three variants: a low end SQL Server, a high end server SQL Server, and a mid-level SQL Server. Below are the test environment configuration details:

Physical machine	DIY PC	S5000 Intel Xeon	Dell R730
Physical memory	8 GB (2x4GB)	16 GB (2x8GB)	32 GB (2x16GB)
CPU	Intel i5-650, 3.2 GHz	E5420 (2.5 GHz)	2xIntel Xeon E5-1620 v3 (2.4 GHz, 8C/16T)
HDD	1x1TB (7200 rpm SATA)	1x1TB (7200 rpm SATA)	1x1TB (7200 rpm SAS 6Gbps)

The hardware configuration depicted in the above table reflects the sizing test environment. Centrify cannot make specific recommendations (such as

physical memory, CPU frequency, or CPU type) for purchasing hardware; use these numbers only as a guideline.

The table below lists the test conditions along with the outcome of tests, and this roughly indicates the recommended number of audited systems that can be supported in this test environment.

Test conditions	60% agents are idle 35% agents are running simple commands	5% agents are running tail command	5% agents are idle 2% agents are running "su" sessions 93% agents are running "dzdo" command sessions	60% agents are idle 40% agents are active	100% agents are active
Low end SQL Server	1100	1800	400	1300	
Mid-range SQL Server	1500	3600	400	2400	
High end SQL Server	2000	4500	640	3000	

- The numbers depicted in the above table reflects the outcome of a sizing test in a very specific test; use these numbers only as a guideline.
- Refer to the table in the next section for actual recommendations.

Based on these test results, Centrify recommends using the table below when planning a deployment of Centrify Audit & Monitoring Service. Please note that the recommended SQL Server configuration is only applicable to the SQL Server hosting the audit store database. It's generally a good practice to host the Management database on the same SQL Server where the other audit store databases are hosted.

UNIX	Command auditing	1800	5% agents are idle 2% agents are running "su" sessions 93% agents are running "dzdo" command sessions	Low end	2	83	
UNIX	Command auditing	3600	5% agents are idle 2% agents are running "su" sessions 93% agents are running "dzdo" command sessions	Mid-range	2	60	
UNIX	Command auditing	4500	5% agents are idle 2% agents are running "su" sessions 93% agents are running "dzdo" command sessions	High end	4	102	
UNIX	Session auditing	1100	60% agents are idle 35% agents are running simple commands 5% agents are running tail command	Low end	2	87	
UNIX	Session auditing	1500	60% agents are idle 35% agents are running simple commands 5% agents are running tail command	Mid-range	2	76	

UNIX	Session auditing	2000	60% agents are idle 35% agents are running simple commands 5% agents are running tail command	High end	4	104	
Windows	Video	disabled	1300	100% agents are active	Low end	2	91
Windows	Video disabled	2400	100% agents are active	Mid-range	3	67	
Windows	Video	disabled	3000	100% agents are active	High end	4	100
Windows or Linux Desktop	Video enabled	400	60% agents are idle 40% agents are active	Low end	5	85	
Windows or Linux Desktop	Video enabled	400	60% agents are idle 40% agents are active	Mid-range	5	88	
Windows or Linux Desktop	Video enabled	640	60% agents are idle 40% agents are active	High end	8	113	

- Expected activity is based on 8 hours of work every day. Results may vary if the target environment has a different pattern for user activity/behavior, different workload/ratio of idle to active systems compared to the test environment.
- Average response time is the total time taken in milliseconds to send a unit of data from audited system to the SQL Server by way of collector.
- All recommended numbers are based on the assumption that the target environment is stable in terms of performance of individual components and network throughput. Intermittent transient errors are expected and typically do not impact the sizing assessments.
- Windows and Linux Desktop audited systems generate large amount of audit data when video capture is enabled and such environments require high performance SQL Server storage. This is the primary reason why the number of agents supported between the low and medium SQL Server configuration are similar. The artificial load generated by the test simulators is also higher than the expected daily activity in a typical production environment. With high performance storage, the total number of Windows and Linux Desktop audited systems supported will likely be higher compared to the numbers recommended.
- When monitoring both Windows and UNIX/Linux audited systems in the same environment, use the Windows numbers as a guideline.

Identifying Typical Deployment Issues

It's fairly easy to identify scaling/performance issues with a Centrify Audit & Monitoring Service system that are typically a result of poor planning or deployment. Below are some of the most common deployment issues.

Large Spool Files on Audited Systems

A healthy audit and monitoring service system should be able to keep up the pace with users' audited activity. When the system cannot keep up the pace, it means either the user's audited activity is generating too much data (such as when a user runs the cat command on a very large file) or the audit and monitoring service system components (such as collectors and databases) are not able to process and store the generated data fast enough. In such cases, you'll typically see large spool files on the audited systems that often need more time to get despooled completely.

Constant High CPU on Collector/SQL Server

It's perfectly normal to see high CPU activity on collector and SQL Server machines during peak hours as this is the time when data is continuously getting pumped from the audited system to the collector and finally to the database. However, when you see similar activity during off-peak hours (especially when it doesn't correspond to the number of active users in that environment at that time), it indicates that the audit and monitoring service system is getting

backlogged.

Low Despool Rate

The despool rate largely depends on the type of data being captured, the speed of network/latency between audited system and collector, the speed of the network/latency between the collector and the database, and ultimately the performance of the SQL Server itself. Because of these factors, there's no ideal value or range for the despool rate. However, you should not see a despool rate that's significantly lower than the rate of data capture, especially when there are no known issues related to network speed or SQL Server performance.

False "Agent disconnected" Alerts

Each Agent periodically sends its heartbeat to the database (by way of collector) and the Audit Manager console relies on this ping to determine if the Agent is connected or not. If there are deployment issues with audit and monitoring service, the Agent heartbeat may not get registered even if the Agent is online, and this may raise false alarms as the system will be shown as disconnected in Audit Manager Console. Whenever you see such contradicting information regarding the status of the audited system, it typically is indicative of underlying deployment issues.

Too many SQL Server Tasks In Queue

SQL Server has a fixed set of worker threads that it can use to perform its job and this number depends on the CPU architecture, such as 32-bit or 64-bit, and the total number of CPUs on the SQL Server. If SQL Server is given more tasks than it can finish, they'll end up waiting at the bottom of this queue, thus consuming memory and degrading overall system performance. Always consult the DBA to confirm if the environment is consistently showing a lot of tasks in the worker queue; this can indicate that the workload is too much for this SQL Server to handle. For more information, see the Microsoft article https://msdn.microsoft.com/en-us/library/ms177526(v=sql.105).aspx.

Settings to Adjust for Performance Improvement

In an environment where Centrify Audit & Monitoring Service is already deployed and experiencing scalability/performance issue, it's not always possible to re-architect the deployment or make significant configuration changes (such as re-scoping the audit stores or adding a new SQL Server may not be practical); this is true especially in large environments. The table below that lists some key settings that you may try to change in order to improve the overall performance of various audit and monitoring service components.

Agent Settings			
Agent heartbeat interval for Unix/Linux Audited Systems (dad.timer.update.agent.status)	Controls the interval for sending Unix/Linux Audited System's heartbeat to the Collector	When SQL activity monitor shows high CPU usage at a predictable interval as a result of heartbeat registration or when Collector logs reveal repeated failures in registering Audited System's heartbeat or when Audit Manager console frequently shows a lot of disconnected Audited Systems even if they are all online. For more details about the configuration parameter, see the Configuration and Tuning Reference Guide.	Unix/Linux Agent (centrifyda.conf)
Agent heartbeat interval for Windows Audited Systems (SessionPingInterval)	Controls the interval for sending Windows Audited System's heartbeat to the Collector	When the SQL activity monitor shows high CPU usage at a predictable interval as a result of heartbeat registration or when Collector logs reveal repeated failures in registering Audited System's heartbeat or when Audit Manager console frequently shows a lot of disconnected Audited Systems even if they are all online.	Windows Agent (registry setting)
User blacklisting (dash.user.skiplist)	Allows specifying blacklist of users that should not be audited on Unix/Linux systems	Useful in preventing capture of audit activity of users such as BMC Patrol agent or ServiceNow service accounts or users that do not really need to be audited. For more details about the configuration parameter, see the Configuration and Tuning Reference Guide.	Unix/Linux Agent (centrifyda) and also available via Group Policy
Audited/Non-audited users list	Allows specifying whitelist or blacklist of users that should or should not be audited on Windows systems	Useful in preventing capture of audit activity of unwanted users.	Group Policy

BindingCheckInterval	Controls the interval at which Agent checks if it's connected to the correct Collector or not	When binding check causes load on the Domain Controller as a result of periodic Active Directory calls (for example, when you notice an Active Directory call from each Audited System every 10 seconds)	Windows Agent (registry setting)
Collector settings			
Agent global heartbeat interval (AgentMinimumUpdateInterval)	Controls the interval for sending Audited System's heartbeat to the Collector at the Collector level (in case it's not practical to tweak this setting on each of the Audited Systems)	When SQL activity monitor shows high CPU usage at a predictable interval as a result of heartbeat registration or when Collector logs reveal repeated failures in registering Audited System's heartbeat or when Audit Manager console frequently shows a lot of disconnected Audited Systems even if they are all online.	Collector (registry setting)
Maximum concurrent SQL connections per Collector (MaxPoolSize)	Controls how many SQL connections (maximum) can be opened by the Collector at a time	In order to reduce the workload caused by Collector on the SQL Server. Reducing the MaxPoolSize will reduce the total number of connections open on the SQL Server but may also reduce the despool rate.	Collector (registry setting)
Installation level settings			
Command blacklisting	Allows specifying one or more commands whose output is not required to be captured	When you see large audited sessions that are a result of running commands with large output (for example, commands such as tail or top) and you need to control disk space consumed by such audited activity.	Group Policy
Enable/Disable video audit	Allows enabling or disabling video capture (at installation level or on a per machine basis) when storing audited user activity in the database	When video capture is resulting into large sessions consuming a lot of disk space and/or it's not desirable to store the video.	Audit Manager console or group policy

- Not all configuration parameters/settings are available in releases prior to Suite 2015.1. Please contact Centrify Support for additional information on older releases.
- Agent heartbeat interval can configured per audited system or globally by configuring it in collector's registry setting. Centrify recommends configuration the heartbeat interval on the collector if you want all the audited systems to send their heartbeat at an identical interval.
- Tweaking the configuration settings may not always help or eliminate the deployment issues completely. In such cases, making significant deployment/configuration changes may be the only option. Please contact Centrify Support to evaluate possible solutions.

Conclusion

This sizing recommendation section has provided some information as to what factors can affect Centrify Audit & Monitoring Service performance. Keep in mind, however, that every installation is unique and we cannot anticipate every use case. If you continue seeing performance degradation after following the best practices outlined in this document, contact Centrify Support for assistance.

Server Suite provides an auditing infrastructure that enables your organization to capture and store session activity on audited computers. The auditing infrastructure also enables auditors to query and report on specific events, view all or selected session activity, change the status of reviewed sessions, and delete sessions that are no longer needed. The auditing infrastructure relies on two types of databases to store information: the management database and the audit store database.

If you are not familiar with the components and architecture of the auditing infrastructure, see the Auditing Administrator's Guide. That guide provides detailed information about how the components in the auditing infrastructure communicate with each other and how to configure and manage an audit installation.

Introduction to the Databases Used for Auditing

Server Suite provides an auditing infrastructure that enables your organization to capture and store session activity on audited computers. The auditing infrastructure also enables auditors to query and report on specific events, view all or selected session activity, change the status of reviewed sessions, and delete sessions that are no longer needed. The auditing infrastructure relies on two types of databases to store information: the **management database** and the **audit store database**.

If you are not familiar with the components and architecture of the auditing infrastructure, see the *Auditing Administrator's Guide*. That guide provides detailed information about how the components in the auditing infrastructure communicate with each other and how to configure and manage an audit installation.

Management Databases Store Installation Information

In most organizations, there is only one management database for each audit installation and it stores information about the components of the auditing infrastructure for that installation. For example, the management database stores information about which computers are audited, where the collector service is installed, and the scope (site or subnet) of each audit store.

In most cases, you create the management database when you create a new installation and update it whenever you add components to the auditing infrastructure. For example, if you enable auditing on additional computers or deploy the collector service on a new server, the change is recorded in the management database. Because the management database stores information about the auditing infrastructure and not audited sessions, it requires little to no maintenance over time.

Audit Store Databases Store Audited Sessions

Like the management database, you create the first audit store database during deployment. However, unlike the management database, the audit store database stores the activity collected from audited computers. Over time, the audit store database would grow and become unmanageable. Therefore, most organizations periodically add a new audit store database to capture current activity. When the new audit store database becomes active, the previous audit store database can remain “attached” to provide access to stored information or be “detached” if access to the information stored in that database is no longer required.

The process of adding a new audit store database and changing the status of an existing audit store database from “active” to “attached” is called database rotation. Database rotation is the primary on-going administrative task to manage the auditing of user activity using Centrify software. There are, however, also steps to take during the planning phase and during deployment that apply specifically to preparing Microsoft SQL Server to support the auditing infrastructure.

The audit store database stores all of the activity collected on audited computers. When auditors or administrators want to review captured activity, they must be able to connect to the audit store database to retrieve it. Therefore, the audit store database must be accessible and the auditors and administrators who need to retrieve data from it must have the appropriate permissions to connect to the database instance, and to read and write data where applicable.

Using Multiple Databases for the Audit Store

Depending on the number of computers you are auditing, the level of detail you capture, and the length of time captured activity must be available for review, an audit store database can grow too large to manage effectively in a short period of time.

To prevent the audit store database from growing too large, you can split it into multiple databases. Only one database at a time can be the active—that is, the database currently receiving captured activity from an audited computer and its collector service.

However, because large databases are harder to manage and take longer to search than smaller ones and you cannot allow a single active database to grow indefinitely, you can change the active database to be an attached database—that is, available for searching and retrieving stored information but no longer receiving captured activity—and make a new database the currently active database.

Changing which database is active without interrupting the monitoring of audited computers is also referred to as *rolling* or *rotating* the database. By adding new databases and changing the audit store's active database to an attached database before it gets too large, you can optimize database performance and storage requirements.

Detaching and Retiring Audit Store Databases

All of the information stored in audit store databases that are attached to an audit installation is available for queries and reports and can be viewed in the session player. When the information in an attached database is no longer needed, you can detach the database from the installation. You cannot detach a database while it is the active database.

After a database that has been the active database is made an attached or detached database, it is considered a retired or decommissioned database. It cannot be used as the active database again.

Automating Database Rotation

Although you can do database rotation manually using Audit Manager, you might want to automate the process to perform it automatically on a regular schedule. You might also want to automate and schedule the detachment of old databases from the audit store. The API described in the reference enables you to write scripts to perform database rotation and attach or detach databases.

The software development kit (SDK) for auditing includes four sample scripts that you can modify to suit your purposes: two VBScript samples and two Power Shell samples. One pair of sample scripts (db_rotation) use default database settings. The second pair (db_rotation_sql_script) let you customize the database scripts to set up the database and the server.

The sample scripts perform the following steps:

1. Create a new audit store database and attach it to an audit store.
2. Grant permission to the management database and collectors to access the newly created audit store database.
3. Make the newly created audit store database the active database.
4. Detach any audit store databases older than two years.
5. Publish the settings to Active Directory so that audited computers and collectors can look up the information.

Note that the sample scripts require the user to respond to informational messages at various points during execution. To make these scripts run without user interaction, remove or comment out all the wscript.echo commands in the script, or redirect the echo commands to STDOUT so that the scheduled task will not hang waiting for user input.

The following command adds the script db_rotation.vbs as a monthly scheduled task named rolldb to be run as user domain_name\administrator. By using cscript.exe to launch the script, it redirects output to STDOUT.

PS C:\Program Files\Centrify\Audit\SDK\Samples> schtasks.exe /Create /TN "rolldb" /TR "cscript.exe 'C:\Program Files\Centrify\Audit\SDK\Samples\db_rotation.vbs' DefaultInstallation DefaultAuditStore sqlserver.domain_name.com subtest3" /RU domain_name\administrator /SC Monthly /MO 1

The components of this command are as follows:

Schtasks.exe /Create /TN <*Task_name*> /TR <*Task_Command*> /RU <*Run_As_User*> /SC <*Reoccurance_rate*> /MO <*Reoccurance_increment*>

where

- *Task_Name*: rolldb
- *Task_Command*: cscript.exe 'C:\Program Files\Centrify\Audit\SDK\Samples\db_rotation.vbs' DefaultInstallation DefaultAuditStore sqlserver.domain_name.com subtest3
- *Run_as_user*: domain_name\Administrator
- *Reoccurance_rate*: Monthly
- *Reoccurance_increment*:1

The task command consists of the following elements:

<*parser*> '<*install_path*>\<*VBS_script*>' <*Installation*> <*auditstore*> <*DB_Server*> <*DB_prefix*>

where

- *parser*: cscript.exe
- *install_path*: C:\Program Files\Centrify\Audit\SDK\Samples
- *VBS_script*: db_rotation.vbs
- *Installation*: DefaultInstallation
- *auditstore*: DefaultAuditStore
- *DB_Server*: sqlserver.domain_name.com

- *DB_prefix*: subtest3

The prefix is attached to a date stamp in the name of the newly created audit store database.

Delinea

Audit-related object reference

This chapter describes the classes, methods, and properties in the Centrify software development kit for auditing. The following classes are used for managing auditing features and are defined in the Centrify.DirectAudit.API namespace:

Account class	Manages Account objects.
Accounts class	Enumerates Account objects.
AuditServer class	Manages AuditServer objects.
AuditServers class	Enumerates AuditServer objects.
AuditStore class	Manages AuditStore objects.
AuditStoreDatabase class	Manages AuditStoreDatabase objects.
AuditStoreDatabases class	Enumerates AuditStoreDatabase objects.
Connection class	Manages an auditing connection.
Installation class	Manages Installation objects.

Account Class

Manages Account objects.

Syntax

class Account

Properties of the Account class

The Account class provides the following properties:

IsSystemAccount property	Gets a value indicating whether the account is a Windows system account.
IsWindowsAccount property	Gets a value indicating whether the account is a Windows domain account.
UserName property	Gets the user name of the account.

Description of the Account class

The accounts used for auditing include the management database account, audit store database account, and collector accounts. This class provides properties to retrieve information about an account.

See also

- Accounts class
- OutgoingAccount property
- AuditServerAccounts property
- CollectorAccounts property

IsSystemAccount Property

Gets a value indicating whether the account is a Windows system account.

Syntax

bool IsSystemAccount{get;}

Return Value

Returns true if the account is a Windows system account; otherwise, false.

Discussion of the IsSystemAccount Property

When you attach a new database to the audit store, you must set the database to allow access by the management database account. Before you call the AddAuditServerAccount method, you should check to see if the management database account is a Windows system account because if it is, the Account.UserName property is not a Windows domain account name and therefore cannot be passed directly to the AddAuditServerAccount method.

Example

The following code sample first checks to make sure the management database account is not a system account. If it is not a system account, the sample calls the AddAuditServerAccount method. If the management database is a system account, the sample returns an error message.

...

```
' Grant permission to management database to access the audit store database
SET objAuditServers = objInstallation.AuditServers
FOR EACH objAuditServer IN objAuditServers
SET objAuditServerAccount = objAuditServer.OutgoingAccount
IF NOT objAuditServerAccount.IsSystemAccount THEN
objAuditStoreDatabase.AddAuditServerAccount objAuditServerAccount.UserName, & _

objAuditServerAccount.IsWindowsAccount
wscript.echo "Added management database account '" & objAuditServerAccount.UserName & "'."
ELSE
wscript.echo "Cannot add account for management database '" & objAuditServer.Name & _
& "' because the account '" & objAuditServerAccount.UserName & _
& "' is a system account."
wscript.echo "NOTE: Please add allowed incoming management database for '" & _

& objAuditServer.Name & _
& "' to the new audit store database in Audit Manager."
END IF
```

See also

- IsWindowsAccount property
- AddAuditServerAccount method

IsWindowsAccount Property

Gets a value indicating whether the account is a Windows domain account.

Syntax

```
bool IsWindowsAccount {get;}
```

Return Value

Returns true if the account is a Windows domain account; false if the account is an SQL Server login account.

Discussion

The management database-to-audit store database connection and the collector-to-audit store connection can use either Windows authentication or SQL Server authentication.

Example

The following code sample illustrates using this property as an input parameter to the AddAuditServerAccount method:

...

```
'Add management database accounts for those management databases running in
' system account; e.g. NT Authority/Network Service
'
DIM strAuditServerAccount
DIM isAuditServerWindowsAccount
isAuditServerWindowsAccount = true
strAuditServerAccount = "DOMAIN\MACHINE$"
objAuditStoreDatabase.AddAuditServerAccount strAuditServerAccount, & _
isAuditServerWindowsAccount
wscript.echo "Added management database account '" & strAuditServerAccount & "'."
```

See also

- AddAuditServerAccount method
- AddCollectorAccount method

UserName Property

Gets the user name of the account.

Syntax

string UserName {get;}

Return Value

Returns the user name of the account.

Discussion

If the account is a Windows account, the user name is the Windows domain account name. If the account is an SQL Server login account, the user name is the SQL Server account name.

Example

The following code sample illustrates using this property as an input parameter to the AddCollectorAccount method:

...

```
' Copy Collector accounts from current active audit store database
SET objCollectorAccounts = objActiveDatabase.CollectorAccounts
FOR EACH objCollectorAccount IN objCollectorAccounts
objAuditStoreDatabase.AddCollectorAccount objCollectorAccount.UserName
wscript.echo "Added Collector account '" & objCollectorAccount.UserName & "'."
```

Accounts class

Enumerates Account objects.

Syntax

class Accounts

Discussion

The accounts used for auditing include the management database account, the audit store database account, and collector accounts. Use this class to enumerate a set of accounts.

Example

In the following code sample, the CollectorAccounts property returns an Accounts object and a FOR EACH—IN statement is used to enumerate the collector accounts:

...

```
' Copy Collector accounts from current active audit store database
SET objCollectorAccounts = objActiveDatabase.CollectorAccounts
FOR EACH objCollectorAccount IN objCollectorAccounts
objAuditStoreDatabase.AddCollectorAccount objCollectorAccount.UserName
wscript.echo "Added Collector account '" & objCollectorAccount.UserName & "'."
```

See also

- Account class
- AuditServerAccounts property
- CollectorAccounts property

AuditServer class

Manages AuditServer objects.

Syntax

class AuditServer

Properties

The AuditServer class provides the following properties:

DatabaseName property	Gets the database name of the management database.
Name property (management database)	Gets the display name of the management database.
OutgoingAccount property	Gets the outgoing account of the management database.
ServerName property	Gets the Microsoft SQL Server instance name of the management database.

Discussion

An AuditServer object holds information about an management database that is part of the audit installation. The management database stores license information, audit roles, and information about the components of the auditing infrastructure, including the scope of each audit store and the active and attached audit store databases.

See also

- AuditServers class

DatabaseName Property

Gets the database name of the management database.

Syntax

string DatabaseName {get;}

Return Value

Returns the database name of the management database.

Discussion

The management database stores license information, audit roles, and information about the components of the auditing infrastructure, including the scope of each audit store and the active and attached audit store databases.

See also

- Name property (management database)
- ServerName property
- AuditStoreDatabase class

Name Property (management database)

Gets the display name of the management database.

Syntax

string Name {get;}

Return Value

Returns the display name of the management database.

Discussion

The management database display name is used in the Audit Manager console and must be unique in the installation. Note that this is not the management database instance name, which is the fully-qualified domain name of the management database, and is not necessarily the same as the management database name, which need not be unique in the installation.

See also

- DatabaseName property
- ServerName property

OutgoingAccount Property

Gets the outgoing account of the management database.

Syntax

Account class OutgoingAccount {get;}

Return Value

Returns the outgoing account of the management database.

Discussion

The user name of the outgoing account is the name by which the management database identifies itself when connecting to an audit store.

ServerName Property

Gets the Microsoft SQL Server instance name of the management database.

Syntax

string ServerName {get;}

Return Value

Returns the Microsoft SQL Server instance name of the management database.

Discussion

The Microsoft SQL Server instance name is the fully qualified domain name of the management database.

See also

- DatabaseName property
- Name property (management database)

AuditServers class

Enumerates AuditServer objects.

Syntax

class AuditServers

Discussion

In most cases, an audit installation includes only one management database.

See also

- AuditServer class

AuditStore class

Manages AuditStore objects.

Syntax

class AuditStore

Properties

The AuditStore class provides the following properties:

ActiveDatabase property	Gets the active audit store database.
Databases property	Gets the list of the audit store databases.
Name property (audit store)	Gets the display name of the audit store.

Methods

The AuditStore class provides the following methods:

AddDatabase method	Creates a new audit store database and attaches the database to the audit store using default settings.
AddDatabaseByScript method	Creates a new audit store database and attaches the database to the audit store using custom settings specified in SQL scripts.
AttachDatabase method	Attaches an existing audit store database to the audit store.
ChangeActiveDatabase method	Changes which database is currently active in the audit store.
DetachDatabase method	Detaches a database from the audit store.
GetDatabase method	Retrieves the audit store database object given the database display name.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time. This class allows you to manage the audit store, including attaching and detaching databases and specifying which database is active. To get information about the attached databases, use the AuditStoreDatabase class and the AuditStoreDatabases class.

See also

- AuditStoreDatabase class

ActiveDatabase Property

Gets the active audit store database.

Syntax

AuditStoreDatabase class ActiveDatabase {get;}

Return Value

Returns the active audit store database.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time.

See also

- Databases property

Databases Property

Gets the list of the audit store databases.

Syntax

AuditStoreDatabases class Databases {get;}

Return Value

Returns the list of the audit store databases.

Discussion

This property returns a list of all the databases attached to the audit store.

See also

- ActiveDatabase property

Name property (audit store)

Gets the display name of the audit store.

Syntax

string Name {get;}

Return Value

Returns the display name of the audit store.

Discussion

The display name of the audit store is used in the Audit Manager console. It is distinct from the display name of the active database.

See also

- Name property (audit store database)

AddDatabase Method

Creates a new audit store database and attaches the database to the audit store using default settings.

Syntax

AuditStoreDatabase class AddDatabase(

string *name*,

string *serverName*,

string *database*

)

Parameters

Return Value

Returns the AuditStoreDatabase object of the new audit store database.

Errors

The AddDatabase method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance that hosts the management database or you do not have permission to connect to the Microsoft SQL Server instance of the audit store database to be created.
- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the instance is not running or does not allow remote connections.
- Centrify.DirectAudit.Common.Logic.UnauthorizedException if you do not have the Manage Database permission on the audit store or you do not have the SQL Server permission to create SQL Server databases on the Microsoft SQL Server instance.
- Centrify.DirectAudit.Common.Logic.AlreadyExistsException if the specified display name is already being used by another audit store database, or the specified database name is already being used by another database in the Microsoft SQL Server instance.

Discussion

Use this method to create a new audit store database and attach it to the audit store. To customize the database or attach an existing database to the audit store, use one of the methods listed in the “See also” section.

Example

The following code sample argument illustrates the use of AuditStore.AddDatabase:

```
...

strInstallationName = wscript.arguments.item(0)
strAuditStoreName = wscript.arguments.item(1)
strServerName = wscript.arguments.item(2)
strDatabaseName = wscript.arguments.item(3)

SET objAuditStoreDatabase = objAuditStore.GetDatabase(strDatabaseName)

IF NOT objAuditStoreDatabase IS NOTHING THEN
wscript.echo "Audit Store database '" & strDatabaseName & "' already exists."
wscript.quit
END IF

' Create a new audit store database and attach to the audit store
SET objAuditStoreDatabase = objAuditStore.AddDatabase(strDatabaseName, & _
strServerName, strDatabaseName)

IF objAuditStoreDatabase IS NOTHING THEN
wscript.echo "Failed to add audit store database '" & strDatabaseName & "'."
wscript.quit
END IF
wscript.echo "Created and attached audit store database '" & strDatabaseName & "'."
```

See also

- AddDatabaseByScript method
- AttachDatabase method
- ChangeActiveDatabase method

AddDatabaseByScript Method

Creates a new audit store database and attaches the database to the audit store using custom settings specified in SQL scripts.

Syntax

AuditStoreDatabase class AddDatabaseByScript(

string *name*,

string *serverName*,

string *database*,

string *scriptFile1*,

string *scriptFile2*

)

Parameters

Return Value

Returns the AuditStoreDatabase object of the new audit store database.

Errors

The AddDatabaseByScript method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance that hosts the management database or you do not have permission to connect to the Microsoft SQL Server instance of the audit store database to be created.
- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the instance is not running or does not allow remote connections.
- Centrify.DirectAudit.Common.Logic.UnauthorizedException if you do not have the Manage Database permission on the audit store or you do not have the SQL Server permission to create SQL Server databases on the Microsoft SQL Server instance.
- Centrify.DirectAudit.Common.Logic.AlreadyExistsException if the specified display name is already being used by another audit store database, or the specified database name is already being use by another database in the Microsoft SQL Server instance.

Discussion

The database name you specify in the database parameter is substituted for the keyword #database in the SQL script. To create a new database using standard settings or to attach an existing database to the audit store, use on the methods listed in the "See also" section.

Example

The following code sample illustrates using AuditStore.AddDatabaseByScript in a script:

...

' Create a new audit store database and attach to the audit store

```
SET objAuditStoreDatabase = objAuditStore.AddDatabaseByScript(strDatabaseName, & _
strServerName, strDatabaseName, strServerScriptFile, strDatabaseScriptFile)

IF objAuditStoreDatabase IS NOTHING THEN
wscript.echo "Failed to add audit store database '" & strDatabaseName & "'."
wscript.quit
END IF
wscript.echo "Created and attached audit store database '" & strDatabaseName & "'."
```

See also

- AddDatabase method
- AttachDatabase method
- ChangeActiveDatabase method

AttachDatabase method

Attaches an existing audit store database to the audit store.

Syntax

AuditStoreDatabase class AttachDatabase(

string *name*,

string *server*,

string *database*

)

Parameters

Return Value

Returns the AuditStoreDatabase object of the attached audit store database.

Errors

The AttachDatabase method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance that hosts the management database or you do not have permission to connect to the Microsoft SQL Server instance of the audit store database to be created.
- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the instance is not running or does not allow remote connections.
- Centrify.DirectAudit.Common.Logic.UnauthorizedException if you do not have the Manage Database permission on the audit store or you do not have the SQL Server permission to create SQL Server databases on the Microsoft SQL Server instance.
- Centrify.DirectAudit.Common.Logic.AlreadyExistsException if the specified display name is already being used by another audit store database, or the specified database name is already being use by another database in the Microsoft SQL Server instance.

Discussion

Use this method if you already have a database that you want to attach to the audit store. To create a new database and attach it to the audit store, use the AddDatabase or AddDatabaseByScript method instead.

Example

The following code sample illustrates using AuditStore.AttachDatabase in a script:

...

```
' Attach an audit store database to the audit store
SET objAuditStoreDatabase = objAuditStore.AttachDatabase(strDatabaseName, & _
strServerName, strDatabaseName)

IF objAuditStoreDatabase IS NOTHING THEN
wscript.echo "Failed to attach audit store database '" & strDatabaseName & "'."

wscript.quit
END IF
wscript.echo "Attached audit store database '" & strDatabaseName & "'."
```

See also

- AddDatabase method
- AddDatabaseByScript method

ChangeActiveDatabase Method

Changes which database is currently active in the audit store.

Syntax

void ChangeActiveDatabase(

AuditStoreDatabase class*database*

)

Parameters

Errors

The ChangeActiveDatabase method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance that hosts the management database or you do not have permission to connect to the Microsoft SQL Server instance of the audit store database to be created.
- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the instance is not running or does not allow remote connections.
- Centrify.DirectAudit.Common.Logic.UnauthorizedException if you do not have the Manage Database permission on the audit store or you do not have the SQL Server permission to create SQL Server databases on the Microsoft SQL Server instance.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time. Once you have made a database inactive by calling this method, you cannot make it active again. You cannot detach the active database.

Example

The following code sample illustrates using AuditStore.ChangeActiveDatabase in a script:

```
' Change active Audit Store database
objAuditStore.ChangeActiveDatabase(objAuditStoreDatabase)
wscript.echo "Changed active database to '" & objAuditStore.ActiveDatabase.Name & "'."
```

See also

- IsActive property

DetachDatabase Method

Detaches a database from the audit store.

Syntax

void DetachDatabase(

AuditStoreDatabase class*database*

)

Parameters

Errors

The DetachDatabase method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance that hosts the management database or you do not have permission to connect to the Microsoft SQL Server instance of the audit store database to be created.
- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the instance is not running or does not allow remote connections.
- Centrify.DirectAudit.Common.Logic.UnauthorizedException if you do not have the Manage Database permission on the audit store or you do not have the SQL Server permission to create SQL Server databases on the Microsoft SQL Server instance.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time. You cannot detach the active database.

Example

The following code sample illustrates using AuditStore.DetachDatabase in a script:

...

```
' Detach any Audit Store databases older than 2 years
FOR EACH objDatabase IN objAuditStore.Databases
IF DateDiff("d", today, objDatabase.ActiveEndTime) > 728 THEN
objAuditStore.DetachDatabase(objDatabase)
wscript.echo "Detached Audit Store database '" & objDatabase.Name & "'."
END IF
```

GetDatabase Method

Retrieves the audit store database object given the database display name.

Syntax

AuditStoreDatabase class GetDatabase(

string *displayname*

)

Parameters

Return Value

Returns the AuditStoreDatabase object of the specified database.

Errors

The GetDatabase method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance that hosts the management database or you do not have permission to connect to the Microsoft SQL Server instance of the audit store database to be created.
- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the instance is not running or does not allow remote connections.

Discussion

Use this method to obtain the audit store database object of any database attached to the audit store if you already have the audit store database display name.

Example

The following code sample illustrates using AuditStore.GetDatabase in a script:

```
...

today = Date
strDatabaseName = strDatabaseName & "-" & Year(today) & "-" & Month(today) & _

& "-" & Day(today)

SET objAuditStoreDatabase = objAuditStore.GetDatabase(strDatabaseName)

IF NOT objAuditStoreDatabase IS NOTHING THEN
wscript.echo "Audit Store database '" & strDatabaseName & "' already exists."
wscript.quit
END IF
```

AuditStoreDatabase Class

Manages AuditStoreDatabase objects.

Syntax

class AuditStoreDatabase

Properties

The AuditStoreDatabase class provides the following properties:

ActiveEndTime property	Gets the end time of a formerly active database.
ActiveStartTime property	Gets the start time of an active or formerly active database.
AuditServerAccounts property	Gets the list of management database accounts that are allowed to access this audit store.
CollectorAccounts property	Gets the list of collector accounts that are allowed to access this audit store.
DatabaseName property	Gets the audit store database name.
IsActive property	Indicates whether this database is the current active database in the audit store.
IsRetired property	Indicates whether this database was formerly the active database and is now retired.
Name property (audit store database)	Gets the display name of the audit store database.
ServerName property	Gets the Microsoft SQL Server instance name of the audit store database.

Methods

The AuditStoreDatabase class provides the following methods:

AddAuditServerAccount method	Adds a management database account to the list of accounts allowed to access this audit store database.
AddCollectorAccount method	Adds a collector account to the list of accounts allowed to access this audit store database.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time. This class provides information about any attached database. You can also add an management database or collectors to the list of accounts allowed access to an audit store database. To get information about the audit store, use the AuditStore class.

See also

- AuditStoreDatabases class
- AuditStore class

ActiveEndTime Property

Gets the end time of a formerly active database.

Syntax

DateTime ActiveEndTime {get;}

Return Value

Returns the end time of the database's active period. If the database was never active or is currently active, the return value is System.DateTime.MinValue (12:00:00 AM).

See also

- ActiveStartTime property
- IsRetired property

ActiveStartTime Property

Gets the start time of an active or formerly active database.

Syntax

DateTime ActiveStartTime {get;}

Return Value

Returns the start time of the database's active period. If the database was never active, the return value is System.DateTime.MinValue (12:00:00 AM).

See also

- ActiveEndTime property
- IsRetired property

AuditServerAccounts Property

Gets the list of management database accounts that are allowed to access this audit store.

Syntax

Accounts class AuditServerAccounts {get;}

Return Value

Returns the list of allowed incoming management database accounts.

Discussion

Although most audit installations include only one management database, it's possible to add more.

See also

- CollectorAccounts property
- AddAuditServerAccount method

CollectorAccounts Property

Gets the list of collector accounts that are allowed to access this audit store.

Syntax

Accounts class CollectorAccounts {get;}

Return Value

Returns the list of allowed incoming collector accounts.

See also

- AuditServerAccounts property
- AddCollectorAccount method

DatabaseName Property

Gets the audit store database name.

Syntax

string DatabaseName {get;}

Return Value

Returns the database name of the audit store database.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time. This property returns the database name of the database.

To get information about the active database attached to the management database, use the AuditServer class.

See also

- Name property (audit store database)
- ServerName property
- DatabaseName property

IsActive Property

Indicates whether this database is the current active database in the audit store.

Syntax

Bool IsActive {get;}

Return Value

Returns true if the database is the current active database in the audit store; otherwise, false.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time.

See also

- ChangeActiveDatabase method
- IsRetired property

IsRetired Property

Indicates whether this database was formerly the active database and is now retired.

Syntax

Bool IsRetired {get;}

Return Value

Returns true if the database was formerly the active database for the audit store and is now retired; otherwise, false.

Discussion

An audit store can have multiple databases attached, but only one can be active at a time. Once a database has been retired, it cannot be made active again.

See also

- ChangeActiveDatabase method
- IsActive property

Name Property (Audit Store Database)

Gets the display name of the audit store database.

Syntax

string Name {get;}

Return Value

The display name of the audit store database.

Discussion

The display name of the audit store database is the name used in the Audit Manager console when displaying information about the database.

Example

...

wscript.echo "Changed active database to '" & objAuditStore.ActiveDatabase.Name & "'."

See also

- DatabaseName property
- ServerName property

ServerName Property

Gets the Microsoft SQL Server instance name of the audit store database.

Syntax

string ServerName {get;}

Return Value

Returns the Microsoft SQL Server instance name of the audit store database.

Discussion

The SQL Server instance name of the audit store database is the fully qualified domain name of the SQL Server to which the audit store database is attached.

See also

- DatabaseName property
- Name property (audit store database)

AddAuditServerAccount Method

Adds a management database account to the list of accounts allowed to access this audit store database.

Syntax

void AddAuditServerAccount(

string *userName*,

bool *isWindowsAccount*

)

Parameters

Errors

The AddAuditServerAccount method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance or the management database.
- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the Microsoft SQL Server instance is not running and does not allow remote connections.
- Centrify.DirectAudit.Common.Logic.UnauthorizedException if you do not have the Manage SQL Login permission on the audit store.

Discussion

When you attach a new database to the audit store, you must set the database to allow access by the management database account. If the management database account is a Windows system account, you must explicitly specify the Windows domain account name in the username parameter. For other Windows accounts and for SQL accounts, you can pass the management database's Account.UserName property to this method as the user name.

Example

The following code sample first checks each account to see if it's a Windows system account. If the installation does not use a system account, the code passes the Account.UserName property to the AddAuditServerAccount method as the user name. If the installation uses a system account, it passes the Windows domain account name instead.

...

' Grant permission to management database to access the audit store database

SET objAuditServers = objInstallation.AuditServers

FOR EACH objAuditServer IN objAuditServers

SET objAuditServerAccount = objAuditServer.OutgoingAccount

IF NOT objAuditServerAccount.IsSystemAccount THEN

```
objAuditStoreDatabase.AddAuditServerAccount & _
objAuditServerAccount.UserName, & _
objAuditServerAccount.IsWindowsAccount
wscript.echo "Added management database account '" & objAuditServerAccount.UserName & "'."
ELSE
'Add management database accounts for those management databases running in
' system account; e.g. NT Authority/Network Service
'
DIM strAuditServerAccount
DIM isAuditServerWindowsAccount
isAuditServerWindowsAccount = true
strAuditServerAccount = "DOMAIN\MACHINE$"
objAuditStoreDatabase.AddAuditServerAccount strAuditServerAccount, & _
isAuditServerWindowsAccount
wscript.echo "Added management database account '" & strAuditServerAccount & "'."
END IF
NEXT
```

- AddCollectorAccount method
- AuditServerAccounts property
- IsSystemAccount property
- IsWindowsAccount property
- UserName property

AddCollectorAccount Method

Adds a collector account to the list of accounts allowed to access this audit store database.

Syntax

```
void AddCollectorAccount(
string userName,
)
```

Parameters

Errors

The AddCollectorAccount method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance or the

management database.

- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the Microsoft SQL Server instance is not running and does not allow remote connections.
- Centrify.DirectAudit.Common.Logic.UnauthorizedException if you do not have the Manage SQL Login permission on the audit store.

Discussion

When you attach a new database to the audit store, you must set the database to allow access by each collector account that passes data to that audit store. You can pass the collector's Account.UserName property to this method as the user name.

Example

The following code sample illustrates using AuditStoreDatabase.AddCollectorAccount in a script:

...

```
' Copy Collector accounts from current active Audit Store database
SET objCollectorAccounts = objActiveDatabase.CollectorAccounts
FOR EACH objCollectorAccount IN objCollectorAccounts
objAuditStoreDatabase.AddCollectorAccount objCollectorAccount.UserName
wscript.echo "Added Collector account '" & objCollectorAccount.UserName & "'."
NEXT
```

See also

- AddAuditServerAccount method
- CollectorAccounts property

AuditStoreDatabases class

Enumerates AuditStoreDatabase objects.

Syntax

class AuditStoreDatabases

Example

In the following code sample, the AuditStore.Databases property returns an AuditStoreDatabases object and a FOR EACH—IN statement is used to enumerate the audit store databases:

...

```
' Detach any Audit Store databases older than 2 years
FOR EACH objDatabase IN objAuditStore.Databases
IF DateDiff("d", today, objDatabase.ActiveEndTime) > 728 THEN
objAuditStore.DetachDatabase(objDatabase)
wscript.echo "Detached Audit Store database '" & objDatabase.Name & "'."
END IF
NEXT
```

See also

- AuditStoreDatabase class
- AuditStore class

Connection class

Manages an auditing connection.

Syntax

class Connection

Constructors

The Connection class provides the following overloaded constructor:

Connection constructor	Creates a Connection object.

Methods

The Connection class provides the following overloaded method:

GetInstallation method	Retrieves an audit installation by name or by management database connection.

Discussion

The Active Directory domain controller stores information about the audit installation, including the installation name and the management database being used by the installation. The Connection object provides a way to connect to an Active Directory domain controller and retrieve the installation information stored there.

See also

- Installation class

Connection Constructor

Creates a Connection object.

Syntax

Connection()

Connection(string *domainController*)

Parameters

Specify the following parameter when needed:

domainController	The domain controller of the Active Directory domain to which you wish to connect in order to get information about the audit installation.

Discussion

The Connection object constructor is overloaded. Use the constructor without parameters to create a connection in the current domain. Use the second version of the constructor if you want to specify the Active Directory domain of the connection in order to administer an audit installation on an Active

Directory domain other than the one to which your workstation is joined.

GetInstallation Method

Retrieves an audit installation by name or by management database connection.

Syntax

Installation class GetInstallation(

string *installationName*)

Installation class GetInstallation(

string *server*,

string *database*)

Parameters

Return value

Returns the Installation object found.

Errors

The GetInstallation method may throw the following exception:

- Centrify.Cfw.DirectoryServices.ServerNotOperationalException if the domain controller is not operational. Check to make sure you entered the correct domain name when you called the constructor for the Connection object.

Discussion

The Connection.GetInstallation method is overloaded to provide two ways to search for an installation: by the name of the installation, or by the management database that is part of the installation.

Example

The following code sample illustrates using Connection.GetInstallation in a script to get the Installation object for the audit installation in the current Active Directory domain. The Installation object is then used to get the name of the object store database:

...

```
SET objInstallation = objConnection.GetInstallation(strInstallationName)
SET objAuditStore = objInstallation.GetAuditStore(strAuditStoreName)
SET objAuditStoreDatabase = objAuditStore.GetDatabase(strDatabaseName)
```

See also

- Installation class

Installation class

Manages Installation objects.

Syntax

class Installation

Properties

The Installation class provides the following properties:

AuditServers property	Gets the list of management databases in this installation.
CurrentAuditServer property	Gets the currently connected management database.
Name property (audit installation)	Gets the name of the audit installation.

Methods

The Installation class provides the following methods:

GetAuditStore method	Retrieves an audit store given its display name.
Publish method	Publishes installation information to Active Directory.

Discussion

An Installation object holds information about a specific audit installation. This class lets you retrieve information about an installation and publish changed information to the Active Directory domain controller so that it can be retrieved by the components of the installation.

See also

- GetInstallation method

AuditServers property

Gets the list of management databases in this installation.

Syntax

AuditServers class AuditServers {get;}

Return value

Returns the list of management databases in the installation.

Discussion

In most cases, an installation includes only one management database.

See also

- AuditServer class

CurrentAuditServer property

Gets the currently connected management database.

Syntax

AuditServer class CurrentAuditServer {get;}

Return value

Returns the connected management database.

Discussion

You can use the SQL Server instance name property of the management database object returned by this property as a parameter value when you call the Connection.GetInstallation (server,database) method.

See also

- [AuditServer class](https://docs.centrify.com/Content/aud-dbmgmt/AuditServerClass.htm)
- GetInstallation method

Name property (audit installation)

Gets the name of the audit installation.

Syntax

String Name {get;}

Return value

Returns the installation name.

Discussion

The audit installation is named when it is created and this name is not normally changed during the life of the installation.

GetAuditStore method

Retrieves an audit store given its display name.

Syntax

AuditStore class GetAuditStore(

string *Name*

)

Parameters

Errors

The GetAuditStore method may throw one of the following exceptions:

- Centrify.DirectAudit.Common.Logic.AuthenticationException if you do not have permission to connect to the Microsoft SQL Server instance or the

management database.

- Centrify.DirectAudit.Common.Logic.ConnectDatabaseException if you cannot connect to the Microsoft SQL Server instance either because the Microsoft SQL Server instance is not running and does not allow remote connections.

Example

The following code sample accepts the audit store display name as an argument when the script is executed, calls the GetAuditStore method to get the audit store, then attaches a new audit store database to the audit store:

```
...

strInstallationName = wscript.arguments.item(0)
strAuditStoreName = wscript.arguments.item(1)
strServerName = wscript.arguments.item(2)
strDatabaseName = wscript.arguments.item(3)

SET objConnection = CreateObject("Centrify.DirectAudit.Connection")
SET objInstallation = objConnection.GetInstallation(strInstallationName)
SET objAuditStore = objInstallation.GetAuditStore(strAuditStoreName)
today = Date
strDatabaseName = strDatabaseName & "-" & Year(today) & "-" & Month(today) &_
& "-" & Day(today)

SET objAuditStoreDatabase = objAuditStore.GetDatabase(strDatabaseName)

' Create a new Audit Store database and attach to the Audit Store
SET objAuditStoreDatabase = objAuditStore.AddDatabase(strDatabaseName, strServerName, strDatabaseName)
```

See also

- AuditStore class

Publish method

Publishes installation information to Active Directory.

Syntax

```
void Publish()
```

Errors

The Publish method may throw the following exception:

- Centrify.DirectAudit.Common.Logic.DirectAuditException if you do not have write permission for the installation's service connection point (SCP) object in Active Directory.

Discussion

Audit Manager publishes installation information to a service connection point (SCP) object in Active Directory so that audited computers and collectors can look up the information. For example, collectors publish which audit store they are part of so that once an agent determines which audit store is to receive its audit data, it can determine the list of collectors that service that audit store by querying Active Directory.

When you use the methods in the API to change settings in the installation, you must call the Publish method to write the new settings to the Active Directory domain controller so that other auditing components in the installation can find the new information.

Example

The following code sample illustrates using Installation.Publish in a script:

...

objInstallation.Publish
wscript.echo "Published settings to Active Directory."

Find Sessions is a separate executable file, installed in the same directory as Audit Analyzer, that you can use to find and open audited sessions. The program provides a graphical user interface and a command line interface for specifying the search criteria. You can use either interface to find sessions of interest. From the Find Sessions graphical user interface, you can also replay, update the review status, view the desktops used for any sessions found, display the list of indexed commands or events, and copy the session URI.

Starting Find Sessions

You can start Find Sessions from the Windows command line, using a web browser, or by selecting the View DirectAudit Sessions menu option in other applications, such as Access Manager and Active Directory Users and Computers.

For example, in Access Manager or Active Directory Users and Computers, you can select a computer or user, right-click, then select View DirectAudit Sessions to open Find Sessions. To start Find Sessions from the Windows command line, you can navigate to the Audit Analyzer installation directory and run the following command in a command prompt window:

```
findsessions /ia
```

Find Sessions Return Codes

For your reference, Find Sessions supports the following return codes to report the status of an operation performed:

0	The operation was successful.
1	The operation failed because Find Sessions could not parse the Session URI.
2	The operation failed because Find Sessions could not parse the user input.
3	The operation failed because Quick queries are not supported.
4	The operation failed because there were errors in the AQL format.
5	The operation failed because of an incompatible version of AQL was detected.
6	The operation failed because no installation was selected.
7	The operation failed because the installation specified was not found.
8	The operation failed because the AQL string contains the <group by> keyword.
9	The operation failed because no sessions were selected.
10	The operation failed because Find Sessions could not export the list of events.
11	The operation failed because Find Sessions could not export the session list.
12	The operation failed because Find Sessions could not export UNIX input or output.
13	Not all selected sessions were deleted.
14	An unknown error occurred.

Specifying the Sessions to Find

After you start Find Sessions by selecting View DirectAudit Sessions, from the Windows command line, or in a web browser, the program displays a graphical user interface for selecting search criteria. You can use the Common or Advanced search criteria to find sessions of interest. The Find Sessions dialog box then displays the results that match the criteria you specify. You can then replay, update the review status, display the list of indexed commands or events, copy session URI, or view the desktops used in any of the sessions returned.

In most cases, you can find the sessions you are interested in through some combination of user name, computer name, and session time displayed on the Common tab. If you right-click to View DirectAudit Sessions from a specific computer or user, that computer or user is automatically defined as the search criteria. If you want to specify additional criteria, such as review status or auditor name, you can click the Advanced tab.

To specify criteria by which to find sessions:

1. Start Find Sessions.
2. Select the desired installation from the Installation list.
3. On the Common tab, enter the basic search criteria as applicable for the sessions you want to find:
    1. User: Type all or part of the user name to find sessions for a particular user account.
    2. Machine: Type all or part of the computer name to find sessions run on a particular computer.
    3. Session start time: Select this option to find sessions based on when the session started. If you select this option, you can refine the search to include sessions started or not started in a specific number of days, hours, or minutes, or to include sessions started or not started today, yesterday, this week, last week, this month, last month, this year, or last year.
4. Click **Find Now** to find the sessions that match the criteria you specified.
5. Click **Clear All** to start a new query.

Specifying the Sessions to Find

After you start Find Sessions by selecting View DirectAudit Sessions, from the Windows command line, or in a web browser, the program displays a graphical user interface for selecting search criteria. You can use the Common or Advanced search criteria to find sessions of interest. The Find Sessions dialog box then displays the results that match the criteria you specify. You can then replay, update the review status, display the list of indexed commands or events, copy session URI, or view the desktops used in any of the sessions returned.

In most cases, you can find the sessions you are interested in through some combination of user name, computer name, and session time displayed on the Common tab. If you right-click to View DirectAudit Sessions from a specific computer or user, that computer or user is automatically defined as the search criteria. If you want to specify additional criteria, such as review status or auditor name, you can click the Advanced tab.

To Specify Criteria to Find Sessions:

1. Start **Find Sessions**.
2. Select the desired installation from the **Installation list**.
3. On the **Common** tab, enter the basic search criteria as applicable for the sessions you want to find:
    - User: Type all or part of the user name to find sessions for a particular user account.
    - Machine: Type all or part of the computer name to find sessions run on a particular computer.
    - Session start time: Select this option to find sessions based on when the session started. If you select this option, you can refine the search to include sessions started or not started in a specific number of days, hours, or minutes, or to include sessions started or not started today, yesterday, this week, last week, this month, last month, this year, or last year.
4. Click **Find Now** to find the sessions that match the criteria you specified.
5. Click **Clear All** to start a new query.

Specifying Advanced Criteria

In some cases, you might want to specify additional criteria for a search or to search exclusively on an attribute not found on the Common tab. For example, you might want to find only those sessions that have yet to be reviewed or all of the sessions where a specific command or application was used. To add criteria or perform these types of specialized searches, you can click the **Advanced** tab.

To Specify Advanced Criteria for Finding Sessions:

1. Start **Find Sessions**.
2. Select the desired installation from the **Installation list**.
3. Click the **Advanced** tab.
4. Click **Add** to add a new criterion.
5. Select an appropriate attribute from the Attribute list based on the sessions you want to find.

   For example: You can search for sessions based on the period of time in which they were active or based on a specific state. You can also search for sessions based on the activity that took place during the session. For example, you can find sessions where specific UNIX commands or Windows applications were used.
6. Select the appropriate criteria for the attribute you selected, then click **OK**.
7. The specific selections you can make depend on the attribute selected. For example, if the attribute is Review Status, you can choose Equals and the review state you want to find. If you select the attribute Comment, you can specify Contains any of and type the string that you want to find any part of.
8. When searching for user names or computers on the **Advanced** tab, use the Starts with option. If you use the default to match exactly, you must include the fully qualified domain name of the user or computer.
9. Click **Add** to add another criterion until you have defined all of the attributes for which you want to find sessions.
10. Click **Find Now** to find the sessions that match the criteria you specified.
11. Click **Clear All** to start a new query.

Adding Advanced Criteria

If you have more than one advanced criteria, different criteria attributes, such as Session Time and State, are separated by an implicit AND operation. Onl sessions that match both criteria are returned. If you have repeated criteria attributes, for example, time is not in past 10 days; time is in last month, the attributes are separated by an implicit OR operation. Sessions that match either criteria are returned.

Editing and Removing Advanced Criteria

You can edit and remove any of the advanced criteria you specify in Find Sessions. For example, if you are not finding the appropriate sessions, you might need to change or remove the criteria you have defined.

To Edit or Remove Find Sessions Criteria:

1. Start Find Sessions.
2. Select the desired installation from the Installation list.
3. Click the **Advanced** tab.
4. Select the criterion in the list of Define Criteria.
5. Click **Edit** to modify the definition or **Remove** to remove the criterion.

Finding Sessions From a Command Line

You can run Find Sessions as a command line utility on computers where Audit Analyzer is installed. The command line interface can be useful, for example, if you may want to find, export, or delete sessions as part of a script.

You can view usage information for the command line interface using the /help option.

To Use the Command Line Interface for Find Sessions:

1. Open a Command window and navigate to the Audit Analyzer directory.

   ```
   cd “C:\\Program Files\\Centrify\\Audit\\AuditAnalyzer”
   ```

2. Run the findsessions command with the /help option to view usage information.

   ```
   findsessions /help
   ```

3. Specify search criteria for finding sessions using the following format:

   ```
   findsessions /i=”*InstallationName*” /u=”*username*” /m=”*computerName*”/t=”*yyyy-MM-dd HH:mm:ss*”
   ```

   The installation name is required. You must also specify at least one of the other criteria (user name, computer name, or time). You can also combine the search criteria to refine your search.

   For user name and computer name, you can specify a portion of a name to find all sessions matching that name portion. For time, if you specify a date without a time, the assumed time is 12 midnight. For example, if you do the following search and you have sessions on computers named “KH-Win7” and “KH-W8,” the results include sessions for both computers.

   ```
   FindSessions /i=”DefaultInstallation” /m=”KH-W”
   ```

   The following example finds sessions for “Admin” and “Administrator” users:

   ```
   FindSessions /i=”DefaultInstallation” /u=”Admin”
   ```

   The following example finds sessions that were running at a specific time regardless of what time the sessions started or ended:

   ```
   FindSessions /i=”DefaultInstallation” /t=”2015-01-21 5:25:00”
   ```

   You can also find sessions for multiple users or computers by separating the user names or computer names using a semi-colon (;).For example, to search for audited sessions for the users maya and fred, you can specify both users in the command line like this:

   ```
   FindSessions /i=”DefaultInstallation” /u=”maya;fred”
   ```

   For more complex queries, you can also use AQL syntax on the command line.

   For details, see Finding sessions using AQL syntax.

Delinea

Find Sessions Command Line Usage Examples

You can view usage information for the command line interface using the /help option. That information is included here as well.

Usage:

FindSessions.exe [Connection] [Query] [Action] [Parameter]

Connection:
/i=<installation name> or /installation=<installation name>
Make a connection to the specified DirectAudit Installation.

Query:
Query can be defined by AQL or individual search criteria

/a=<aql statement> or /aql=<aql statement>
Use the specified AQL as a search criteria to find the audited sessions from DirectAudit databases.
This option should not be used together with /user, /machine or /activetime.

/u=<user name> or /user=<user name>
Find all audited sessions for a particular user from DirectAudit databases.
This option can be used together with /machine and /activetime, which means the returned sessions need to fulfill all specified criteria.
This option should not be used with /aql option.

/m=<machine name> or /machine=<machine name>
Find all audited sessions for a particular machine from DirectAudit databases.

This option can be used together with /user and /activetime, which means the returned sessions need to fulfill all specified criteria. This option should not be used with /aql option/t=<time> or /activetime=<time>.

/t=<time> or /activetime=<time>
Find all active audited sessions at a particular time from DirectAudit databases. This option can be used together with /user and /machine, which means the returned sessions need
to fulfill all specified criteria. This option should not be used with the /aql option.

/r="role1;role2" or /role="role1;role2"
Find all sessions with role role1 OR role2. Must be used with /export="UnixCommandlUnixInputlUnixInputOutput". If /role and /ticket are used together, sessions meeting role AND ticket criteria are searched.

/k="ticket1;ticket2" or /ticket="ticket1"
Find all sessions with trouble ticket ticket1 OR ticket2. Must be used with /export="UnixCommandlUnixInputlUnixInputOutput". If /role and /ticket are used together, sessions meeting role AND ticket criteria are searched.

Action:
/delete
Delete the sessions by the query.

/export=[SessionListlWashEventslUnixCommandlUnixInputlUnixInputOutput]
Export the sessions by the query. This option should used with /path option.

Parameter:
/path
Folder to save the export files. This option should used with /export option

/format=[htmllhtmlcsvlpdflxml]
Export the session list. this option should used with /export=SessionInfo /path=<folder path>

/suppresswarning
Suppress warning messages.

/onerror=[continue]
Continue processing session list if one or more databases are unreachable.

Examples:

FindSessions /installation="installation sample" /aql="1 time is in this week"

FindSessions /installation="installation sample" /aql="1 inputcommand = \"dzdo*\"\"" /delete

FindSessions /installation="installation sample" /aql="1 text = \"dzdo\"\"" /suppresswarning
/export="UnixInput" /path="folder path"

FindSessions /installation="installation sample" /user="user sample" /machine="machine sample"
/activetime="2011-12-24 15:30:45"

FindSessions /installation="installation sample" /aql="1 module = \"Windows PowerShell\"\""
/export="SessionList" /format="html" /path="folder path"

FindSessions /installation="installation sample" /aql="1 time is in this month"

/export="UnixInputOutput" /path="folder path" /role="role1;role2" /ticket="ticket1;ticket2"

Note: If the last field that you're search for includes double quotes, you need to escape the quotes. For example, findsessions -i="MyInstallation" /aql="1 time is in this week" doesn't have this issue but FindSessions /i="MyInstallation" /a="1 sessionid = \"a4006f206465-4db1-a2e7-a4e1f646c835\"\" does.

Editing and removing advanced criteria

You can edit and remove any of the advanced criteria you specify in Find Sessions. For example, if you are not finding the appropriate sessions, you might need to change or remove the criteria you have defined.

To edit or remove Find Sessions criteria:

1. Start Find Sessions.
2. Select the desired installation from the Installation list.
3. Click the **Advanced** tab.
4. Select the criterion in the list of Define Criteria.
5. Click **Edit** to modify the definition or **Remove** to remove the criterion.

Delinea

Finding sessions from a command line

You can run Find Sessions as a command line utility on computers where Audit Analyzer is installed. The command line interface can be useful, for example, if you may want to find, export, or delete sessions as part of a script.

You can view usage information for the command line interface using the /help option.

To use the command line interface for Find Sessions:

1. Open a Command window and navigate to the Audit Analyzer directory.
2. cd "C:\Program Files\Centrify\Audit\AuditAnalyzer"
3. Run the findsessions command with the /help option to view usage information.
4. findsessions /help
5. Specify search criteria for finding sessions using the following format:
6. findsessions /i="*InstallationName*" /u="*username*" /m="*computerName*" /t="*yyyy-MM-dd HH:mm:ss*"
7. The installation name is required. You must also specify at least one of the other criteria (user name, computer name, or time). You can also combine the search criteria to refine your search.
8. For user name and computer name, you can specify a portion of a name to find all sessions matching that name portion. For time, if you specify a date without a time, the assumed time is 12 midnight. For example, if you do the following search and you have sessions on computers named "KH-Win7" and "KH-W8," the results include sessions for both computers.
9. FindSessions /i="DefaultInstallation" /m="KH-W"
10. The following example finds sessions for "Admin" and "Administrator" users:
11. FindSessions /i="DefaultInstallation" /u="Admin"
12. The following example finds sessions that were running at a specific time regardless of what time the sessions started or ended:
13. FindSessions /i="DefaultInstallation" /t="2015-01-21 5:25:00"
14. You can also find sessions for multiple users or computers by separating the user names or computer names using a semi-colon (;).For example, to search for audited sessions for the users maya and fred, you can specify both users in the command line like this:
15. FindSessions /i="DefaultInstallation" /u="maya;fred"

For more complex queries, you can also use AQL syntax on the command line. For details, see Finding sessions using AQL syntax.

Find sessions command line usage examples

You can view usage information for the command line interface using the /help option. That information is included here as well.

Usage:

FindSessions.exe [Connection] [Query] [Action] [Parameter]

Connection: /i=<installation name> or /installation=<installation name>

Make a connection to the specified DirectAudit Installation.

Query:
Query can be defined by AQL or individual search criteria

/a=<aql statement> or /aql=<aql statement>
Use the specified AQL as a search criteria to find the audited sessions from DirectAudit databases.
This option should not be used together with /user, /machine or /activetime.

/u=<user name> or /user=<user name>
Find all audited sessions for a particular user from DirectAudit databases.
This option can be used together with /machine and /activetime, which means the returned sessions need to fulfill all specified criteria.
This option should not be used with /aql option.

/m=<machine name> or /machine=<machine name>
Find all audited sessions for a particular machine from DirectAudit databases.

This option can be used together with /user and /activetime, which means the returned sessions need to fulfill all specified criteria. This option should not be used with /aql option/t=<time> or /activetime=<time>.

/t=<time> or /activetime=<time>
Find all active audited sessions at a particular time from DirectAudit databases. This option can be used together with /user and /machine, which means the returned sessions need
to fulfill all specified criteria. This option should not be used with the /aql option.

/r="role1;role2" or /role="role1;role2"
Find all sessions with role role1 OR role2. Must be used with /export="UnixCommandlUnixInputlUnixInputOutput". If /role and /ticket are used together, sessions meeting role AND ticket criteria are searched.

/k="ticket1;ticket2" or /ticket="ticket1"
Find all sessions with trouble ticket ticket1 OR ticket2. Must be used with /export="UnixCommandlUnixInputlUnixInputOutput". If /role and /ticket are used together, sessions meeting role AND ticket criteria are searched.

Action:
/delete
Delete the sessions by the query.

/export=[SessionListlWashEventslUnixCommandlUnixInputlUnixInputOutput]
Export the sessions by the query. This option should used with /path option.

Parameter:
/path
Folder to save the export files. This option should used with /export option

/format=[htmllhtmlcsvlpdflxml]
Export the session list. this option should used with /export=Sessionlnfo /path=<folder path>

/suppresswarning
Suppress warning messages.

/onerror=[continue]
Continue processing session list if one or more databases are unreachable.

Examples:

FindSessions /installation="installation sample" /aql="1 time is in this week"

FindSessions /installation="installation sample" /aql="1 inputcommand = \"dzdo*\"\"" /delete

FindSessions /installation="installation sample" /aql="1 text = \"dzdo\"\"" /suppresswarning
/export="UnixInput" /path="folder path"

FindSessions /installation="installation sample" /user="user sample" /machine="machine sample"
/activetime="2011-12-24 15:30:45"

FindSessions /installation="installation sample" /aql="1 module = \"Windows PowerShell\"\""
/export="SessionList" /format="html" /path="folder path"

FindSessions /installation="installation sample" /aql="1 time is in this month"

/export="UnixInputOutput" /path="folder path" /role="role1;role2" /ticket="ticket1;ticket2"

Note:If the last field that you're search for includes double quotes,
you need to escape the quotes. For example, findsessions -i="MyInstallation"
/aql="1 time is in this week" doesn't have this issue but FindSessions
/i="MyInstallation" /a="1 sessionid =
\\"a4006f206465-4db1-a2e7-a4e1f646c835\\"\\" does.

Finding sessions using AQL syntax

If you are an experienced programmer and want to write complex queries, you can use AQL statements on the command line.

To use AQL to find sessions at the command line:

1. Open a command window and navigate to the Audit Analyzer directory.

   cd "C:\Program Files\Centrify\Audit\AuditAnalyzer"

2. Run the findsessions command with the following syntax:

   FindSessions /i="*InstallationName*" /aql="*AQL query text*"

   For example, the following is a simple query that searches for sessions that were running in the current week:

   findsessions -i="MyInstallation" /aql="1 time is in this week"

   To find a specific session using the session identifier, you might write a query similar to the following:

   FindSessions /i="MyInstallation" /a="1 sessionid = \"a4006f206465-4db1-a2e7-a4e1f646c835\"\"

   To find a specific session using the user display name, you might write a query similar to the following:

   findsessions /i="installationname" /a="1 displayname=\"maya*\"\"

Note: When you enter a search term, AQL looks for an exact match. To search for sessions that start with the term you entered, add an asterisk to the search term. For example, user=\\"maya*\\"\\" finds sessions for users such as maya@acme.com, mayan@acme.com, and so forth. Otherwise, a search for user=\\"maya\\"\\" returns nothing and a search for user=\\"maya@acme.com\\"\\" returns sessions for just that one user.

Note: If the last field that you're search for includes double quotes, you need to escape the quotes. For example, findsessions \-i="MyInstallation" /aql="1 time is in this week" doesn't have this issue but FindSessions /i="MyInstallation" /a="1 sessionid = \\"a4006f206465-4db1-a2e7-a4e1f646c835\\"\\" does.

Simplifying AQL queries

Writing valid AQL queries for the command line can be challenging. The basic format for AQL statements in Backus-Naur notation consists of the following parts:

<aql> ::= <version> {<quick_terms>} | {<type> | <filter>}

To simplify the process of generating the AQL queries you want to use on the command line, you can use Audit Analyzer to create a new private query and use the user interface to specify the query criteria. After you have created the query, you can right-click the query node, and click **Export Query Definition** to save the query definition as a file. You can then extract the AQL statement from the query definition. You can then delete the private query node from Audit Analyzer if it is not needed.

For example, run the command with the definition from the private query:

findsessions -i="MyInstallation" /aql="1 type= shellui, wingui; time is in this week; review = Reviewed"

Delinea

Audit Query Language overview

You can use the Audit Query Language to search for audited sessions with Find Sessions from a command line interface.

The Audit Query Language (AQL) serves two purposes:

- **Query definition:** The Audit Management Server database stores the query definition as an AQL statement.
- **Query language:** In order to query for audit information, the audit & monitoring service sends AQL statements to the Audit Management Server database.

When you enter an AQL query, the system stores this as the query definition. The query definition defines what information is of interest and how to group the results. In some cases, you might retrieve the results over multiple phases, depending on how you want to present the information.

For example: The query "get all Windows audit sessions, grouped by user" has two phases:

1. Gather a list of all users who have Windows audit sessions
2. Show all the Windows sessions for each user who is listed in Step 1.

In each phase, the Audit & Monitoring generates the AQL statement and sends it to the Audit Management Server database in order to query for audit information. This part is when the AQL statements function as a query language.

Here is an AQL statement example:

1 Type=wingui; orderby=time DESC; time is in this week; user="joe*","mark*";machine="domaincontroller"'

The example query would return audited Windows sessions in the last week where Joe or Mark logged in to the domain controller system, and the results would be listed in descending order of when they occurred.

In general, the format of an AQL statement can either be just some quick search terms or a statement with the following parts:

- Audit trail types
- Group-by
- Order-by
- Predicates

Backus-Naur Form (BNF) definition of AQL

Here is the Backus-Naur Form (BNF) definition of the AQL language syntax so that you can see how the query language is constructed.

<aql> ::= <version> {<quick_terms>} | {<type> | <groupby> | <filter>}

<version> ::= any numeric number. Currently, we support only 1.

<quick_terms> ::= <word> | <and_words> | <or_words> | <exact_combined_words>

<and_words> ::= <word> (" " <word>)+

<or_words> ::= <word> ("OR" <word>)+

<exact_combined_words> ::= """ <and_words> """

<word> ::= any printable string except white spaces

<type> ::= "type" ("=" | ":") <typename> {"," <typename>}

<groupby> ::= "groupby" ("=" | ":") <groupname> {"," <groupname>}

<orderby> ::= “orderby” (“=”|”:”) <columnname> {“ASC”|”DESC”}

<filter> ::= <normal_filter> | <negative_filter>

<normal_filter> ::= <string_filter> | <time_filter> | <number_filter> | <enum_filter> |

<boolean_filter> | <ip_filter>

<negative_filter> :: = "not(" <normal_filter> ")"

<string_filter> :: = <string_field> <string_op> """ <string_val> """ {"," """ <string_val> """}

<string_op> ::= "=" | "!="

<time_filter> ::= <single_time_filter> | <between_time_filter> | <in_predefined_time_filter> |

<in_past_filter>

<single_time_filter> ::= <time_field> <single_time_op> <single_time_val> <!-- single_time_val is in

format of "yyyy-mm-dd hh:mm:ss" -->

<time_op> :: = "is before" | "is after" | "is not before" | "is not after"

<between_time_filter> ::= <time_field> <between_time_op> <between_time_val>

<between_time_op> ::= "is between" | "is not between"

<between_time_val> ::= <single_time_val> " and " <single_time_val>

<in_predefined_time_filter> ::= <time_field> <in_predefined_time_op> <predefined_time_val>

<in_predefined_time_op> ::= "is in" | "is not in"

<predefined_time_val> ::= "today" | "yesterday" | "this week" | "last week" | "this month" | "last month" |

"this year" | "last year"

<in_past_filter> ::= <time_field> <in_past_op> <digit>+ <unit_of_time>

<in_past_op> ::= "is in_past" | "is not in_past"

<unit_of_time> ::= "day" | "hour" | "minute"

Note:Currently, AQL has filters only for strings and time.

AQL usage examples

AQL usage examples

Find Sessions Usage formats:

FindSessions /i=<installationName> /a=<AQL query>

FindSessions /i=<installationName> /u=<user or semi-colon-separated list of users> /m=<machine or semi-colon-separated list of machines> /t=<YYYY-MM-DD HH:MM:SS>

FindSessions /i=<installationName> /a=<AQL query> /

FindSessions /i=<installationName> /a=<AQL query> /export=<SessionList> /format=<html|htm|csv|pdf|xml> /sw /path=<folderPath>

FindSessions /i=<installationName> /a=<AQL query> /export=<SessionList|WashEvents|UnixCommand|UnixInput|UnixInputOutput> /sw /path=<folderPath>

FindSessions /i=<installationName> /a=<AQL query> /export=<UnixCommand|UnixInput\UnixInputOutput> /sw /path=<folderpath> /r="role1;role2" /"ticket1;ticket2"

Find Sessions: Usage examples without AQL:

FindSessions /i="DirectAudit" /user="user sample" /machine="machine sample" /activetime="2018-12-24 15:30:45"

FindSessions /i="DirectAudit" /user="maya;fred" /machine="KH-Win7;KH-Win8" /activetime="2018-12-24 15:30:45"

Find Sessions: Usage examples with AQL:

FindSessions /i="DirectAudit" /aql="1 time is in this week"

FindSessions /i="DirectAudit" /aql="1 module = \"Windows PowerShell\"\"" /delete

FindSessions /i="DirectAudit" /aql="1 text=\"dzdo\"\"" /export="UnixCommand" /path="folder path"

FindSessions /i="DirectAudit" /aql="1 inputcommand = \"dzdo*\"\"" /suppresswarning /export="UnixInputOutput" /path="folder path"

FindSessions /i="DirectAudit" /aql="1 sessionid=\"D108F7B2-F4FB-FB42-A6E7-A40454780690\"\"

AQL quick search terms

ou can just enter a series of keywords if you just want to do a quick search.

Here are some examples:

- joe : any data fields that contain the word 'joe'
- joe john : any data fields that contain both words 'joe' and 'john'
- joe OR john : any data fields that contain 'joe' or 'john'
- "joe john" : any data fields that contain the exact phrase “joe john”

The default operator designated by a space between terms is evaluated as an “AND” operator, so there is no need to include “AND” between terms. Explicit operator takes precedence over implicit operator, thus “OR” is always evaluated before the absence of an operator.

Here are some examples of quick search term queries in AQL:

The database searches the following data fields with the keywords in quick search terms:

- User (username)
- Machine (machine name)
- Time (audit trail data record start time)
- Module
- Text

AQL audit trail types example

AQL audit trail types example

If desired, you can refer to the types of audit trails to include in the results, such as Windows sessions or UNIX sessions. You can specify one or more audit trail types with the "type:" parameter.

If you don't include this parameter, the results include all audit trail types.

If you specify more than audit trail type, the results are those that fit all specified parameters.

Example:

type=wingui, shellui

AQL group-by example

If desired, you can specify how to group the results.

Example:

groupby=user, date

When you specify multiple groupby criteria, the database groups the results by the first criterion and displays the immediate result by ignoring the remaining criteria. When you double-click the results, then the database displays more results according to the remaining criteria.

Note:FindSessions does not support the use of groupby.

AQL order-by example

If desired, you can specify how to sort the AQL query results by using orderby.

For example:

orderby=time, user ASC, machine DESC

The sort order options are as follows:

- ASC: sort results in ascending order
- DESC: sort results in descending order

If you don't specify a sort order, the system uses 'ASC' by default.

AQL Predicates

Using predicates in your AQL query is entirely optional. You can filter the result set by any number of predicates or none at all. Each predicate expresses a condition that must be true in order for the service to include a record in the result set.

There is an implicit 'AND' between each predicate. If you repeat a predicate for a field, there is an implicit 'OR' between them.

Each predicate refers to a field in the schema of an audit trail type. If the field name does not specify an audit trail type, then the field must exist for all selected audit trail types. If the field name specifies an audit trail type specified with the "type:" parameter, then the predicate applies only to that audit trail type.

AQL predicate behavior examples

Example A: Type=wingui, shellui; user = “joe”

The above example selects all Windows and UNIX sessions for joe.

Example B: Type=wingui, shellui; shellui.user = “joe”

The above example selects all Windows sessions but only UNIX sessions for joe.

The service categorizes predicates according to the field data type:

- String
- Number
- Boolean
- Date / time
- IP
- Enumeration

AQL string predicate behavior

Here are some examples of how to filter an AQL query based on string predicates:

field = "<string>","<string2>",...	exact match
field != "<string>", “<string2>”,...	not equals (exact match)
field = "<string>*", “<string2>*”,...	starts with
field != "<string>*", “<string2>*”,...	not starts with

AQL number predicate behavior

Here are some examples of how to filter an AQL query based on number predicates:

field = <number>	equals
field != <number>	not equal
field >= <number>	greater than or equal
field > <number>	greater than
field <= <number>	smaller than or equal

field < <number>	smaller than

You can replace <number> with any integer or floating point number, such as 1 or -3.14.

AQL boolean predicate behavior

Here are some examples of how to filter an AQL query based on boolean predicates:

field = true	true
field != false>	false

AQL Date and time predicate behavior

Here are some examples of how to filter an AQL query based on date and time predicates:

field is (not) before <datetime>	before a specific date and time or not
field is (not) after <datetime>	after a specific date and time or not
field is (not) between <datetime> <datetime>	between two dates and time or not
field is (not) in_past <number> <unit>	in the past period of time or not, where the unit is day, hour, or minute
field is (not) in <predefined time>	field is not in the predefined time or not

Replace <datetime> with a particular date and time with the following format:

- Y-M-D, for example 2019-12-15
- Y-M-D h:m:s, for example 2019-12-15 15:30:00

Replace <predefined time> with any of the following values:

- today
- yesterday
- this week
- last week
- this month
- last month
- this year
- last year

AQL IP predicate behavior

Here are some examples of how to filter an AQL query based on IP address predicates:

field = <ip>	equals
field != <ip>	not equal
field >= <ip>	greater than or equal
field > <ip>	greater than
field <= <ip>	smaller than or equal
field < <ip>	smaller than

AQL enumeration predicate behavior

Here are some examples of how to filter an AQL query based on enum predicates:

field = <enum>	equals
field != <enum>	not equal

Replace <enum> with the values appropriate for the field you're querying against.

For example, filtering for a session state involves specifying an enum value:

state = Terminated

state != InProgress

AQL keywords

Session time	Date/Time predicate
UNIX command time	Date/Time predicate
State	Enum predicate: Unknown, InProgress, Terminated, Disconnected, Completed, ToBeDeleted
Review status	Enum predicate: None, ToBeReviewed, Reviewed, PendingForAction, KeepForever, ToBeDeleted
Session size	Numeric predicate (in kilobytes)
Unix outputs and commands	String predicate
User	String predicate
Machine	String predicate
Auditstore	Number predicate
Parameters of commands and applications	String predicate
Unix command name	String predicate

Windows applications	String predicate
Comment	String predicate
Session Id	String predicate
Client name	String predicate
User display name	String predicate
Account	String predicate
Text	String predicate
Module	String predicate
Tag	String predicate

FindSessions /i=<installationName> /a=<AQL query> /export=<SessionList> /format=<html|htm|csv|pdf|xml> /sw /path=<folderPath>

FindSessions /i=<installationName> /a=<AQL query> /export=<SessionList|WashEvents|UnixCommand|UnixInput|UnixInputOutput> /sw /path=<folderPath>

FindSessions /i=<installationName> /a=<AQL query> /export=<UnixCommand|UnixInput\UnixInputOutput> /sw /path=<folderpath> /r="role1;role2" /"ticket1;ticket2"

Find Sessions: Usage examples without AQL:

FindSessions /i="DirectAudit" /user="user sample" /machine="machine sample" /activetime="2018-12-24 15:30:45"

FindSessions /i="DirectAudit" /user="maya;fred" /machine="KH-Win7;KH-Win8" /activetime="2018-12-24 15:30:45"

Find Sessions: Usage examples with AQL:

FindSessions /i="DirectAudit" /aql="1 time is in this week"

FindSessions /i="DirectAudit" /aql="1 module = \"Windows PowerShell\"\"" /delete

FindSessions /i="DirectAudit" /aql="1 text=\"dzdo\"\"" /export="UnixCommand" /path="folder path"

FindSessions /i="DirectAudit" /aql="1 inputcommand = \"dzdo*\"\"" /suppresswarning /export="UnixInputOutput" /path="folder path"

FindSessions /i="DirectAudit" /aql="1 sessionid=\"D108F7B2-F4FB-FB42-A6E7-A40454780690\"\"

Accessing sessions via web browser

On computers that have Audit Analyzer installed, you can also find and play back sessions from a web browser. Because the cda:// protocol is automatically registered on the computer with Audit Analyzer, you can use a web browser to open Find Sessions or to replay a specific session. For example, you can embed a cda:// link in a web page to automatically generate a list of sessions, or you might want to embed a link to a session or set of sessions in a web-based report or event notification.

Opening Find Sessions from a web browser

You must be able to specify a query using AQL syntax to open Find Sessions from a web browser. If you want to start playing back a session from a web browser, you must know the session identifier. You can extract the session identifier from the session URI.

To start Find Sessions from a web browser:

1. Open a web browser.
2. Type the installation name and a search string using AQL syntax in the address bar of the web browser.
3. For example, if you want to search an installation named MyInstallation5 for sessions that involved the Administrator user, you would type the following in the address bar:
4. cda://MyInstallation5/?search=\"1 user=\"Administrator*\"\
5. Click **Allow** to open the Find Sessions with the Advanced tab displayed and "user=Administrator*" listed for the Define Criteria.
6. Click **Find Now** to find sessions matching the criteria you specified.

Playing back a session from a web browser

If you want to start playing back a session from a web browser, you must know the session identifier. You can extract the session identifier from the session URI.

To get the session identifier:

1. In the session player, select File > Copy Session URI.
2. Open a text editor and paste the session URI into the file.
3. Delete the portion of the URI that identifies the player and installation, so that only the object GUID remains.
4. For example, if the URI looks like this:
5. rep://myInstallation/b62bc280-678c-439a-aec3-09a9b7ee4395
6. Remove the part of the URI so that you only have the session identifier:
7. b62bc280-678c-439a-aec3-09a9b7ee4395

To play back a specific session from a web browser:

1. Open a web browser.
2. Type the installation name and session ID in the address bar of the web browser:
3. cda://‹*installationName*›/‹*session_id*›
4. For example:
5. cda://myInstallation/b62bc280-678c-439a-aec3-09a9b7ee4395
6. The session player opens and plays the specified session.

Exporting sessions and session data

In addition to specifying the criteria for finding sessions of interest, you can use Find Session to selectively export session data to a file. You can export the following information:

- A list of sessions matching the criteria you specify.
- An indexed list of events associated with the Windows sessions that match the criteria you specify.
- An indexed list of commands associated with the UNIX sessions that match the criteria you specify.
- The UNIX input associated with the UNIX sessions that match the criteria you specify.
- The UNIX input and output associated with the UNIX sessions that match the criteria you specify.

You specify the export operation, type of data to export, file format, and file location using the following command line options:

/export=[SessionList|WashEvents|UnixCommand|UnixInput
|UnixInputOutput]
/format=[html|htm|csv|pdf|xml]
/path=<folder_path>

You can use these options in combination with other criteria, such as /user or /machine, to export information for a specific user, computer, or time. You can specify the /format option used for exporting the sessions of interest. If you don't specify the /format option, sessions matching the criteria you specify are exported as comma-separated values (.csv) in a text file. If you are exporting Windows events, UNIX commands, UNIX input, or UNIX input and output, each session is exported as a separate file in the format you specify.

If you are exporting UNIX commands, UNIX input, or UNIX input and output, you can also use the command line options /role and /ticket to export sessions based on specific role or trouble-ticket information. Before you can use these options, however, you must configure the information required. For example, if you want to find all of the UNIX commands executed by a user running the db_backup role, you must first define and assign the db_backup role using Access Manager.

Exporting a session list

To export a list of sessions from the command line, use the following syntax:

FindSessions /i="*InstallationName*" /export="SessionList"
/format="*format*" /path="*folder*"

For example, to export the session list for all users in HTML format and save the output in the C:\Temp\Exported Sessions folder, you would type a command like this:

FindSessions /i="MyInstallation" /export="SessionList"
/format="html" /path="C:\Temp\Exported Sessions"

The command generates the list of sessions in the format specified. In this case, the command would generate an HTML file named SessionList in the C:\Temp\Exported Sessions folder with the following information for each session exported:

- User name, display name, account used, computer name, and audit store for the session.
- Start time, end time, and current state of the session.
- Client name associated with the session.
- Review status, user who last modified the review status, the time the status was last modified, and the comment added when the session was last modified.
- Size of the session in KB.
- Session URI that can be used to replay the session.

Exporting Windows events

To export an indexed event list for Window sessions from the command line, use the following syntax:

FindSessions /i="*InstallationName*" /export="WashEvents" /path="*folder*"

For example, to export the indexed event list for the sessions associated with a specific user and save the output in the C:\Temp\Session Events folder, you would type a command like this:

FindSessions /i="MyInstallation" /user="chris.howard"
/export="WashEvents" /path="C:\Temp\Session Events"

The command generates the list of events as comma-separated values in a text file. For example:

"Time","Application","Title","Type","Desktop","Audited","Role","Ticket"

"1/29/2015 1:53:14 PM", "Windows Explorer", "Start", "Application Activate", "Default", "Y","<None>","<None>"
"1/29/2015 1:53:56 PM", "DirectAuthorize System Tray", "Options", "Application Activate", "Default", "Y","<None>","<None>"
...
"1/29/2015 3:00:51 PM", "Windows Explorer", "Start", "Window Activate", "LocalSQLAdmin", "Y","<None>","<None>"
"1/29/2015 3:01:16 PM", "Microsoft SQL Server Management Studio Express", "Microsoft SQL Server Management Studio Express", "Application Activate", "LocalSQLAdmin", "Y","<None>","<None>"
.

Exporting UNIX command lists

To export an indexed command list for UNIX sessions from the command line, use the following syntax:

FindSessions /i="*InstallationName*" /export="UnixCommand" /path="*folder*"

For example, to export the indexed command for the sessions associated with a specific computer and save the output in the C:\Temp\UNIX folder, you would type a command like this:

FindSessions /i="MyInstallation" /machine="rhes-63"
/export="UnixCommand" /path="C:\Temp\UNIX"

The command generates the list of commands as comma-separated values in a text file. For example:

"Time","Command","Role","Ticket"
"10/9/2014 3:12:14 PM","/bin/bash ","<None>","<None>"
"10/9/2014 3:12:19 PM","adflush","<None>","<None>"
"10/9/2014 3:12:23 PM","su -","<None>","<None>"
"10/9/2014 3:12:27 PM","Password: ","<None>","<None>"
"10/9/2014 3:12:30 PM","adflush","<None>","<None>"
"10/9/2014 4:26:14 PM", "exit","<None>","<None>"

Searching for sessions by role or trouble-ticket information

When you use the /export=UnixCommand option, you can also use the command line options /role and /ticket to export sessions based on specific role or trouble-ticket information.

Use /role to specify search criteria based on one or more privilege elevation service roles. You can specify multiple roles separated by semicolons (;). For example, add /role="db_backup/zonename;mail_admin/zonename" to the command line to search for UNIX sessions that were run using the db_backup or mail_admin role.

Tip: When you search for sessions by role name, be sure to include the zone name. Otherwise, FindSessions doesn't return the sessions and instead displays the message, "No session is selected to be exported".

FindSessions /i="MyInstallation" /export="UnixCommand"
/role="db_backup/zonename;mail_admin/zonename" /path="C:\Temp\UNIX"

You can use the /ticket option to specify search criteria based on the trouble-ticket information if you have configured in the dzcheck script to collect this information. You can specify multiple tickets separated by semicolons (;). For example, add /ticket="ticket 1;ticket 2" to the command line to search for sessions ticket1 or ticket2 were specified.

You cannot use wildcards to search for role names or ticket information. If you specify both the /role and /ticket options, FindSessions returns the sessions that match both the specified roles and the specified trouble-ticket information. For information about configuring the dzcheck script and how to capture trouble-ticket information, see the *Administrator's Guide for Linux and UNIX*.

Exporting UNIX input

To export UNIX input from the command line, use the following syntax:

FindSessions /i="*InstallationName*" /export="UnixInput" /path="*folder*"

For example, to export the UNIX input for a specific user and save the output in the C:\Temp\Input folder, you would type a command like this:

FindSessions /i="MyInstallation" /user="tai-u1" /export="UnixInput" /path="C:\Temp\Input"

The command exports UNIX input to a text file. For example:

"UnixInputData","Role","Ticket"
"[1/20/2015 4:13:38 PM] K: PS1=NetShell:<CR>","<None>","<None>"
"[1/20/2015 4:13:38 PM] K: stty kill ^u erase ^h<CR>","<None>","<None>"

"[1/20/2015 4:13:38 PM] K: TERM=dumb<CR>","<None>","<None>"
"[1/20/2015 4:13:38 PM] K: set TERM=dumb<CR>","<None>","<None>"
"[1/20/2015 4:13:40 PM] K: cat /etc/passwd<CR>","<None>","<None>"
"[1/20/2015 4:13:40 PM] K: echo $?<CR>","<None>","<None>"
"[1/20/2015 4:13:40 PM] K: cat /etc/group<CR>","<None>","<None>"
"[1/20/2015 4:13:40 PM] K: echo $?<CR>","<None>","<None>"

When you use the /export=UnixInput option, you can also use the command line options /role and /ticket to export sessions based on specific role or trouble-ticket information. For details about using these options, see Using Find Session.

Exporting UNIX input and output

To export UNNIX input and output from the command line, use the following syntax:

FindSessions /i="*InstallationName*" /export="UnixInputOutput" /path="*folder*"

For example, to export UNIX input and output for a specific computer and save the output in the C:\Temp\Output folder, you would type a command like this:

FindSessions /i="MyInstallation" /m="firefly-sf" /export="UnixInputOutput" /path="C:\Temp\Output"

The command exports UNIX input and output to a text file. For example:

"UnixInputOutputData","Role","Ticket"
"[1/21/2015 10:53:20 AM] 0: /bin/bash ","<None>","<None>"
"[1/21/2015 10:53:23 AM] 1: [maya@firefly-sf Desktop]$ pwd","<None>","<None>"
"[1/21/2015 10:53:23 AM] K: pwd<CR>","<None>","<None>"
"[1/21/2015 10:53:23 AM] 2: /home/maya/Desktop","<None>","<None>"
"[1/21/2015 10:53:34 AM] 3: [maya@firefly-sf Desktop]$ cd /tmp","<None>","<None>"
"[1/21/2015 10:53:34 AM] K: cd /tmp<CR>","<None>","<None>"
"[1/21/2015 10:53:54 AM] K: ls -al in*<CR>","<None>","<None>"
"[1/21/2015 10:53:54 AM] 4: [maya@firefly-sf tmp]$ ls -al in*","<None>","<None>"
"[1/21/2015 10:53:54 AM] 5: -r-xr-xr--. 1 root root 313027 Dec 16 05:51 install.sh", "<None>","<None>"
"[1/21/2015 10:54:04 AM] K: su -<CR>","<None>","<None>"
"[1/21/2015 10:54:04 AM] 6: [maya@firefly-sf tmp]$ su -","<None>","<None>"

"[1/21/2015 10:54:10 AM] 7: Password: ","<None>","<None>"
"[1/21/2015 10:54:10 AM] K: xxxxxxxx<CR>","<None>","<None>"

When you use the /export=UnixInputOutput option, you can also use the command line options /role and /ticket to export sessions based on specific role or trouble-ticket information. For details about using these options, see Using Find Sessions.

Suppressing warning messages

By default, Find Sessions will generate warning messages if you attempt to export sessions without expected activity. For example, if you run a command to export UNIX input and output using /export="UnixInputOutput" and there is no user input activity, you might see warning messages similar to the following:

Finished exporting the sessions successfully.

Warning, URI:rep://BLD08/f435d61c-f191-4344-8adf-9d1432cb35ea,
Message: There is no user inputs captured in this session.

You can safely suppress these warning messages using the /suppresswarning or /sw command line option. For example, you might run a command similar to this:

C:\AuditAnalyzer› findsessions /i="BLD08" /role="verify"
/format=csv /path="C:\Temp" /export="UnixInputOutput"
/a="1 time is in today" /suppresswarning

This command would export the UNIX output without displaying warning messages about there being no user input.

Deleting sessions

You can also use Find Sessions to delete sessions matching the criteria you specify from the command line. You can use the /delete option in combination with other criteria, such as /user or /machine, to delete information for a specific user, computer, or time. However, if you specify the /delete on the command line, all of the sessions returned by the query are deleted.

To delete sessions from the command line, use the following syntax:

FindSessions /i="*InstallationName*" /delete

For example, to delete the sessions for a specific user on a specific computer, you would type a command like this:

FindSessions /i="MyInstallation" /user="tai-u1"
/machine="rhes63" /delete

Note that you cannot use the /delete option in combination with the /export option. If you want to export session information before deleting, you must do so in two separate operations.

Sample script for deleting multiple sessions

You can use Find Sessions to delete multiple sessions manually from the command line or using Windows Task Scheduler to automate the task. However, if you are deleting multiple sessions at once, you might want to execute the command from a batch file to ensure that Find Sessions will wait for the operation to complete and return the result of the operation.

The following is a sample script to delete sessions from TestInstallation recorded in the current month.

```
----------Start of FindSessions_Delete.bat----------
@ECHO OFF
cd "C:\Program Files\Centrify\Audit\AuditAnalyzer"
Start /WAIT FindSessions.exe /i="TestInstallation" /a="1 time is in this month" /delete
if ERRORLEVEL 1 (goto FindSessionError)
goto Succeeded
:FindSessionError
echo
##################################################################################

echo ## FindSession execution failed. ErrorLevel: %ERRORLEVEL% ##
echo
##################################################################################

goto exit
:Succeeded
echo FindSession execution succeeded.
:exit
----------End of FindSessions_Delete.bat----------
```

You can use a similar batch file if you want to export multiple sessions at the same time. To write a script for exporting information, you would specify the type of information to export and the path for saving the exported output. For example, if you want to export UNIX commands for MyInstallation to the C:\UNIX folder, the script could include a command like this:

```
Start /WAIT FindSessions.exe /i="MyInstallation"
/export="UnixCommand" /path="C:\UNIX"
```

Using Windows and Linux/Unix

The following OS User Reference topics are available:

- User's Guide Linux/Unix
- User's Guide Windows

The following topics are covered:

Getting started

This chapter describes how to use Centrify to access applications and run commands with privileges on a UNIX or Linux computer that has the Centrify Agent installed.

Verify You can Log in

If an administrator has installed the Centrify Agent on a UNIX or Linux computer you use, the next step is to verify that you can log in successfully. The Centrify Agent does not change how you log in to your computer. However, you must be assigned at least one role that allows you to log in.

When you are prompted for a user name and password, type your Active Directory or UNIX user name and your Active Directory password. If you provide valid credentials and have been assigned a role with permission to log in, you should be able to log in to your computer with a standard UNIX shell. If this is a computer you used earlier, before it became a Centrify-managed computer, there should be no noticeable changes to your working environment.

As a part of the deployment of Centrify software, your computer may or may not have been joined to a zone. To verify that the Centrify Agent is installed, that you are connected to an Active Directory Domain, and that you are connected to a zone, run the adinfo command. For example, if you are a user named billy in a zone named KHeadquarters, your output may look similar to the following:

```
[billy@kh-rh Desktop]$ adinfo
Local host name: kh-rh
Joined to domain: demo.acme.com
Joined as: kh-rh.demo.acme.com
Pre-win2K name: kh-rh
Current DC: deploy.acme.com
Preferred site: Default-First-Site-Name
Zone: demo.acme.com/Program Data/Acme/Zones/KHeadquarters
CentrifyDC mode: connected
Licensed Features: Enabled
```

To learn more about commonly used commands that may be available to you, see Commands available for users.

If the Centrify Agent is installed but not connected to a zone, or if the agent is not installed on your local computer, you should contact your administrator.

If the zone information for the agent is configured, but the agent status is Disconnected, restart the agent.

To restart the agent type the following:

```
$ adclient -x
$ adclient
```

If the agent status is still Disconnected, contact your system administrator.

Multi-Factor Authentication

Your organization may require multi-factor authentication in order for you to log in to your computer, or to execute commands using elevated privileges (dzdo) in a normal or restricted shell (dzsh) environment.

If multi-factor authentication is required as part of the login process, you will have to provide a password as well as a second form of authentication to log in to your computer. If multi-factor authentication is required as part of a re-authentication process, such as when you use command rights with elevated privileges or in a restricted shell, you must provide a password and either one or two other forms of authentication other than a password.

Checking Your Rights and Role Assignments

Your role assignments control where you can log in, the type of account you use to log in, the specific access rights you have on local or network computers, the types of commands you can execute, and whether you must log in using a restricted shell. As discussed in Types of access rights, there are three categories of access rights for UNIX and Linux computers:

- Command rights
- PAM application rights
- Secure shell session-based rights

Depending on the details of how roles are defined in your organization and the specific roles you have been assigned, you might have some or all of the access rights described in the following sections.

You can use the dzinfo command to look up detailed information about your rights and role assignments, any restrictions on when they are available, and what the roles allow you to do. To learn more about the dzinfo command, see Check your rights and roles using dzinfo.

> **Note**: You can view information about your own access rights and role assignments only.

Working with Command Rights

Command rights allow you to use commands to perform specific operations. The most basic rights—such as the right to log in—are defined when your administrator defines roles. Other, more granular command rights control access to individual command-line programs.

Using Command Rights in a Standard Shell

Command rights are assigned to you so that you can perform privileged operations that are not available to you by default.

On most UNIX and Linux computers, commands that require elevated permissions can be run by invoking the sudo command. The Centrify Agent provides similar functionality, but the commands are instead invoked using the dzdo command, then typing the command to execute, including any command-line options that you are allowed to use.

For example, assume your administrator has defined a command right for adjoin that enables you to execute the command as the root user. If this right is added to a role that has been assigned to you, you can execute the command by typing the following:

dzdo adjoin

Using Command Rights in a Restricted Shell Environment

Centrify provides a customized Bourne shell, dzsh, to serve as a restricted shell environment that is used to limit what commands you can execute for certain roles. For most operations, working in the dzsh shell is similar to working in an unrestricted shell except that the command set is limited to the command rights added by the administrator.

After your administrator has defined command rights, added them to role definitions, and assigned the roles to you, you can execute those commands in a restricted shell environment by typing the command, including any command-line options you are allowed to use. When you are finished running the command, you can switch back to your standard shell if you have the appropriate login right on that computer.

For example, assume that on your own computer, you can run the adinfo command in the standard shell, but you need to execute the command on a computer that is not yours. Your administrator has assigned you a role, AdminADinfo that grants you a UNIX login right and a right that requires you to run the adinfo command in a restricted shell on the computer you need to access. You must switch to this role to run the command on the specified computer. To do this, you log in to the computer you want to access and select the role your administrator has assigned to you. If you are a member of the zone Headquarters, you would type the following:

```
$ dzsh
$ role AdminADinfo/Headquarters
$ adinfo
```

Running Unauthorized Commands

If your administrator has assigned you to a role that requires a restricted shell environment, the dzsh shell allows you to run only the subset of commands to which you have rights. If you attempt to run a command you are not authorized to use in your current role, the shell displays a warning.

Setting or Changing your Active Role

If you are assigned only to one or more restricted shell environment roles, you are only allowed to run commands within the dzsh shell. Within the restricted shell, you can only be in one active role at a time to prevent ambiguity about the commands you can run or what account should be used to execute those commands.

For example, if you are assigned the lab_staff restricted shell environment role that specifies that the tar command should run as root, and also the temps restricted shell environment role that specifies that the tar command should be run as the account tmp_admin, you need to specify which role you are using to run the tar command under the proper account.

You can see what roles are assigned to you, as well as switch between roles, using the role command. For example, to view the list of roles to choose from, you would type:

$ role -ls

To choose the lab_staff role, you would type:

$ role lab_staff

Using PAM Application Rights

Most of the applications you run on Linux and UNIX computers are configured to use a pluggable authentication module (PAM) to control access. Secure shell (ssh), login, and file transfer (ftp) services are all examples of PAM-enabled applications.

If you have a role assignment with access to PAM-enabled application rights, you can run one or more specific applications using the administrative privileges defined for your role. The administrator defines the specific PAM application rights that you have in each role you are assigned. If you have a role assignment with application access rights, the administrator specifies the arguments you can use when running the application and the account used to run the application.

Using Secure Shell Session Rights

If your administrator has assigned you the sshd or ssh right, login-all right, or a custom PAM access right, you can use secure shell rights to perform specific operations on remote computers. The following are a list of predefined secure shell session-based rights that might be assigned to you:

- dzssh-all grants access to all available secure shell services.
- dzssh-direct-tcpip allows local and dynamic port forwarding (ssl-L, ssh -D).
- dzssh-exec allows command execution.
- dzssh-scp allows secure copy (scp) operations.
- dzsh-shell allows secure terminal (tty/pty) connections.
- dzssh-Subsystem allows external subsystems, with the exception of the sftp subsystem, which has its own right.
- dzssh-tcpip-forward allows remote port forwarding (ssh -R).
- dzssh-tunnel allows tunnel device forwarding.
- dzssh-x11-forwarding allows X11 forwarding.
- dzssh-sftp allows SSH File Transfer Protocol.

Role-based Auditing of Session Activity

Your administrator may install the Centrify Agent with or without auditing features. Depending on whether auditing features are activated on your computer and whether your role requires auditing or not, your session activity might be captured and stored in a database. You can check whether session-level or desktop auditing is requested or required for the roles you are assigned by running the dzinfo command. You are notified that your session activity might be audited only if the administrator has enabled notification. If auditing is required for your role, but the auditing service is not available on computer you attempt to use, you will be denied access to that computer until auditing is available.

If your administrator has configured the Centrify Agent to audit your session when you log in, everything you do on your terminal is captured, including all of your keystrokes and anything displayed on your screen. If your administrator has configured auditing on a per-command basis, auditing only begins when you use a privileged dzdo command, and ends when you are finished running those privileged commands.

If your administrator has configured desktop auditing, everything you do in the Linux graphical user interface is captured. Note that for web browser activity, desktop auditing captures the web page title but not the contents or activity within a web page.

Delinea

Welcome to the Delinea software User Guide for Windows.

This section provides an overview of Delinea software features for Windows computers and how you can use Delinea software to temporarily elevate your privileges to perform administrative tasks locally on your computer or remotely on a network server.

What is Server Suite?

Server Suite is a multi-tier software solution that enables administrators to centrally manage access to on-premise servers and workstation, mobile devices, and applications across a broad range of platforms. With Server Suite, administrators can accomplish the following:

- Manage local and remote access to computers with Linux, UNIX, Mac OS X, and Windows operating systems.
- Enforce security policies and control access to applications on mobile devices such as iPhone and Android smart phones and tablets.
- Enable single sign-on and role-based rights for on-site and cloud-based applications.
- Capture detailed information about user activity and the use of administrative privileges.

Using Delinea software, an Active Directory administrator creates **zones** to organize the enterprise's on-premise computers, mobile devices, and applications into groups. For each group, the administrator then defines rights, roles, and group policies to control access to the computers and applications in that zone. By using zones and role assignments, the administrator can establish fine-grain control over who is authorized to perform administrative tasks and when user activity should be audited.

With Delinea software, your organization can reduce the risk of unauthorized access to critical resources, ensure accountability and regulatory compliance for users with access to privileged accounts or sensitive information, and simplify the management of shared accounts and role-based access rights.

Using Delinea software to Manage Access to Windows Computers

Delinea provides a cross-platform solution that relies on the deployment of an Agent. To manage access to Windows servers and workstations, an administrator installs the Agent for Windows and identifies the zone the computer should use. If an administrator has installed the agent and added your computer to a zone, the computer is a **managed computer**. When you log on, the agent will check that you have been assigned a role that allows a local or remote logon. As long as you have a role assignment that allow you to log on, logging on proceeds normally. If you have not been assigned a role that allows you to log on, you will be denied access to the computer.

In most cases, an Active Directory administrator or another delegated administrator will also define rights and roles that enable you to run as another account that has elevated privileges. For example, the administrator might create a role that allows you to manage a Microsoft SQL Server instance using administrative privileges and another role that enables you to run an Exchange management tool using a shared service account.

The administrator is responsible for defining the specific rights that are available in different roles and for assigning those roles to the appropriate Active Directory users and groups. The administrator can also assign selected roles to local Windows users and groups.

As a user logging on to a **Delinea-managed computer**, you have the option to select from and switch between the roles you have been assigned. For example, you begin the day by logging on to your computer using your Active Directory credentials. In most cases, this account does not have elevated privileges. In your work queue, you find that you need to add a new database to the SQL Server instance you manage. Because this change requires administrative privileges not available in your logon account, you select the role that has elevated privileges that you have been assigned for managing SQL Server instances. When you are done adding the database in Microsoft SQL Server Management Studio, you switch back to your default logon account.

The administrator determines whether the elevated privileges in your role are limited to a specific application, for example, Microsoft SQL Server Management Studio, any application on your desktop, or only allowed on a remote server. You are responsible for selecting the appropriate role to do the work required from the list of roles available to you.

Auditing Role-based Activity

The administrator can also define an auditing requirement for each role. If you switch to a role that is audited, the switch is recorded in the local Windows event log. If the computer you are using is configured to audit session activity, all of the actions you take during the session are captured in a video recording until you end the session or log out. If session activity is audited, the agent on your computer captures everything displayed on the screen, including your keystrokes and the windows you have open while you are using an audited role on an audited computer. If you switch from a role that requires auditing to one that has no audit requirement, the recording stops until you resume the role that requires auditing.

The administrator determines which roles and computers require auditing of user activity and can enable auditing notification to inform you if your actions might be audited.

Roles Grant Different Types of Access Rights

There are three types of access rights that an administrator can add to any role you might be assigned:

Desktop	If you have been assigned a role that grants a desktop right, you can create a separate desktop on your computer to run applications as yourself but with the elevated privileges associated with a specific Active Directory or built-in group. In most cases, an administrator assigns you a role with a desktop right if you have more than one local application for which you need elevated privileges and you need to use those privileges frequently. For example, if you use several administrative applications on a daily basis, you are likely to be assigned a role that has a desktop right. **Note:** On Windows 10 and Windows Server 2016 systems, task bar menus are not available in an Elevated Desktop.
Application	If you have been assigned a role that grants an application right, you can run a specific application with the elevated privileges associated with a specific user account or as yourself but with the elevated privileges associated with a specific Active Directory or built-in group. In most cases, an administrator assigns you a role with an application right if you have only occasional administrative responsibilities for a specific application or only need temporary use of the elevated privileges.
Network access	If you have been assigned a role that grants a network access right, you can connect to a remote computer as an account with privileges on that computer. In most cases, an administrator assigns you a role with a network access right if you need to take administrative action on a remote server. This access right does not change any of your privileges on your local computer.

Every role includes one or more rights. Depending on the roles you have been assigned, you might have one or more of these access rights available.

Computers Must be in a Zone for Roles to be Available

The administrator can define different rights and different roles for every zone. Your computer must be joined to a zone for those rights and roles to be available. In addition, a computer can be joined to only one zone at a time. The rights you have in any zone are based on the roles assigned to you in that zone and its parent zone. If the administrator has not added your computer to a zone, no local or network roles will be available for you to use.

After a computer is added to a zone, it is possible that your role assignments might enable you to access remote computers in zones other than the local computer's zone. Roles that enable access to remote computers do not require you to have any local roles available in your local computer's zone.

In most cases, the administrator should add your computer to the appropriate zone. Changing the zone assignment requires local administrative privileges. If you have administrative privileges on your local computer, you can use the Privilege Elevation Service Settings to view information about your current configuration and perform administrative tasks, if required. For example, if the administrator notifies you that you should join a zone they have prepared, you can use the Privilege Elevation Service Settings to complete the operation for your local computer.

Using the dzjoin Command

The dzjoin command line program enables you to automatically join users to the zone in which their roles and rights are assigned, or to join them to a specific zone by zone name, when they log on to their computer. The dzjoin command line program is particularly useful for organizations that use non-persistent virtual desktop infrastructures.

The syntax for the dzjoin command is:

dzjoin [/c ‹domain controller›] [/d] [/u ‹username›] [/f] [/h] [/r [ylnlyeslno]] {/z ‹zonename› I /s I /v]

Note: {/b}If the u option is specified but no password is found in the redirected input, you will be prompted for a password.

/c	Specify a domain controller to connect to.
/d	Retrieve zone data before restarting
/u	Specify the user name to join zone using custom credentials. The user name must be in the format: USER@DOMAIN or DOMAIN\USER. The credentials are for remote access only. For the password, you can specify by redirected input. Otherwise, this tool will prompt user for password.

/f	Suppress any warnings and/or questions.
/h	Displays the command help.
/r	Suppress the restart warning and specify to restart machine, if required, after joining zone. If no restart is required, this option is ignored. If no argument is provided, e.g. '/r', the default is to restart (example: '/r yes').
/z	Join a zone using the zone name. If the zone name is not unique, use the canonical name instead.
/s	Join to the zone where this computer is already pre-created in the zone or had previously been joined to the zone (but remotely left in a disconnected situation).
/v	Display the agent version.

Note: {/b}You can also use the PowerShell command Join-CdmZone to join a zone.

Using the dzleave Command

To leave a zone, use the dzleave command. The syntax for the dzleave command is:

dzleave [/c <domain controller>] [/u <username>] [/a|/f] [/r [y|n|yes|no]] [/v] [/h]

/a	Remove the role assignment from the computer zone.
/c	Specify a domain controller to connect to.
/u	Specify the user name to leave zone using custom credentials. The user name must be in the format: USER@DOMAIN or DOMAIN\USER. The credentials are for remote access only. For the password, you can specify by redirected input. Otherwise, this tool will prompt user for password.
/f	Suppress any warning and/or question(s). In case the domain cannot be contacted, this tool will perform a local zone leave automatically.
/h	Displays the command help.
/r	Specify whether to restart machine, if required, after leaving zone without prompt. If no restart is needed, this option is ignored. If no argument is provided, example: '/r', the default is to restart ('/r yes').
/v	Show the agent version.

Note: You can also use the PowerShell command Exit-CdmZone to leave a zone.

Why You Should Use Roles for Administrative Tasks

Roles give the administrator complete flexibility for delegating control and limiting risk. For example, the administrator can define a role that lets you do specific administrative functions on your local or a remote computer without giving you the administrator's password. By eliminating the use of a shared password for the administrator's account, you can prevent an audit finding that could be costly for your organization. Using a role also limits your authority on the computer, ensuring appropriate accountability, and limits the potential damage a compromised password might cause.

In addition, roles enable targeted auditing of user activity, so that only the actions when you have elevated privileges or access certain computers are recorded. In many cases, these activities must be recorded for regulatory or industry compliance. With roles, you can go about your normal activity, such as

reading and responding to email, without auditing, then capture detailed information about the use of SQL Server Management Studio or the Exchange Management Console.

What Gets Installed on a Managed Computer

The Agent for Windows package contains software to support auditing, access control, and privilege management on Windows computers. These features must be installed together on any supported Windows computer. Depending on the services to be enabled, your computer might include the following:

- Privilege Elevation Service manages your access rights, including your ability to log on locally, connect to a remote server, and access applications using administrative privileges.
- Privilege Elevation Service desktop applet that enables you to select roles, open new desktops, switch between open desktops, and view details about our role assignments. The applet is visible on your computer as the Delinea icon in the system tray.
- Privilege Elevation Service Settings that enable an administrator to join, change, or leave the zone, run diagnostics, and configure and view logged activity.
- Identity Platform Settings that enable multi-factor authentication (MFA) login, enable RADIUS authentication, and other identity services.

If you are assigned roles that define application and desktop rights on your local computer, or access rights on remote computers, the Agent for Windows must be installed on your local computer and on the remote computer.

The administrator can deploy the Agent for Windows from a central location on the network to your computer or you can install it directly on your local computer.

This section includes information on how to use Delinea software to access applications with privileges on a Windows computer that has the Agent for Windows installed.

Verify That You Can Log On

The Agent for Windows can be centrally deployed by a system administrator or deployed locally directly on a computer. If an administrator has installed a Agent on a computer you use, the next step is to verify that you can log on successfully and locate the Delinea applet on your computer. The Agent does not change how you log on your computer. However, you must be assigned at least one role that allows you to log on locally, remotely, or both.

When you are prompted for a user name and password, type your domain or local credentials as you normally would. If your administrator has enabled multi-factor authentication for log in, you will be asked to perform one or more authentication challenges, such as responding to a text message or email message, answering a security question, or answering an automated phone call. If you provide valid credentials and have been assigned a role with permission to log on, you should see your default desktop as it normally displays with the addition of a Delinea applet that is added to the system tray notification area. By left-clicking on the Delinea applet, you can view your current desktop and assigned roles.

As part of the deployment, your computer may or may not have been joined to a zone. If the administrator has not specified a zone for your computer to join as part of the deployment process, you can specify a zone using the Privilege Elevation Service on your local computer. Contact your system administrator to find out which zone you should join.

You can check whether the agent is installed and running, and whether you are connected to a zone using the Services Control Panel or the Privilege Elevation Service. For example, click **Start > All Programs > Server Suite 2021.1 > Agent Configuration > Privilege Elevation Service** to view the control panel.

If the agent is installed but not connected to a zone, you should contact your system administrator to determine the zone to use. You should note, however, that setting or changing the zone assignment requires local administrative privileges. If the agent is not installed on the local computer, you should contact your administrator to find out if you are responsible for deploying the Agent for Windows on your computer.

If the zone information for the agent is configured, but the agent status is not Connected, your current rights, roles, and role assignment privileges should still be available, in most cases, from the local authorization cache. If you are unable to perform administrative tasks that you normally can perform, contact your system administrator to determine whether the authorization cache needs to be refreshed.

If you cannot log on, see What to do if you cannot log on.

What to Do if the Delinea Icon is Not Displayed

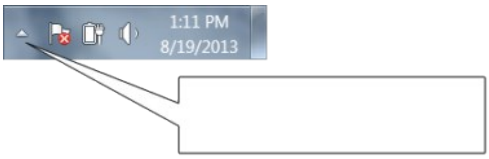
By default, the Windows system tray notification area is the located to the right of the task bar on the bottom of your screen. You can customize this area to display icons for different applications.

If the Delinea icon is not displayed by default, you can click the up arrow in the notification area to add it.

To display the Delinea icon if it is not displayed by default:

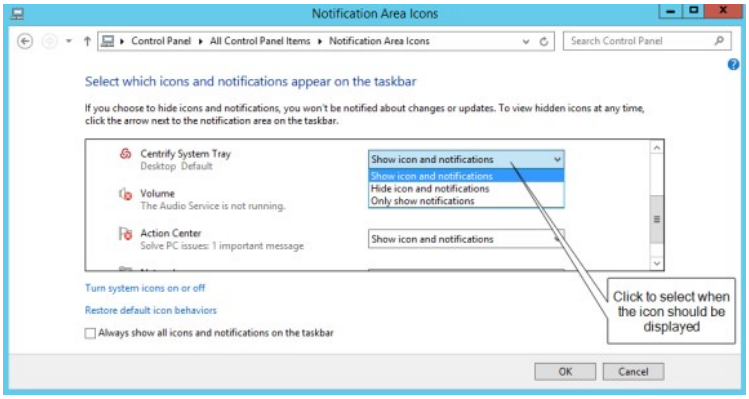
1. Click the up arrow in the notification area.

   For example:

2. Click **Customize** to change the icons displayed.
3. Scroll to the System Tray icon, then select **Show icon and notifications** to display the Delinea icon at all times.

   For example:



4. Click **OK**.

What to Do if You Cannot Log On

There are several reasons why an attempt to log on can fail. If you are denied access to a computer:

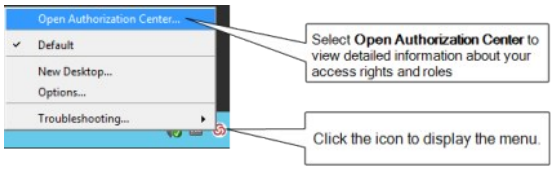
- Verify that the computer you trying to log on to allows the type of access you are attempting. For example, most users cannot log on locally on computers that are Active Directory domain controllers. Similarly, a computer's properties must be configured to allow remote access for you to be able to connect remotely. These settings are Windows policies and properties and are not related to the Agent for Windows.
- Check whether you are attempting to log on using a local account or a domain account. The administrator can assign a role that allows you to log on to your local account, your domain account, or both. It is possible that only one of those accounts has been assigned a role with access to the computer. For example, your administrator may have your account configured so you can log on using your local account credentials but not with your domain credentials.
- Verify that the computer where you are trying to log on has access to an Active Directory domain controller. If an Active Directory domain controller is not available or the local computer is not a member of an Active Directory domain, you might be prevented from logging on because the agent cannot verify you have authority to access the computer.
- Determine whether you are attempting to log on to a remote computer with an appropriate role. The administrator can assign a role that allows you to log on locally, log on remotely, or both. It is possible that only one of those rights has been configured for the role you have been assigned. For example, your administrator may have configured the role you are assigned to allow you to log on to your local computer but not allow remote connections.

After the Agent for Windows has been installed, you must have a role assigned to your account that gives you log on privileges. If an attempt to log on fails, contact your Active Directory administrator or helpdesk to determine the roles you have been assigned, the type of access your roles grant, and any limitations associated with your role assignment. For example, roles can have time constraints with specific periods of availability. If you attempt to log on, but the role is not available, you will be denied access.

For more information about the steps you can take, see Troubleshooting.

Checking Your Rights and Role Assignments

The roles you are assigned control your access rights and the accounts you can use to log on. You can look up detailed information about your rights and role assignments by right-clicking the Delinea icon, then selecting Open Authorization Center. For example:



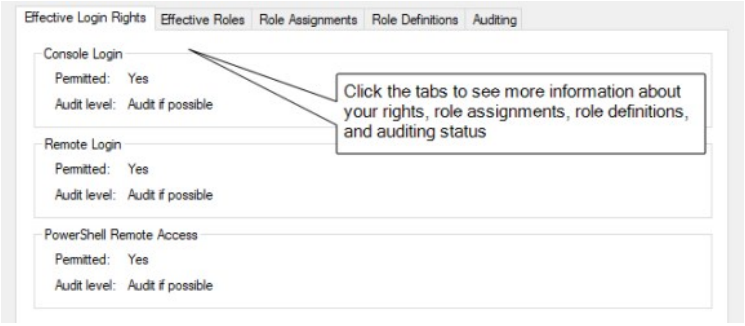
You can then click the tabs to see information about your current role and any other roles you have been assigned. For example, from Authorization Center, click the following tabs to see more detailed information about how the roles you have been assigned are configured:

- Click **Effective Login Rights** to see information about your local, remote, and PowerShell login rights and whether auditing is requested, required, or not applicable.
- Click **Effective Roles** to see information about the roles you have been assigned and the current status of each role. For any roles, you can right-click a

role, then select Role Properties to view additional details. For example, if any of your roles are Inactive, you can right-click to see the time constraints defined for the role. You can also view the specific type of rights granted by each role.

- Click **Role Assignments** to see detailed information about your role assignments, including where the assignment was made, whether the role is a local or network role, and the start and end times that are in effect for the role. You can right-click a role assignment, then select Assignment Properties or Role Properties to view additional details.
- Click **Role Definitions** to see detailed information about the login rights and audit requirements that have been defined for the roles you have been assigned. You can rightclick a role definition, then select Properties to view additional details.
- Click **Auditing** to see information about the auditing status for each desktop started in a session.

You can only view information about your own access rights and role assignments in the Authorization Center. Click **Close** when you are finished viewing authorization information.



After you review information about your access rights and role assignments using Authorization Center, you should have a basic understanding of the roles you have been assigned, any restrictions on when they are available, and what the roles allow you to do. Your role assignments control where you can log on, the type of account you use to log on, the specific access rights you have on local or network computers. As discussed in Roles grant different types of access rights, there are three categories of access rights for Windows computers:

- Desktop
- Application
- Network access

Depending on the details of how roles are defined in your organization and the specific roles you have been assigned, you might have some or all of the access rights described in the next sections.

Working with Desktop Access Rights

When you first log on, the default desktop is your only desktop. Depending on whether you logged on using a local user account or an Active Directory domain user account, you have the default privileges associated with that account. If you have been assigned a role with a desktop access right, the Agent enables you to run individual applications using a selected role from your default desktop or create one or more new desktops to run multiple applications using the administrative privileges associated with your roles.

If you have one or more roles with desktop rights, you can create, select, and switch between desktops on computers that have a traditional Windows desktop.

> **Note**: If the computer you are using is running Windows 8 or 8.1, or Windows Server 2012 or 2012 R2, Windows does not provide access to applications natively when you switch from the default desktop to a privileged desktop due to changes to the underlying interfaces and supported features within the operating system. To enable access to applications on computers running these versions of Windows, the Agent for Windows provides a custom start menu. The start menu allows you to open and run applications as you would on Windows 7 or Windows Server 2008 R2. The start menu is installed on the left side of the taskbar and displays the Delinea logo. This start menu is only available if you are using a role with Delinea desktop rights and cannot be modified.
>
> **Note**: If you launch a Universal Windows Platform (UWP) application in the default desktop, there won't be a response if you click the same application in the privileged desktop. You need to close the application in the default desktop before you can open it in the privileged desktop.

Running an Individual Application Using a Role

If you have a role assignment with a desktop access right, you don't have to create a new desktop to run a local application using your administrative privileges. You can select any local application directly from your default desktop, then select a role you have been assigned without creating a new desktop

or switching from one desktop to another. This is often the best solution if you only run one application using your administrative privileges or rarely need to invoke those privileges.

To run a local application using a selected role:

1. Navigate to and select the application you want to run.
2. Right-click the executable or shortcut for the application.

   If you want to open the application from the Start menu, press the Shift key when you right-click.
3. Select **Run with Privilege**.

   Selecting **Run with Privilege** is similar to selecting standard Windows "Run as" or "Run as administrator" menu items, but does not require you to provide a password for an administrative or shared service account. Instead, you always use your own password to authenticate your identity.
4. If the Select Role dialog box opens, select a role from the list of available roles, then click **OK**.

   > **Note**: If there is only one role assigned to you that allows you to run the application, the application will automatically run using that role, and the dialog box does not open. If you would like to access the Select Role dialog box, press the Shift key when you select **Run with Privilege**.
5. Type the password for your login account if you are prompted for it, then click **OK**.

   If your administrator has enabled privilege elevation justification, a justification dialog box appears.
6. Enter the following information to justify why you need to run the application with privilege:

   - **Ticket number**: If your administrator has instructed you to enter a ticket number, do so here. (This field can be used with ticketing systems such as ServiceNow and so forth.)
   - **Reason**: Select the reason category that best fits your situation. Your choices are:
     - Software Installation
     - Remote System Administration
     - Local System Administration
     - Windows Feature Management
     - System Networking Change
     - Maintenance (Shutdown, Reboot, Power Off)
     - PowerShell or Other CLI
     - Operation (Services, Zone Operations, etc.)
     - Other
   - **Comment**: Enter any comments about your need to run with privilege.
7. If your administrator has enabled multi-factor authentication, complete the additional authentication challenges after entering your password.

   After you select a role, you have the rights associated with that role. The application opens with the privileges associated with a specific user account or with the members of a particular administrative group and an audit trail event is recorded in the Windows Application event log. When you close the application, you resume working with your normal account privileges and group membership.

Creating a New Desktop

Desktop access rights enable you to create a separate desktop working environment for each role the administrator has assigned to you. You might have multiple role assignments with different desktop access rights so that you can run applications with elevated privileges. For example, you might be assigned two separate roles—one for running applications as a member of the domain administrators group and another for running applications as a member of the local administrators group.

If you have been assigned roles that have desktop access rights, you can create a desktop for each role.

To create a new desktop:

1. Click the Delinea icon in the notification area.
2. Select **New Desktop**.

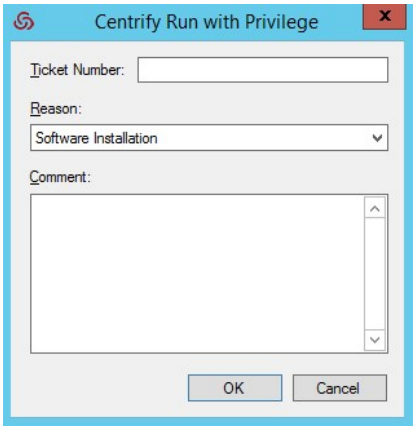
   If you have not been assigned to any role that has a desktop access right, a message is displayed to inform you that you are not a member of any role that permits opening a new desktop.

   If you have been assigned to any roles that have desktop access rights, you can continue to the next step.
3. Select a role from the list of your available roles, then click **OK**.

   For example, if you are assigned multiple roles that include desktop access rights, you can select from these role assignments to control which account privileges are in effect for the new desktop.

   Note that the roles listed might allow you to run as your own account locally, but grant access to remote servers. To see more information about the context associated with your roles, click **Advanced View**.

   When you select a role, you also have the option to run the desktop with User Account Control (UAC) restrictions enforced. Selecting this option gives you filtered privileges, prompting you to confirm actions before continuing with operations that require elevated privileges. You can leave this option unselected to use a desktop with full privileges and without being prompted to confirm your actions. You should note, however, that when you run a desktop without enforcing UAC restrictions, no warnings are displayed, even if you have configured User Account Control Settings on the local computer.
4. Type the password for your login account, if you are prompted for it, then click **OK**.
5. If your administrator has enabled privilege elevation justification, a dialog box appears. Enter the following information to justify why you need to run the application with privilege:



- **Ticket number**: If your administrator has instructed you to enter a ticket number, do so here. (This field can be used with ticketing systems such as ServiceNow and so forth.)
- **Reason**: Select the reason category that best fits your situation. Your choices are:
  - Software Installation
  - Remote System Administration
  - Local System Administration
  - Windows Feature Management
  - System Networking Change
  - Maintenance (Shutdown, Reboot, Power Off)
  - PowerShell or Other CLI
  - Operation (Services, Zone Operations, etc.)
  - Other
- **Comment**: Enter any comments about your need to create a new desktop.

6. If your administrator has enabled multi-factor authentication, complete the additional authentication challenges after entering your password.
7. After you select a role and click **OK**, the new desktop becomes your working environment. You can view the local and network roles you are using for the new desktop by left-clicking on the Delinea icon in the system Notification Area on the taskbar.

   If the role is only applicable on a remote computer, the local role is displayed as Self. If the role does not have network access rights, the network role is displayed as Self.

   To see complete information about the desktop, application, and network access rights for each of your roles, open the Authorization Center as described in Checking your rights and role assignments.

Setting a Desktop Name

By default, new desktops uses the name of the role you select as the desktop name. You can click **Change** if you want to change the name of desktop. For example, you might want to add your name, a computer name, or other information to the information displayed when you left-click the Delinea icon in your system Notification Area to help identify the context when switching from one desktop to another.

After you click **Change**, select **Use the following desktop name**, type the name you want displayed for the desktop, then click **OK**.

Switching from one desktop to another

To switch desktops, click the Delinea icon and select the desktop you want. You can also set up hot keys to switch between desktops using a keystroke combination.

Setting hot keys for switching between desktops

Hot keys are keystroke combinations that enable you to switch between desktops without clicking the Delinea icon or accessing the applet menu. By selecting hot key combinations, you can move from one desktop to another more quickly when you have more than one desktop open at a time.

To set up hot keys for switching between desktops:

1. Click the Delinea icon.

2. Select **Options**.
3. Click the **Hotkey** tab.
4. Select the **Enable hotkey** option, then select a key or key combination from the list of Modifiers and whether to use a number, function key, or letter from the list of Specifiers.

   For example, if you want to switch from one desktop to another using the Alt and a number, Alt+1 and Alt+2, select Alt from the list of Modifiers and Number from the list of Specifiers.
5. Click **OK**.

Using a desktop with network access rights

When you open a desktop and select a role, you get all of the access rights associated with that role. Depending on how the role is configured, those access rights may be limited to running applications with locally elevated privileges or include access to remote servers on the network. The Delinea icon in the system Notification Area always displays the current Local and Network roles you are using. However, it is up to the administrator to decide whether network access rights should be included in roles that grant desktop access rights.

If roles granting network access rights are defined separately from roles that include desktop access rights, you might have to select your local and network roles separately. In some cases, you might also need to select more than one network role to work with multiple remote computers. To handle these more complex situations, you can use the Advanced View to select the appropriate combination of local and network roles.

To view and select your local and network roles for a desktop:

1. Open a new desktop.
2. In the Select Role dialog box, click **Advanced View**.

   If there are any network roles listed, those roles grant network access rights for specific remote computers. For example, if you are assigned separate roles with network access rights to two separate SQL Server instances, you might see the roles with network access rights listed separately from your roles with local desktop access rights.

   In this example, the DesktopAdmin role is a local role that has desktop access rights but does not include any network access rights. By selecting both MS SQL Server-Finance and MS SQL ServerWest network roles, you can create a single local desktop that has remote network access to both SQL Server instances. Alternatively, you could create separate desktops for accessing each SQL Server instance. You can left-click on the Delinea icon in the system Notification Area to view the roles you have selected so that you know whether you have network access rights for one SQL Server instance or both.
3. For the local role, select a role that grants desktop access rights or application access rights on the local computer.
4. Type the password for your login account, if you are prompted for it, then click **OK**.

   If your administrator has enabled multi-factor authentication, complete the additional authentication challenges after entering your password.

Closing a desktop

In some cases, you might have multiple desktops open at the same time to allow you to switch between several different roles quickly. If you have more than one desktop open at a time, you can selectively close the desktops you are no longer using.

To close a desktop:

1. Switch to the desktop you want to close.
2. Click the Delinea icon.
3. Select **Close Desktop**.

The agent removes that desktop from your list and returns you to the default desktop. You cannot close your default desktop.

Running a specific application with privileges

With desktop access rights, you can run any application using one of the roles assigned to you. Application access rights are assigned on an application-by-application basis.

If you have a role assignment with application access rights, you can run one or more specific applications using the administrative privileges defined for your role. The administrator defines the specific application rights that you have in each role you are assigned. If you have a role assignment with application access rights, the administrator specifies the location of the application executable, the arguments you can use when running the application, and the account used when you run application. You can only select a role to run a local application for which you have application rights.

Selecting **Run with Privilege** is similar to selecting standard Windows "Run as" or "Run as administrator" menu items, but does not require you to provide a password for an administrative or shared service account. Instead, you always use your own password to authenticate your identity.

For information about running an application as an alternate user, see Run with privilege as an alternate user.

To run a local application using a selected role:

1. Navigate to and select the application you want to run.
2. Right-click the executable or shortcut for the application and select **Run with Privilege.**

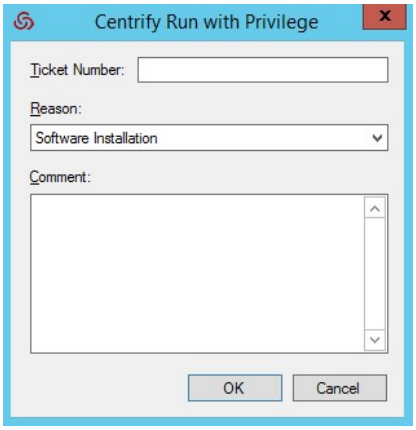
   (If you want to open the application from the Start menu, press the Shift key when you right-click.)

   If you have not been assigned to any role that has application access rights for the application you are trying to open, a message displays to inform you that you are not a member of any role associated with the selected application.

   The **Run with Privilege** dialog box displays. (If it doesn't display, it's because you're assigned to just one role, so there's no need to select a role.)

   Note: {/b}Note: If you pressed the Shift key when you right-clicked the application in Step 2, the **Run with Privilege** dialog box displays even if you're assigned to just no roles or just one role for access to that application.
3. Select the desired role.
4. If the application requires network access rights for a remote server, click **Advanced View** to see if you have a role with network access rights available.
5. If you'd prefer to use your environment variables instead of the variables that are associated with the selected role, select **Use current environment variables instead of "Run As" user's**.
6. Click **OK** to continue.
7. Enter the password for your login account, if you are prompted for it, then click **OK**.

   If your administrator has enabled privilege elevation justification, a dialog box appears.
8. Enter the following information to justify why you need to run the application with privilege:



- **Ticket number**: If your administrator has instructed you to enter a ticket number, do so here. (This field can be used with ticketing systems such as ServiceNow and so forth.)
- **Reason**: Select the reason category that best fits your situation. Your choices are:
  - Software Installation
  - Remote System Administration
  - Local System Administration
  - Windows Feature Management
  - System Networking Change
  - Maintenance (Shutdown, Reboot, Power Off)
  - PowerShell or Other CLI
  - Operation (Services, Zone Operations, etc.)
  - Other
- **Comment**: Enter any comments about your need to run with privilege.

9. If your administrator has enabled multi-factor authentication, complete the additional authentication challenge.
10. Click **OK**.

    After you've successfully authenticated, the application opens and an audit trail event is recorded in the Windows Application event log. You can use the application with the privileges granted to the specific user account or administrative group defined for your role. You have the privileges associated with the role or roles you selected until you exit the application. When you close the application, you resume working with your normal account privileges and group membership.

Using the runasrole command line

As an alternative to selecting Run with Privilege from the right-click menu for an application, you can use the runasrole command-line program. The RunAsRole program enables you to run a specified Windows application in a Command Prompt windows using a specified access role. You can use command line options to control whether the role is used as a local role, a network role, or both, and whether to use the current environment or the environment variables associated with the "Run As" user account. The runasrole command line program is equivalent to selecting the Run with Privilege menu option when right-clicking an application shortcut or executable.

The syntax for the runasrole command is:

runasrole /role:role[/zone] [options] application [argument]

runasrole /localrole:role[/zone] [options] application [argument]

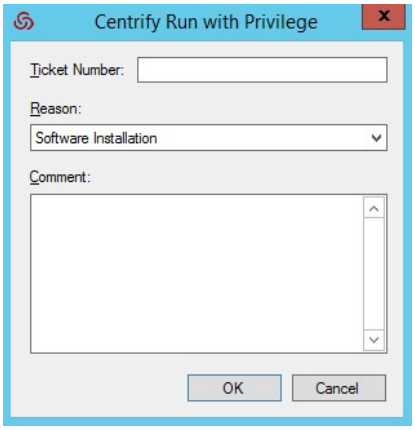
runasrole /networkrole:role[/zone] [options] application [argument]

You must specify the role to use in the rolename/zonename format. You must also specify an appropriate path to the application you want to access, including any required or optional arguments.

You can use the following command line arguments with the runasrole command:

/role	Use the role name you specify as both a local role and a network role. You can specify this option to run an application locally and access a remote server using the same role, if applicable. You should only use this option if the role you are assigned and want to use has both local and network access rights defined.
/localrole	Use the role name you specify as a local role.
/networkrole	Use the role name you specify as a network role.
/env	Use the current environment variables instead of the environment variables associated with the "Run As" user account.
/netdrives	Use mapped network drives when running an application with the selected role. By default, you cannot use mapped network drives that are associated with you logged-on user account when running applications using a role with elevated privileges. If you want to use a mapped network drive when accessing an application using a selected role, include the /netdrives option in the command line.
/removetimestamp	Remove the grace period on Windows authentication and MFA for the current user session.
/wait	Prevents the runasrole program from exiting immediately after opening the specified application. If you specify this option, the runasrole program starts the specified application and waits until the application session ends before exiting. When the application session ends, the runasrole program exits and returns the same result code as the application. If you specify this option and the application is a command line utility, the runasrole program redirects the application's input and output to the command line console. You should note that some applications use a Microsoft API that does not support redirection of standard input and output. For applications that don't support redirection, the /wait option has no effect and is ignored.
/h	Displays the command help.

Note: If your administrator has enabled privilege elevation justification, a dialog box appears. Enter the following information to justify why you need to run the application with privilege:



- **Ticket number**: If your administrator has instructed you to enter a ticket number, do so here. (This field can be used with ticketing systems such as ServiceNow and so forth.)
- **Reason**: Select the reason category that best fits your situation. Your choices are:
  - Software Installation
  - Remote System Administration
  - Local System Administration
  - Windows Feature Management
  - System Networking Change
  - Maintenance (Shutdown, Reboot, Power Off)
  - PowerShell or Other CLI
  - Operation (Services, Zone Operations, etc.)

  - Other
- **Comment**: Enter any comments about your need to run as role.

Examples of using runasrole

To use the same role to open the Computer Management application locally and access a remote server in zone1, you might run a command similar to the following:

runasrole /role:role1/zone1 mmc.exe c:\windows\system32\compmgmt.msc

To use the role named SQLdba from the finance zone as a local role to open the Services application, you might run a command similar to the following:

runasrole /localrole:SQLdba/finance mmc.exe c:\windows\system32\services.msc

To use role1 from zone1 as a local role to open the Computer Management application and use network access rights from role2 in zone2, you might run a command similar to the following:

runasrole /localrole:role1/zone1 /networkrole:role2/zone2 mmc.exe compmgmt.msc

To open the Services application using the role named SQLdba from the finance zone and have the runasrole program remain open until you close the Services application, you might run a command similar to the following:

runasrole /wait /role:SQLdba/finance mmc.exe c:\windows\system32\services.msc

Running an application from a shortcut

In most cases, you can use the runasrole program to run specified Windows applications using the application shortcut. However, there are many different types of application shortcuts and the RunAsRole program does not support all of them. You can use the RunAsRole program to execute applications with the following recognized shortcut target extensions:

.bat

.cmd

.cpl

.exe

.msc

.msi

.msp

.ps1

.vbs

.wsf

How to determine whether RunAsRole supports an application shortcut

You can determine whether you can use the RunAsRole program to execute an application from the application shortcut by checking the file extension for the target application in the application's shortcut properties dialog box.

To check the file extension for a target application shortcut

1. Select an application shortcut.
2. Right-click the shortcut, then click **Properties** to display the file properties.
3. Click the Shortcut tab and check the target field.

   If the target file extension displayed is a supported file extension, you can use RunAsRole to execute the application from the application shortcut. You should note that a shortcut target field might include both the file name for the application executable and one or more arguments. As long as the application executable has a supported file extension, you can use RunAsRole to execute the application with the specified arguments from the

shortcut. For example, if the shortcut target is C:\Windows\System32\control.exe printers, the application executable C:\Windows\System32\control.exe is a supported file extension with printers supplied as an argument. Therefore, you would be able use RunAsRole to run the application from its shortcut.

Run with privilege as an alternate user

If your administrator has enabled the group policy for this feature and assigned you to a role with rights for a specific application, you can run the application with elevated privileges of an alternate user.

For example, if your user account doesn't have privileges to install an application on the computer but your administrator does, you can stay logged in and run the application with privilege and your administrator can enter her credentials so that you can install the application.

To run a local application as an alternate user:

1. Navigate to and select the application you want to run.
2. Right-click the executable or shortcut for the application and select **Run with Privilege.**

   (If you want to open the application from the Start menu, press the Shift key when you right-click.)

   If you have not been assigned to any role that has application access rights for the application you are trying to open, a message displays to inform you that you are not a member of any role associated with the selected application.

   The **Run with Privilege** dialog box displays. (If it doesn't display, it's because you're assigned to just one role, so there's no need to select a role.)

   Note: {/b}Note: If you pressed the Shift key when you right-clicked the application in Step 2, the **Run with Privilege** dialog box displays even if you're assigned to no roles or just one role for access to that application.
3. To specify the alternate user, click **Change User** and specify the alternate user account.
4. When prompted, enter the alternate user's login credentials to authenticate as that user.

   The dialog box now lists the alternate user and the roles assigned to that account.
5. Select the desired role.
6. If your administrator has configured the system to re-authenticate, enter the alternate user's credentials again and click **OK**.
7. If your administrator has enabled multi-factor authentication, complete the additional authentication challenge.
8. If you'd prefer to use your environment variables instead of the variables that are associated with the alternate user, select **Use current environment variables instead of "Run As" user's**.

   For example, this option is useful if you're installing a program that's dependent on one that you've installed and is set in your path variable
9. Click **OK**.

   After you've successfully authenticated with the alternate user's credentials, the application opens and an audit trail event is recorded in the Windows Application event log. You can use the application with the privileges granted to the specific user account. You have the privileges associated with the specified user account until you exit the application.

Running an application with an alternate account

If your administrator has configured the ability to run an application with an alternate account, you can run applications with an alternate, privileged account without having to log in to PAS and check out the password for that alternate account.

Alternate accounts are typically a privileged or administrator account in Active Directory that's associated with an owner account. You can log in to the alternate account using your main account.

For example, system administrators typically have several accounts, a user account for general log-ins and an administrative account to access specific systems and services.

To run an application with an alternate account:

1. Right-click the desired application and choose Run with Alternate Account.

2. If you have multiple alternate accounts, you can then choose which account to use.

   The application runs under your alternate account.

Selecting roles with network access rights

As discussed in Using a desktop with network access rights network access rights can be included in roles with other rights or defined separately. Therefore, it is not always possible to see where your rights apply or the scope of your role assignment.

If you are assigned multiple roles, you should work with the administrator to identify which roles grant local and network access rights and the computers where the roles apply. You can see detailed information about the rights associated with each role you are assigned and the zones where different roles are defined using the Authorization Center. You have less visibility, however, of which computers are in scope for your network access rights.

Selecting a role that is not applicable on a local computer

In some cases, you might have roles that are visible on your local computer in the list of roles you have been assigned that are not applicable on the local computer. You can select the role, but the privileges associated with the role are only granted when you access computers over the network where the assignment applies.

For example, an administrator might create an Exchange Admin role that contains a network access right, and assign you to that role in a zone that only contains Exchange servers or assign you to that role explicitly on the computers that host Exchange.

When you log on to your laptop, the Exchange Admin role is included in your list of available roles even though the assignment is out of scope for the laptop. You can select the Exchange Admin role and continue working on the laptop without elevated privileges.You know that the Exchange server requires maintenance and you are planning to get to it later in the day.

When you are ready to do maintenance on the Exchange server, you connect to the server over the network. At that point, the elevated privileges associated with the Exchange Admin role are applied. The Exchange server you are accessing from your laptop is in scope for where you have been assigned the Exchange Admin role. You complete the maintenance required on the Exchange server with your elevated privileges, then resume working on your laptop where the Exchange Admin role does not apply.

Role-based auditing of session activity

The Agent for Windows can be installed with or without auditing features. Depending on whether auditing features are activated on your computer and whether your role requires auditing or not, your session activity might be captured and stored in a database. You can check whether session-level auditing is requested or required for the roles you are assigned using Authorization Center. You are only notified that your session activity might be audited if the administrator has enabled notification. If you select a role that requires auditing but auditing features are not available on computer you attempt to use, you will be denied access to that computer until auditing is available.

If session-level auditing is activated, everything you do on your computer is captured, including all of your keystrokes and the screens displayed on the desktops you use. At a minimum, any time you use a role that elevates your privileges on a computer, an audit trail event is recorded in the Windows Application event log.

Setting up the offline MFA profile (multi-factor authentication)

If you are required to use multi-factor authentication, you may be prompted to set up an offline MFA profile so that you can access your computer in the event that the authentication server cannot be reached.

Note: {/b}If you have already set up your offline MFA profile and want to reconfigure (override) it, you will be prompted for multi-factor authentication. That profile is set in the MFA Login Policy.

If your administrator has enabled offline multi-factor authentication, you will see a notification message each time you log on which will prompt you to set up your offline MFA profile. Depending on the configuration settings, you may not be able to access your machine in the event that you are unable to connect to the authentication server if you do not set up the offline MFA profile.

To set up an offline MFA profile:

1. Right click the notification icon in the system notification area, and select **Setup Offline MFA Profile**.
2. Click **Next** to begin the Offline Authentication Wizard.
3. Select one of the following methods to create an authenticator account profile on your mobile device:
   - **Scan barcode**

If you select this option, a QR code is displayed for you to scan using your mobile authenticator application. You can use either the Delinea application or a third-party authenticator application.

- **Manual entry**

  If you select this option, you must manually enter the displayed account profile information into your authenticator application.

- **Program YubiKey**

  If you select this option, you can use a YubiKey as the second form of authentication. You'll then need to select which slot on the YubiKey to use, and whether or not to use Yubikey's touch-to-sign feature.

4. Enter the passcode that is generated after you have created your authenticator profile. Click **Next**.
5. Click **Finish** to exit the Wizard.

After you have set up your offline MFA profile, you will be prompted to enter the mobile passcode generated by your authentication application as the second form of authentication when you attempt to log on to your machine if it cannot connect to the authentication server.

Authentication grace periods

When you have authenticated with a Delinea software component either with Windows authentication or MFA, you have a short period of time where you won't need to re-authenticate for the same type of item.

Understand that there are 3 types of grace periods for authentication:

- Lock Screen MFA grace period
- User Privilege Elevation for MFA grace period
- User Privilege Elevation for Windows Authentication grace period

Your administrator enables and configures these grace periods by way of a group policy, and each grace period type has its own policy. By default, these grace periods are not in effect.

For the lock screen MFA grace period, when you lock the screen within the grace period (either you lock the screen yourself or if your screen saver does it for you), you can unlock the login session without an MFA challenge.

If the group policy "Continue with MFA Challenges after failed windows authentication in Logon Screen" is enabled, then the lock screen MFA grace period is disabled automatically.

For the user privilege elevation grace period (MFA or Windows authentication) , the grace period is triggered when you either run an application with privilege, switch to a privileged desktop, or create a new privileged desktop. During the grace period, you aren't requested to re-authenticate by way of MFA or Windows authentication, respectively.

For both the user privilege elevation grace periods (MFA and Windows authentication), you can clear the grace period manually. To clear the grace period, right-click the Delinea icon in the system tray and select **Clear Grace Period** › **MFA or Clear Grace Period** › **Windows Authentication**. The Clear Grace Period option is only enabled if you're within the user privilege elevation grace period.

Agents can be installed on Windows computers that are configured to run the Server Core operating environment. Server Core is a Windows installation option that provides a low-maintenance server environment with limited functionality.

Most Agent operations are not affected by running on Server Core. However, there are specific features that are not available or not applicable because of the limitations of the Server Core environment itself. For example, the Run with Privilege menu option is not available on Server Core computers because Server Core does not support Windows Explorer and other graphical user interface applications. However, you can use the runasrole command line utility to run specific applications using a specified role.

Similarly, there's no notification area applet or desktop rights available on Server Core computers. However, you can access the Authorization Center, agent control panels, and agent command-line utilities from the Server Core command prompt.

The following list summarizes the Agent for Windows features that are not supported on Server Core computers:

- You cannot create, select, or switch desktops or use any desktop-related features because the Windows desktop is not available on Server Core.
- You cannot select Run with Privilege as a right-click menu option for applications because Windows Explorer is not available on Server Core.
- You cannot open the Authorization Center or access the notification area applet because the Windows desktop and Windows Explorer are not available on Server Core.
- You cannot open applications such as the Privilege Elevation Service Settings or DirectAudit Agent Control Panel from Start menu shortcuts because the Windows desktop and Windows Explorer are not available on Server Core.

You should note that only Agents for Windows are supported for the Server Core environment. A small number of other Server Suite for Windows support a command line interface, but are not configured to support a Server Core environment.

Server Core supported platforms

Delinea supports the following versions of the Server Core environment:

- Windows Server 2012 Server Core
- Windows Server 2012 Minimal Server Interface
- Windows Server 2012 R2 Server Core
- Windows Server 2012 R2 Minimal Server Interface

You should note that Server Core is not supported on Windows Server 2008 because Windows Server 2008 Server Core does not support any version of the .NET Framework. The Agent for Windows requires the .NET Framework. For more information about the supported libraries and .NET functionality on Server Core, see the reference material available on the Microsoft Developer Network website for the operating system you have deployed.

Joining a zone

One of the first tasks after installing the Agent is to join a zone. You can do by launching the Privilege Elevation Service Settings from the command prompt.

To open the Privilege Elevation Service Settings to join a zone:

1. Navigate to the Agent installation directory.

   By default, the agent files are installed in the C:\Program Files\Centrify\Agent for Windows directory.

2. Run Centrify.DirectAuthorize.Agent.Config.exe.

3. Click **Join zone**.

4. Type all or part of the zone name, click Find Now, then select the zone to join and click **OK**.

5. Click **Close** to close the control panel.

If you later need to change the zone, run diagnostics, refresh the authorization cache, or view or modify log settings, you can run Centrify.DirectAuthorize.Agent.Config.exe to perform those tasks.

Viewing authorization details

By default, access control, privilege management, and auditing features are enabled after you install and configure the Agent for Windows. To see details

about your rights, role definitions, role assignments, and auditing status, you can launch the Authorization Center from the command prompt.

To open the Authorization Center on a computer with the Server Core operating system:

1. Navigate to the Agent for Windows installation directory.

   By default, the agent files are installed in C:\Program Files\Centrify\Agent for Windows directory. <!---TODO update path--->

2. Run Centrify.DirectAuthorize.Auth.Center.exe. <!---TODO update filename--->

Configuring auditing options

By default, access control, privilege management, and auditing features are enabled when you install the Agent for Windows. To configure auditing options and specify the audit installation for the agent, you can launch the DirectAudit Agent Control Panel from the command prompt.

To open the DirectAudit Agent Control Panel to configure auditing features:

1. Navigate to the Agent installation directory.

   By default, the agent files are installed in the C:\Program Files\Centrify\Agent for Windows directory. <!---TODO update path--->

2. Run Centrify.Winagent.serviceconfig.exe to launch Agent <!---TODO update filename---> Configuration. Click **Add Service** to add **Auditing and Monitoring Service**. Choose an installation. Click **Setting** on the Agent Configuration for configuration.

3. Click **Configure**.

4. Select a color quality, then click **Next**.

   Because the Server Core operating system uses very few graphical elements, in most cases you should accept the default setting of Low for the color quality. This setting minimizes the storage requirements for auditing if you have enabled video capture auditing.

5. Accept the default offline data location and maximum size or type a different location, then click **Next**.

   You can also drag the slider to change the maximum percentage of the drive the offline data can consume. In most cases, however, you should leave the default setting unchanged.

6. Select the audit installation, then click **Next**.

7. Review your configuration settings, then click **Next**.

8. Click **Finish** to close the configuration wizard.

9. Click **Close** to close the control panel.

Running command line programs

The Agent for Windows includes several command line programs for performing administrative tasks. The following command line programs are supported on Server Core computers:

- dzinfo
- dzdiag
- dzrefresh
- dzflush
- dzdump
- runasrole

For more information about the command line options or output for these commands, see the *Administrator's Guide for Windows*or run the command with the /help option.

The topics in this section describe how to resolve issues with logging on, find log files, set the level of detail recorded in log files, and use diagnostic tools to retrieve information about the operation of the Agent for Windows.

Solving problems with logging on

Once you have the Agent installed on your computer, you cannot log on without a role assignment. The role, however, may be assigned to your local account, your domain account, or a remote computer. Consequently, you might encounter problems logging on after the agent is deployed. For example, you might find that you can log on to your computer using your local account but cannot log on using your domain account or have trouble connecting to a remote server.

You have no control over the roles assigned to your local, domain, or remote server accounts. These are all set by the administrator. There are a couple of things you can try if you cannot log on:

- Try to log on using a local user account or using a different domain account if you have more than one account available.
- Determine whether the computer you are using is connected or disconnected from the network. In rare cases, authorization information might not be available when a computer disconnected from the network.
- If you cannot log on to a remote computer, confirm that you have role that has the remote logon system right and that the computer is configured to allow users to log on remotely. Open the Authorization Center to see details about your roles and their rights.

Your administrator is the only person who can correct any log on problems. You should contact an administrator for your organization to proceed.

Accessing network computers with privileges

Depending on how your administrator has defined the roles you are assigned, it is possible for you to see potentially misleading information in certain applications or be unable to perform administrative tasks as you expect. For example, if you select a role with administrative privileges to access an application such as SQL Server Configuration Manager or Microsoft SQL Server Management Studio and connect to a remote SQL Server instances, it might appear as if you have permission to start and stop services or perform other tasks. However, if your role does not include network access rights for the remote SQL Server instance, you will not have the appropriate permission to perform those tasks.

You can check whether your selected role includes network access rights using the Authorization Center. If the role you are using does not include network access rights, you should click **Advanced View** to see if you have additional network roles available to use in conjunction with your local role. If the role you are using includes network access rights, you should contact your administrator to find out if those rights are applicable on the network computer you are attempting to manage.

Running diagnostics and viewing logs for the agent

The Agent for Windows provides logging and diagnostic services. If you have administrative access on a local computer, you can generate diagnostic information about the operation of the Agent for Windows and view and save the current content of the log file from the agent configuration panel. For example, you can generate diagnostic information about user sessions, user roles, desktops, and elevated account access, as well as detailed information about auditing from the agent configuration panel.

You can view these diagnostics tools either from the Windows system tray or from the agent configuration panel.

- Delinea icon in the Windows system tray - right-click it and click **Troubleshooting**, and then the service for which you want diagnostic information.
- Agent Configuration - select the service for which you want diagnostic information, then click the **Troubleshooting** tab.

Refreshing cached information

If you are a local administrator on a managed computer, you can refresh the authorization information stored in the cache to ensure the agent has the most up-to-date information about your current rights and roles. For example, if you are assigned a new role or been granted new application rights, you can refresh the cache to get the new assignment or application rights.

Checking your rights and roles using dzinfo

You can use the dzinfo command line program in a Command Prompt window to view detailed information about your rights, roles, and role assignments. The dzinfo command line utility provides the same functionality as the Authorization Center described in Checking your rights and role assignments, but allows you to view and capture the output from the command in a single window.

The syntax for the dzinfo program is:

dzinfo

The command returns detailed information about your rights, roles, and role assignment similar to the following:

```
Effective roles for AJAX\rey.garcia:
weblogic2/portland
Zone: CN=portland,CN=mainoffice,CN=Zones,OU=Acme,DC=ajax,DC=org

Evaluations

This section contains evaluation guides for

- Windows
- Linux/Unix

Delinea

December 2021 (release 2021.1)

- Setting Up the Evaluation Environment
- How Authentication Works for Windows
- Creating and Using Roles and Desktops
- Auditing Sessions

This section describes how to prepare for an evaluation of Server Suite on a Windows computer. It includes instructions for installing Server Suite components and the Agent for Windows to enable a full evaluation of access control, privilege management, and auditing on Windows computers.

Installing and configuring Server Suite requires about a half hour. If you need to install Microsoft SQL Server Express with Advanced Features, which is also included in the package, add another 10 to 15 minutes to the setup.

Preview of Tasks

You will perform the following tasks to set up the evaluation environment. You should perform the tasks in the order shown to prepare your environment for a meaningful evaluation that demonstrates the key features of the solution for Windows computers.

1. Ensure you have at least one Active Directory *domain controller* and one Windows *domain computer*—also referred to as the Windows *client computer*.

   See Basic Requirements for the Evaluation for details about the system requirements for these computers.

2. Acquire Delinea software for the Windows client computer.

   See Downloading Delinea Software for Windows Evaluations for details about acquiring Delinea software.

3. On the Active Directory domain controller, create an Active Directory user and group to be used in the evaluation.

   See Creating an Active Directory User and Group for details about this procedure.

4. Install Access Manager and administrative tools on the Windows client computer.

   See Preparing to Evaluate Access Management for details about installing these features.

5. Use Access Manager to configure Active Directory on the domain controller.

   See Configuring Active Directory Using Access Manager for details about configuring Active Directory from Access Manager.

6. Use Access Manager to create a zone.

   See Creating the First Zone for details about creating a zone.

7. Use Access Manager to assign the Windows Login role to your Active Directory account.

   See Assigning Yourself the Default Windows Login Role for details about this procedure.

8. If you are evaluating auditing features, you need access to an instance of Microsoft SQL Server and an audit installation, which consists of several auditing-specific components.

   See Identifying a Microsoft SQL Server Instance for details about installing a SQL Server Express instance for demonstration purposes.

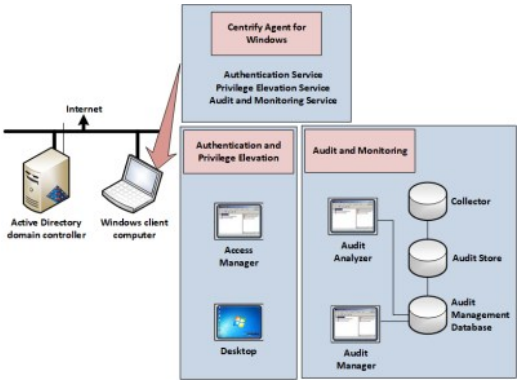
   See Preparing to Evaluate Auditing for details about installing audit components.

9. Install the Agent for Windows on the Windows client computer.

   See Installing the Agent for Windows for details about this procedure.

Basic Requirements for the Evaluation

The installation procedures described in this guide are based upon a minimal configuration with one Windows Delinea-managed computer (the *Windows client computer*) and one Windows Active Directory domain controller, as illustrated in the following figure.



You can add more Windows computers to the configuration to expand the scenario or to make the evaluation more consistent with a production deployment.

Preparing an Active Directory Domain Controller

You must have an Active Directory domain controller to use in this evaluation. You should also have a properly configured Domain Name Service that enables the computers used in the evaluation to communicate.

For details about supported platforms, please consult the release notes.

> **Note**: In the configuration illustrated in the previous topic, no software is installed on the domain controller. However, because this is just an evaluation environment, you could install all of the software on the domain controller. In a production environment it is not recommended to install this software on domain controllers.

Selecting a Windows Domain Computer

The Windows client computer that you use for the evaluation should have a supported Windows operating system and minimum system requirements.

Windows operating system	Windows 7 or later or a Windows server platform. Please consult the release notes for supported platform versions.
.NET Framework	.NET Framework 4.6.2 or later If .NET is not installed, the setup program will install it for you.
CPU speed	Minimum 2 GHZ
RAM	4 GB
Disk space	20 GB free space

Desktop rights can be used on Windows servers and workstations that have a traditional Windows desktop. If the computer you are using is running Windows Server 2012 or 2012 R2, Windows does not provide access to applications natively when you switch from the default desktop to a privileged desktop due to changes to the underlying interfaces and supported features within the operating system. To enable access to applications on computers running these versions of Windows, the Agent for Windows provides a custom start menu. The Delinea start menu allows you to open and run applications as you would on Windows 7 or Windows Server 2008 R2. The Delinea start menu is installed on the left side of the taskbar and displays the Delinea logo. This start menu is only available if you are using a role with Delinea desktop rights and cannot be modified.

Delinea also recommends that you install the Microsoft Windows Server Administration Tools Pack on the computer on where you install Access Manager. The Administration Tools Pack includes the Active Directory Users and Computers utility—`dsa.msc`—used in many of the exercises.

If you are using the recommended configuration with a separate Windows client computer that is not the domain controller, be sure that the Windows client computer is joined to the Active Directory domain.

Downloading Delinea Software for Windows Evaluations

You can go to the this website to sign up for a free trial. Once you're signed up with an account, you can download the software.

To register for a free trial:

1. Navigate to https://www.delinea.com/free-trial/.
2. Enter your contact and company information, click the checkbox to indicate that you agree to the terms of use and privacy policy, and then click **Start My Trial**.

   Note: You will receive an email with the next steps in downloading your free trial.

Downloading Server Suite Software for Windows Evaluations

You can download all of the components for Server Suite from the Delinea website to your Windows computer. Before you begin, be sure you have the email address and password you used to register for your trial.

To download the Windows software for Server Suite:

1. Open a browser on the Windows computer you plan to use for the evaluation and go to https://www.delinea.com.
2. In the upper area of the web page, click **Login**.
3. Enter your email address and your account password, then click **Login**.
4. Go to **Support** > **Downloads**.
5. Select **Zero Trust Privileges - Enterprise** to locate the latest software bundles.
6. Next to the latest version for 64-bit Windows systems, click either the **ISO** or **ZIP** button to download the software in that format.

   The latest version of the Windows software bundle is called Server Suite.
7. Close the window when the download is complete.

Creating an Active Directory User and Group

Evaluation scenarios covered in this guide require an Active Directory user with normal user privileges to demonstrate different features. For example, you will create access rights that grant elevated privileges to a role and assign this user to the role to use those rights.

To prepare for the evaluation scenarios:

1. On the Active Directory domain controller, open Active Directory Users and Computers.

   For example, create the user amy.adams to represent a domain user with a valid logon account.
2. Select **Action > New > User** and follow the prompts to create a new Active Directory user.
3. Select **Action > New > Group** and follow the prompts to create a new Active Directory group.

   For example, create the group Eval Group to represent a typical Active Directory security group to which you would assign a role.
4. Right-click the user name and select **Add to a group** to add the new user to the new group.

   You might also want to add your own Windows account to the new group. Adding your own account to the Evaluation group makes it easier to demonstrate some features, such as assigning roles to group members.

Preparing to Evaluate Access Management

If you are evaluating access control and privilege management features, you must install the administrative tools on the Windows client computer to prepare for the evaluation. Later, you will also install the Agent for Windows on the Windows client computer as described in Installing the Agent for.

To install Access Manager from the installer:

1. Log on to the Windows client computer using a Windows account that has Active Directory administrator privileges on the domain controller.
2. From the Delinea CD or directory that has Delinea software, open **autorun**.

3. On the Getting Started page, click **Authentication & Privilege** to start the setup program for Authentication Service and Privilege Elevation Service.
4. Follow the prompts displayed and select Administration as the components to install.

   For a Windows-only evaluation, none of the Utilities components are applicable.
5. Accept the defaults for the remaining selections, then click **Finish** to close the setup program.

Configuring Active Directory Using Access Manager

The setup program adds shortcuts for selected components to your desktop to give you immediate access to the consoles you will use. Before you can use Access Manager to create zones, define access rights and roles, and assign roles to users and groups, however, you use it to run a Setup Wizard that prepares the Active Directory forest with parent containers for licenses and zones.

To use the Setup Wizard to configure Active Directory:

1. From the desktop, open Access Manager.
2. Select **Use currently connected user credentials** to use your current log on account, then click **Next**.
3. Select **Generate recommended deployment structure** and **Generate default deployment structure**, then click **Next**.
4. Click Browse to select the container you would like to use for the deployment structure.

   You can select any domain in the forest, including the forest root domain.
5. Select a location for installing license keys in Active Directory, then click **Next**.

   The Setup Wizard displays information about the Read permissions that must be granted on the container. Click **Yes** to continue.
6. Type, copy and paste, or import the license key you received, click **Add**, then click **Next**.
7. Click **Next** to use the default container for zones.
8. Click **Next** to skip the following options:
   - Grant computer accounts permission to update their own account information.
   - Register the administrative notification handler.
   - Activation of profile property pages.
9. Review the summary, click **Next**, then click **Finish**.

The wizard opens the Access Manager console. For reference, the user account under which you are logged in displays in the main panel just below **Access Manager**.

Creating the First Zone

In this section, you create a zone for the Windows client computer. After you create the zone, you can start creating access rights, defining roles, and assigning roles to Active Directory users and groups.

To create a new zone:

1. In Access Manager, click **Create Zone**.

2. Type a name and description for the zone, for example Headquarters, then click **Next** to accept the defaults for the other fields.
3. Click **Finish**.

You now have one parent zone in Access Manager. Expand **Access Manager > Zones** to view your new zone in the console.

Assigning Yourself the Default Windows Login Role

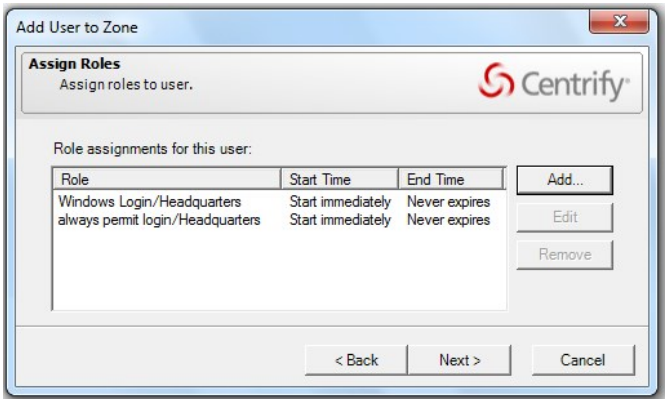
After you install the Agent for Windows, you must be assigned to a role that allows you to log on. To finish the preparation of the evaluation environment for access control and privilege management, you are going to assign a role with the log in privilege to your Active Directory account. The Windows Login role is a predefined role that grants permission to log on locally and connect remotely for Delinea-managed Windows computers.

To assign the Windows Login role to your account:

1. In Access Manager, expand Zones and select the zone you created in Creating the First Zone.
2. Right-click the zone, and select **Add User**.
3. Select **Active Directory user** and click **Next**.
4. Type the path to your account or click **Browse** to search for and select your Active Directory user account, then click **Next**.

   For example, click Browse and type all or part of the name, then click **Find Now**. You can then select your account name in the list of results and click **OK**.
5. Deselect **Define user UNIX profile** and make sure **Assign roles** is selected, then click **Next**.
6. Click **Add**, select the predefined **Windows Login** role, and click **OK**.
7. Check the role assignment start and end times for your account are set to Start immediately and Never expire, then click **OK**.
8. Repeat Step 6 and Step 7 to add the **Rescue - always permit login** role.

   Your Add User to Zone window should show the following roles:



9. Click **Next**, then click **Finish**.

If you are evaluating auditing features, go on to Preparing to Evaluate Auditing. If you are only evaluating access-related features, skip to Installing the Agent for Windows.

Preparing to Evaluate Auditing

If you are evaluating access and auditing features or only auditing, there are several components that make up the auditing infrastructure. For evaluation, you can install all of the components on the same computer.

Identifying a Microsoft SQL Server Instance

If you are evaluating both access and auditing features or only auditing, you must have at least one Microsoft SQL Server instance for storing audit-related information.

For evaluation purposes, you can use an existing Microsoft SQL Server database instance to which you have administrative access or automatically install and configure an instance of Microsoft SQL Server Express with Advanced features directly from the Audit Configuration Wizard.

You should only use Microsoft SQL Server Express for evaluation and testing. You should not use Microsoft SQL Server Express for a production environment.

Installing the Auditing Components

In this section, you run the setup program to install the auditing and monitoring components, including the Audit Manager and Audit Analyzer consoles, on the Windows client computer.

To install the Audit & Monitoring Service from the installer:

1. Log on to the Windows client computer using a domain account with administrative privileges, such as DEMO\\administrator. Do not log on as a local user.
2. From the Delinea CD or directory that has Delinea software, open **autorun**.
3. On the Getting Started page, click **Audit & Monitor** to start the setup program for the audit and monitoring service.
4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I accept the terms in the license agreement**, then click **Next**.
6. Select **Administration** and **Services** to install both Audit Manager and Audit Analyzer, then click **Next**.
7. Accept the defaults for the remaining selections and confirm that the **Launch Configuration Wizard** option is selected, then click **Finish** to close the setup program.

   Note If the **Launch Audit Configuration Wizard** option is not selectable, a possible cause is that you are logged on to the Windows client computer as a local user (for example, local administrator) rather than as a user with domain administrative privileges. In this scenario, select **Start > Switch user** and log on as a Windows domain user with administrative privileges (for example, DEMO\\administrator). Then launch Audit Manager from the desktop icon, and select **Action > New Installation** to start the audit configuration wizard.

8. In the Welcome page for the audit configuration wizard, click **Next**.
9. Select **Create a new installation** and type a name for your installation, then click **Next** to capture audit trail events without recording video of an audited user's desktop activity.

   Audit trail events provide a summary of user activity, for example, when users log on and off, open and close applications, and use role assignments with elevated rights. If you want to be able to review what was displayed on the screen during an audited user's session, you can select **Enable video capture auditing of user activity**. This option increases the database storage required for auditing.
10. Select **Install a new SQL Server Express instance on this computer** and specify the instance name, then click **Next**.
11. Verify the default path to the Microsoft SQL Server Express setup program, the disk space requirements, and the location for the files, then click **Next**.

    Note: If an incompatible instance of SQL Server Express is already installed, the wizard displays an error message instructing you to uninstall that instance. Use the Windows control panel to uninstall the incompatible instance of SQL Server Express, and then try the SQL Server Express installation from the wizard again.
12. Review the summary, then click **Finish**.

The audit configuration wizard automatically configures the audit store scope, audit store database, and a collector on the local computer. After the auditing infrastructure is in place, you can install the Agent for Windows and join the computer to the zone you created.

Installing the Agent for Windows

You are now ready to install the Agent for Windows on the client computer to begin the evaluation. In a production environment, you would install the agent on all of the Windows computers in the domain that you want to manage or audit.

> **Note**: The following instructions assume you are still logged in with your administrator account. Be sure that this account has at least the Windows Login and Rescue - always permit login roles assigned as described in Assigning Yourself the Default Windows Login Role to ensure you can log on after the agent is installed. If the account you are using to install the agent does not have the Windows Login role assigned, the agent configuration wizard will allow you to assign the Windows Login role to the domain administrators (Domain Admins) group when you join a zone.

To install the Agent for Windows using the setup program:

1. Insert the Delinea distribution CD into the computer on which you wish to install the agent or browse to the location where you have saved downloaded Delinea files.
2. On the Getting Started page, click **Agent** to start the setup program for the agent.

   If the Getting Started page is not displayed, open the autorun.exe file to start the software installation.
3. If a previous version of the agent is installed, click **Yes** when prompted to upgrade the Agent for Windows.
4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I accept the terms in the License Agreement**, then click **Next**.
6. Accept the default location for installing components, or click **Change** to select a different location, then click **Next**.
7. In the Ready to install Agent for Windows page, click **Install**.
8. Click **Finish** to complete the installation and start the agent configuration panel.

You must restart the computer after you configure the Privilege Elevation Service. When prompted, click **Yes** to restart the computer immediately.

After you restart the computer, log on with your administrator account. Left-click on the Delinea icon on your taskbar to confirm that you are viewing your default desktop. In the next chapter, you will see how to configure access rights and roles and how to select from roles you are assigned.

Configuring the Agent

By default, when you click **Finish**, the setup program opens the agent configuration panel. In the agent configuration panel, you can enable the agent to connect to Delinea services that are installed on the main administrative computer as described in Installing the Agent for Windows. After a service is enabled, you can use the agent configuration panel to configure settings that define how the agent will interact with each service.

The first time the agent configuration panel opens, it does not display any services for you to enable. Services display in the agent configuration panel only after you manually instruct the configuration panel to check for services and display those that are eligible to be enabled.

Only services that are installed and configured as required are eligible to be enabled. For example, if you installed the Privilege Elevation Service earlier (as described in Preparing to Evaluate Access Management) but did not create a zone, the Privilege Elevation Service does not display on the list of services that you can enable.

To enable services using the agent configuration panel:

1. If the agent configuration panel is not open, open it by clicking **Agent Configuration** in the list of applications in the Windows Start menu.
2. In the agent configuration control panel, click **Add service**.

   All services that are available to be enabled are displayed.
3. In the list of services, highlight a service and click **OK**.
4. Provide additional information about the service that you are enabling:
   - **Audit & Monitoring Service**:

     In the Select an Audit Installation page, select an audit store from the list of available audit stores. Click **Next**, and the computer is connected to the audit store.
   - **Identity Platform Settings**:

     1. In the Connect to Identity Platform page, type the URL of the identity platform instance to connect to, or select an instance from the list of registered platform instances in the forest. Click **Next**.
     2. In the Multi-factor authentication for Windows Login page, ensure that the check box to enable multi-factor authentication is selected. Next, use the **All Active Directory accounts** button or **Accounts below** button to specify which Active Directory accounts are enabled for multi-factor authentication login. If you select **Account below**, use the **Add** and **Remove** buttons to select accounts. Click **Next** when you are finished.
   - **Privilege Elevation Service**:

     1. In the Join to a zone page, type a zone or select a zone from the list of available zones. You can also choose to select the option to retrieve the zone data before the computer restarts. This option can be helpful in situations where you might lose connection to the domain after restarting, such as when you're using a VPN connection.

        Click **Next**, and the computer is joined to the zone.
     2. After the computer is joined to a zone, you must reboot the computer to activate all privilege elevation service features on the computer.

        If the zone that you select is already configured with a Privileged Access Service tenant, the message **Identity Platform enabled** displays after the computer joins the zone. In this situation, the instance is managed by the zone, and is shown as read-only.
5. To add additional services, click **Add service** and repeat the preceding steps.

   When you are done, the services that you enabled are shown in the **Enabled services** section of the agent configuration panel.
6. If necessary, continue to configure services after their initial configuration during enablement as described in these sections:
   - Configuring Agent Settings for the Audit and Monitoring Service
   - Configuring Agent Settings for Offline Audit and Monitoring Service Storage
   - Configuring Agent Settings for the Identity Platform
   - Configuring Agent Settings for Privilege Elevation

Configuring Agent Settings for Audit and Monitoring Service

If you want to reconfigure agent settings for auditing on a Windows computer after initially configuring them during enablement (or if you did not use the agent configuration panel when you enabled the service), you can open the agent configuration panel manually and configure the agent as described in this section.

To configure agent settings for audit and monitoring service:

1. In the Windows Start menu, click **Agent Configuration** in the list of applications.

   The agent configuration panel opens, and displays the services that are currently enabled. You can configure any service listed in the **Enabled services** section.

2. Click **Audit & Monitoring Service**, and then click **Settings**.

3. In the General tab, click **Configure**.

4. Select the maximum color quality for recorded sessions, then click **Next**.

   See Selecting the Maximum Color Quality for Recorded Sessions for more information on the configuration of this setting.

5. Specify the offline data location and the maximum percentage of disk that the offline data file should be allowed to occupy, then click **Next**.

   See Configuring Agent Settings for Offline Audit and Monitoring Service Storage for more information on the configuration of this setting.

6. Select the installation that the agent belongs to, then click **Next**.

7. Review your settings, then click **Next**.

8. Click **Finish**.

9. Click **Close** in the General tab to save your changes.

For information about using the Troubleshooting tab, see the *Administrator's Guide for Windows*.

Selecting the Maximum Color Quality for Recorded Sessions

Because auditing Windows computers captures user activity as video, you can configure the color depth of the sessions to control the size of data that must be transferred over the network and stored in the database. A higher color depth increases the CPU overhead on audited computers but improves resolution when the session is played back. A lower color depth decreases network traffic and database storage requirements, but reduces the resolution of recorded sessions.

The default color quality is low (8-bit).

Configuring Agent Settings for Offline Audit and Monitoring Service Storage

The "Maximum size of the offline data file" setting defines the minimum percentage of disk space that should be available, if needed, for audit and monitoring service. It is intended to prevent audited computers from running out of disk space if the agent is sending data to its offline data storage location because no collectors are available.

For example, if you set the threshold to 10%, auditing will continue while spooling data to the offline file location as long as there is a least 10% of available disk space on the spool partition. When the available disk space reaches the threshold, auditing will stop until a collector is available.

The agent checks the spool disk space by periodically running a background process. By default, the background process runs every 15 seconds. Because of the delay between background checks, it is possible for the actual disk space available to fall below the threshold setting. If this were to occur, auditing would stop at the next interval. You can configure the interval for the background process to run by editing the HKLM\Software\Centrify\DirectAudit\Agent\DiskCheckInterval registry setting.

Configuring Agent Settings for the Identity Platform

If you want to reconfigure agent settings for Privileged Access Service on a Windows computer after initially configuring them during enablement (or if you did not use the agent configuration panel when you enabled the service), you can open the agent configuration panel manually and configure the agent as described in this section.

To configure agent settings for the Identity Platform:

1. In the Windows Start menu, click **Agent Configuration** in the list of applications.

   The agent configuration panel opens, and displays the services that are currently enabled. You can configure any service listed in the **Enabled services** section.

2. Click **Identity Platform**, and then click **Settings**.
3. In the General tab, review the Status field in the Features area:
    - If the status is **Enabled**, the computer is not joined to a zone, and you can configure all Identity Platform settings that are shown in the General tab.
    - If the status is **Enabled per zone settings**, the computer is joined to a zone, and most Identity Platform settings are based on the zone configuration. In this situation, the **Browse** and **Details** buttons in the General tab are disabled, because those features are controlled by the zone configuration. The only configuration that you can perform in the General tab is to change the proxy server settings.
4. To change proxy server settings:
    1. Click **Change**.
    2. Specify a new proxy server address.
    3. Click **OK**.
5. To change to a different Identity Platform instance (only configurable if the computer is not joined to a zone):
    1. Click **Browse**.
    2. Select an instance from the list of registered platform instances in the forest.
    3. Click **OK**.
6. To specify which Active Directory accounts require multi-factor authentication (only configurable if the computer is not joined to a zone):
    1. Click Details.
    2. Use the **All Active Directory accounts** button or **Accounts below** button to specify which Active Directory accounts are enabled for multi-factor authentication login. If you select **Account below**, use the **Add** and **Remove** buttons to select accounts.
    3. Click **OK**.
7. Click **Close** in the General tab to save your changes.

For information about using the Troubleshooting tab, see the *Multi-factor Authentication Quick Start Guide*.

Configuring Agent Settings for Privilege Elevation

If you want to reconfigure agent settings for privilege elevation on a Windows computer after initially configuring them during enablement (or if you did not use the agent configuration panel when you enabled the privilege elevation service), you can open the agent configuration panel manually and configure the agent as described in this section.

To configure agent settings for privilege elevation:

1. In the Windows Start menu, click **Agent Configuration** in the list of applications.

    The agent configuration control panel opens, and displays the services that are currently enabled. You can configure any service listed in the **Enabled services** section.
2. Click **Privilege Elevation Service**, and then click **Settings**.
3. In the General tab, click **Change**.
4. In **Change the zone for this computer**, click **Browse**.
5. Click **Find Now** to search for an appropriate zone for the agent.
6. Select a zone from the list of search results, then click **OK**.
7. Click **OK** to use the zone you selected.
8. Click **Close** in the General tab to save your changes.

For information about using the Troubleshooting tab, see the *Administrator's Guide for Windows*.

This chapter introduces core concepts and features that you should be familiar with before starting an evaluation of Delinea software for managing Windows computers.

Providing Access Control and Accountability

In many organizations, most computer users are given very restricted access privileges to minimize the exposure of sensitive services and data to possible compromise. However, there are often a few applications, procedures, or services that require enhanced privileges and to which these users need access. For example, a user might occasionally have to install software or run a restricted internal application. For this purpose, these organizations often provide these users with login information for accounts with enhanced privileges. Unfortunately, this policy substantially undermines security, because there's no way to tell—even on an audited system—who actually logged on to these accounts, and once logged on, a malicious user is not restricted to the procedures for which he was given the login information in the first place.

Delinea solves this problem by enabling you to assign roles that give a user access to only those services or applications and restricted access privileges only when the user needs them.

For Windows computers, Delinea provides three main services: access control, privilege management, and auditing. These services can be used together or independently.

To provide access control, privilege management, and auditing for Windows computers, Delinea relies on the following:

- **Authentication Service** and **Privilege Elevation Service** features enable you to define access control privileges, create roles composed of a set of privileges, and assign users or groups to those roles. You can also use zone technology to limit the scope of a role to limited sets of computers. You can, also, configure roles with start and expiration dates or to be active on specific days of the week and hours of the day.
- **Audit & Monitoring Service** enables you to collect and store an audit trail of user activity and provides a console for searching and replaying captured sessions.
- **Agent for Windows** enables you to deploy access and auditing features on the Windows computers you want to manage.

You can use Privilege Elevation Service without auditing if you aren't interested in collecting and storing information about session activities. You can also deploy Server Suite without access and privilege management features if you are only interested in auditing activity on Windows computers. However, the real value of Delinea software for Windows computers comes from using the services together as an integrated solution for managing elevated privileges and ensuring regulatory compliance across all platforms in your organization. That way you can restrict access to only those instances when elevated permissions are absolutely necessary, and audit only user activity that merits auditing.

Organizing Computers and Access Rights

This guide is intended to help you evaluate how you can use Delinea software to manage access and administrative privileges for Windows computers and applications. However, Delinea also enables you to include UNIX, Linux, and Mac OS X computers in Active Directory, providing you with a single repository for all managed computers, users, privileges, and roles. Delinea enables this cross-platform integration through the use of **Zones**.

A zone is a logical object that you create using Access Manager. You use the zone to organize computers, rights, and roles into groups. In each group, you can define different access rights, different role availability rules, and different role assignments. You can create the zones in a hierarchy of parent and child zones, so that rights and roles can inherited or zone-specific.

As part of the evaluation, you will create a zone for the Windows computers, define access rights that are specifically for Windows computers, create roles that include those access rights, and assign roles to users and groups.

Restricting Access to Administrative Privileges

By defining roles with specific access permissions, you can use Access Manager to specify the conditions under which users can perform privileged operations. A user logs on to the Windows computer with his or her normal, restricted login, and then selects the role they need to perform a privileged operation only when that access is needed. You can restrict a role or desktop to certain times or days of the week, and you can set a beginning and expiration date for the access. You can set any role or desktop to require auditing, so that the user cannot use the role or desktop unless it is being audited.

Access Manager provides three kinds of Windows access rights. For Windows computers, these specialized access rights are:

- **Desktop** access rights enable you to create additional working environments and run any application in that desktop as a member of Active Directory or built-in group.
- **Application** access rights enable you to run a specific local application as another user or as a member of an Active Directory or built-in group. This access right is similar to the standard **Run as** menu option, except that someone assigned a role with this right doesn't need to know the privileged

user's password to use it.
- **Network** access rights enable you to connect to a remote computer as another user or as a member of an Active Directory or built-in group to perform operations, such as start and stop services, that require administrative privileges on the remote computer.

You configure these access rights using the Access Manager console. The rights are enforced through an Agent for Windows installed on each computer you want to manage.

Auditing User Activity on a Managed Computer

When you install the Agent for Windows on a computer, you have the option to enable access management, auditing, or both. If you enable auditing features, the agent can capture detailed information about user activity and all of the events that occurred in each user session on the managed computer. The user activity captured includes an audit trail of the actions a user has taken and a video record of everything displayed on the screen. For users who have privileged access to computers and applications, the audit and monitoring service helps ensure accountability and improve regulatory compliance. By recording user sessions, you can see exactly who had access to which computers and what they did, including any changes they made to key files or configurations.

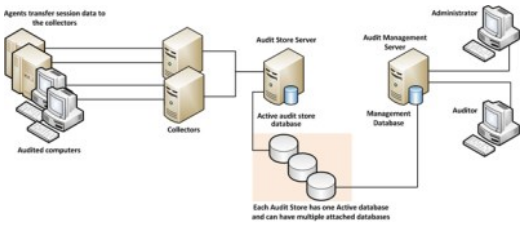
The audit and monitoring service collects user activity as it occurs. The recorded activity is transferred to a Microsoft SQL Server database so that it is available for querying and playback. You can search the stored user sessions to look for policy violations, user errors, or malicious activity.

To ensure scalability and enterprise readiness, the auditing infrastructure consists of multiple components called a **audit and monitoring service installation**:

- **Audited computers** are the computers on which you want to monitor activity. To be audited, the computer must have the Agent for Windows installed with auditing enabled and be joined to an Active Directory domain.
- One or more **collectors** receive the captured activity from the agents on audited computers and forward it to an audit store database.
- An **audit store** defines a scope, such as an Active Directory site or a subnet, and one or more databases that store captured activity and audit trail records from the collectors and store it for querying.
- A **management database** keeps track of all the agents, collectors, and audit stores that make up a single DirectAudit installation.
- **Consoles** enable administrators to configure and manage all of the audit-related components and auditors to query and review user sessions.

When you enable auditing on a computer with the Agent for Windows, the agent captures user activity on that computer and forwards it to a collector computer. If no collectors are available, the agent caches the session data locally and transfers it to a collector later. The collector sends the data to an audit store database. When administrators or auditors want to review the captured data, they use the Audit Analyzer to search for and play back the session. The Audit Analyzer connects to the management database which retrieves the data from the appropriate audit store. The administrator can control the audit data available to any specific user or group through auditor roles that limit audit access rights and privileges.

The following figure illustrates the basic architecture and workflow in a small scale installation.



At the end of the last chapter, you restarted the Windows client computer and logged in with your administrator account.

This chapter describes how to define access rights and create roles that grant elevated privileges, assign roles to users and groups, and view details about the rights and roles available. This chapter also shows you how to select and switch between roles for running local applications and connecting to network computers.

Verifying that your Account is Assigned Basic Login Rights

At this point, you should be logged on to the Windows client computer with an administrator account that has been assigned the "Windows Login" and "Rescue always permit login role" predefined roles as described in Assigning Yourself the Default Windows Login Role. Because the client computer has Access Manager and the Agent for Windows installed, you can verify that your account has been assigned these predefined roles using Access Manager or the Authorization Center.

To use Access Manager to verify your assigned roles:

1. Expand Zones and the zone you created in Creating the First Zone.
2. Expand Authorization and select Role Assignments.

   In the right pane, you should see your role assignments displayed similar to this:

In this example, the Windows Login and Rescue roles are assigned to the Administrator account in the zone named Headquarters

Assigning the Windows Login Role to a Group

After a computer joins a zone, users must be granted access to that computer by being assigned a role with the right to log on. So far, only the Administrator account has that privilege. This exercise illustrates how you can give that privilege to other users through their Active Directory group membership.

In most cases, you can assign the Windows Login role to all local Windows users, all Active Directory users, or both, if you want to automatically allow new users to log on locally or remotely. However, the Window Login role does not override any native Windows security policies. For example, if the Local Security Policy on the domain controller does not allow Domain Users to log on locally, assigning the Windows Login role to the Domain Users security group will not allow members of that group to log on locally.

If the Windows client computer you are using for the evaluation does not allow users to log on locally or does not accept remote desktop connections, you might have to make Eval Group a member of a specific Windows security group, such as Server Operators or Remote Desktop Users, to complete further exercises.

To assign the Windows Login role to an Active Directory group:

1. On the Window client computer, open Access Manager.
2. Expand the zone, then expand Authorization.
3. Right-click **Role Assignments** and select **Assign Role**.
4. Select **Windows Login** from the list of role definitions, then click **OK** to display Assign Role.

   By default the role is set to start immediately and never expire.
5. Select **Accounts below** to assign the role to the group you created in Creating an Active Directory User and Group.

   For purposes outside of this exercise, you could assign the role to more users by selecting **All accounts** and then specifying **All Active Directory** accounts, **_All local Windows accounts**, **All local UNIX accounts**, or any combination of these three selections.
6. Click **Add AD Account** to display Add User Role Assignment.
7. Change the **Find** filter from **User** to **Group**.

8. Type all or part of the group name, click **Find Now**, then select the group in the results and click **OK**.

   For example, type Eval to search for Eval Group and select that group in the results.

9. Click **OK** to complete the assignment and close the Assign Role window.

   Now all members of Eval Group can log on to this computer.

To verify the role assignment, you can log off as the administrator and log in as the user you created in Creating an Active Directory User and Group, for example, amy.adams. When you log on using the new account, the default desktop has no administrative privileges. For example, the new user cannot stop or start services on the local computers because the account do not have the administrative privileges required to do so. The next exercise shows you how to give a user elevated privileges when she is running a specific application.

Adding Predefined Rights to a Zone

There are many predefined rights available that grant access to specific Windows applications. For example, there is a predefined Performance Monitor right that allows you to run Performance Monitor on a computer without being a local administrator or knowing an administrative password.

You can add any or all of these predefined rights to any zone so they are available to include in role definitions. Alternatively, you can add predefined rights to individual role definitions without adding them to zones. In either case, you create grant predefined rights in the context of a role definition.

To add predefined rights to a zone and the Windows Login role:

1. On the Windows client computer, open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone (for example, Headquarters) where you want to add predefined rights.
3. Expand **Authorization > Role Definitions**.
4. Select the Windows Login role definition, right-click, then select **Add Right**.
5. Select **Any Windows Rights** from the Type list to filter the list of rights displayed.
6. Select the Headquarters zone from the list of zones, and then click **Create Predefined Rights**.

   The list of predefined rights that you can add to the Headquarters zone and to the Windows Login role is displayed. In the next steps, you will select which rights to add to the Headquarters zone. From the rights that you add to the Headquarters zone, you will select which, if any, to also add to the Windows Login role.

7. From the list of predefined rights, select the rights that you want to add to the Headquarters zone and to the Windows Login role, and then click **OK**.

   By default, all of the predefined rights that you select will be added to the Headquarters zone and to the Windows Login role. In the next step, you will deselect rights so that they are added only to the zone and not to the role.

8. Deselect predefined rights that you do not want to add to the Windows Login role.

   Rights that you deselect are added only to the Headquarters zone. Rights that you leave selected are added to both the Headquarters zone and the Windows Login role.

9. Click **OK** to add the predefined rights to the zone, role, or both according to your selections in Step 8.

   If you deselected all available predefined rights, the **OK** button is not available to click. In this scenario, click **Cancel** to add the rights to the zone without adding them to the role definition.

   After you perform this step, the predefined rights that you deselected are not added to the Windows Login role, but are added to the Headquarters zone so that they can be added later to roles in the zone as needed.

You can click **Refresh** in Access Manager to see the predefined rights listed as Windows application rights.

Creating an Application Right

An application right lets you run a specific application as a different user. An administrator assigns an application right rather than a desktop right when the user needs only occasional administrative responsibilities for a specific application and needs only temporary or infrequent use of the elevated privileges.

(Desktop rights provide administrative access to more than a single application at a time. See Creating a Desktop Right for details about desktop rights.)

If you have completed the exercises in the previous sections, you are ready to create your first application right. If you have not completed all of the exercises to this point, you might not be able to perform all of the following exercises successfully.

In the following exercises, you will:

- Verify the Active Directory domain user amy.adams does not have permission to use the Windows Control Panel to change security settings.
- Configure a new application right that gives administrative privileges for the Control Panel application.
- Define a new role that uses the application right.
- Assign the role definition that includes the Control Panel application right to the Active Directory domain user amy.adams.
- Verify that the role assignment grants the user amy.adams the right to change a setting in Control Panel.

To verify the user does not have administrative privileges for the Control Panel:

1. On the Windows client computer, log on as the amy.adams domain user account.
2. Use Windows Explorer to open the C:\Windows\System32 folder.
3. Create a shortcut for the control.exe program on the desktop.
4. Use the shortcut to open the Control Panel, select System and Security, then open **Allow a program through Windows Firewall**.

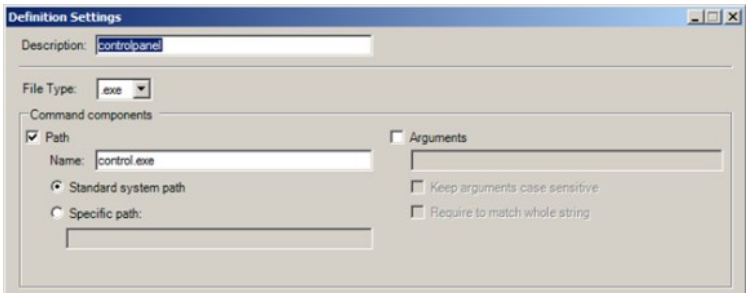
   Notice that you cannot make changes to the list of Allowed programs and features. If you click Change Settings, you are prompted to enter an administrator account name and password.
5. Click **Cancel** to close **Allow programs to communicate through Windows Firewall** and close the Control Panel.
6. Log off as amy.adams and log on with your administrator account.

To create a new application right for the Control Panel:

1. On the Windows client computer, open Access Manager and expand to display **Authorization > Windows Right Definitions**.
2. Select **Applications**, right-click, then select **New Windows Application**.
3. On the General tab, type Control Panel Right for the name of this application right and an optional description.
4. Click the Match Criteria tab, then click **Add**.

   In the Match Criteria tab, you specify one or more application executable files to be included in this application right. You can specify application executable files in many ways. The capability to specify more than one executable file in a single application right takes into account situations in which one application might reside in different locations on different computers. For details about different ways of specifying executable files, see the "Defining desktop application rights" help topic in the Access Manager online help.

   In this example, you will specify one application executable file using the application executable name and path.
5. Type a name for the criteria definition, select **Path**, then type the application executable name control.exe to specify the Windows Control Panel as the application to which this right grants access. For example:



6. Click **OK** to use the default standard system path for the application without specifying any other criteria.
7. Click the **Run As** tab, select **Self with added group privileges**, then click **Add Built-in Groups** to select the administrative group to use.

For the evaluation, you should use a built-in group to avoid adding test users and groups to your Active Directory environment. Alternatively, you could specify an existing user account, create a new user account for this right, or select **Self with added group privileges**, then click **Add AD Groups** to search for and select a previously-defined Active Directory group with administrative privileges.

8. Select the **Administrators** group, then click **OK**.
9. Select **Re-authenticate current user** to require users to authenticate their identity when they use a role with this right.
10. Select **Require multi-factor authentication** If you would like to enable multi-factor authentication for the right.

    Before you enable multi-factor authentication, you should be aware that multi-factor authentication for Delinea-managed Windows computers relies on the infrastructure provided by Privileged Access Service. For more information on preparing to use multi-factor authentication, see the *Multi-factor Authentication Quick Start Guide*.

11. Click **OK** again to complete the definition of the application right.

    The new application right is now defined. Next you must create a new role definition to use the application right.

12. To update the list of application rights in Access Manager so that you can review the new application right, select **Action > Refresh**.

To define a new role with an application right for the Control Panel:

1. Select **Role Definitions**, right-click, then select **Add Role**.
2. In the General tab, type ControlPanelAdmin as the name of the new role.

   Do not change the default settings for the System Rights tab and the Audit tab.

3. Click **OK**.

   The new role definition is created, but the role does not have any rights yet.

4. Select the ControlPanelAdmin role listed under **Role Definitions**, right-click, then select **Add Right**.
5. Select **Control Panel Right** in the list of rights, then click **OK**.

   You can filter the list of rights. For example, you can filter rights by name, type, zone, or description. After you select the right and click OK, the role definition has one right. You can add other rights to it. After you have identified all of the access rights for the role definition, you can assign the role to a user or group.

To assign the role definition with the application right to a user or group:

1. Select **Role Assignments**, right-click, then select **Assign Role**.
2. Select ControlPanelAdmin in the list of role definitions, then click **OK** to display **Assign Role**.
3. Click **Add AD Account** to search for and select the user amy.adams, then click **OK**.
4. Select **Role Assignments** to see that the user amy.adams is assigned the Windows Login and ControlPanelAdmin roles.
5. Open the **Privilege Elevation Service Settings** (from the Agent Configuration shortcut > Privilege Elevation Service > Settings), click the **Troubleshooting** tab, then click **Refresh** to force the agent to get the latest authorization information without waiting for the cache to expire.

To verify the user has administrative privileges for the Control Panel:

1. Log off as the administrator and log in as amy.adams.
2. Right-click the control.exe shortcut on the desktop.

   If you want to open an application from the Start menu, press the Shift key when you right-click.

3. Select **Run with Privilege**.

   Selecting **Run with Privilege** is similar to selecting standard Windows “Run as” or “Run as administrator” menu items, but does not require you to provide a password for an administrative or shared service account. Instead, you always use your own password to authenticate your identity.

4. Select ControlPanelAdmin in the list of the roles available, then click **OK**.
5. Type the password for the amy.adams login account, then click **OK**.

6. Select System and Security, then open **Allow a program through Windows Firewall**.

   Notice that you can now make changes to the list of programs allowed through the firewall.

This section showed you how to set up a role that allows privilege escalation for a single application and how the user can select that role to run the application with privileges without knowing the administrator's user name or password.

Creating a Desktop Right

In the preceding section, you saw how to elevate privileges by creating an application right for a specific application. To grant administrative access to more than a single application at a time, you can allow users to open a desktop that has administrative privileges.

If you have completed the exercises in the previous sections, you are ready to create your first desktop right. If you have not completed all of the exercises to this point, you might not be able to perform the following exercise successfully.

In the next exercise, you will create a desktop access right, create a new role, assign the desktop right to the new role, and assign the role to Eval Group. At the end of this exercise, you will use the desktop right to modify a restricted folder. The steps in this exercise are similar to the steps that you performed in the preceding exercise to create an application right.

To create a role definition with a desktop access right:

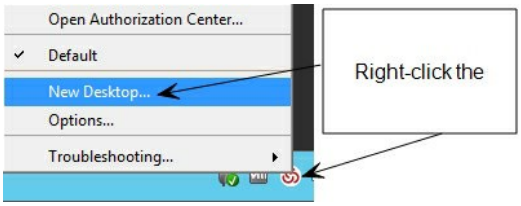
1. Log on with your administrator account and open Access Manager.
2. Create the new desktop right.
   - Select **Windows Right Definitions > Desktops**, right-click, then select **New Windows Desktop**.
   - Type DesktopRight as the name of the new desktop right on the General tab.
   - Click the **Run As** tab, then click **Add Built-in Groups**.
   - Select the **Administrators** group, then click **OK**.
   - Select **Re-authenticate current user** to require users to authenticate their identity when they use a role with this right, then click **OK**.
   - Select **Require multi-factor authentication** If you would like to enable multi-factor authentication for the right.

     Before you enable multi-factor authentication, you should be aware that multi-factor authentication for Delinea-managed Windows computers relies on the infrastructure provided by Privileged Access Service. For more information on preparing to use multi-factor authentication, see the *Multi-factor Authentication Quick Start Guide*.
3. Create a new role definition.
   - Select **Role Definitions**, right-click, then select **Add Role**.
   - Type DesktopAdmin as the name of the new role on the General tab.
   - Click **OK**.
4. Add the desktop right to the new role.
   - Select **Role Definitions**, right-click the DesktopAdmin role, and select **Add Right**.
   - Select DesktopRight and click **OK**.
5. Assign the role to a group.
   - Select **Role Assignments**, right-click, then select **Assign Role**.
   - Select DesktopAdmin from the list and click **OK** to display **Assign Role**.
   - Click **Add AD Account**.
   - Change the **Find** filter from User to Group.
   - Search for and select the group you created for the evaluation (for example, Eval Group), then click **OK**.
   - Verify that the account is included in the Accounts list in the Assign Roles dialog box, then click **OK**.
   - Open the **Privilege Elevation Service Settings** (from the Agent Configuration shortcut > Privilege Elevation Service > Settings), click the Troubleshooting tab, then click **Refresh** to get the latest authorization information.

To verify that the role with desktop rights grants elevated privileges:

1. Log off as the administrator and log on as amy.adams.
2. Open Windows Explorer and go to the C:\Windows folder.
3. Try to create a new folder in this location.

   From the default desktop for this account, the user does not have the necessary privileges to create a new folder. The only way she can create a new folder is by using administrator credentials.
4. Click the carat in the system tray notification area to display hidden icons, then click the Delinea icon to display the applet options.
5. Select **New Desktop**.



6. Select the DesktopAdmin role, then click **OK**.
7. Type the password for the logon account, then click **OK**.

   Notice that your new role is displayed when you left click on the Delinea icon in your task bar.
8. Try to create a new folder in the C:\Windows directory.

   Now you can create a new folder because the desktop that you are using has all of the rights associated with the Administrators group.

   Note: On Windows 10 and Windows Server 2016 systems, task bar menus are not available in an Elevated Desktop.

In this exercise, you created a role with the right to create a desktop with administrator privileges. You found that opening a new desktop with that role allowed you to perform administrative functions using your own credentials.

Switching Among Active Desktops

You can have multiple desktops available for you to use. For example, you might have separate desktop roles for managing Exchange and SQL Server that grant different rights. After you create a desktop for each role, you can switch between desktops by clicking the Delinea icon, then selecting the desktop you want to use. You can also set up hot keys to switch between desktops using a keystroke combination.

When you are finished working with a desktop, you can click the Delinea icon, then select **Close Desktop**.

Creating a Network Right

In the preceding section, you saw how you can provide a user with a desktop that has elevated privileges on a local computer (the Windows client computer in this case). However, using administrative privileges on your local Windows client computer does not give you privileges on a remote computer. In this section, you create a network access right that gives a user administrator privileges on a remote computer.

To illustrate network access rights using the local Windows client computer and a remote computer, you must install the Agent for Windows on the remote computer and join that remote computer to the zone you created in Creating the First Zone ("Creating the First Zone").

You can use the domain controller or another computer as the remote computer for this exercise. Install the Agent for Windows on the computer that you are using as the remote computer and join that computer to the Headquarters zone before proceeding.

If you are using only one Windows client computer for the evaluation and cannot install the agent on the domain controller or another remote computer, you should skip this exercise.

To prepare for the exercise that demonstrates this feature:

1. Install the Agent for Windows on the computer that you are using as the remote computer.

See Installing the Agent for Windows for more information.

2. Log on to the remote computer with your administrator account and create a folder on the C: drive named ShareFolder.
3. Select the folder, right-click, then select **Properties**.
4. Click the **Sharing** tab, then click **Share**.
5. Select Find people, type "back" to search for and select the built-in Backup Operators group, then click **OK**.
6. Right-click the Backup Operators group and set the Permission Level to Read/Write, then click **Share**.
7. Click **Done**, click **Close** to exit, then log off the remote computer as the administrator.
8. Log on to the local Windows client computer as amy.adams.
9. Try to open ShareFolder on the remote computer.
10. Verify that Windows tells you that you do not have sufficient permissions, then click **Cancel**.

To create a network access right and add it to the DesktopAdmin role:

1. Log on to the local Windows client computer with your administrator account and open Access Manager.
2. Create the new network access right.
   - Select *Windows Right Definitions > Network Access_*, right-click, then select **New Network Access**.
   - Type ShareAccess as the name of the new access right on the **General** tab.
   - Click the **Access** tab, select **Self with added group privileges**, then click **Add Built-in Groups**.
   - Select the **Backup Operators** group, then click **OK**.
   - Select **Re-authenticate current user** to require users to authenticate their identity when they use a role with this right, then click **OK**.
   - Select **Require multi-factor authentication** If you would like to enable multi-factor authentication for the right.

     Before you enable multi-factor authentication, you should be aware that multi-factor authentication for Delinea-managed Windows computers relies on the infrastructure provided by the Privileged Access Service. For more information on preparing to use multi-factor authentication, see the *Multi-factor Authentication Quick Start Guide*.
3. Add the new right to the existing DesktopAdmin role.
   - Under **Role Definitions**, select the DesktopAdmin role, right-click, then select **Add Right**.
   - Select the **ShareAccess** right in the list, then click **OK**.
4. Assign the role to a selected computer in the zone.
   - Expand the zone to **Computers > computer name> Role Assignments** node. If you are using a local and remote computer for this exercise, select the remote computer for making the role assignment.
   - Select **Role Assignments**, right-click, then select **Assign Role**.
   - Select DesktopAdmin in the list of roles, then click **OK**.
5. Assign the role to an Active Directory group.
   - Click **Add AD Account**.
   - Change the **Find** filter from User to Group to search for and select the group you created for the evaluation (for example, Eval Group), then click **OK**.
   - Verify that the account is included in the Accounts list in the Assign Roles dialog box, then click **OK**.
   - Open the **Privilege Elevation Service Settings** (from the Agent Configuration shortcut > Privilege Elevation Service > Settings), click the Troubleshooting tab, then click **Refresh** to get the latest authorization information.

To verify the role with network access rights grants elevated privileges:

1. Log on to the local Windows client computer as amy.adams.

   If you try to open ShareFolder in the default desktop, Windows denies access.

2. Open the applet, select **New Desktop**, and select the DesktopAdmin role.

   This role has the network access right that gives you remote access to the computer running as the account with Read/Write permission.

3. Open ShareFolder and verify that Windows gives you access.

In this exercise, you added a remote access right to a role that already had a desktop right and saw how changing desktops changes the user's rights.

Reviewing Rights and Roles in the Authorization Center

The Authorization Center is an option available from the applet menu. You can use the Authorization Center to display detailed information about your currently available rights and role assignments.

To view the Authorization Center:

1. Click the Delinea icon in the notification area.
2. Select **Open Authorization Center**.
3. Click through the tabs to view detailed information about your rights, roles, role assignments, and auditing status.

If you have completed all the steps in the preceding chapters, the audit and monitoring service has been auditing your sessions as an administrator and the user account you created. This chapter describes how to view audited sessions, update the review status, and use queries to find the sessions in which you're interested.

Using Audit Analyzer to Replay a Session

If you selected both Privilege Elevation Service and Auditing and Monitoring Service features, the Agent for Windows has been capturing your activity as you logged on and off and switched between roles. You can replay those recorded sessions to see detailed information about what you did during the evaluation. Before you can replay the sessions captured, however, you use Audit Analyzer to locate the sessions you are interested in using a set of predefined queries. For example, there are predefined queries for sessions that started Today and This Month and sessions where the Windows Command Prompt or Windows MMC tools were used.

To select and replay a session:

1. Open Audit Analyzer to view captured sessions grouped by predefined queries.
2. Select a predefined query, such as **Today** or **Active Sessions**, in the left pane to display a list of sessions in the right pane.

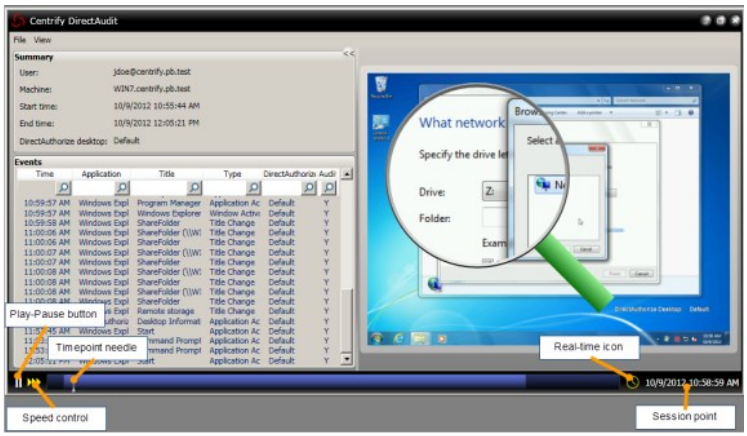
   Note that the date queries show sessions that started during the specified time interval. If a session started three days ago and is still active, it is listed under This Week and Active Sessions, but not under Today or Yesterday.
3. Double-click a session to retrieve the session from the database and open the session replay window.

   The session replay window displays information similar to the following:

   The replay progress is shown in the play bar along the bottom of the window. If you double-click an event, you can watch the recording of just that event.

Magnifying the Recorded Session

You can click the magnifier in the replay window to enlarge a portion of the recorded screen. The magnifier appears as a magnifying-glass pointer in the replay pane. Click to toggle the magnifier on or off.



Controlling Playback Speed or Session Location

For normal playback operation, you can click Play or Pause to start or pause a session. You can also fast forward by clicking the Speed control. The Timepoint needle shows you the current location in the session. You can drag the needle to any point in the session. The Real-time icon to the right of the time bar indicates that the session plays in a smooth time sequence. If you want to play back the session moving swiftly from one user action to the next, click the icon to gray it out. The Session point indicates the date and time of the Timepoint needle.

Marking Sessions for Review or Action

You can use Audit Analyzer to manage the status of sessions that are pending review or action. For example, you can update the status of individual sessions using the following states:

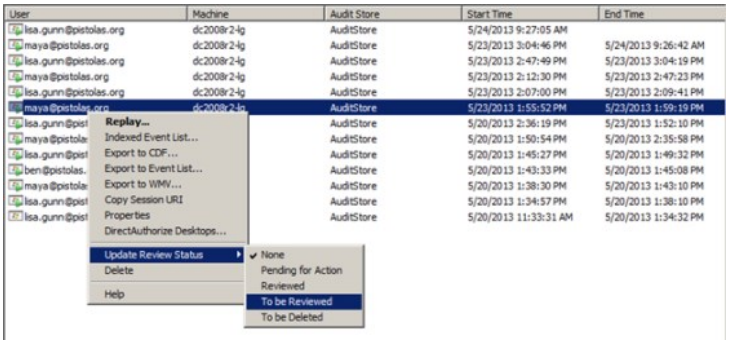
- To be Reviewed
- Reviewed
- Pending for Action
- To be Deleted

After you have marked sessions to be reviewed or pending action, you can use the predefined queries **Sessions to be Reviewed** and **Sessions Pending for Action** to see only the sessions in those states.

To update the review status for a session:

1. Select a query then select an individual session.
2. Right-click and select **Update Review Status**, then select a review state.

   For example, if the session is new and has not been reviewed, select **To be reviewed**.



3. Type a comment at the prompt, then click **OK**.
4. Click **Sessions to be Reviewed** in the left pane to see the session displayed.

   You can also view the review status and comments for a session by right-clicking a session, then select Properties.
5. Select one or more sessions and update the review status to Reviewed.

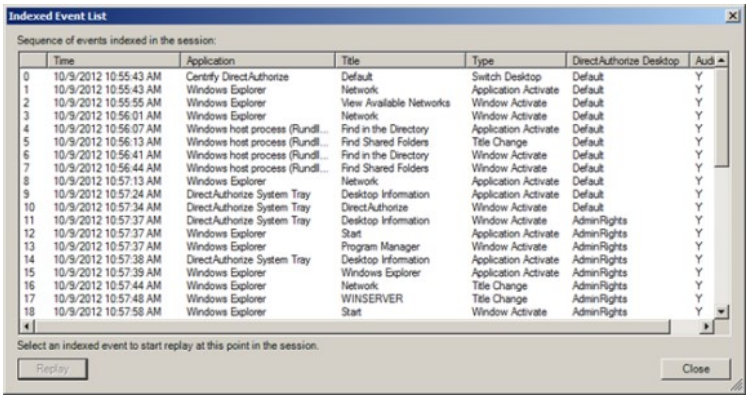
   Again, you will be prompted to provide a comment for the change in status. Type a new comment and click OK.

Using the Indexed Event List

If you don't want to replay an entire session, you can use the indexed event list to view a summary of events recorded in a session, then selective start the replay at a specific event of interest.

To use the indexed event list:

1. Select a query then select an individual session.
2. Right-click and select **Indexed Event List**.



3. Select a session event in the lists to start the replay at that event.

Creating Custom Queries

Predefined queries searches the audit store database for sessions that meet the specific criteria. To see the search criteria, right-click a query, select **Properties**, then click the Definition tab.

You can write your own queries to search for sessions that meet specific criteria of your choosing. The following example illustrates how to build a query that finds all of the sessions that have been reviewed.

To create a custom query for sessions that have been reviewed:

1. Open Audit Analyzer.
2. Select **Audit Sessions**, right-click, then select **New Shared Query**.
3. Type Reviewed Sessions for the name of the query and enter a description for the query. For example, type Sessions that have been reviewed by department auditors.
4. Deselect UNIX session as the type of session to include.
5. Click **Add** to add criteria.

   Notice that review = Reviewed appears in the Criteria field of the New Query dialog box.
6. Select **Review Status** from the Attribute list, select **Reviewed**, then click **OK**.
7. Click **Add** again.
8. Select **Session Time**, select the bottom radio button and **Is in**, then select **this month** and click **OK**.
9. Verify the Criteria displays both rules, then click **OK** to complete the query.

   
   After you click OK, the query is listed under **Shared Queries**.
10. Click the custom query to get the results.

Creating a Quick Query

You can also perform quick text string searches in Audit Analyzer.

To create a quick text string query for sessions:

1. Open Audit Analyzer.

2. Select **Audit Sessions**, right-click, then select **New Quick Query**.
3. Type a search string into the dialog box.

   As you type, the Quick Query displays a list of possible matches that start with the text you are typing. If an item in the list is what you are looking for, select it, then click **Find** to display all matching sessions in the right pane.

Auditing Only Specific Events

The integration of access management and auditing makes it possible for you to audit only when a user switches to a specific desktop or role. Although you can use database queries in Audit Analyzer to find recorded events of a particular type, you can save space in your database by recording only those events in which you're most interested.

Specifying which Roles or Desktops to Audit

To limit auditing to specific roles or desktops, you turn off more generalized auditing and enable auditing for just the roles you care about. The following example illustrates how to audit only when the user switches to a privileged desktop.

To audit only when the user switches to a privileged desktop:

1. Log in to the computer as the Administrator and open Access Manager.
2. Expand the console tree to the Authorization node for your evaluation zone.
3. Expand Role Definitions, select the DesktopAdmin role, right-click, then select **Properties**.
4. Click the Audit tab, select **Audit if possible** or **Audit required**.If auditing is required, users are prevented from using the role if auditing is not available or the agent is not running.
5. Log off and then log in as amy.adams.
6. Verify that you do not have elevated privileges by trying to change firewall settings in Control Panel.
7. Open a new desktop and select the DesktopAdmin role.
8. Perform operations, such as running the Firewall Control Panel and accessing the remote share on the Windows server, for which you need elevated privileges.
9. Switch back to your default desktop.
10. Open Audit Analyzer, select the Active Sessions node, and refresh the display.
11. Open the currently active session for the Windows client computer.

    You should find that only the portion of the session when you were using the DesktopAdmin desktop was recorded.

Audit Trail of Privileged Events

Even when the auditing and monitoring service is not recording a session, it keeps a record of every event in which the user selected a role that provides elevated privileges.

To view audit trail events for elevated privileges:

1. Log in using your administrator account and open Access Manager.
2. Expand the console tree to the Authorization node for your evaluation zone.
3. Select the **ControlPanelAdmin** role, right-click, then select **Properties**.
4. Click the **Audit** tab and select **Audit not requested/required**.
5. Log off and then log in as amy.adams.
6. Verify that you do not have elevated privileges by trying to change firewall settings in Control Panel.

7. Right-click your Control Panel shortcut, select the **ControlPanelAdmin** role, and verify that you now have the rights to change firewall settings.
8. Close Control Panel and perform several more operations.
9. On the Windows client computer, open **Audit Analyzer**, select **Active Sessions**, and refresh the display.
10. Open the currently active session for your Windows client computer. You should find that none of your recent operations were recorded.
11. Right-click the Audit Events node, then select **Query Audit Events**.
12. In the dialog box, enter your search criteria, such as a role name, event time, or the type of event you are interested in locating, then click **OK**. All of the events that match the criteria you specify are listed. If the event involved an audited role and you are capturing video records of audited activity, you can right-click an event to **Replay** the activity recorded.

    All of the events that match the criteria you specify are listed. If the event involved an audited role and you are capturing video records of audited activity, you can right-click an event to **Replay** the activity recorded.

Additional Auditing Tools

Because the evaluation computer has the complete auditing infrastructure, you have several additional tools available for managing different components of that infrastructure. For example, computers that have the Agent for Windows installed also have the following Auditing and Monitoring Service Settings. You also have access to the Audit Collector Control Panel, Audit Management Control Panel, and Audit Manager console. All of these programs are available from the Windows Start menu.

You use the control panels to configure and troubleshoot the component operations. Audit Manager provides a overview of all audit-related components. From Audit Manager, you can view the status of components, modify component properties and relationships, and manage audit store databases. You can also use Audit Manager to create audit roles, assign users to the audit roles, and manage permissions.

Audit Manager includes one Master Auditor role with full control over the installation. As the Master Auditor, you can manage and control all permissions for the installation.

The *Server Suite Evaluation Guide for Linux and UNIX* describes how to install and configure the Server Suite software on a Windows computer joined to an Active Directory domain controller and on the Linux and UNIX computers you want to manage. After you install the software, you can follow the steps in this guide to create Active Directory users and groups and set up a test environment with Server Suite zones, roles, privileges, and group policies. Through this test environment, you can see how Server Suite enables you to control users access, manage privileges, and monitor activity on UNIX and Linux computers in your organization.

Intended Audience

This guide is for system and network administrators who want to evaluate Server Suite software. The guide assumes you have a working knowledge of Windows Server and Active Directory and are familiar with Active Directory features, functionality, and terminology. This guide also assumes you are familiar with the Linux or UNIX-based computers you plan to manage and how to perform common administrative tasks.

Using this Guide

Server Suite provides an integrated set of software components that centrally control, secure, and audit user access to servers, workstations, mobile devices, and applications through Microsoft Active Directory. The purpose of this guide is to give you hands-on experience using Server Suite software to manage identities, access privileges, and administrative tasks on UNIX and Linux computers.

The guide is divided into the following chapters:

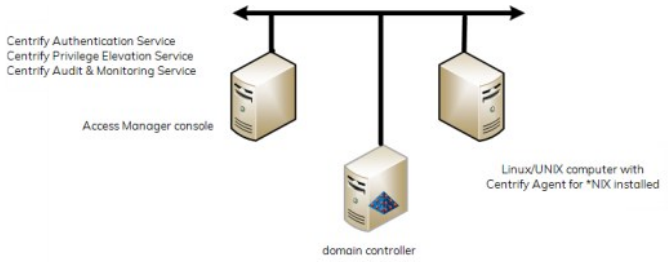
- Preparing Hardware and Software for an Evaluation describes what you will need and how to prepare for the evaluation.
- Configuring the Basic Evaluation Environment provides step-by-step instructions for setting up the evaluation environment.
- Exploring Additional Management Tools describes the features of Server Suite software that reduce complexity and ease the workload in large organizations.
- Auditing Sessions describes how you can audit user activity and search and replay user sessions.
- Frequently Asked Questions provides answers to the most common questions about Server Suite products and features.
- Removing Software after an Evaluation describes how to optionally uninstall Server Suite software.

Preparing Hardware and Software for an Evaluation

This chapter describes the hardware and software you need to prepare for the evaluation of Server Suite software. It includes instructions for downloading SErver Suite software from the Delinea website if you do not have the CD and the permissions required to install and configure the evaluation environment.

What You Need for the Evaluation

To follow the instructions in this guide, you need a simple configuration of networked Windows domain computer, Windows Server domain controller, and a Linux, UNIX, or Mac OS X computer to manage as illustrated in the following example.



To complete this evaluation, you install Server Suite software on two physical or virtual computers:

- **Authentication & Privilege** and **Audit** components on a Windows computer joined to an Active Directory domain.
- **Server Suite Agent for *NIX** on a supported Linux-based or UNIX-based platform that you want to manage.

In most organizations, Server Suite software is not installed on the domain controller. However, you must be able to connect to a domain controller from the other two computers to complete the evaluation.

- Windows Computer Requirements
- Linux and UNIX Computer Requirements
- Domain Controller Requirements

Windows Computer Requirements

You use the Windows computer where Access Manager is installed to perform most of the procedures described in this guide.

Before installing on Windows, check that you have a supported version of one of the Windows operating system product families.

For details about supported platforms, please consult the release notes.

You should also verify that you have the .NET Framework, version 4.5 or later, installed. If the .NET Framework is not installed, the setup program can install it for you. Alternatively, you can download the .NET Framework from the Microsoft Download Center, if needed.

The Windows computer should have the following minimum hardware configuration:

CPU speed	550 MHZ
RAM	256 MB
Disk space	1.5 GB

You should also verify that the Windows computer you plan to use for the evaluation is joined to the Active Directory domain.

> **Note**: If you are installing the software on virtual computers, see Using a Virtual Environment for additional guidelines.

Linux and UNIX Computer Requirements

A platform-specific Server Suite Agent for *NIX must be installed on each computer you want to manage through Active Directory. Delinea supports several hundred distributions of popular operating systems, including AIX, HP-UX, and Solaris versions of the UNIX operating environment and both commercial and open source versions of the Linux operating system. For the most complete and most up-to-date list of supported operating systems and vendors, see the supported platforms listed in the release notes.

You can download platform-specific agent packages from the Delinea **Customer Download Center** if you register for a free account. You can also download agents for free from the Centrify Express website.

The UNIX or Linux computer must be connected to the same network as the domain controller.

Domain Controller Requirements

For the Active Directory domain controller, you should verify that you have access to a computer with a supported version of the Windows Server product family and is configured with the domain controller and DNS server roles. For details about supported platforms, please consult the release notes.

In addition, you should verify that the domain functional level is at least Windows Server 2008 R2.

To determine the domain functional level

1. Open **Active Directory Users and Computers** (dsa.msc).
2. Select the domain.
3. Select **Action**, then click **Raise domain functional level**.

   If the current domain functional level is not at least Window Server 2008 R2, use the drop down list to raise the level.

Verifying Administrative Access for the Evaluation

To prepare for the evaluation, you should confirm that you have the local Administrator account and password for the root domain of the Active Directory forest. The forest root Administrator account is the account created when you install the first Windows Server in a new Active Directory site.

If you set up a separate Active Directory domain for testing purposes, you should have this account information. If you are using an existing Active Directory forest that was not expressly created for the evaluation, you should identify the forest root domain and confirm that you have an account that is a member of the Domain Admins group on the Windows computer you use for the Access Manager console. This ensures that you have all the permissions you need to perform the procedures in this evaluation.

If you are not a member of the Domain Admins group on the Windows computer you use for the Access Manager console, have the Active Directory administrator create a separate organizational unit for Delinea objects and delegate control of that organizational unit to the user account you are using for evaluation. For more information about delegating control, see Delegating control for the Delinea organizational unit.

You should also verify that Administrative Tools are visible in the Start menu on the Windows computer you are using for the evaluation. If the Administrative Tools option is not displayed, download and install the Microsoft Remote Server Administrator Tools from the Microsoft website. For download and installation instructions, see http://www.microsoft.com/en-us/download/details.aspx?id=7887.

Checking the DNS Environment

The Server Suite Agent is designed to perform the same set of DNS lookups that a typical Windows computer performs in order to find the nearest domain controller for the local site. For example, the Server Suite Agent for *NIX looks for service locator (SRV) records in the DNS server to find the appropriate controller for the domain it has joined.

In most cases, when you configure the DNS Server role on a Windows computer, you configure it to allow dynamic updates for Active Directory services. This ensures that the SRV records published when a domain controller comes online are available in DNS. If your DNS Server is configured to prevent dynamic updates, however, or if you are not using the Window computer as the DNS server, the Server Suite Agent for *NIX might not be able to locate the domain controller.

Do the following to ensure the UNIX computer can look up the SRV records in the DNS server for the evaluation environment:

- Configure the DNS Server role on the Windows computer to **Allow secure dynamic updates**.
- Make sure that each UNIX or Linux computer you are using includes the Windows DNS server as a nameserver in the /etc/resolv.conf file.

When you configure the DNS Server, you should configure it to perform both forward and reverse lookups and to allow secure dynamic updates.

Using a Virtual Environment

To simplify the hardware requirements, you might find it useful to set up your evaluation environment using either Microsoft Virtual PC or VMware Workstation. To set up a virtual environment, you need a computer with enough CPU, RAM, and available disk space to run three virtual machines simultaneously. Delinea recommends the following minimum configuration:

- CPU: at least 1.70 GHz
- RAM: at least 8 GB
- Available disk space: 15 GB

The virtual environment should also be configured to run as an isolated evaluation environment using **Local/Host-only** or **Shared/NAT** networking.

In addition, because the virtual environment runs as an isolated network, each virtual machine should be manually assigned its own static TCP/IP address and host name.

Downloading Server Suite Software for UNIX Evaluations

You can go to the Centrify website to sign up for a free trial. Once you're signed up with an account, you can download the software.

To register for a Delinea free trial

1. Navigate to https://www.centrify.com/free-trial/.
2. Enter your contact and company information, click the checkbox to indicate that you agree to the terms of use and privacy policy, and then click **Start My Trial**.

   Note: You will receive an email with the next steps in downloading your free trial.

Downloading Server Suite Windows Software

You can download all of the components for Server Suite from the Delinea website to your Windows computer. Before you begin, be sure you have the email address and password you used to register for your trial.

To download the Windows software for Server Suite

1. Open a browser on the Windows computer you plan to use for the evaluation and go to www.centrify.com.
2. In the upper area of the web page, click **Login**.
3. Enter your email address and your account password, then click **Login**.
4. Go to **Support** › **Downloads**.
5. Select **Zero Trust Privileges - Enterprise** to locate the latest software bundles.
6. Next to the latest version for 64-bit Windows systems, click either the **ISO** or **ZIP** button to download the software in that format.

   The latest version of the Windows software bundle is called Server Suite.
7. Close the window when the download is complete.

Downloading the Linux and UNIX Agents

You can download individual platform-specific packages directly from the Delinea website to a local Linux or UNIX computer.

To download UNIX and Linux agent packages

1. Open a browser on the Linux or UNIX computer you plan to use for the evaluation and go to www.centrify.com.
2. In the upper area of the web page, click **Login**.
3. Enter your email address and your account password, then click **Login**.
4. Go to **Support** › **Downloads**.
5. If you want the bundle that has all of the UNIX/Linux agents:
   1. Select **Zero Trust Privileges - Enterprise** to locate the latest software bundles.
   2. Next to the Agents for UNIX/Linux - All-in-One disk, click either the **ISO** or **ZIP** button to download the software in that format.
6. If you want the agent package just for your specific UNIX/Linux system:
   1. Select **Authentication Service** to locate the latest software bundles for the various *NIX systems.
   2. Next to the Agent for your preferred operating system, click the **TGZ** button to download the software in that format.

Verifying that You Have Active Directory Permissions

Many of the procedures in this guide add or modify Active Directory user, group, and computer accounts. You should verify you have the appropriate Active Directory permissions to make these kinds of changes in the evaluation environment. If you are not an Active Directory administrator or a domain administrator, you might not have access to the domain controller or sufficient permission to modify Active Directory objects and attributes.

To conduct the evaluation, have an Active Directory administrator create an organizational unit for you to use and delegate full control of the organizational unit to you. For more information about creating an organizational unit and delegating control, see the following topics:

- Creating an organizational unit for Delinea
- Delegating control for the Delinea organizational unit

In addition to the organizational unit for Delinea objects, you need to have **Log on as a service** user access rights to start the Zone Provisioning Agent included in the package.

To confirm that your account has "Log on as a service" access rights

1. Open the **Windows Administrative Tools Local Security Policy**.
2. Expand the **Local Policies** node and select **User Rights Assignments**.
3. Scroll down to **Log on as a service** and double-click to display properties for this right.
4. Click **Add User or Group**.
5. Type the user or group name or click **Browse** to search for and select your account, then click **OK** to add this right to your account in the Local Security Setting.

Next Steps

This concludes the site preparation, Server Suite software download, and permissions assessment. You are now ready to install the software and create the fundamental elements of the evaluation environment.

Configuring the Basic Evaluation Environment

In this chapter, you install Server Suite software on your evaluation computers and configure users, groups, roles, and group policies to integrate the UNIX environment into Active Directory. After you complete these steps, your UNIX or Linux computer will be a Server Suite-managed computer that is joined to the Active Directory domain, allowing UNIX users to log in using their Active Directory credentials.

Complete the tasks in order, as described in the following sections.

Creating an Organizational Unit

To isolate the evaluation environment from other objects in Active Directory, you can create a separate organizational unit for all of the Delinea-specific objects that are created and managed throughout the evaluation. You must be the Active Directory administrator or have Domain Admins privileges to perform this task.

To create an organizational unit for Delinea

1. Open **Active Directory Users and Computers** and select the domain.
2. Right-click and select **New > Organizational Unit.**
3. Deselect **Protect container from accidental deletion.**
4. Type the name for the organizational unit, for example, Delinea, then click **OK**.

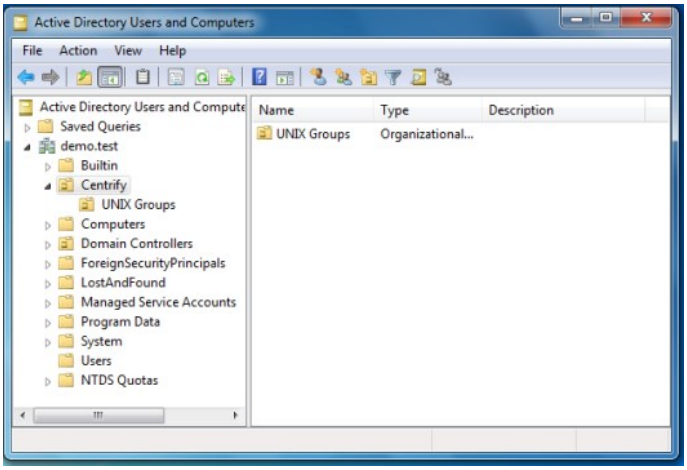
Create Additional Organizational Units

Additional organizational units are not required for an evaluation. In a production environment, however, you might create several additional containers to control ownership and permissions for specific types of Delinea objects. For example, you might create separate organizational units for UNIX Computers and UNIX Groups.

To illustrate the procedure, the following steps create an organizational unit for the Active Directory groups that will be used in the evaluation to assign user access rights to the Delinea-managed computers within the top-level organizational unit for Delinea-specific objects.

To create an organizational unit for evaluation groups

1. In **Active Directory Users and Computers**, select the top-level organizational unit you created in Creating an organizational unit for Delinea.
2. Right-click and select **New > Organizational Unit.**
3. Deselect **Protect container from accidental deletion.**
4. Type the name for the organizational unit, for example, UNIX Groups, then click **OK**.



In later exercises, you will use this organizational unit and add other containers to manage additional types of information.

Delegating Control for the Organizational Unit

To allow another person who is not an Active Directory administrator to perform all of tasks in the evaluation, you can delegate control of the Delinea organizational unit to that person. If you are an Active Directory administrator or a member of the Domain Admins group in the evaluation domain, you can skip this step.

To delegate control of the organizational unit for Delinea

1. Open **Active Directory Users and Computers** and select the domain.
2. Select the top-level organizational unit for Delinea objects, Delinea.
3. Right-click, then select **Delegate Control**.
4. In the Delegation of Control wizard, click **Next**.
5. Click **Add**.
6. Search for and select the user or group for delegation, then click **Next**.
7. Select the tasks to delegate, then click **Next**.

   At a minimum, select the following common tasks:

   - Create, delete, and manage user accounts
   - Reset user passwords and force password change at next logon
   - Read all user information
   - Create, delete, and manage groups
   - Modify the membership of a group
8. If you are delegating the task of joining computers to a zone, you can specify the scope of computers you can join to the zone; you pick a container in Active Directory to grant access to.

   If you leave the scope blank, the scope is the domain root. Be aware that the postalAddress field is used for information about joining computers to a zone; if you lookup the permissions for people you've delegated the task of joining computers to a zone, they'll have permissions to the postalAddress field for the affected computers.
9. Click **Finish.**

Installing and Configuring Access Manager

You are now ready to install Access Manager and other components on the Windows computer you are using for the evaluation.

To install components on the Windows computer

1. On the physical or virtual computer where you downloaded Server Suite software, double-click **autorun.**
2. On the **Getting Started** page, click **Authentication & Privilege.**
3. On the **Welcome** page click **Next**.
4. Review the terms of the license agreement, click **I agree to these terms**, then click **Next**.
5. Type your name and organization, then click **Next**.
6. Select the components to install, then click **Next**.
7. Accept the default **C:\Program Files\Centrify** location for installing components, or click **Browse** to select a different location, then click **Next**.
8. Click **Next** to disable publisher verification.
9. Review the components you have selected, then click **Next** to begin installing components.
10. Deselect the Configure and start Zone Provisioning Agent option, then click **Finish**.

    Because you are going to configure the service account for the Zone Provisioning Agent in a later exercise, click **Yes** to dismiss the warning about the Zone Provisioning Agent running as the local system account.
11. Click **Exit** to close the Getting Started page.

Starting Access Manager for the First Time

After installing Access Manager and other components, you should have the new Access Manager icons on your desktop.

You are now ready to start using Access Manager. The first time you open Access Manager it creates Active Directory containers to store Delinea licenses and zone information.

To start Access Manager for the first time

1. Open **Access Manager** by double-clicking the icon on the desktop.
2. Verify the name of the domain controller, then click **OK**.

    The default is the domain controller to which the Windows computer is joined. If you want to connect to a different forest, type the name of a domain controller in that forest. If you want to connect to the forest with different credentials, select **Connect as another user**, then type a user name and password to connect as.
3. In the Setup Wizard Welcome page, click **Next**.
4. Verify that **Use currently connected user credentials** is selected to use your current logon account, then click **Next**.

    You must be logged on with an account that has Active Directory administrator rights in the target organizational unit.

    If your logon account does not have those rights, select **Specify alternate user credentials** and enter a different user name and password.
5. Select **Generate Delinea recommended deployment structure** and **Generate default deployment structure**, then click **Next**.
6. Select a location for installing license keys in Active Directory, then click **Next**.

    The Setup Wizard displays information about the Read permissions that must be granted on the container. Click **Yes** to continue.
7. Type or copy and paste the license key you received, click **Add**, then click **Next**.

    If you received the license key in a text file, you can click **Import** to import the key directly from the file, then click **Next**.

8. Click **Next** to use the default container for the Delinea zones.
9. Accept the default permission delegation and click **Next**.
10. Review the summary of your selections, then click **Next**.
11. Click **Finish**.

    After you click Finish, Access Manager displays.

Creating the First Zone

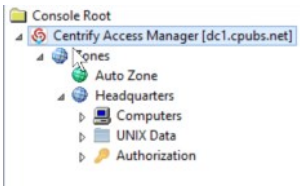
The next step in configuring your evaluation for access control and privilege management is to create a Delinea zone. Zones enable you to define and control access privileges for users and groups in your organization. By using zones, you can limit who has access to different computers and where users have permission to exercise elevated privileges.

To create a parent zone

1. Open **Access Manager**.
2. Click **Create Zone**.

3. Type a name and description for the zone, for example Headquarters, then click **Next**.
4. Leave **Use default zone type** selected, and click **Next**.
5. Verify information about the zone you are creating, then click **Finish**.

You now have one parent zone. You can have multiple parent zones or a single parent zone, depending on your needs. If you expand the **Zones** node, the left pane displays your new zone.



Access Manager automatically creates the Computers, UNIX Data and Authorization nodes for each zone you create. These nodes enable you specify precise access privileges for computer and application administrators in each zone.

A parent zone can have one or more child zones. Child zones inherit information from the parent zone. For example, you can define access rights, roles, and role assignments in a parent zone and use them or change them in a child zone. You will work with child zones in a later exercise.

Now that you have Access Manager installed and have configured your first zone, you are ready to install the Server Suite Agent on a UNIX or Linux computer.

Installing the Server Suite Agent for

The Centrify Agent must be installed on each UNIX or Linux computer you want to manage. After you have downloaded platform-specific agents for the operating systems you want to evaluate, you should make sure the software is on the physical or virtual UNIX or Linux computer you are using for the evaluation.

To install the agent package

1. Log on to the UNIX or Linux computer with root privileges.
2. Copy the Centrify Agent for *NIX package for the local operating system to the computer and change to that directory.
3. Extract the contents of the package.

   For example, if you have a Red Hat Enterprise Linux based computer, you might enter the following:

   gunzip centrify-server-suite-‹*release*›-rhel5-x86_64.tgz
4. Expand the archive file.

   For example, if you have a Red Hat Enterprise Linux based computer, you might enter the following:

   tar -xvf centrify-server-suites-‹*release*›-rhel5-x86_64.tar
5. Run the install.sh script.

   For example, if you are running Red Hat Enterprise Linux you would enter the following:

   /bin/sh install.sh
6. Follow the prompts displayed to check whether the local computer is ready for the installation.

   If there are errors, you must fix them before installing the software. Warning messages are informational, but do not prevent you from installing the software.
7. Follow the prompts displayed using the following instructions:

Do you want to run adcheck to verify your AD environment?	Enter N to skip post-installation checks.
Join an Active Directory Domain?	Enter N to join later.
Enable auditing on this computer (audit and monitoring service NSS mode)?	Enter Y to enable auditing.
Do you want to continue (Y) or re-enter information?	Enter Y to install the default packages.
Enable Linux Desktop auditing on this computer?	Enter Y to enable Linux desktop auditing.

If you have more than one Linux or UNIX computers included in the evaluation, repeat Step 1 through Step 7 on each computer.

8. Verify the installation by running the adinfo command at the UNIX command prompt.

   adinfo

   This command-line program displays information about the Linux or UNIX computer's status in Active Directory. At this point, the output should show you that you are not joined, but Licensed Features are enabled.

Joining the Domain

You are now ready to use the adjoin command-line program to join the Linux or UNIX computer to the Active Directory domain you are using for evaluation.

The most basic syntax for the adjoin command is:

```
adjoin domain -z zone -u username
```

For more information about adjoin syntax and options, see the man page for the adjoin command.

To join an Active Directory domain from a Linux or UNIX computer

1. Log on to the UNIX or Linux computer with root privileges.
2. Run the adjoin command, specifying the domain, zone, and the account name for an Active Directory administrator with permission to join the domain.
3. Enter the password for the Active Directory account used to join the domain.
4. Verify the UNIX or Linux computer is joined to Active Directory by running the adinfo command.

   adinfo

   The output should look similar to the following:

   ```
   Local host name: my-eval
   Joined to domain: test.acme.com
   Joined as: my-eval.test.acme.com
   Pre-win2K name: my-eval
   Current DC: dc-mine.test.acme.com
   Preferred site: CA
   Zone: test.acme.com/acme/zones/HQ
   Last password set: 2020-08-14 11:24:32 PDT
   CentrifyDC mode: connected
   Licensed Features: Enabled
   ```

5. Restart the Linux or UNIX computer.

   Restarting the computer is not required, but is recommended to ensure that all services are restarted.

Verifying your Progress in Access Manager

You now have a Server Suite-managed computer. To see the computer in Access Manager, expand **Zones > Headquarters > Computers**. The Linux or UNIX computer is listed under the Computers node. The computer has successfully joined an Active Directory domain and is prepared for access control and privilege management. However, no Active Directory users can log on to the computer yet.

Adding and Provisioning an Evaluation User and Group

Before any Active Directory users can log on to the Server Suite-managed computer, you must provision an Active Directory account with UNIX profile attributes and assign the user a role that has login privileges. To demonstrate the process in the evaluation, you will create a new Active Directory user, provision the user with a UNIX profile, and assign the user basic access privileges.

To create a new Active Directory user with access to the Server Suite-managed computer

1. Open **Active Directory Users and Computers** and create a new **User** object.
    1. Fill in the **First**, **Last**, and the **User logon** name fields.
    2. Type and confirm a password and select the **Password never expires** option.
    3. Acknowledge the warning, click **Next**, then click **Finish**.
2. Create a new Active Directory group in the UNIX Groups organizational unit you created under the Delinea organizational unit.
    1. For the **Group name** enter Login Users.
    2. Select **Global** as the scope for the group and **Security** for the type of group, then click **OK**.
3. Add the evaluation user to the Login Users group.
    1. Select the user you created in Step 1, right-click and select **Add to a group**.
    2. Select the **Login Users** group, then click **OK**.
4. Provision a UNIX profile for the new user using Access Manager.
    1. Expand the Zones node and select the Headquarters, right-click, then select **Add User.**
    2. Select the user you created for the evaluation.
    3. Select **Define user UNIX profile only** and deselect **Assign roles**.
    4. Accept the default values for all profile properties.
    5. Review your selections, click **Next**, then click **Finish**.
5. Assign the default UNIX Login role to the Login Users group using Access Manager.
    1. Expand the **Authorization** node under the Headquarters zone.
    2. Select **Role Assignments**, right-click, then select **Assign Role**.
    3. Select the **UNIX Login role** and click **OK**.
    4. Click **Add AD account**.
    5. Change the object to **Find from User to Group**, then search for and select the Login Users group, then click **OK**.
    6. Click **OK** to complete the role assignment.

Verify Access by Logging On

The Active Directory user can now log on to the UNIX or Linux computers that has joined the domain and the parent zone.

To verify the user can log on using Active Directory credentials

1. Open a terminal on your joined Linux or UNIX computer and switch to the root account.
2. Run adflush to clear the Server Suite Agent for *NIX's cache.

    This step simply ensures that the agent will make a new connection to Active Directory to get the latest user and group information.

3. Log off as root.
4. Log in using the Active Directory credentials for the evaluation user you created and added to the Login User group.

Creating a UNIX Administrator Role

Now that you have verified an Active Directory user can access the Linux or UNIX computer you are using for the evaluation, you will see to how to create users that have elevated privileges and how you can limit the use of those privileges to specific computers.

To illustrate this scenario, you will create a UNIX administrator role that grants root privileges for the computers in a zone without requiring users to know the root password. Instead, users who are assigned the UNIX administrator role use their Active Directory credentials.

You can use the same steps to define roles with different and more granular rights. For example, you will follow similar steps to create an Apache administrator role that can only perform a limited set of tasks on computers in a child zone.

At the end of this section, you will have two accounts with UNIX Login privileges: one of which has only standard user privileges, the other account has full administrative privileges.

To create a new Active Directory user and group with administrative access

1. Open Active Directory Users and Computers and create a new **User** object.
    1. Fill in the First, Last, and the User logon name fields.
    2. Type and confirm a password and select the Password never expires option.
    3. Acknowledge the warning, click Next, then click Finish.
2. Open Active Directory Users and Computers and create a new **Group** object in the UNIX Groups organizational unit.
    1. For the Group name, enter EnterpriseUnixAdmins.
    2. Select Global as the scope for the group and Security for the type of group, then click OK.
3. Add the administrative user to the EnterpriseUnixAdmins group.
    1. Select the user you created in Step 1, right-click and select Add to a group.
    2. Select the EnterpriseUnixAdmins group, then click OK.
4. Provision a UNIX profile for the new user using Access Manager.
    1. Expand the Zones node and select the Headquarters, right-click, then select **Add User.**
    2. Select the user you created for UNIX administration.
    3. Select Define user UNIX profile only and deselect Assign roles.
    4. Accept the default values for all profile properties.
    5. Review your selections, click Next, then click Finish.

Defining a Command Right and a New Role

You are now ready to define a new privileged command right that uses the asterisk (*) wild card to give the user the equivalent of all commands, all paths, and all hosts in the sudoers file. In a production deployment, you would define more specific sets of privileged commands and run them using accounts with no restricted access than the root user.

To create new UNIX right definition for the administrative role

1. Create a new privileged command using Access Manager.
    1. Expand the Authorization node under the Headquarters zone, then expand UNIX Right Definitions and select Commands.
    2. Right-click then select New Command. For this example, you will only set information on the General tab.
    3. Type a command name and description, for example root_any_command and All commands, all paths, all hosts.
    4. Type an asterisk (*) in the Command field to match all commands.

5. Leave the default setting for Glob expressions.
6. Select the Specific path options and type an asterisk (*) to match all command paths, then click OK.

You now have a root_any_command that grants privileges to run any command in your role definitions. In the next steps, you create a role that will give members of the EnterpriseUnixAdmins group the root_any_command privileges.

To create and assign the UNIX administrators role

1. Create a new role definition using Access Manager.
    1. Expand the Authorization node under the Headquarters zone, select Role Definitions, right-click, then select **Add Role**.
    2. Type a role name (UnixAdminRights) and a description (Set of rights for UNIX administrators) for the new role.
    3. Click the **System Rights tab** and select all of the UNIX rights and the Rescue right.
    4. Click the Audit tab and select Audit if possible, then click **OK**.
2. Add the root_any_command and several default rights to the new role.
    1. Select the UnixAdminRights role, right-click, then select **Add Right**.
    2. Use CTRL-click to select rights, including login-all, secure shell (ssh, sshd, and dzsshall) rights, and the root_any_command right you just created, then click **OK**.
3. Assign the UnixAdminRights role to the enterprise UNIX administrators group using Access Manager.
    1. Expand the Authorization node under the Headquarters zone, select Role Assignments, right-click, then select Assign Role.
    2. Select the UnixAdminRights role and click **OK**.
    3. Click **Add AD Account**.
    4. Change the object to Find from User to Group, then search for and select the **EnterpriseUnixAdmins group**, then click **OK**.
    5. Click **OK** to complete the role assignment.

Verifying Administrative Privileges

You now have two role assignments—Login Users and EnterpriseUnixAdmins—in the zone. Any Active Directory user you add to the Login Users group and provision a UNIX profile for will have access rights but no administrative privileges on the computers in the zone. Any Active Directory users you add to the EnterpriseUnixAdmins group and provision a UNIX profile for will be able to run any command with root-level permissions using their Active Directory credentials.

The Active Directory user you added to the EnterpriseUnixAdmins group can now log on and run privileged commands on the UNIX or Linux computers you are using for evaluation.

To verify the user can run privileged commands using Active Directory credentials

1. Log on to the Linux or UNIX computer using the Active Directory logon name and password you created for the UNIX administrator.
2. Open a terminal on the Linux or UNIX computer.
3. Run a command that requires root-level privileges.

    For examples, run the dzinfo command to view the rights and roles for the UNIX Login user you created Adding and provisioning an evaluation user and group.

    dzinfo user_name

    Because you are logged on as the Active Directory user and not invoking the command using your role assignment, the command displays an error message indicating that you are not allowed to view authorization information for another user.
4. Re-run the command using your role assignment by typing dzdo before the command.

dzdo dzinfo user_name

The command runs successfully and returns information about the evaluation user similar to this partial output.

User: lois.lane
Forced into restricted environment: No

Role Name Avail Restricted Env
--- --- ---
UNIXLogin/Headquarters Yes None
Effective rights:
Password login
Non password login
Allow normal shell

Audit level:
AuditIfPossible

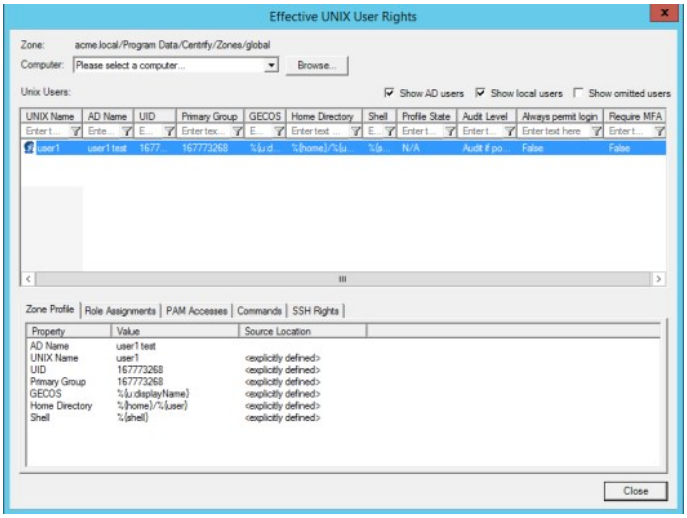
Viewing Effective Rights

Often, you need to see which users have what privileges in a zone. Access Manager provides you a single view of all of the effective users in a zone and lets you tab through their account properties.

To view effective rights for Linux and UNIX users

1. Open Access Manager.
2. Expand Zones, right-click your parent zone name, then select **Show Effective UNIX User Rights**.

   For example, the following illustrates the effective users in the evaluation zone.



3. Select a user, then click the tabs to see details about that user's profile, role assignments and UNIX rights.

Creating Child Zones and a Service Administrator Role

In many cases, you don't want a service administrator to have root privileges. For example, there's no reason to give database or web service administrators root-level privileges if their role only requires limited access to a few privileged operations.

To illustrate how to grant more limited privileges to an administrator, you will now create a role that gives an Apache server administrator permission a few specific tasks, such as edit the Apache configuration file and start and stop the Apache service. In this scenario, you will also create child zones to further limit the Apache administrator's authority to just the computers in the child zones.

To create child zones

1. Open Access Manager.
2. Expand Zones, right-click your parent zone name, then select **Create Child Zone.**
3. Type a Zone name (Nevada) and a brief description (Western field office), then click **Next**.
4. Click **Finish**.
5. Repeat Step 1 through Step 4 giving the second child zone a different name (Delaware) and description (Eastern web farm office).
6. Expand Child Zones and each new zone you created to view the nodes of the child zones.

To create a new Active Directory user and group for Apache administrators

1. Open Active Directory Users and Computers and create a new **User** object.
    1. Fill in the First, Last, and the User logon name fields.
    2. Type and confirm a password and select the Password never expires option.
    3. Acknowledge the warning, click Next, then click Finish.
2. Open Active Directory Users and Computers and create a new **Group** object in the UNIX Groups organizational unit.
    1. For the Group name, enter ApacheAdmins.
    2. Select Global as the scope for the group and Security for the type of group, then click OK.
3. Add the web administrator to the ApacheAdmins group.
    1. Select the user you created in Step 1, right-click and select Add to a group.
    2. Select the ApacheAdmins group, then click OK.
4. Provision a UNIX profile for the new user using Access Manager.
    1. Expand the Zones node and select the Headquarters, right-click, then select **Add User.**
    2. Select the user you created for web administration.
    3. Select Define user UNIX profile only and deselect Assign roles.
    4. Accept the default values for all profile properties.
    5. Review your selections, click Next, then click Finish.

Defining Command Rights and a New Role for Apache Administrators

You are now ready to create the privileged commands and role definition for the Apache administrators much as you did for the UNIX administrators. However, in this scenario, you will add the following new commands:

web_edit_http_config	vi /etc/httpd/conf	Edit the httpd daemon configuration file

web_apachectl	apachectl *:	Front end command for managing the httpd daemon
web_httpasswd	htpasswd *	Create and update HTTP server user name and password file

These commands will be added to a new role definition, ApacheAdminRights. As an alternative to creating the commands and role manually using Access Manager, as you did in the previous section, the following steps illustrate how you can use an ADEdit script.

ADEdit is a command-line scripting environment included with the Delinea Agent for *NIX. You can use ADEdit commands and scripts to modify Active Directory objects interactively directly from a UNIX or Linux computer terminal. The sample script ApacheAdminRole illustrates how you can use an ADEdit script to create UNIX rights and an Apache administrator role. This sample script is located in the /usr/share/centrifydc/samples/adedit directory on the UNIX or Linux computer where you have installed the Delinea Agent.

To create the ApacheAdmin commands and the ApacheAdminRights role

1. Log on to the Linux or UNIX computer using the Active Directory logon name and password you created for the UNIX administrator.
2. Open a terminal on the Linux or UNIX computer.
3. Change the directory to /usr/share/centrifydc/samples/adedit.
4. Run the ApacheAdminRole script.

   ./ApacheAdminRole

   If you see the error /bin/env: bad interpreter: No such file or directory, try changing the first line in the script to #!/usr/bin/env adedit.
5. Follow the prompts displayed to provide the following information for connecting to Active Directory:
   - Domain name.
   - The Active Directory account name that has administrator privileges in the organizational unit you're using for the Delinea zones.
   - The password for the Active Directory account.
6. Select the zone from the list of zones in your domain.

   For example, enter 2 to create the commands and role in the Nevada child zone or 3 to create the commands and role in the Delaware zone. The script then creates the commands and the role in the selected zone.

Verifying the Success of the Script

You can verify the new command rights and role in Access Manager.

To verify the script created command rights new role

1. Open Access Manager.
2. Expand the Nevada or Delaware child zone, then expand Role Definitions.
3. Select the ApacheAdminRights role to view the new command rights in the right pane.

   The new rights are also listed in the under the child zone UNIX Right Definitions > Commands node. If the new role is not listed, right-click, then select Refresh.

Adding Rights to the New Role Definition

The ApacheAdminRole script created the new UNIX command rights for Apache-related tasks. However, the Apache administrators require a few more rights to do their job. For example, the ApacheAdminRights role created using the sample script does not include the UNIX Login right for any computers.

To add more rights to the ApacheAdminRights role

1. Open Access Manager.
2. Expand the Nevada or Delaware child zone, then expand Role Definitions.
3. Select the ApacheAdminRights role, right-click, then select **Add Right**.
4. Select the Nevada or Delaware child zone from the list of zone to restrict the list of rights to the rights available in the child zone.
5. Select the following default rights:
    - login-all to allow Apache administrators to log on.
    - ssh to allow Apache administrators to use the PAM secure shell client application.
    - sshd to allow Apache administrators to use the secure shell server application.
    - dzssh-scp to allow Apache administrators to use the secure copy application.
    - dzssh-sftp to allow Apache administrators to use the secure file transfer application.
6. Click **OK**.

Assigning the Apache Administrator Role to a Group

You can now assign the ApacheAdminRights role to the Active Directory ApacheAdmins group. The members of this group will only have the Apache access rights on the computers in the Nevada or Delaware child zone you selected. Outside of the selected zone, members will have no access rights on any UNIX computers.

To assign the ApacheAdminRights role to the Apache administrators

1. Open Access Manager.
2. Expand the Nevada or Delaware child zone and its Authorization node.
3. Select Role Assignments, right-click, then select **Assign Role.**
4. Select the ApacheAdminRights role, then click **OK**.
5. Click **Add AD Account**.
    1. Change the object to Find from User to Group, then search for and select the ApacheAdmins group, then click OK.
    2. Click OK to complete the role assignment.

Deploying Group Policies to UNIX Computers

Centrify provides group policy templates for managing UNIX and Linux computers. The group policies are centrally managed through the Group Policy Management Editor, but modify configuration settings on the managed computers where they are applied. This mechanism allows you to manage the group policy settings from a single location and have them applied on remote UNIX and Linux computers.

To illustrate how to configure and apply group policies, you will create a Group Policy Object for the Centrify organizational unit.

To load and apply group policies for UNIX and Linux computers

1. Open the Group Policy Management utility (gpmc.msc) and expand your evaluation domain.
2. Right-click the Delinea organizational unit, and select **Create a GPO in this domain, and Link it here.**
3. Type a name for the new GPO (UNIX policies), then click OK.
4. Expand the Delinea organizational unit, right-click the GPO, then select **Edit**.
5. Expand the Computer Configuration > Policies node and select **Delinea Settings**.
6. Right-click and select **Add/Remove Templates**
7. Click **Add** and select all of the templates listed, click **Open**, then click **OK**.

   This step adds both computer and user group policies under the Delinea Settings node. Expand Delinea Settings to explore the specific policies available. You can click the Explain tab for any group policy to see more information about what it does. The remainder of this section illustrates how you would enable and configure a few simple policies for Delinea-managed. You should note that all policies—including Delinea group policies—are "Not configured" by default.

Configuring User Mapping by Group Policy

To illustrate how to configure a Delinea group policy, you will enable the Set user mapping policy. This policy maps a UNIX user, for example root, to an Active Directory user account, for example Amy.Adams. After this policy is set, root attempts to log on must use the mapped Active Directory user's credentials.

To configure a Delinea group policy

1. Expand Delinea Settings > DirectControl Settings, scroll down and double-click the **Set user mapping** policy.
2. Select **Enabled**, then click **Add**.
3. Type the UNIX user account name (root).
4. Click Browse to search for and select the Active Directory account to use, then click **OK**.
5. Click **OK** to enable the policy.

   Note: If you enable this policy, the root user in the zone will **not** be able to log in to the managed computers in the zone.

Configuring Password Prompts

There are several group policies that enable you to customize the text displayed when a user attempts to log on to a managed computer. For example, you can customize the text displayed when a password is expiring in a certain number of days or when authentication fails. To illustrate how to configure the Delinea group policies for password-related prompts, you will enable the Set login password prompt policy.

1. Expand **Delinea Settings > DirectControl Settings > Password Prompts** and double-click **Set login password prompt**.
2. Select **Enabled**.
3. Type the text string you want displayed, then click **OK**.

Next Steps

You now have a basic foundation for working with Server Suite software. You have created a parent zone and child zones, provisioned users to log on to computers in those zones, defined rights and roles in different zones, and granted Active Directory users and groups specific rights by assigning them to roles. You've also seen how to apply and configure group policies for Centrify-managed computers. From here, you can experiment on your own or explore some of the additional tools that Server Suite provides.

Exploring Additional Management Tools

In configuring a basic evaluation environment, you saw how you can use Active Directory to centrally manage user accounts, access privileges, and group policies on Linux and UNIX computers through Server Suite zones. This chapter introduces some of the additional Server Suite tools that you can use to manage the UNIX users and computers in your organization.

Adding UNIX Profiles Automatically

Adding UNIX user accounts to Active Directory on a large scale poses several challenges:

- Provisioning: How do you provision large numbers of UNIX users and map them to unique Active Directory user objects?
- Assigning roles: Once the UNIX users have profiles stored in Active Directory, how do you give each user just the privileges required?
- Accommodating legacy UIDs: How do you migrate UNIX users who have different UIDs on different servers and maintain existing file ownership requirements?

One strategy for adding and managing a large number of UNIX profiles is to use the Zone Provisioning Agent and provisioning properties. The Zone Provisioning Agent can automatically provision new users with the full complement of UNIX profile attributes when you add them to an Active Directory group. Configuring the environment to illustrate automated provisioning with the Zone Provisioning Agent, however, requires several steps that are only applicable if you choose that deployment scenario.

The following steps summarize the process, but are not recommended for an evaluation.

To deploy the Zone Provisioning Agent

1. Create an Active Directory service account with the "Log on as a service" user right.
2. Open the Centrify Zone Provisioning Agent Configuration Panel and configure the service to use the service account you created for it.
3. Create or identify the Active Directory groups you will use as source groups for UNIX users.
4. Set the provisioning properties for the zone or zones where users will be automatically provisioned.

   For example, open Access Manager, select the parent zone, right-click, then select Properties to see the Provisioning properties. You can then set the Active Directory source group and how you want UNIX attributes to be automatically generated.
5. Migrate all existing users using the appropriate override attributes into zones to preserve their profiles.
6. Start the Zone Provisioning Agent service.

Keep in mind that the Zone Provisioning Agent takes over all user provisioning if enabled for a zone. After you start the service, you cannot use the Access Manager **Add User** option to add a user to the zone. This ensures that all UIDs are unique in the domain.

If you configure the Zone Provisioning Agent, you can add and remove users from selected Active Directory groups to automatically add or remove their UNIX profiles in a zone.

To add users after configuring zone provisioning

1. Open the users.txt file in the /usr/share/centrifydc/samples/adedit directory to add more or change names.

   Use an editor that does not insert a carriage return at the end of each line. Each line must end with a line feed.
2. Run the AddUnixUsers sample script in the directory to create the Active Directory account for each UNIX user and add each user to the Active Directory UNIX Users group.

   ./AddUnixUsers users.txt.
3. Follow the prompts displayed to provide the following information for connecting to Active Directory:
   - Domain name.
   - The Active Directory account name that has administrator privileges in the organizational unit you're using for the Delinea zones.
   - The password for the Active Directory account.
4. Type an initial password that meets the Active Directory requirements to be used for all of the accounts added.
5. Open the Delinea Zone Provisioning Agent Configuration Panel and click **Restart**.
6. Open Access Manager or Active Directory Users and Computers and assign users to the appropriate Active Directory groups to assign rights.

Delinea

Managing UNIX Information from a UNIX Terminal

Many organizations find it least disruptive for their UNIX administrators to continue to manage their UNIX and Linux computers directly from their own computer rather than from a Windows computer. If you plan to manage zones, UNIX user and group accounts, access privileges, roles, and role assignments from a UNIX or Linux computer, you can use the command-line tools described in this section.

Using UNIX Commands

This following table summarizes the most commonly used Centrify command line programs.

adcheck	/usr/share/centrifydc/bin	Performs operating system, network, and Active Directory tests to verify a computer meets the system requirements for a successful installation. For example, the install.sh script runs the adcheck program.
adedit	/usr/bin	Starts the adedit application for interactive commands or running scripts For more information about the adedit application, see Using ADEdit.
adflush	/usr/sbin	Clears the computer's agent cache. Use this after you have made changes to Active Directory accounts to remove and replace the previous values.
adgpupdate	/usr/bin	Retrieves group policies from the Active Directory domain controller and applies the policy settings to the local computer and current user immediately. If you do not use the command, group policies are automatically updated at a random interval between 90 and 120 minutes.
adinfo	/usr/bin	Displays summary or detailed diagnostic information for the managed computer.
adjoin	/usr/sbin	Joins the local computer to an Active Directory domain, organizational unit and zone.
adleave	/usr/sbin	Removes the local computer from the Active Directory domain.
adpasswd	/usr/bin	Changes the Active Directory account password for the current user or a specified user.
adquery	/usr/bin	Queries Active Directory for information about users and groups.
dzinfo	/usr/bin	Displays information about the effective rights and roles for the current login account.
dzdo	/usr/bin	Enables you to run privileged commands as root or another user.

Some UNIX commands require you to be logged on as root or as a user with root privileges. Other commands allow different operations or return different results if you are logged on as root. For the complete list of Server Suite command line programs you can run on Linux and UNIX computers, see the *Administrator's Guide for Linux and UNIX*. For detailed information about the options available for any command, see the man page for that command.

Using ADEdit

The Server Suite Agent for *NIX also includes the Tcl-based ADEdit program. ADEdit has two basic components:

- the adedit command-line application
- the ade_lib Tcl library

ADEdit provides a scripting language that you can use to bind to one or more Active Directory domain controllers. You can then use ADEdit to retrieve, modify, create, and delete Active Directory objects of any kind, including Server Suite specific objects such as zones, rights, and roles. For example, you used ADEdit and a sample script to create rights and a role in Defining command rights and a new role for Apache administrators.

The following sections introduce a few of the key features for ADEdit. For more information about using ADEdit commands and the ade_lib library, see the *ADEdit Command Reference and Scripting Guide*.

ADEdit Application

ADEdit uses Tcl as its scripting language. The Tcl scripting language includes all standard programming features, such as variables, logical operators, and predefined functions (called "procedures" in Tcl). The ADEdit application also includes a Tcl interpreter and Tcl core commands, which allow it to execute standard Tcl scripts, and a comprehensive set of its own commands designed to manage Server Suite-specific objects in Active Directory.

You can use ADEdit to execute individual commands interactively or to execute sets of commands together in the form of an ADEdit script.

ade_lib Tcl Library

The ade_lib Tcl library is a collection of Tcl procedures that provide helper functions for common Centrify-specific management tasks such as listing zone information for a domain or creating an Active Directory user. You can include ade_lib in other ADEdit scripts to use its commands.

Using adedit Sample Scripts

The Server Suite Agent for *NIX includes several sample adedit scripts that you can run in your evaluation environment. The scripts are in the /usr/share/centrifydc/samples/adedit directory on the UNIX or Linux computer where you have the agent installed.

To run scripts that have the .sh extension, enter /bin/sh filename.sh.

To run scripts that do not have an extension, you can just enter ./filename.

> **Note**: If you get the error /bin/env: bad interpreter: No such file or directory when you run a script, this means that the env command is not in the /bin directory. In most cases, it is in /usr/bin instead. To fix this, change the first line in the script to:

```
#!/usr/bin/env adedit
```

The following table lists the sample scripts and the arguments.

AddUnixUsers	users.txt	none
ApacheAdminRole	none	none
computers-report	-domain domain_name -u AD_user_name -sep separator	-m -p password Use -m if you want to authenticate using the computer account credentials instead of an Active Directory user account. If using an Active Directory user account, use -p if you want to include the user's password in the command line. If you don't specify this option, you are prompted for the password.
CreateChildZones	-d domain_name -z parent_zone_name -u AD_user_name	-p password Use -p if you want to include the user's password in the command line. If you don't specify this option, you are prompted for the password.
CreateParentZone	-d domain_name -z zone_name	none
GetChildZones	none	none
GetComputers	none	none
GetGroups	none	none
getopt-example	-d domain_name -u AD_user_name	-p password Use -p if you want to include the user's password in the command line. If you don't specify this option, you are prompted for the password.
Getusers	none	none
GetZones	none	none
MakeRole	Role_apacheAdmin.txt	none

MktDept.sh	List of names, for example, Mary, Joe, and Lance	none
useracc-report	-domain domain_name -u AD_user_name -sep separator	-m -p password Use -m if you want to authenticate using the computer account credentials instead of an Active Directory user account. If using an Active Directory user account, use -p if you want to include the user's password in the command line. If you don't specify this option, you are prompted for the password.
user-report	-z zone_distinguished_name	-m -p password Use -m if you want to authenticate using the computer account credentials instead of an Active Directory user account. If using an Active Directory user account, use -p if you want to include the user's password in the command line. If you don't specify this option, you are prompted for the password.

For more information about the sample scripts and how they can be used or modified, see the *ADEdit Command Reference and Scripting Guide*.

Next Steps

You have now explored some of the additional tools available for working with Server Suite-managed computers, including the basic features of ADEdit sample scripts and default reports. You are now ready to see how you can use the audit and monitoring service to capture, replay, and manage user sessions on managed Linux and UNIX computers.

Auditing Sessions

This chapter describes how to install and use the Delinea Administration and Services components. The auditing service is a process on each managed UNIX and Linux computer that captures user session input and output and transfers this information to a collector service. The collector service forwards the audited sessions to a database, where it is available for review and replay.

Install Auditing Components on Windows

For the evaluation, you are going to install the auditing infrastructure on a single Windows computer. To complete these steps, you will install a Microsoft SQL Server database for the evaluation environment, a single collector, and the Audit Manager and Audit Analyzer consoles from the Audit & Monitoring Service setup program. You have already installed the auditing service on the Linux or UNIX computer you are using for the evaluation.

To install auditing components on the Windows computer

1. On the physical or virtual computer where you downloaded Server Suite software, double-click **autorun.**
2. On the Getting Started page, click **Audit & Monitor**.
3. At the Welcome page, click **Next**.
4. Review the terms of the license agreement, click **I accept the terms in the license agreement**, then click **Next**.
5. Select both **Centrify Administration** and **Centrify Services** to install all components, then click **Next**.
6. Accept the default location for installing files by clicking **Next**, then click **Next** to proceed with the installation.
7. Confirm that the Launch Configuration Wizard box is selected by default, then click **Finish**.
8. Click **Exit** to close the **Getting Started** page.

Configure a New Audit Installation

An audit *installation* is a logical object similar to an Active Directory forest or site. It encompasses all of the auditing components you deploy—agents, collectors, audit stores, audit store databases, management database, and consoles—regardless of how they are distributed on your network. The installation also defines the scope of audit data available. All queries and reports are against the audit data contained within the logical boundary of the installation.

To create a new installation for auditing in the evaluation environment

1. If you have launched the new installation wizard automatically, at the **Welcome** page, click **Next**.

   You can also use Audit Manager to launch the new installation wizard.

2. In the New Installation wizard, accept the default audit installation name by clicking **Next**.

   For the evaluation, use the default installation name to automatically collect the sessions cached on the managed computers. If you use a different name, you must manually specify the installation an audited computer should use.

3. Select the option to create a new management database and verify the SQL Server computer name, instance name, and database name are correct, then click **Next**.

4. Select **Use the default NT AUTHORITY\SYSTEM account** to run the stored procedures that read and write information to the management database, then click **Next**.

5. Type the license key you received, then click **Add** or click **Import** to import the keys directly from a file, then click **Next**.

6. Accept the default location for publishing installation information, then click **Next**.

7. Select the installation-wide auditing options you want to enable, then click **Next**.

   For the evaluation, select **Enable video capture recording of user activity** to capture shell activity on the audited computer, then click **Next**. Do not select the options that disallow the review and deletion of your own sessions.

8. Review details about the installation and management database, then click **Next**.

   If you have SQL Server system administrator (sa) privileges and can connect to the SQL Server instance, the wizard automatically creates the management database.

9. Select the **Launch Add Audit Store Wizard** option if you want to start the Add Audit Store wizard, then click **Finish**.

Enabling Linux Desktop Auditing

In addition to shell auditing, for some Linux systems you can also enable desktop auditing. When desktop auditing is enabled, the user's entire screen is continuously monitored to record all graphical interactions. More specifically, desktop auditing captures the following:

- The application name and window title when the user switches the focus to that application. For example, if a user opens a web browser or a terminal window.
- Changes to the application window title that currently has focus. For example, if a user opens a web browser and goes to a new web page, desktop auditing records the title of a web page.

The supported platforms for Linux desktop auditing are as follows:

- RHEL 6, 7, and 8 with GNOME v3
- CentOS 6, 7, and 8 with GNOME v3

Linux sessions must be running X as the primary display manager (not Wayland).

Linux desktop auditing requires shell session auditing.

To enable desktop auditing on a Linux computer

1. Log on as a user with root privileges.
2. Run dacontrol with the -x option or the --desktop-audit option:

   ```
   dacontrol -x
   ```

   ```
   dacontrol --desktop-audit
   ```

   To enable both shell and desktop auditing at the same time, use both the -e and -x options:

   ```
   dacontrol -e -x
   ```

3. Run dainfo to verify that desktop auditing has been enabled.

   For example, the relevant information from the dainfo command looks like this:

```
Pinging adclient: adclient is available
 Daemon status: Online
 Current installation: 'DirectAudit' (configured locally)
 Current collector: test.acme.com:5063:HOST/test.acme.com@acme.com
 DirectAudit NSS module: Active
 ...
 DirectAudit desktop auditing: Enabled
 User (root) audited status: Yes
```

When you enable auditing, the desktop auditing module shows as Enabled. You can also see if auditing is enabled or not for a system in the Audit Manager console.

Verify that Auditing is Enabled

After the auditing infrastructure is installed and configured, you are ready to audit activity on the managed computers where the Server Suite Agent is installed.

To check that auditing is enabled on the managed computer

1. Log on to the managed computer as root.
2. Run the following command verify auditing is enabled:

   ```
   dacontrol -e
   ```

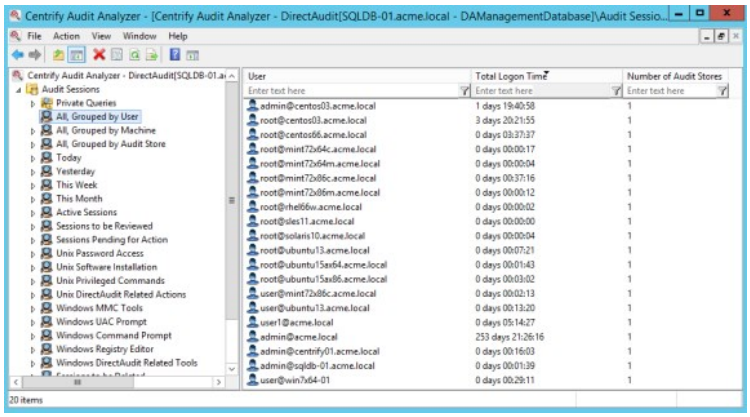
   This command will enable auditing or display a message indicated that auditing is already enabled.

Within a few minutes the collector service should start to retrieve session activity for the managed computer. For more information about configuring and managing the auditing infrastructure, see the Unexpected Link Text.

Viewing Sessions with Predefined Queries

After you have started collecting user activity on a managed computer, you can use Audit Analyzer to view and replay the sessions captured. For example, you can open Audit Analyzer and select **Active Sessions** to see sessions that are currently in progress.

Audit Analyzer includes many predefined queries like the Active Sessions query that you can use to find the sessions in which you are interested. To access the predefined queries, expand Audit Sessions. You can then select a predefined query to display a list of the audited sessions that meet the conditions of that query. For example, if you want to search for sessions by user, you can select the "All, Grouped by User" query, then select the specific user whose sessions are of interest to see a list of all the sessions captured for that user. For example, in the right pane, you would select a user from the list.



After you select a specific user, Audit Analyzer displays detailed information about each of that user's sessions. For each session, Audit Analyzer lists the user name who started the session, the user display name, the account name used during the session, the name of the audited computer, the audit store used, start and end time, current state, whether the audited session is a console or terminal client session, the review status of the session, the name of the user that modified the status, the size of the session in kilobytes, and any comments that have been added to the session.

In addition to the predefined queries for audited sessions, Audit Analyzer includes predefined queries for audit trail events and predefined queries for basic reports. You can explore these queries on your own as you capture additional activity.

Replaying a Session

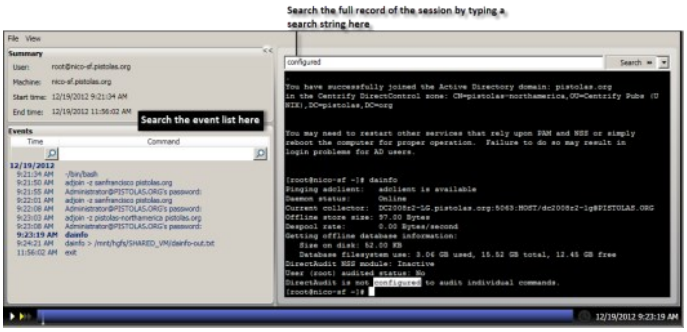
If you accepted the defaults when you created the installation for auditing, you should have video capture auditing enabled. Video capture auditing records all standard input (stdin), standard output (stdout), and standard error (stderr) activity that occurs on the managed computer. With video capture enabled, you can select a session, right-click, then select **Replay** to review the session in the session player.

At this point in the evaluation, you have had very limited activity on the Linux or UNIX computer you are managing and auditing. Before replaying any sessions, you might want to log on to the managed computer and run several simple UNIX shell commands, then close the UNIX terminal and log off.

To replay the sample session

1. Open Audit Analyzer from the desktop icon.
2. Click **Today** in the left pane to list the sessions that have run today.
3. Select the session that has UNIX shell command activity, right-click, then click **Replay** to display the session player.

   The left pane of the session player displays a summary of activity. You can search on any column to find events of interest. You can also search for a specific text string. For example:



4. Click the **Play**/**Pause** icon at the bottom of the session player to start or stop the session you are viewing.

   You can also fast forward session playback by clicking the **Speed control** icon to play back at 2x or 3x the normal speed. The dark blue playback line across the bottom of the window represents the total time of the session. You can drag the **Timepoint needle** to go directly to a specific point in the session.

   The **Real-time** icon toggles to allow you to play back a session as it was recorded in real time or move swiftly from one user action to the next. The **Session point** in the lower right corner identifies the date and time of the current point in the session playback.

5. Close the session player.

Managing Audited Sessions

You can right-click any session to view an indexed list of the commands captured, export the session activity to another format for sharing or further analysis, update the review status for the session, or delete the session.

Using Command Summaries

You can view a list of the commands the user executed in a selected session by right-clicking the session, then selecting Indexed Command List. This option provides a summary of user activity so that you can quickly scan for events of interest or for suspicious activity without replaying activity. You can then start the session player from a specific command in the list by selecting the command and clicking **Replay**.

Exporting Sessions

You can export session activity to several different formats to enable you to share information for review and analysis. After selecting a session, you can right-click to export the session to the following formats:

- As a plain text (TXT) file that includes the time of each input and output event that occurred during the session.
- As a comma separated values (CSV) file where each row represents a single command input or output line from the terminal window.
- As a Microsoft Windows Media Video (WMV) file can be played by using any media player that supports the WMV format. This option enables you to share the video capture of activity with auditors or other users who don't have access to Audit Analyzer. You should note, however, that WMV files do not include all of the information available in the session player. For example, exporting a session to a WMV files does not preserve information such as the session summary that includes the user name, computer, start and end time for the session and the summary of events.
- As a uniform resource identifier (URI) by selecting **Copy Session URI**. This option enables you to share the session with auditors or other users who don't have access to Audit Analyzer. Once copied to the clipboard, you can paste the URI into a browser to open the session for replay.

Viewing and Editing Session Properties

If you select a session, right-click, then select **Properties** you can view detailed information about the session, including the type of session, the session start and end times, the zone where the session took place, the audit store where the session is stored, details about the user whose activity was recorded and computer where the session ran, and the current status of the session. From the properties section, you can also view the current review status for the session, when the review status was last modified, and who made the change to the review status. You can also click on the Reviewers tab in Properties to see the list of users that are authorized to review the session, change the status of the session, and add comments to the session. By clicking the Comments tab, you can also view and add comments to the session. For example, you might want to use the Comments tab to add details about what to look for in a session to assist a reviewer or to provide additional information when you change the review status of a session.

Updating Review Status for a Session

You can use the **Update Review Status** for a session to distinguish sessions that warrant attention and to mark their progress through your review cycle. For example, if you find a session that warrants analysis, you might right-click to select Update Review Status, then select **To be Reviewed**. After you select a new status, you are prompted to add comments and the session is added to the appropriate predefined query in the left pane. For example, if you selected To be Reviewed status, the session to the **Sessions to be Reviewed** list.

After you review the session and you determine it needs further action, you might select the **Pending for Action** review status. Selecting this status removes the session from **Sessions to be Reviewed** list and adds it to **Sessions Pending for Action** list.

Deleting Sessions

You can select a session, right-click, then select **Delete** to delete a session after you have finished reviewing activity and taken appropriate action or when it is no longer needed. Selecting this option deletes the session from all predefined and custom query lists. For example, if you delete the session from the results for the **Today** predefined query, the session might also be deleted from the results for the predefined **Sessions to be Reviewed** query or any shared or private queries where it was previously listed.

Creating Custom Queries

In addition to the predefined queries, you can use Audit Analyzer to create your own queries for locating sessions using specific criteria. For example, you might want to find all sessions that contain the string sudo or that ran a specific program. To search for these sessions, you can create a custom query definition.

For audited sessions, you can create:

- Quick queries
- Private queries
- Shared queries

If you create a quick, private, or shared query, a new node is added to the Audit Analyzer console for that type of query under the Audit Sessions node. If you want to search for audit trail events, you can also create queries for audit events, which are added to Audit Analyzer under the Audit Events node.

To create a new custom query

1. Open Audit Analyzer, select Audit Sessions, right-click, then select one of the following options for a new query:
    - New Quick Query
    - New Private Query
    - New Shared Query
2. Type a name and description for the query.
3. Select the type of sessions that you want the query to find.

    For example, select UNIX sessions to limit the search to only include UNIX sessions. By default, new queries search for both UNIX and Windows sessions.
4. Select an attribute for grouping query results, if applicable.
5. Select an attribute for ordering query results within each group, if applicable.
6. Click **Add** to add search criteria to filter the results of the query.
7. Select an appropriate attribute from the Attribute list based on the sessions you want to find.
8. Select the appropriate criteria for the attribute you have selected, then click **OK**.

    The specific selections you can make depend on the attribute selected. For example, if the attribute is **Review status**, you can choose between "Equals" and "Not equals" and the specific review status you want to find., such as "To be Reviewed." If you select the attribute **Comment**, you can specify "Contains any of" and type the text string that you want to find any part of.
9. Click **Add** to add another filter to the criteria for the query, or click **OK** to save the query and find the sessions that match the criteria you have specified.

Frequently Asked Questions

This section provides answers to common questions and information about specific features that are not applicable for all organizations. You should review the questions covered to see if there are any topics of interest or are relevant to your situation.

How Do I Accommodate Legacy or Conflicting Identity Information?

If you plan to migrate existing UNIX and Linux users to Active Directory, you might have users that already have different login names or UIDs on multiple UNIX or Linux computers. For file and directory ownership to continue uninterrupted, those users must be able to continue using those legacy identity attributes.

To accommodate different login names and UIDs on different computers, you can create computer-level overrides that let you change just those UNIX attributes you need to change for individual UNIX or Linux computers. The legacy attributes remain tied to a single Active Directory account, but enable you to deploy with no changes to your existing environment.

To set computer-level overrides

1. Expand Zones and parent and child zones to find the zone for the computer requiring an override.
2. Expand **Computers** to display the computer requiring an override.
3. Expand the computer name and UNIX Data.
4. Right-click **Users** under the selected computer, click **Add User to Zone**
5. Search for and select the Active Directory user.
6. Select the UNIX properties to change in the user's UNIX profile.

   For example, you can change the UID used for the selected user. The new profile attribute is only used on the computer where you make the change.
7. Set the new value, then click **OK**.

For all other computers in the selected zone and in other zones, the user's UNIX profile remains unchanged. You can change any or all profile attributes on other computers to accommodate your legacy identity information.

Can I have Separate Role Assignments for Specific Computers?

Yes. Server Suite-managed computers get their role assignments from three places:

- Parent and child zone role assignments made in the Authorization node.
- Role assignments made at the computer level.
- Role assignments made in the zone's computer roles.

Generally, you start assigning roles at the child zone and then the computer role levels. However, there are occasions when you need to make the role assignment for a single computer. In this case, you use the computer-level override functionality.

To make a role assignment as a computer-level override

1. Expand Zones and parent and child zones to find the zone for the computer requiring an override.
2. Expand **Computers** to display the computer requiring an override.
3. Expand the computer name and select Role Assignments.
4. Right-click **Role Assignments** under the selected computer, click **Assign Role.**
5. Select the role requiring a computer-specific assignment.
6. Click **Add AD Account** to search for and select a user or group.

How Can I Manage Access Rules for Computers in Different Zones?

You can use computer roles—groups of computers with a common purpose—to simplify assigning access roles. A computer role is simply an Active Directory group of computers. You create this group because a specific set of computers have something in common. For example, you can create a security group for all Oracle database servers in your organization, or all Oracle servers in a specific location, or all Oracle servers owned by a certain team of administrators. The same computers might be in multiple Active Directory groups, but each group defines a specific purpose. The computers might also be in the same zone or different zones.

A computer role enables you to associate an Active Directory group of computers with a specific set of access rules that apply to just that set of computers.

To create a computer role that defines access rules for a group of computers

1. Create Active Directory groups for the sets of users who have specific access rights.

   For example, you might create a group for OracleUsers and a group for OracleAdmins in the Delinea UNIX Groups organizational unit.

2. In Access Manager, expand Zones and parent and child zones to find the zone for the computer requiring a computer role.

3. Expand Authorization, right-click Computer Roles, then select **Create Computer Role**.

4. Type the name and description, then select **Create group** to create the Active Directory security group for the computers than share a common purpose.

   For example, create a new global group named Oracle Servers.

5. In Access Manager, create or identify the access rights and role definitions that will be specifically applicable for the set of computers.

   For example, define the access rights appropriate for the Oracle users and for the Oracle administrators.

   Add role definitions for the Oracle users (OracleLoginRights) and administrators (OracleAdminRights), then add the appropriate rights to each role.

6. Assign the role definitions to the appropriate Active Directory groups.

   For example, assign the OracleLoginRights role to the OracleUsers group and the OracleAdminRights role to the OracleAdmins group.

7. Add the computers to the computer role group.

   For example, expand Computer Roles and Oracle servers, right-click Members, then select **Add Computer** to add each Oracle server to the Members node.

Delinea

How do I Manage Access Privileges during Application Development?

In-house application development and deployment typically require three sets of computers, each with its own set of users and privileges:

- Development: The set of computers with the source code and tools for application development. You only want your developers and maybe one or two users to have access to these computers.
- Test: The set of computers used by QA to confirm that the application conforms to specifications. You only want the QA staff to have access to these computers.
- Production: The computers deployed throughout the enterprise. You don't want developers or QA to have access to these computers.

You can use computer roles to ensure that only specified users have access at each stage. In this case, you would define two computer roles in the zone:

- DevelopmentSystems
- TestSystems

Then, you would do the following:

- Create Developer and Tester groups in Active Directory.
- Create Developer and Tester roles and add the rights in Access Manager.
- Assign the roles to the groups in the DevelopmentSystems and TestSystems roles.
- Add the development and test computers as a member to each role.

Now, only the members of the Developer and Tester Active Directory groups have access to the corresponding computer role's member computers.

How do I Terminate a User Account but Keep the Account Profile?

When a user leaves the company, you might want to retain their account profile to ensure all of the files they created on your organization's UNIX and Linux computers have an owner. You can use the predefined listed role to retain an account profile with no access privileges.

To create the group and assign the role

1. Create an Active Directory group in the UNIX Groups organizational unit called Listed. In the description enter, Terminated users.
2. In Access Manager, expand Zones and find the zone where the account profile is required.
3. Expand Authorization and Role Assignments, then select **Assign Role**.
4. Select the listed role, click **Add AD Account**, search for and select the select the Listed Active Directory group, then click **OK**.

To terminate a user

1. Remove the user account from all of the UNIX Groups that have access rights.
2. Verify that the user has no role assignments and no effective rights in any zone.
3. Add the user account to the Listed group.

If the user rejoins the company, you simply delete the user from the Listed group and add the user to groups, as needed.

Can Active Directory Credentials be used to Log in to Applications?

Yes. Delinea provides additional packages that let you configure single sign-on for Apache, Tomcat, JBoss, WebSphere and WebLogic web servers, and for Oracle, DB2, and SAP database applications.

Can Active Directory Credentials be used for Phone and Tablet Users?

Yes. Delinea offers software that enables you to authenticate users on iOS and Android devices before they can access their company email, web, and SaaS applications. A separate evaluation package is available for you to try out mobile device management for smart phones or tablets. Contact your sales representative for a free evaluation.

How Do I Migrate from NIS Maps to Server Suite?

Access Manager provides an extension that enables you to import and manage NIS network maps in Active Directory on a zone-by-zone basis. For UNIX and Linux computers and applications that submit lookup requests directly to a NIS server listening on the NIS port, you can also deploy the Delinea Network Information Service, adnisd, to receive and respond to NIS client requests from the NIS map information stored in Active Directory.

Removing Software after an Evaluation

The evaluation software can only be used for a limited time. After you complete the evaluation, you should remove the software to free up space on the physical or virtual computers you used for the evaluation. This section describes the steps for removing components from the Windows computer you used for the evaluation and the UNIX or Linux computer you added to Active Directory.

- Removing Authentication and Privilege Services
- Removing the Audit and Monitoring Service
- Removing Server Suite Agents

Removing Authentication and Privilege Services

The most efficient way to remove the Authentication & Privilege Services components from a Windows computer is to rerun the setup program that installed them.

To remove Authentication & Privilege components

1. On the physical or virtual computer where you downloaded Server Suite software, double-click **autorun.**
2. On the **Getting Started** page, click **Authentication & Privilege**.
3. At the **Welcome** page, click **Next**.
4. Select **Uninstall**, then click **Next**.
5. Review the list of software to be removed, then click **Next**.
6. Click **Finish** to exit the wizard.

The Authentication & Privilege components are now removed from the host Windows computer. You should note, however, that these steps do not remove any of the Active Directory organizational units, users, or groups you used for the evaluation. You should manually remove these objects with Active Directory Users and Computers or ADSI Edit.

Removing the Audit and Monitoring Service

The most efficient way to remove Delinea Management Services components from a Windows computer is to rerun the setup program that installed them.

To remove the Audit & Monitoring Service components

1. On the physical or virtual computer where you downloaded Server Suite software, double-click **autorun.**
2. On the **Getting Started** page, click **Audit & Monitor**.
3. Select **Uninstall**, then click **Next**.
4. Click **Finish** to exit the wizard.

The Audit & Monitoring Service components are now removed from the host Windows computer. You should note, however, that these steps do not remove the installation service connection point, databases, or database instances. You should manually remove these objects with ADSI Edit and Microsoft SQL Server Management Studio.

Removing Server Suite Agents

Follow the steps below to remove the Server Suite Agent for *NIX and command line programs—such as adinfo, adjoin, adquery, dacontrol, and dzinfo— from the computer.

You can rerun the **install.sh** script interactively or silently using a configuration file to remove Server Suite software from a managed computer.

To remove the agent and other packages using the install.sh script

1. Log on and open a terminal on the managed computer.
2. Run the adleave command to remove the computer from the domain controller.

   ```
   adleave -u administratorname
   ```

   The user name you specify with the **administratorname** argument should be an account with Active Directory administrator privileges.
3. Type the password for the an account name you specified.
4. Change to the directory that contains the extracted agent package.
5. Run the installation script.

   ```
   /bin/sh install.sh
   ```

   The script determines the Server Suite software you have installed on the computer and displays the details for you to review.
6. Enter **E** to proceed.
7. Confirm the removal of packages by entering **Y** to proceed.
8. Enter **Y** to reboot the computer after removing software packages.

Delinea Server Suite Free (formerly Centrify Express)

The following Server Suite Free docs are available:

- Delinea Server Suite Free Guide
- Delinea Server Suite Free Administrator's Guide for Linux and UNIX

In previous releases, this product was called Centrify Express.

The *Server Suite Free Administrator's Guide for Linux and UNIX* describes how to install, configure, and use the components in Delinea Server Suite Free for UNIX and Linux. Delinea Server Suite Free products are available for free to provide identity and access control for cross-platform data centers using Active Directory. With support for a wide range of operating systems, hypervisors, and applications, Delinea Server SuiteAgents can help your organization strengthen security and regulatory compliance while reducing IT expenses and costly interruptions to user productivity.

Delinea Server Suite Agents provide simplified cross-platform integration with Active Directory. In most cases, Delinea Server Suite Free agents require little or no configuration, and are available for download directly from the Delinea web site. By installing Delinea Server Suite Agents, you can add UNIX and Linux computers to Active Directory, authenticate user credentials from a central identity store, and support local and remote cross-platform single sign-on at no cost.

The following topics are available:

This chapter provides an introduction to Delinea Server Suite Free for Linux and UNIX, including a brief overview of how Delinea can help you take advantage of your investment in Active Directory.

Key Components

Delinea bundles products and features in different editions to address different customer requirements. The Delinea Server Suite Free family of products provides the most basic set of functionality and is available for free from the Delinea website.

The main Delinea components that enable cross-platform authentication and authorization services using Active Directory are platform-specific agents. Agents are packaged in compressed platform-specific files that you can download and extract to enable non-Windows computers to join an Active Directory domain. After you install an agent and join a domain, Active Directory users are authenticated on the UNIX or Linux computer without any further configuration.

The Delinea Server Suite Free family of products also includes Kerberos-enabled versions of OpenSSH and PuTTY packages.

Features Not Supported by Delinea Server Suite Free

Taken together, Delinea Server Suite Free products provide a solid foundation of functionality that is suitable for many organizations without upgrading to Server Suite. However, Delinea Server Suite Free does not provide central management of policies, delegated administration, identity control, role-based access rights, or auditing services.

If your organization outgrows the basic functionality of Delinea Server Suite Free, you can upgrade to Server Suite to take advantage of these additional features.

The following table describes features that are limited or not enabled in Delinea Server Suite Free.

Centralized identify and access management	You cannot centrally manage user and group profiles, control access privileges on specific computers, or delegate administrative activities.
Group policies	You cannot centrally manage configuration settings for non-Windows computers and users.
Auditing	You cannot audit user session activity.
Role-based authorization and access rights	You cannot define rights, roles, and role assignments to enforce role-based access to privileged commands and other operations.
Unlimited Delinea managed computers	The number of Delinea-managed computers that can be connected to the Active Directory domain at the same time is limited. The limit is described in the End User License Agreement (EULA) that is specific to Delinea Server Suite Free.
User login controls	You can only use a limited set of parameters to control which users or groups are granted or denied access.
Active Directory lookup filtering	You cannot use the NSS override parameters to filter Active Directory lookups requests.
The adcert command	You cannot use the adcert command, which enables certificate operations to be performed directly on agent-managed UNIX computers.
Data isolation and encryption	You cannot dynamically isolate and encrypt data in motion.

You must upgrade to a license version of Server Suite to use any of these features.

Managed Computers are Active Directory Clients

The agent enables non-Windows servers and workstations to participate in an Active Directory domain as Active Directory clients. You install the agent on each computer that you want to make part of an Active Directory domain. After you install the agent and join a domain on a computer, the computer is considered a Delinea managed computer. The agent then manages the connection to Active Directory domain controllers when users log on or connect to the computer remotely.

What the Agent Does

The agent makes a computer look and behave like a Windows client computer to Active Directory. The agent performs the following key tasks:

- Joins the computer to an Active Directory domain.
- Communicates with Active Directory to authenticate users when they log on.
- Caches users credentials for offline access.
- Enforces Active Directory authentication and password policies.
- Provides a Kerberos environment so that existing Kerberos applications work transparently with Active Directory.

Agents Consist of Multiple Components

Agents provide an integrated set of services that enable programs and applications to use Active Directory. The core agent service is the adclient process. The adclient process handles all of the direct communication with Active Directory and coordinates with other services to process requests for authentication, authorization, directory assistance, or policy updates.

Other services handle specific types of operations. For example, the pam_centrifydc module enables any PAM-enabled program, such as ftpd, telnetd, login, and sshd, to authenticate using Active Directory. A custom NSS module modifies the nsswitch.conf configuration file so that system look-up requests use the information in Active Directory. A configurable local cache stores user credentials and other information for offline access and network efficiency.

In addition to the core agent services, agents can include Delinea compiled versions of other programs, such as OpenSSH and OpenLDAP, to work with Active Directory.

Provisioning is Automatic

When you deploy an agent on a computer, the agent adds the computer account to Active Directory and automatically creates consistent UIDs across the joined domain for Active Directory users with access to the computer. The agent authenticates all valid Active Directory users without any configuration or account management. Because there is only one zone for the forest, you can deploy without creating any zones of your own. Because profiles are generated automatically, you do not need to configure any zone properties or manage who has access to which subsets of UNIX and Linux computers.

Deciding Whether to Use Zones

The primary reason to use Delinea Server Suite Free is that it enables Active Directory authentication without any planning, manual configuration, or account management. A primary limitation to using Delinea Server Suite Free is that all computers are placed in a single, automatically defined zone.

Zones provide a powerful and flexible structure for managing user identities, role-based access controls, and delegated administrative authority. However, deciding on the best strategy for using zones requires some planning and preparation. If your organization does not require more than one zone, you can begin deploying agents immediately.

Working With a Single zone

Delinea Server Suite Free is designed for organizations that do not want to centrally manage user profiles, role assignments, or administrative activities. After the agent is installed, all valid Active Directory users and groups in the entire Active Directory forest are automatically assigned a unique UNIX profile that allows them to log on. Because the Delinea Server Suite Free agent requires no configuration or central management, it is most suitable for organizations that:

- Want to add computers to a domain quickly without configuring any zones.
- Do not need to maintain or manage existing UIDs and GIDs.
- Have a limited number of users and domains.
- Have a relatively flat organizational structure.

If a single zone suits the needs of your organization, Delinea Server Suite Free provides a no-cost, cross-platform solution for authentication services. If your organization grows in size and complexity or if you want more granular access controls, you can upgrade to a licensed version of Delinea software at a later time. For more information about Delinea service offerings and Server Suite, see "Comparing Delinea Server Suite Free to other services" on page 30.

All Active Directory Users Have Access

After you install an agent and join an Active Directory domain, all of the users and groups in the Active Directory forest automatically become valid users and groups for the joined computer. In addition, all Active Directory users defined in any forest with a two-way trust relationship with the forest of the joined domain are valid users for the joined computer.

> **Note**: If a computer joins a domain and the domain has a one-way trust relationship with another domain, users and groups in the trusted domain **do not** become valid users and groups on the computer.

By default, all valid users can perform the following tasks:

- Log on interactively to the shell or a desktop program and use standard programs such as telnet, ssh, and ftp.
- Log on to a computer that is disconnected from the network or unable to access Active Directory, if they have successfully logged on and been authenticated by Active Directory previously.
- Manage their Active Directory passwords directly from the command line, provided they can connect to Active Directory.

How the Agent Generates Profile Attributes

Computers with a Delinea Server Suite Free agent always connect to the domain through the Auto Zone. In the Auto Zone, user profile attributes, such as the UID, default shell, and home directory are automatically derived from user attributes in Active Directory or from configuration parameters. No local account information is used or migrated into Active Directory.

When an Active Directory user logs on to a UNIX or Linux computer for the first time, the agent automatically creates a 31-bit UID for the user and a 31-bit GID for any groups to which the user belongs. To create unique GIDs and UIDs, the agent creates a prefix from the last 9 bits of the user or group Security Identifier and combines it with the lower 22 bits of the user or group relative identifier (RID).

Although the agent caches these UID and GID values, they are not stored in Active Directory. You cannot edit or change them in any way with Active Directory Users and Computers (ADUC). If the cache expires, the agent uses the same algorithm to create the same UID and GID the next time the user logs on so you are guaranteed consistent ownership for files and resources. In addition, users who log on to more than one computer will have the same generated UID on each managed computer.

> **Note**: All profile attributes—including the UID and GID values—are stored in Active Directory. If you upgrade to a licensed version of Delinea software, you can migrate and manipulate UID and GID properties for individual computers. You can also map multiple UIDs to a single Active Directory account to allow different UIDs settings on different computers for the same user account. This type of manipulation is not possible when using Auto Zone and Delinea Server Suite Free agents.

In addition to the UID and GID, the agent automatically creates a home directory for the user with all the associated profile and configuration files. The location for the home directory is:

- UNIX or Linux: /home/username
- Mac OS X: /Users/username

Deploying an agent does not affect local users. User accounts that are defined in the local /etc/passwd directory can still log on. If you want to control access through Active Directory, however, you should create Active Directory accounts for each user. After you verify user access for the Active Directory user, you can then either delete the local account, or map the local users on each computer to an Active Directory account to preserve access to current home directories and files. For more information about mapping accounts, see "Mapping local accounts to Active Directory" on page 56.

Using Delinea Server Suite Free to Deploy Agents

With Delinea Server Suite Free, you can discover and analyze computers on your network or in the cloud, then download and install or update the correct agent for each discovered computer. You can also use Delinea Server Suite Free to manage account information for remote UNIX users and groups, and run programs on the computers discovered.

Like other Delinea products, you can download Delinea Server Suite Free agents from the Delinea website.

Comparing Delinea Server Suite Free to other services

Delinea Server Suite Free provides a subset of the features available in authentication and privilege elevation services. Over time, this basic set of functionality may be insufficient. Depending on the needs of your organization, you may want to upgrade the Server Suite you use to take advantage of additional feature sets. The following table provides a brief description of the services available.

Delinea Server Suite Free	Free software that provides basic integration with Active Directory for authenticating users.
Server Suite	Commercial offering that provides a full complement of services to ensure the security of your infrastructure and prevent the breaches that can result when privileged accounts are compromised. With Server Suite, you can protect your organization in a variety of ways. For example, you can:: Require users to log in as themselves. Enforce least-privilege access for administrators and end-users. Control shared access to privileged accounts. Audit and monitor user activity and what takes place during privileged sessions. Isolate and encrypt sensitive information transmitted over the network.

This section provides step-by-step instructions for installing the Delinea Agent on a computer and joining the computer to the Active Directory domain.

Selecting a Deployment Option

The agent must be installed on each computer you want to manage. You must also specify an Active Directory domain for the agent to join either during the installation process or after the agent files are installed.

You can install and manage agent packages independently by running an installation script, package management program, or software distribution tool locally or remotely on individual computers.

For more information, see Options for Deploying Agent Packages.

Installing and Using Delinea Server Suite Free

Delinea Server Suite Free provides a Windows-based MMC console and a self-contained database that stores information about the computers and accounts discovered on the network or in the cloud.

Minimum Hardware Requirements

You can install Server Suite Free on a single Windows computer with a 64bit operating system.

In general, Delinea recommends the following minimum hardware configuration:

- 2 GB RAM
- 1 GB free disc space
- 2 GHz processor

Network Connectivity Requirements

To download and deploy software, you must have network connectivity or an Internet connection between the Windows computer where Access Manager is installed and the computers where you want to deploy the agent. Delinea recommends that you install Access Manager on a computer that allows outbound Internet connections and connectivity between the Windows computer and each computer you want to manage.

Account Credential Requirements

To install software on remote computers and join Active Directory domains, you must have access to an account with appropriate permissions:

- To run privileged commands, you should have access to the root account, the local Administrator account, or an account that has been granted escalated privileges using su or sudo and settings in a sudoers configuration file.
- To join a domain, you need an Active Directory account and password that has permission to add computers to the domain.

Depending on your organization, the Active Directory account might be required to be a member of the Domain Admins group. If you are not sure whether you have permission to add computers to the domain using your own Active Directory account, check with the Active Directory administrator for your site.

Download the Software and Run the Setup Program

If you have a computer that meets the requirements and the appropriate account information, you can download Server Suite Free.

To download and install Delinea Server Suite Free:

1. Go to the Delinea website and register an account, if you have not previously registered
2. Click the **Download** link.
3. Open the downloaded file to start the setup program.
4. Follow the prompts displayed to accept the license agreement and select a location for program files.
5. Install the agents on the desired computers. For details, see "Options for deploying agent packages" on page 37.

Options for Deploying Agent Packages

You can download individual Delinea Agent packages for the platforms you support and install the software in one of the following ways:

- Run the installation script (install-express.sh) locally on any computer and respond to the prompts displayed.
- Create a configuration file and run the installation script remotely on any computer in silent mode.
- Use the install or update operations in the native package installer for your operating environment.

If you want to use one of these installation options and need more information, see the appropriate section.

Install Interactively on a Computer

You must install a platform-specific agent on each computer you want to manage through Active Directory.

The installation script automatically checks the operating system, disk space, DNS resolution, network connectivity, and other requirements on a target computer before installing. You can run this script interactively on any supported UNIX, Linux, or Mac computer and respond to the prompts displayed.

To install agent packages on a computer interactively:

1. Go to the Delinea website and download the Delinea Server Suite Free agent for the platform you want to support.
2. Select the file you downloaded and unzip and extract the contents using the appropriate operating system commands. For example:

   ```
   gunzip -d centrify-package-platform-arch.tgz
   ```

   ```
   tar -xf centrify-package-platform-arch.tar
   ```

3. Run the install-express.sh script to start the installation on the local computer. For example:

   ```
   ./install-express.sh
   ```

4. Follow the prompts displayed to check the computer for potential issues, install the agent, and join a domain automatically at the conclusion of the installation.

   If the adcheck program finds potential issues, you might see warning or error messages. Depending on the issue reported, you might have to make changes to the computer before continuing or after installation.

   For most prompts, you can accept the default by pressing Enter. When prompted for the Active Directory domain, type the fully qualified name of the Active Directory domain to join.

   You must also type the user name and password for an Active Directory user with permission to add computers to the domain.

5. After you have responded to all of the prompts displayed, review your selections, and then enter **Y** to continue with the installation and reboot the computer.

Using Other Programs to Install

If you want to manually install a software package using a native installation program instead of the installation script, use the installation commands and options that are appropriate for the local operating environment. For example, if your operating system supports a package installer, such as Red Hat Package Manager (rpm), SMIT or YAST programs, you can use any of those programs to install the agent.

> **Note**: Delinea recommends that you use the installation script to automatically check a computer for issues and join the computer to a domain.

To install an agent using a native installation program

1. Log on as or switch to the root user.
2. If the software package is a compressed file, unzip and extract the contents. For example, on Red Hat Linux:

   ```
   gunzip -d centrify-*-rhel5-x86_64.tgz
   ```

   ```
   tar -xf centrify-*-rhel5-x86_64.tar
   ```

3. Run the appropriate command for installing the package based on the local computer's operating system or package manager you want to use. For example, on Red Hat Linux:

   ```
   rpm -Uvh centrifydc-*-rhel5-x86_64.rpm
   ```

4. Disable licensed features by running the adlicense --express command:

```
adlicense --express
```

Note: You must run the adlicense command to set the agent to run in Express mode. Express mode is used for the Server Suite Free product.

5. Join the domain by running the adjoin --workstation command, which connects you to Auto Zone:

```
adjoin --workstation domainName
```

Note: If you do not specify the --workstation option, the join operation will fail because adjoin will attempt to connect you to a specific zone rather than Auto Zone.

Verifying the Installation

When a computer is joined to Active Directory, all Active Directory users and groups defined for the forest, as well as any users defined in a two-way trusted forest, are valid users or groups for the joined computer. Therefore, after running the agent and joining the computer to a domain, you can log on as any Active Directory user.

1. Log on using an Active Directory user account.

   When a user logs in for the first time, the agent automatically creates a home directory for the new user.

2. Run the adinfo command to see information about the Active Directory configuration for the local computer. You should see output similar to the following:

```
Local host name: QA1
Joined to domain: sales.acme.com
Joined as: QA1.sales.acme.com
Pre-win2K name: QA1
Current DC: acme-dc1.sales.acme.com
Preferred site: Default-First-Site
Zone: Auto Zone
Last password set: 2014-04-01 12:01:31 PST
CentrifyDC mode: connected
Licensed Features: Disabled
```

   Note that licensed features are disabled and that the zone is Auto Zone. Creating actual zones requires a licensed copy of Delinea software.

Troubleshooting adcheck Errors

You can run adcheck before, during, or after installation to verify that your computer is configured properly. This utility performs three sets of checks that are controlled by the following options:

- -t os checks the operating system, disk size, and Perl and Samba installations.
- -t net checks DNS to verify that the local computer is configured correctly and that the DNS server is available and healthy.
- -t ad includes the -t net checks and verifies that the domain has a valid domain controller.

Correcting Errors for the Operating System Check

The -t os option performs a series of checks that verify operating-system basics for the computer on which you are installing the agent. If your computer fails one of these checks, upgrade the computer with a new operating system version, required patch, a new Perl or Samba version, or free up sufficient disk space.

Correcting Warnings and Errors for the Network Check

The -t net option performs a series of checks that verify that DNS is correctly configured on your local computer and that the DNS server is running properly. There is also a check to verify that you are running a supported version of OpenSSH.

Note: A supported version of OpenSSH is not automatically installed. You must choose to install it during a custom installation.

Because the agent uses DNS to locate the domain controllers for the Active Directory forest, the appropriate DNS nameservers need to be specified in the local /etc/resolv.conf file on each computer before the computer can join the domain. If you receive errors or warnings from these checks, you need to correct them before joining a domain. Each warning or error message provides some help to resolve the problem.

Correcting errors for the domain controller check

The -t ad option locates each domain controller in DNS and then does a port scan and DNS lookup of each. The checks for this option also verify the global catalog and verify clock and domain synchronization.

If you receive errors or warnings from these checks, you need to correct them before joining a domain. Each warning or error message provides some help to resolve the problem.

Joining a Domain After Installation

When you install the agent using installexpress.sh, you can automatically join that computer to an Active Directory domain. If you do not join the domain when you run the installation script, or if you leave a domain and want to rejoin, you can manually join a domain by using the adjoin command.

To manually join a domain, you must use the --workstation option to connect to Auto Zone.

To join an Active Directory domain manually on a Linux or UNIX computer:

1. Log in as or switch to the root user.
2. Run adjoin to join an existing Active Directory domain. You should join the domain using a fully-qualified domain name. You must specify the --workstation option.

   For example, to join the sales.acme.com domain with the user account dylan:

   ```
   adjoin --user dylan --workstation sales.acme.com
   ```

   The user account you specify must have permission to add computers to the specified domain. In some organizations, this account must be a member of the Domain Admins group. In other organizations, the account simply needs to be a valid domain user account. If you don't specify a user with the --user option, the Administrator account is used by default.
3. Type the password for the specified user account.

If the agent can connect to Active Directory and join the domain, a confirmation message is displayed. All Active Directory users and groups defined for the forest, as well as any users defined in a two-way trusted forest are valid users or groups for the joined computer.

Restarting Services

You may need to restart some services on computers where you have installed the agent so that those services will reread the name switch configuration file. For example, if you typically log on to the computer through a graphical desktop manager such as gdm, you need to either restart the gdm service or reboot the workstation to force the service to read the updated configuration before Active Directory users can log on.

The most common services that need to be restarted are sshd and gdm. If you are using these services, you should restart them. For example, to restart sshd:

```
/etc/init.d/sshd restart
```

As an alternative to restarting individual services, you can reboot the system to restart all services.

> **Note**: Because the applications and services on different servers may vary, Delinea recommends you reboot each computer to ensure all of the applications and services on the system read the configuration changes at your earliest convenience.

Upgrading Delinea Server Suite Free

To take advantage of features that are part of Server Suite—- for example to define roles that control access rights and apply group policies to computers and users—you must upgrade from Delinea Server Suite Free to a licensed copy of Server Suite. Upgrading to a licensed version of the product is a three-stage process that involves:

- Installing and upgrading components on Windows.
- Upgrading the agent to enable licensed features on managed UNIX and Linux computers.
- Adding optional packages that are not included in Delinea Server Suite Free.

Upgrading Windows Components

If you are upgrading to a licensed version of Server Suite, there are several additional components available for you to install depending on the services you want to deploy. For example, there are console extensions that enable you to edit group policies and manage NIS maps through Active Directory.

To install and upgrade licensed components on Windows:

1. Obtain a license key and media for Delinea Management Services.

   You can also download an evaluation copy directly from the Delinea website, but you must have a license key to use the software for more than a limited period of time.

2. On a Windows computer that is joined to the Active Directory domain, connect to the distribution media.

   If you received the software on a CD, the Getting Started page is displayed automatically or when you double-click the autorun.exe program.

3. Click Authentication & Privilege to start the setup program for authentication and privilege elevation components.

4. Follow the prompts displayed to accept the license agreement, select the components to install, and a location for files.

5. When setup is complete for the selected packages, click **Finish** to close the setup program.

Upgrading Agents on Managed Computers

To upgrade agents to a licensed product, you must run a command line program to enable licensed features on each managed computer.

To enable licensed features on managed computers:

1. Log on to the computer that is running a Delinea Server Suite Free agent.

2. Run the following command to search the Active Directory forest for the license key and to enable licensed features.

   ```
   adlicense --licensed
   ```

3. Run the following command to verify that licensing has been enabled:

   ```
   adinfo

   Local host name: qa1
   Joined to domain: acme.com
   Joined as: qa1.acme.com
   Pre-win2K name: qa1
   Current DC: acme-dc1.acme.com
   Preferred site: Default-First-Site
   Zone: Auto Zone
   Last password set: 2014-04-01 12:01:31 PST
   CentrifyDC mode: connected
   Licensed Features: Enabled
   ```

   Note: After enabling licensed features, the computer is still connected to Auto Zone. If you are not using zones to migrate existing user populations or define role-based access controls, you can leave the computer in Auto Zone. If you want to take advantage of zones, you must:

   - Create at least one zone using Access Manager, adedit, or another tool.
   - Run adleave to leave the Active Directory domain and Auto Zone.
   - Run adjoin to rejoin the Active Directory domain and a specified zone.

For information about creating and managing zones, using group policies, and other features, see the *Planning and Deployment Guide* and the *Administrator's Guide for Windows*.

Adding Optional Packages After Installation

Depending on the services you choose to deploy, there are several optional packages that might be available for you to use. To add these packages, you must rerun the installation script and select which packages to install.

To add optional packages on computers where the agent is installed:

1. Change to the appropriate directory on the CD or to the directory where you have copied or downloaded the agent package.

2. Run the standard installation script for the agent and follow the prompts displayed:

   ```
   ./install.sh
   ```

3. When you are prompted whether to keep, erase, or reinstall the currently installed packages:

- Accept the default (**K**, keep) for the currently installed packages.
- Type Y (**Y**, yes) for each package you want to add.

4. Follow the prompts displayed to set installation options, such as the option to run adcheck and reboot the computer after installation.

   The computer remains joined to the domain you previously joined, your existing /etc/centrifydc/centrifydc.conf file is backed up, and any modifications you have made to the file are migrated to the new version of the file.

5. Restart running services, such as login, sshd, or gdm, or reboot the computer to ensure all services use the updated configuration.

Removing Delinea Server Suite Free

On most managed computers, you can remove the agent and related files by running the uninstall.sh script. The uninstall.sh script is installed by default in the /usr/share/centrifydc/bin directory on each managed computer.

To remove the agent on a managed computer:

1. Log on to the computer where the agent is installed.
2. Run the uninstall.sh script. For example:

   ```
   /bin/sh /usr/share/centrifydc/bin/uninstall.sh
   ```

   The uninstall.sh script will detect whether the agent is currently installed on the local computer and will ask you whether you want to uninstall your current installation.

3. To uninstall, enter Y when prompted.

If you cannot locate or are unable to run the uninstall.sh script, you can use the appropriate command for the local package manager or operating environment to remove the agent and related files.

This chapter explains how to perform common administrative and end-user tasks on managed computers that have the Delinea Agent installed.

Logging on to Your Computer

You log on to a joined computer in the same way you log on locally. For example, you type a user name and password to start a console session, remote shell session, or a desktop manager. In most cases, you do not have to specify the domain name when you log on. However, you do need to type the Active Directory password for your account and the password must conform to the password policies defined for the domain.

You can use any of the following formats for the user name when you log on:

- Active Directory samAccountName or Mac OS X short name (jcool)
- Active Directory userPrincipalName (jcool@acme.com)
- Windows NTLM format for domain and user name (acme.comjcool)

You can also use any of these formats to locate users in Active Directory.

By default, the Delinea Agent uses the Active Directory samAccountName attribute or the Mac OS X short name for the UNIX profile user name. You can specify a different form for the UNIX user name by setting the value of the auto.schema.name.format parameter in the /etc/centrifydc/centrifydc.conf configuration file.

Getting Configuration Information

After you log on to a computer, you can use the adinfo command to see information about the Active Directory configuration for the local computer. For example, type `adinfo` to display a summary similar to the following:

```
Local host name: QA1
 Joined to domain: sales.acme.com
 Joined as: QA1.sales.acme.com
 Pre-win2K name: QA1
 Current DC: acme-dc1.sales.acme.com
 Preferred site: Default-First-Site
 Zone: Auto Zone
 Last password set: 2014-04-01 12:01:31 PST
 CentrifyDCmode: connected
 Licensed Features: Disabled
```

For Delinea Server Suite Free, licensed features are disabled and the only zone supported is Auto Zone. If you upgrade at a later time, the licensed features will be enabled, and you will be able to use zones to provide secure, granular access control and delegated administration for computers joined to a domain.

Applying Password Policies

The agent enforces all of the password policies you have defined in Active Directory for all valid user accounts in the forest. For example, if your policy requires that new users must change their password the next time they log on, they are prompted to change the password at the next log-on whether they use a Windows or UNIX computer.

The agent also checks passwords to make sure that they conform to Active Directory policies for length and complexity. If a new or changed password meets all of the criteria, the account is updated with the new information in Active Directory and the user logs on successfully.

If you have defined additional policies, such as a maximum duration, reuse policy, failed attempt and account lock out policy, workstation restrictions, and logon hour restrictions, the agent also enforces those policies. Like Windows, the agent displays a warning message each time a user logs on if the user's password is set to expire in a given number of days.

Changing Passwords

As an administrator, you can set, reset, or change the password for other users using Active Directory or from the UNIX command line. Individual users can also change their own password at any time using the adpasswd command.

Changing Your Own Password

If you attempt to log on but your password has expired, you are prompted to provide your old password, a new password, and to confirm your new password. You can also change your own password at any time using adpasswd.

To change your own password

1. At the UNIX command line, run the following command:

   adpasswd

2. Type your old password. When changing your own password, you must always provide your old password.
3. Type the new password. The password should conform to Active Directory password policies.
4. Retype the new password.

For more information about using adpasswd, see the adpasswd man page.

Changing Another User's Password

You can use the adpasswd command to change the password of another Active Directory user if you provide the user name and password of an administrative account with the authority to change another user's password.

To change the password for another user

1. At the UNIX command line, run the adpasswd command and specify an Active Directory administrative account name with the authority to change the password for users in the domain. For example, to use the admin user account to change the password for the user jane in the sales.acme.com domain:

   adpasswd --adminuser admin@acme.com jane@sales.acme.com

2. Type the password for the administrative account. For example:

   Administrator password: xxx

3. Type the new password for the user specified. Because you are changing another user's password, you are not prompted for an old password. For example:

   New password:

4. Retype the new password.

   Repeat password:

For more information about using adpasswd, see the adpasswd man page.

Working in Disconnected Mode

After an Active Directory user logs on to a computer successfully, the authentication is cached on the local computer. These credentials can then be used to authenticate the user in subsequent log on attempts if the user is disconnected from the network or if an Active Directory domain controller is not available.

If there are changes to an account while the account is running in disconnected mode, the changes do not take effect until the user reconnects to Active Directory to start a new session or access a new service. For example, if a user account is disabled or has its password changed in Active Directory while the user is disconnected from the network, the user can still log on and use the old password until reconnected to the network. After the user reconnects to Active Directory, the changes take effect and the user is denied access or prompted to provide an updated password. Because changing the password for an Active Directory account requires a connection to an Active Directory domain controller, users cannot change their own Active Directory password when working in disconnected mode.

> **Note**: If users log out of a session while disconnected from Active Directory, they can be authenticated using the information in the cache when they log back on because they have been successfully authenticated in a previous session. They cannot, however, be authenticated automatically to any additional services after logging back on. To enable automatic authentication for additional services, the user's credentials must be presented to the Key Distribution Center (KDC) then issued a ticket that can be presented to other services for unprompted, single sign-on authentication. Because the KDC is unavailable when disconnected from Active Directory, single sign-on authentication is also unavailable.

You can configure many aspects of how credentials are handled, including how frequently they are updated or discarded, through parameter settings in the centrifydc.conf configuration file. To configure how credentials are handled using group policies, you must upgrade to a licensed version of Delinea software.

Mapping Local Accounts to Active Directory

By default, local user accounts are valid on the computers that join the Active Directory domain. In some cases, you may want to manually map a local user account to an Active Directory account instead of using a generated profile. Mapping a local user account to an Active Directory account gives you Active Directory-based control over password policies, such as password length, complexity, and expiration period.

> **Note**: Mac OS X users can always log on using their local account password. Therefore, you cannot enforce Active Directory password policies for local Mac OS X user accounts.

Mapping local accounts to Active Directory is especially useful if you want to preserve access to a user's current home directory and files. For example, if a local user has a UID of 518 but the Delinea Agent generates a different UID for the user's profile, that user will not have file ownership permissions for his home directory and files.

To map a local account to an Active Directory account, you can set the pam.mapuser.username configuration parameter on any individual local computer. To configure account mapping using group policies, you must upgrade to a licensed version of Delinea software.

Using the pam.mapuser Parameter

To map a local user account to an Active Directory user by modifying the local centrifydc.confconfiguration file:

1. Create the Active Directory user account to use.

   On your Windows Active Directory computer, open Active Directory Users and Computers (ADUC). Navigate to the Users node, right click and select **New > User**.

   You should create a user logon name with the same name as the local user.

2. On the computer with the local account, open the centrifydc.conf configuration file.
3. Locate the pam.mapuser.*username* configuration parameter and un-comment the line to change the default setting.
4. Modify the local account mapping to identify the local user account you want mapped to the Active Directory user you created. For example:

   ```
   pam.mapuser.__joe.cool__: __joe.cool__
   ```

5. Save the changes to the configuration file, then run the `adreload` command to reload the configuration file and have the changes take effect.

Setting a Local Override Account

In most cases, every computer should have at least one account that can be authenticated locally to ensure that you can access the system when the network or Active Directory is not available or adclient is not running. By default, the local override account is set to the root user so that even if you map the root account to an Active Directory account, you can always log on locally using root@localhost and the local root account password.

You can change the default root override account or add additional local users by modifying the computer's centrifydc.conf configuration file. To configure a local override account using group policies, you must upgrade to a licensed version of Delinea software.

Using native telnet, ssh, and ftp programs

By default, authorized users can use standard programs and services such as telnet, ssh, and ftp. For telnet and ftp, you can use the packages installed with the operating system. For ssh operations, however, Delinea recommends that you install the Delinea-compiled version of OpenSSH instead of using the package provided with the operating system. You can download a free copy of OpenSSH from the Delinea website.

Using Samba

Delinea Server Suite Free supports the adbindproxy package, which contains the components to enable an open-source Samba file server to use the Delinea Agent and Active Directory to handle identity management and user credentials.

For more information, see the *Samba Integration Guide*.

Setting Auto Zone Configuration Parameters

Delinea Server Suite Free Agents support a set of configuration parameters specifically intended for computers that are connected to a domain through Auto Zone.

Because Auto Zone is a single zone for an entire forest, you can encounter problems such as UID and GID conflicts and slow searches. If you encounter these

problems, you may need to modify the default configuration. For information about how to set specific parameters to resolve UID and GID conflicts or improve search performance, see [Customizing Operations Using Configuration Parameters] (#customizing).

This chapter describes how to use diagnostic tools and log files to retrieve information about the operation of Delinea Agents and provides tips to help you identify and correct problems on managed computers.

Addressing Log On Failures

In most cases, valid Active Directory users should be able to log on to computers where you have deployed the agent without any configuration. If an attempt to log on fails, the problem is typically caused by one of the following:

- Users attempting to log on to a computer they are not authorized to use.
- Users do not have a valid Active Directory user account in the appropriate forest.
- Users have typed their non-Active Directory password or typed the wrong password more times than allowed.

If users report that they cannot access computer resources they think they should have access to, take the following steps to troubleshoot the problem:

1. Verify that the user has an Active Directory user account in the forest or in a forest with a two-way trust relationship.
2. Check that the account is not disabled or locked out because of repeated log-on failures.
3. Verify that there is an Active Directory domain controller available and that the computer a user is unable to log on to can connect to it and open a communication channel.

   For example, log on to the UNIX computer using a locally authenticated user, and run the ping command with the name of a domain controller in the forest. If the command receives a reply from the domain controller, the DNS service is functioning and the local computer is able to locate the domain controller on the network.

   If the ping command does not generate a reply, check your DNS configuration and check whether the local computer or the domain controller is disconnected from the network.
4. Use adinfo or Active Directory Users and Computers to check that the computer is joined to the domain.
5. Use adinfo to check whether the agent is currently running or disconnected.

   If the adinfo command reports the mode is disconnected, try restarting adclient and testing network response time. On a slow network, adclient may drop the connection to Active Directory if there is a long delay in response time.

   If the adinfo displays an error, try running adleave to leave Active Directory, re-run the adjoin command to re-join the domain. If a problem still exists, check the DNS host name of the local computer and the domain controller, the user name joining the domain, and the domain name you are using.
6. Check the clock synchronization between the local computer and the Active Directory domain controller.

   If the clocks are not synchronized, reset the system clock on the managed computer using the date command.
7. Check the contents of the system log files or the centrifydc.log file after the user attempts to log on. You can use information in this file to help determine whether the issue is with the configuration of the software or with the user's account.
8. Check for conflicts between local user accounts and the user profile generated by the agent.

If these steps do not reveal the problem, you can enable detailed logging of adclient activity using the addebug command. You can use the information in the /var/log/centrifydc.log file to further diagnose the problem or to provide information to Delinea Support.

Understanding Diagnostic Tools and Log Files

The agent includes some basic diagnostic tools and a comprehensive logging mechanism to help you trace the source of problems if they occur. These diagnostic tools and log files allow you to periodically check your environment and view information about agent operation, Active Directory connections, and the configuration settings for individual computers you manage.

Logging is not enabled by default for performance reasons. Once enabled, however, log files provide a detailed record of agent activity. This information can be used to analyze the behavior of adclient and communication with Active Directory to locate points of failure. However, log files and other diagnostic tools provide an internal view of operation and can be difficult to interpret. The log files are primarily intended for Delinea Support and technical staff.

In most cases, you should only enable logging when you need to troubleshoot unexpected behavior, authentication failures, or problems with connecting to

Active Directory or when requested to do so by Delinea Support. Other troubleshooting tools, such as command line programs, can be used at any time to collect or display information about your environment.

Configuring Logging

By default, the agent logs errors, warnings and informational messages in the syslog and /var/log/messages files along with other kernel and program messages. Although these files contain valuable information for tracking system operations and troubleshooting issues, occasionally you may find it useful to activate Delinea-specific logging and record that information in a log file.

Enabling Logging for the Agent

To enable logging on the agent:

1. Log in as or switch to the root user.
2. Run the addebug command:

   /usr/share/centrifydc/bin/addebug on

   Note: You must type the full path to the command because addebug is not included in the path by default.

   After you run this command, all of the agent activity is written to the /var/log/centrifydc.logfile. If the adclient process stops running while you have logging on, the addebug program records messages from PAM and NSS requests in the /var/centrifydc/centrify_client.log file. Therefore, you should also check that file location if you enable logging.

For performance and security reasons, you should only enable logging when necessary. For example, if you open a case with Delinea Support, the Support representative may request that you enable logging and submit log files to investigate your case. You should also limit logging to short periods of time while you or Delinea Support attempt to diagnose a problem. You should keep in mind that sensitive information may be written to this file and you should evaluate the contents of the file before giving others access to it.

When you are ready to stop logging activity, run the addebug off command.

Setting the Logging Level

You can define the level of detail written to the log by setting the log configuration parameter in the centrifydc.conf configuration file:

log: level

With this parameter, the log level works as a filter to define the type of information you are interested in and ensure that only the messages that meet the criteria are written to the log. For example, if you want to see warning and error messages but not informational messages, you can change the log level from INFO to WARN. By changing the log level, you can reduce the number of messages included in the log and record only messages that indicate a problem. Conversely, if you want to see more detail about system activity, you can change the log level to INFO or DEBUG to log information about operations that do not generate any warnings or errors.

You can use the following keywords to specify the type of information you want to record in the log file:

FATAL	Fatal error messages that indicate a system failure or other severe, critical event. In addition to being recorded in the system log, this type of message is typically written to the user's console. With this setting, only the most severe problems generate log file messages.
ERROR	System error messages for problems that may require operator intervention or from which system recovery is not likely. With this setting, both fatal and less-severe error events generate log file messages.
WARN	Warning messages that indicate an undesirable condition or describe a problem from which system recovery is likely. With this setting, warnings, errors, and fatal events generate log file messages.
INFO	Informational messages that describe operational status or provide event notification.

Logging Details for a Specific Component

By default, when you specify a logging level, it applies to all of the agent components that log activity. The logging system, however, provides a hierarchical organization of logical log names for the components within the agent and each of these logical logs can be configured to provide more targeted analysis of it specific operations. For example, if you set your base logging level to only report serious errors but you want to see informational, warning, and error messages for adclient, you can add a separate logging level parameter for the log messages generated by adclient:

```
# Use the following setting to set the base level of detail
# for logging to record Error messages:
 log: ERROR

# Add the name of the adclient logical log and specify the
# logging level to use for it and its children:
 log.com.centrify.adclient: INFO
```

Logging to the Circular In-memory Buffer

If the adclient process is interrupted or stops unexpectedly, a separate watchdog process (cdcwatch) automatically enables an in-memory circular buffer that writes log messages passed to the logging subsystem to help identify what operation the adclient process was performing when the problem occurred. The in-memory buffer is also mapped to an actual file, so that if there is a system crash or a core dump, the last messages leading up to the event are saved. Messages from the in-memory circular buffer have the prefix _cbuf, so they can be extracted from a core file using the strings command.

The in-memory circular buffer allows debug-level information to be automatically written to a log file even if debugging is turned off. It can be manually enabled by restarting the adclient process with the -M command line option. The default size of the buffer is 128K, which should be sufficient to log approximately 500 messages. Because enabling the buffer can impact performance, you should not manually enable the circular buffer or modify its size or logging level unless you are instructed to make the changes by Delinea Support.

Collecting Diagnostic Information

You can use the adinfo command to display or collect detailed diagnostic and configuration information for a local computer. Options control the type of information and level of detail displayed or collected. The options you are most likely to use to collect diagnostic information are the --config, --diag, or --support options, which require you to be logged in as root. You can redirect the output from any adinfo command to a file for further analysis or to forward information to Delinea Support.

For more information about the options available and the information returned with each option, see the adinfo man page.

To display the basic configuration information for the local computer, you can type:

```
adinfo
```

If the computer has joined a domain, this command displays information similar to the following:

```
Local host name: magnolia
 Joined to domain: ajax.org
 Joined as: magnolia.ajax.org
 Current DC: ginger.ajax.org
 Preferred site: Default-First-Site-Name
 Zone: Auto Zone
 Last password set: 2014-04-01 14:47:57 PST
 CentrifyDC mode: connected
 Licensed Features Disabled
```

Resolving Domain Name Service (DNS) issues

In some cases, you may encounter problems with authentication, authorization, or lookup requests because of your DNS configuration. The most common scenarios are:

- The Windows DNS server role is not configured to dynamically update service locator (SRV) records. These records enable Active Directory to find the nearest domain controller, Key Distribution Center (KDC), and Global Catalog (GC) for the site.
- The DNS servers do not publish the SRV records for the domain controllers that provide Active Directory service to the enterprise. These records must be available for computers to connect to Active Directory and locate required services.
- The DNS servers for the enterprise run on UNIX servers that are not configured to locate Active Directory domain controllers. In many cases, DNS servers for an enterprise are configured with a different domain namespace than Active Directory or Active Directory domain controllers are considered internal servers and not registered in the enterprise DNS.

If you encounter problems, you should contact your Active Directory administrator to determine whether the DNS server role is being used and if it is

configured to allow dynamic updates. If the Active Directory DNS server role is not being used to provide DNS to the enterprise, you should contact the DNS administrator to resolve the issue.

There are several possible scenarios:

- If the enterprise uses UNIX-based DNS servers instead of Active Directory-based DNS servers and DHCP, computers should have a snameserver entry in /etc/resolv.conf file that points to a valid DNS server.
- Forward and reverse lookup zones should be configured to allow enterprise DNS servers to locate Active Directory domain controllers.
- If the Active Directory domain namespace is different from the namespace registered in enterprise DNS servers, you should use the --name and --alias join option to resolve the namespace differences.
- If the enterprise DNS servers do not include records for Active Directory domain controllers, you can manually set the location of the Active Directory domain controller using parameters in the centrifydc.conf configuration file.

Command-line programs allow you to perform basic Active Directory administrative tasks directly from a UNIX shell or using a shell script. These commands use the underlying agent service library to enable you to perform administrative tasks, such as adding computers to an Active Directory domain, leaving the Active Directory domain, changing Active Directory passwords, and returning detailed Active Directory, network, and diagnostic information for a host computer.

Understanding When to use Command-Line Programs

Command-line programs are installed by default when you install the agent on a computer. Depending on the operating system, the commands are typically installed in one of the following directories:

```
/usr/sbin
/usr/bin
/usr/share/centrifydc/bin
```

In general, you should only use command-line programs when you must take action directly on a local computer. For example, if you want to join or leave a domain or set a new password while logged on to a shell, you may want to run a command interactively from that shell. You can also use command-line programs in scripts to perform administrative tasks programmatically.

Supported Command-Line Programs

Delinea Server Suite Free supports the following command-line programs:

adcache	The adcache program enables you to manually clear the local cache on a computer or check a cache file for a specific key value.
adcheck	The adcheck program verifies whether a local computer meets the system requirements for joining an Active Directory domain. This command checks whether the computer has sufficient disk and memory, a supported operating system and patch level, required libraries, and network connectivity to an Active Directory domain.
adclient	The adclient program manages most agent operations, and is normally started automatically when a computer starts up. In most cases, you should only run adclient directly from the command line if Delinea Support recommends you do so.
addebug	The addebug program starts or stops logging activity for agent operations.
addns	The addns program enables you to dynamically update DNS records on an Active Directory-based DNS server in environments where the DHCP server cannot update DNS records automatically.
adedit	The adedit program enables you to manage Active Directory and the agent through command-line commands and scripts.
adfinddomain	The adfinddomain program displays the domain controller associated with the Active Directory domain you specify.
adfixid	The adfixid program resolves UID and GID conflicts and enables you to change the ownership of a local user's files to match the user and group IDs defined for the user in Active Directory.
adflush	The adflush program clears the cache on a local computer.
adid	The adid program displays the real and effective UIDs and GIDs for the current user or a specified user.
adinfo	The adinfo program displays summary or detailed diagnostic and configuration information for a computer and its Active Directory domain.
adjoin	The adjoin program adds a computer to an Active Directory domain. This command configures a local computer to use Active Directory. No changes are made to authentication services or configuration files on a computer until you run the adjoin command. This command requires you to be logged on as root.
adkeytab	The adkeytab program enables you to create and manage Kerberos key tables (*.keytab files) and coordinate changes with the Kerberos key distribution center (KDC) provided by Active Directory.

adleave	The adleave program enables you to remove a computer from its current Active Directory domain or from the Active Directory forest entirely.
adlicense	The adlicense program enables or disables licensed features on a local computer. This command requires you to be logged on as root.
adpasswd	The adpasswd program changes the Active Directory account password for a user from within a UNIX shell.
adquery	The adquery program enables you to query Active Directory for information about users and groups from the command line on an agent-managed computer.
adreload	The adreload program forces the adclient process to reload configuration properties in the /etc/centrifydc.conf file and in other files in the /etc/centrifydc directory.
adrmlocal	The adrmlocal program reports and removes local user names that duplicate Active Directory user names.

Other commands that support Delinea operations are also installed in the directory with the commands shown in the preceding list, but they are not applicable to Delinea Server Suite Free agents.

Displaying Usage Information and Man Pages

To display a summary of usage information for a command-line program, type the command and the --help or -h option. For example, to see usage information for the adleave command, type:

```
adleave --help
```

The usage information includes a list of options and arguments, and a brief description of each option.

For more complete information about any command, you can review the information in the command's manual (man) page. For example, to see the manual page for the adleave command, type:

```
man adleave
```

In most organizations, the default settings in the /etc/centrifydc/centrifydc.conf configuration file are appropriate and do not require any customization. In some cases, however, you may find it useful to modify the default settings to optimize operations for your environment.

This section provides reference information for the configuration parameters that control the operations on managed computers. Parameters are also documented in comments within the centrifydc.conf file.

Auto Zone Configuration Parameters

auto.schema.primary.gid	Specifies the primary GID to use in the profiles automatically generated for users. To use this parameter: You should identify an existing group, such as Domain Users, to use as the primary group. You should verify that the auto.schema.private.group parameter is set to false. The default values for this parameter are platform-dependent, for example, 20 on Mac OS X computers and 65534 on Linux, HP-UX, Solaris, and AIX computers.
auto.schema.private.group	Specifies whether the agent should create dynamic private groups. If you set this parameter to true, the primary GID is set to the user's UID and a group is automatically created with a single member. The default value is false, enabling you to set the primary GID using the auto.schema.primary.gid parameter.
auto.schema.shell	Specifies the default shell for the logged in user. The default value is /bin/bash on Delinea Server Suite Free for Linux and UNIX and Linux and /bin/sh on other platforms, including Solaris, HP-UX, and AIX.
auto.schema.homedir	Specifies the home directory for logged in users. The default, if you do not specify this parameter, is: Mac OS X: /Users/%. Linux, HP-UX, and AIX: /home/% Solaris: /export/home/% The variable % is substituted at runtime and replaced with the logon name of the user who is logging on. For example, if the user jsmith logs on to a Delinea Server Suite Free for Linux and UNIX computer, the default home directory is set to: /Users/jsmith For example: auto.schema.homedir:/allusers/home/% This parameter is not used if the parameter auto.schema.use.adhomedir is set to true and a home directory is defined in Active Directory for the user. If auto.schema.use.adhomedir is false or no home directory is defined for the user in Active Directory, the home directory is set to the value defined for this parameter.
auto.schema.use.adhomedir	Specifies whether or not to use the Active Directory value for the home directory on Delinea Server Suite Free for Linux and UNIX computers. Set this parameter value to true to use the home directory defined in Active Directory. If you set this parameter to true but do not define a home directory in Active Directory, the value for auto.schema.homedir is used. Set this parameter to false if you do not want to use the home directory defined in Active Directory.
auto.schema.remote.file.service	Specifies the type of remote file service to use for mounting a network home directory on Mac OS X computers. The valid options are: SMB AFP For example: auto.schema.remote.file.service: SMB On Mac OS X computers, mounting a network directory requires that you specify the remote file service type. By identifying the remote file-service type using this parameter, you can type the network path in the format required by Active Directory: /server/share/path The agent then converts the Active Directory path into the format required by Mac OS X.
auto.schema.name.format	Specifies how Active Directory user names are transformed into UNIX login names. The valid options are: Active Directory samAccountName or Mac OS X short name (jcool) Active Directory userPrincipalName (jcool@acme.com) Windows NTLM format for domain and user name (acme.comjcool)
auto.schema.domain.prefix.*domain*	Specifies a unique prefix for a trusted domain. You must specify a whole number in the range of 0 - 511. The agent combines the prefix with the lower 22 bits of each user or group RID (relative identifier) to create unique UNIX user identifier (UID) and group identifier (GID) for each user and group. In most cases, this parameter is not necessary because the agent automatically generates the domain prefix from the user or group Security Identifier (SID). However, in a forest with a large number of domains or with cross-forest trusts, domain prefix conflicts are possible. If you attempt to join a computer to a domain and the agent detects conflicting domain prefixes, the join fails with a warning message. You can then set a unique prefix for the conflicting domains. To set this parameter, append the domain name and specify a prefix in the range 0 - 511. For example: auto.schema.domain.prefix.acme.com: 3 auto.schema.domain.prefix.finance.com: 4 auto.schema.domain.prefix.corp.com: 5

auto.schema.search.return.max	Specifies the maximum number of users to returned in search results. Because Auto Zone enables access to all users in a domain, a search could potentially return tens of thousands of users. This parameter causes the search to truncate after the specified number of users. The default is 1000 entries.
auto.schema.name.lower	Converts all user names and home directory names to lower case in Active Directory. Set to true to convert user names and home directory names to lowercase. Set to false to leave user names and home directories in their original upper, lower, or mixed case. The default for a new installation is true. The default for an upgrade installation is false.
auto.schema.iterate.cache	Specifies that user and group iteration take place only over cached users and groups. The valid options are: true restricts iteration to cached users and groups. false iterates over all users and groups. The default value is false.
adclient.ntlm.separators	Specifies the separators that can be used between the domain name and the user name when NTLM format is used. For example: adclient.ntlm.separators: +/ The default allows the following formats for the user joe in the acme.com domain: acme.com+joe acme.com/joe acme.comjoe **Note:** The backslash character () can be problematic on some UNIX shells, in which case you may need to specify domain user. The first character in the list is the one that adclient uses when generating NTLM names.

DNS-related configuration parameters

If computers cannot find the Active Directory domain controller, you can use parameters in the centrifydc.conf configuration file to manually identify the domain controllers and the Global Catalog server. You can also use configuration parameters to control how the DNS client processes DNS requests.

dns.dc.*domain_name*	Specifies one or more domain controllers to contact. You must specify the name of the domain controller, not its IP address. In addition, the domain controller name must be resolvable using either DNS or in the local /etc/hosts file. Therefore, you must add entries to the local /etc/hosts for each domain controller if you are not using DNS or if the DNS server cannot locate your domain controllers. For example, to manually specify the domain controller dc1.mylab.test in the mylab.test domain, you would add the following to the /etc/centrifydc/centrifydc.conf file: dns.dc.mylab.test: dc1.mylab.test To specify multiple servers for a domain, use a space to separate the domain controller server names. For example: dns.dc.mylab.test: dc1.mylab.test dc2.mylab.test The agent will attempt to connect to the domain controllers in the order specified.
dns.gc.*domain_name*	Specifies the domain controller that hosts the Global Catalog for a domain. If the Global Catalog is on a different domain controller than the domain controllers you specify with the dns.dc.*domain_name* parameter, you can use this parameter to specify the location of the Global Catalog. For example: dns.gc.mylab.test: dc3.mylab.test
dns.alive.resweep.interval	Controls how frequently the DNS client checks whether there is a faster DNS server available. The default interval for this check is one hour.
dns.sweep.pattern	Specifies the protocol and response time to use when the DNS client scans the network for available DNS servers. The dns.tcp.timeout and dns.udp.timeout parameters determine the amount of time to wait if the current server does not respond to a request. If the current server does not respond to a request within the specified time out period, it is considered down and the agent looks for a different server. If the DNS subsystem cannot find a live server, DNS is considered down, and the agent waits for the period of the dns.dead.resweep.interval parameter before performing a sweep to find a new server.
dns.tcp.timeout	Specifies the amount of time to wait if the current server does not respond to a TCP request. If the current server does not respond to a request within the specified time out period, it is considered down and the agent looks for a different server.
dns.udp.timeout	Specifies the amount of time to wait if the current server does not respond to a UDP request. If the current server does not respond to a request within the specified time out period, it is considered down and the agent looks for a different server.
dns.dead.resweep.interval	Specifies the amount of time to wait if DNS is before performing a sweep to find a new DNS server to use.

Delinea Server Suite Free Quick Start

Delinea Server Suite Free for Linux and UNIX is software that provides a basic set of features for cross-platform authentication and single sign-on using Active Directory. Delinea Server Suite Free for Linux and UNIX is available free of charge from the Delinea website.

After you install the agent and add the computer to an Active Directory domain, the computer becomes a Delinea managed computer and is treated as an Active Directory client.

What you should know about using the Delinea Server Suite Free agent:

- You don't need to install any software on any Windows computers or domain controllers.
- You don't need to make any configuration or schema changes in Active Directory.
- When users log on for the first time using an Active Directory user name and password, the agent automatically provisions the user identity, primary group ID, home directory, and default shell.
- Users can log on with a user name in the format that they are most comfortable with. For example, they can log on using a familiar UNIX user name or the same name they use to log on to a Windows computer.
- Local users with the same account name as Active Directory users are allowed to log on locally.
- Local users can be mapped to Active Directory users so that existing accounts can be migrated.

To use Delinea Server Suite Free, you need to install a Delinea Agent and join a domain. There are several options for installing the agent, including running an installation script locally, downloading a package from the Delinea repository to a local package manager, or installing remotely from a Windows computer using Delinea Server Suite Free.

The instruction here describe how to install using the default installation script. For information about installing using Delinea Server Suite Free, see Server Suite Free Administrator's Guide for Linux and UNIX.

For most prompts, you can accept the default by pressing Enter. When prompted for the Active Directory domain, type the fully qualified name of the Active Directory domain to join.

.

To install an agent on a local computer:

1. Make sure that you have the following information:
    - The root user name and password (or sudo rights) for the computer on which you are installing the agent.
    - The fully qualified name of the Active Directory domain to join.
    - The user name and password of an Active Directory account that has permission to join a computer to Active Directory.
2. Using an account with root permissions, log on to the target UNIX or Linux computer.
3. Go to the Delinea website and download the Delinea agent for the platform you want to support.
4. Select the file you downloaded and unzip and extract the contents using the appropriate operating system commands. For example:

    ```
    gunzip -d centrify-infrastructure-services-*<release>*-platform-arch.tgz
    ```

    ```
    tar -xf centrify-infrastructure-services-*<release>*-platform-arch.tar
    ```

5. Run the install-express.sh script to start the installation on the local computer. For example:

    ```
    ./install-express.sh
    ```

6. Follow the prompts displayed to check the computer for potential issues, install the agent, and join a domain automatically at the conclusion of the installation.

    If the adcheck program finds potential issues, you might see warning or error messages. Depending on the issue reported, you might have to make changes to the computer before continuing or after installation. For details about these messages and corrective actions, see Server Suite Free Administrator's Guide for Linux and UNIX.

    For most prompts, you can accept the default by pressing Enter. When prompted for the Active Directory domain, type the fully qualified name of the Active Directory domain to join.

You must also type the user name and password for an Active Directory user with permission to add computers to the domain.

7. After you have responded to all of the prompts displayed, review your selections, then enter **Y** to finish the installation and reboot the computer.

Steps that you can take after installing the agent include the following:

- **Explore Delinea Agent features.** For details about Delinea Server Suite Free features, see the *Server Suite Free Administrator's Guide for Linux and UNIX*.
- **Browse the Delinea community forum.** Go to http://community.centrify.com for discussions and articles about Delinea Server Suite Free for Linux and UNIX.
- **Install Delinea Server Suite Free.** If you would like to use a single console to manage the authentication and single sign-on services provided by Delinea Agents, download and install Delinea Server Suite Free. You can use Delinea Server Suite Free to discover and analyze computers on your network, download software and install or update the Delinea Agent on discovered computers. You can also use Delinea Server Suite Free to manage account information for remote UNIX users and groups, and to run programs on the computers that are discovered.
- **Upgrade to Server Suite.** Server Suite is available for purchase and includes a common set of authentication and authorization features, including:
  - **Zones.** Zones provide a powerful and flexible structure for managing user identities, role-based access controls, and delegated administrative authority. The ability to create and manage zones is a key element of the Server Suite family of products.
  - **Access controls.** PAM and auto schema parameters are provided to grant or deny access for specific users or groups.
  - **Policy support.** Policy-based enforcement of computer and user configuration settings.
  - **NIS support.** Support for NIS map integration and migration.
  - **Reports.** Standard out-of-the-box reports and a report creation wizard.
  - **Rights and roles.** Rights and role-based entitlements for user accounts and privileged commands.
  - **Commands and configuration parameters.** Advanced command line programs and configuration parameters for tuning operations.
  - **Smart card support.** For Mac OS X and Red Hat users, the ability to use PIV or CAC smart cards for authentication and single sign-on.

In addition to these common features, edition-specific features such as auditing, computer isolation and encryption, and application-specific services are available depending on which edition you purchase.

For more information about Server Suite, see the *Server Suite Free Administrator's Guide for Linux and UNIX*.

Integrations

The following Server Suite integrations docs are available:

- Authentication Guide fo IBM DB2
- Centrify-enabled PuTTY User's Guide
- RSA SecureID Token Config for UNIX/Linux computers
- Samba Integration Guide

In DB2, user and group authentication is performed by a facility that is external to the DB2 database management system, such as the operating system, a domain controller, or a Kerberos security system. It is accomplished using dynamically loadable libraries called security plug-ins.

The default IBM DB2 username/password plug-in authenticates users only in an NIS domain or in the /etc/passwd password file. If another security plug-in has not been explicitly configured, the user credentials provided in the connection request are authenticated by the security facility on the DB2 Universal Database (UDB) server. That is, the default plug-in sends the user ID and password to the operating system for validation.

Contents

Next Step:

DB2

Authorization is the process of determining access information about specific database objects and actions based on a supplied user ID. Privileges can be granted to specific users or to groups of users. Users that are a member of a group automatically inherit the group's privileges. As mentioned before, these users and groups are defined outside the DB2 UDB; for example, in Active Directory.

DB2 supports replacement plug-ins for authentication and authorization. The authentication plug-ins can replace the default user name and password method, and support alternative authentication methods including GSSAPI. DB2 also supports the use of multiple plug-ins for authentication.

Authentication for DB2 Security and Authentication Plug-Ins

Authentication Service for IBM DB2 package provides plug-ins that allow you to connect or attach to a DB2 database using either an Active Directory or a UNIX user identity. In addition, the package includes a group plug-in used for authorization.

The package provides two security plug-ins for authentication:

- centrifydc_db2userpass: a username/password plug-in to replace the DB2 default.
- centrifydc_db2gsskrb5: a GSSAPI plug-in for single sign on support.

The security plug-ins can be used independently or in conjunction with one another.

- If you specify and configure both the username/password plug-in and the GSSAPI plug-in, the GSSAPI plug-in is used when the user connects without specifying a user name and password. The user account can be on an Active Directory domain controller or UNIX computer. If the user does specify a user name and password, the username/password plug-in is used instead.
- If only the GSSAPI plug-in is configured, only Active Directory users can connect to the database instance. In addition, the Active Directory user name instead of the UNIX user name must be used in the SQL GRANT or REVOKE statements when granting or revoking permissions. In this case, the Active Directory user name should follow the DB2 user naming conventions.

DB2 and Delinea Plug-In Compatibility

Starting with DB2 release 10.5.4, DB2 does not allow security plug-ins to fork a process to authenticate DB2 users. To support this behavior, the Delinea plugins starting with Delinea for DB2 5.2.3 use the CentrifyDC service to authenticate Active Directory and local users.

If your environment contains DB2 10.5.4 or later:

- Only Delinea for DB2 5.2.3 or later plug-ins are supported, *and*
- Before you install Delinea for DB2, you must install the Server Suite 2015.1 or later agent (that is, agent version 5.2.3+) on each DB2 server, *and*
- You must ensure that the agent (that is, the centrifydc service) is running on each DB2 server.

Username-Password Plug-In

The Delinea username/password plug-in, centrifydc_db2userpass, supports authentication from both Active Directory and non-Active Directory users. A non-Active Directory user may be one of the following:

- a UNIX user from local stores such as /etc/passwd and Name Service Switch (NSS)
- any user who has been authenticated using Pluggable Authentication Modules (PAM)
- any user who has been authenticated using the AIX Loadable Authentication Module (LAM)

The Delinea username/password plug-in, like the IBM default username/password plug-in, gives you the option to allow users who are already logged in to a DB2 server machine to connect to a database instance without entering a user name or password. However, the default is to require a logged in user to re-enter the user name and password to access the database instance.

GSSAPI Plug-In

The GSSAPI plug-in, centrifydc_db2gsskrb5, supports single sign on to a DB2 instance using the user's Active Directory account. This plug-in assumes that the user requesting access to the database is already logged in to the client computer and has been authenticated through the Kerberos mechanism.

The GSSAPI plug-in allows users to run the connect and attach commands without specifying a user name and password even if the user is connecting from a remote DB2 client. It requires the user to have a valid Kerberos ticket. Generally, users obtain a Kerberos ticket automatically when they log in as an Active Directory user. However, in the following situations the user does not obtain a ticket automatically:

- The user logs in to the DB2 server as a local, non-Active Directory user.
- The user enters the UNIX command su - *user* as root to get a shell owned by another Active Directory user or local user.
- The user logs in as a user who has both an Active Directory account and a local user account. However, the Active Directory account is not in the same zone as the machine you logged in to.

In each of these cases, the user needs to obtain Kerberos tickets before single sign-on support is provided.

To obtain tickets for an Active Directory user, type kinit *user*. The user is prompted for a password. To avoid being prompted, you can create a keytab file in advance using the adkeytab command, set the environment variable KRB5_ KTNAME to the full path of your keytab file, and then run kinit -k *user@DOMAIN* to obtain the tickets.

> **Note**: If a user name is explicitly provided when only the GSSAPI plug-in is installed (for example, by entering the DB2 command connect to testdb user username using password), the plug-in first authenticates the given user to the Kerberos Key Distribution Center (KDC), and then obtains a ticket-granting ticket (TGT) upon success. The plug-in next uses the TGT to get a service ticket for the DB2 server.

Group Plug-In

You install the Group plug-in, centrifydc_db2group to retrieve the list of groups to which a user belongs for authorization. The group plug-in is called automatically after user authentication by DB2. The group info retrieved is used by DB2 to check a user's access rights and determine whether the user has privilege to do specific tasks; for example, connect, query, perform database management, and so on.

The Group plug-in queries Active Directory first for the groups to which the user belongs, and then it looks in the local groups on the host. The two lists are then merged, with duplicates removed and returned to DB2.

Make Connections to the DB2 Administration Server

The DB2 Administration Server (DAS) allows administrators to manage DB2 instances remotely. Using utilities such as DB2 Control Center (db2cc) to perform operations such as creating, removing, starting, or stopping a database instance remotely require a DAS connection. Tasks that can be performed on a running instance (such as creating or dropping a table in the instance) do not require a DAS connection.

The DAS uses a separate authentication scheme from the instance authentication. The DAS does not call into the DB2 security plug-ins or PAM when authenticating users. If you want to log in as an Active Directory user and use utilities such as DB2 Control Center to remotely administer an instance, you have the following options, irrespective of the plug-ins that you select:

- Run the utility that connects to the DAS (such as db2cc) on the DB2 server machine as the user who can perform the desired administrative tasks.

  Make sure that this user is in the same zone as the DB2 server machine.

- Install and configure either the Microsoft or Delinea password synchronization service. For more details about the Delinea password synchronization service, refer to the *Administrator's Guide for Windows*.

- Create a local user on the DB2 server machine and enter that user's user name and password when DB2 Control Center (or other utility connecting to the DAS) requests a user name and password.

Next Step:

Install and Configure the Server

This section describes how to install and configure the Authentication Service for IBM DB2 package on a DB2 server.

To automate Authentication Service for IBM DB2 plug-in installation and configuration, use the setupdb2.sh script provided in the Authentication Service for IBM DB2 package.

To manually install, set up, configure, and verify the Identity Broker Service for IBM DB2 plug-in without using the setupdb2.sh script, see Install Manually.

Use the uninstallation script, /usr/share/centrifydc/bin/ uninstalldb2.sh, included in the Authentication Service for IBM DB2 package, to remove the Authentication Service for IBM DB2:

- When there is partially installed Authentication Service for IBM DB2 release after a failed installation attempt.
- Before upgrading an existing Authentication Service for IBM DB2 to a new release.
- For details about using this script, see Execute the uninstalldb2 Script.

The following sections describe how to install and configure the Authentication Service for IBM DB2 package on each supported platform using the setupdb2.sh script:

- Software Requirements
- Unzip and Restore the Authentication Service for DB2 package
- Install Authentication Service for DB2 Using the Platform Install Program
- Install and Configure PlugIns Using the setupdb2.sh Script
- Install Manually
- Upgrade from an Earlier Release
- If an Installation Attempt Fails

Software Requirements

You must have the Delinea agent installed on each DB2 server, and the DB2 servers must be joined to an Active Directory domain.

If you use the GSSAPI plug-in, the plug-in must be installed on the DB2 server and each DB2 client. In addition, both the DB2 client and the DB2 server computers must be joined to the same Active Directory domain.

If you use the username/password plug-in, you must install the PAM library. You can install the PAM library after you install the Delinea for DB2 package.

See *DB2 and Delinea Plug-in Compatibility* under Authentication and Authorization in IBM DB2

See the release notes for the Delinea software, DB2 versions and versions of Red Hat, SuSE, Solaris, and AIX operating systems supported in this release. In general, the Delinea for DB2 package supports the same versions of Solaris, Red Hat, SuSE and AIX operating systems supported in DB2 version 9.5, 9.7, 10.1, and 10.5 with the following exception:

For Red Hat and SuSE Linux, only x86 and x86-64 bit (AMD style) architectures are supported.

Unzip and Restore the Authentication Service for DB2 Package

> **Note**: If Authentication Service for IBM DB2 is already installed, uninstall it now as described in Execute the uninstalldb2 Script.

To begin the installation, unzip and restore the Authentication Service for IBM DB2 package on each DB2 server.

Depending on the platform, download the plug-ins from the customer support portal.

The following sections describe how to unzip and restore the package on each supported platform. In each example:

- *release* is the release number of the Authentication Service for IBM DB2 software (for example, 4.5.0)
- *os_release* is the release number of the operating system (for example, 10.0)
- *architecture* is the processor architecture that is supported (for example, i386)

Unzip and Restore AIX Files

Execute the following commands to unzip and restore the Authentication Service for IBM DB2 package files on an AIX computer:

```
gunzip centrify-db2-release-aixos_release-ppc.tgz
```

```
tar -xvf centrify-db2-release-aixos_release-ppc-bff.tar
```

```
gunzip centrify-db2-release-aixos_release-ppc-bff.gz
```

After you execute these commands, the file centrify-db2-release-aixos_release-ppc-bff is ready to be installed using the native AIX installer. Go to Install Authentication Service for DB2 Using the Platform Install Program and continue from there.

Unzip and Restore Linux Files

Execute the following commands to unzip and restore the Authentication Service for IBM DB2 package files on a Linux computer. The examples shown here assume that you are installing on Red Hat Linux.

```
gunzip centrify-db2-release-rhelos_release-architecture.tgz
```

```
tar -xvf centrify-db2-release-rhelos_release-architecture.tar
```

After you execute these commands, the file centrify-db2-release-rhelos_release-architecture.rpm is ready to be installed using the native Linux installer. Go to Install Authentication Service for DB2 Using the Platform Install Program and continue from there.

Unzip and Restore Solaris files

Execute the following commands to unzip and restore the Authentication Service for IBM DB2 package files on a Solaris computer:

```
gunzip centrify-db2-release-solos_release-ppc-bff.tgz
```

```
tar -xvf centrify-db2-release-solos_release-ppc-bff.tar
```

After you execute these commands, the file centrify-db2-release-solos_release-ppc-bff is ready to be installed using the native Solaris installer. Go to Install Authentication Service for DB2 Using the Platform Install Program and continue from there.

Install Authentication Service for DB2 Using the Platform Install Program

After you have unzipped and restored the Authentication Service for IBM DB2 package files, install the package using the platform's native installation program. The following sections describe the installation procedure on each supported platform. In each example:

- *release* is the release number of the Authentication Service for IBM DB2 software
- *os_release* is the release number of the operating system.

Install the AIX Files

Execute the following command to install the Authentication Service for IBM DB2 package using the native AIX installation program:

```
installp -d centrify-db2-release-aixos_release-ppc-bff CentrifyDC.db2
```

After you execute this command, you are ready to install and configure the Authentication Service for IBM DB2 plug-ins. You can install and configure the plug-ins using the setupdb2.sh script, or manually without using the setupdb2.sh script. See Install and Configure PlugIns Using the setupdb2 Script or Install Manually for details about these procedures.

Install the Linux Files

Execute the following command to install the Authentication Service for IBM DB2 package using the native Linux installation program. The examples shown here assume that you are installing on Red Hat Linux.

If you are installing the Authentication Service for IBM DB2 package for the first time:

```
rpm -ivh centrify-db2-release-rhelos_release-architecture.rpm
```

After you execute this command, you are ready to install and configure the Authentication Service for IBM DB2 plug-ins. You can install and configure the plug-ins using the setupdb2.sh script, or manually without using the setupdb2.sh script. See the next section or Install Manually for details about these procedures.

Install the Solaris Files

Execute the following command to install the Authentication Service for IBM DB2 package using the native Solaris installation program.

```
pkgadd -a admin -n -d centrify-db2-release-solos_release.rpm
```

After you execute this command, you are ready to install and configure the Authentication Service for IBM DB2 plug-ins. You can install and configure the plug-ins using the setupdb2.sh script, or manually without using the setupdb2.sh script. See Install and Configure PlugIns Using the setupdb2 Script or Install Manually for details about these procedures.

Install and Configure Plug-Ins Using the setupdb2 Script

The /usr/share/centrifydc/bin/setupdb2.sh script is an interactive script. Provide the following information at the script prompts:

- The DB2 authentication you want to use (both user name/ password and single sign on, single sign on only, or username/ password only)
- What data sent to DB2 you want to encrypt
- The Active Directory administrator password

For GSSAPI-related plug-in installation using the setupdb2.sh script, additionally provide the following information at the prompts:

- An account name, password, and container for an Active Directory user with administrator privileges on the domain controller.

The scripts then installs, configures, and verifies the plug-in(s) according to your entries.

The following table lists the setupdb2.sh command line options:

inst	Yes	A string value	The name of a DB2 database instance.
verbose	No	0 or 1 The default is 1	If the value is 0, only the basic questions are asked. All 3 Authentication Service for IBM DB2 plug-ins are installed. If the value is 1, the script prompts for different installation and setup options.
debug	No	0 or 1 The default is 0	If the value is 0, installation and setup are performed. If the value is 1, the script simulates the steps without actually performing them. Each command is displayed with a "#" prefix. Use this option to preview what commands are executed in an actual invocation.

The format for all command options is option=value. Separate each option with a space.

Run the setupdb2.sh Script

Perform the steps described in this section to run the setupdb2.sh script now.

In the example used here, db2inst1 is the name of a DB2 database instance, you want to run the script in verbose mode, and you do not want to run the script in debug mode.

To run the setupdb2.sh script:

1. Change to the /usr/share/centrifydc/bin directory:

   ```
   cd /usr/share/centrifydc/bin
   ```

2. Run the setupdb2.sh script. The instance name that you specify with the setupdb2.sh command cannot exceed 8 bytes. In this example, the database instance is named db2inst1, verbose mode is invoked so that all prompts for different installation and setup options are displayed, and debug mode is not invoked.

   ```
   ./setupdb2.sh inst=db2inst1 verbose=1
   ```

   In this example, the database instance is named db2inst1, verbose mode is invoked so that all prompts for different installation and setup options are displayed, and debug mode is not invoked.

3. Type y or n at the prompt, Is db2inst1 a DB2 server install?

   In this example, db2inst1 is a server installation, so select the default (y for yes).

This is confirming that the running component is a DB2 server. Entering yes directs the script to also install the DB2 client component. A message indicates if the script determined the instance is 32 or 64 bit.

```
db2inst1 is a 64 bit instance. DB2 server and client setup will be done.
```

4. Enter a number at the prompt, Which DB2 auth method do you want to use?

   Select an authentication method. From the listed choices, enter the corresponding number.

   ```
   [1] Username/Password and Single sign-on
   [2] Single Sign-on only
   [3] Username/Password only
   [4] Skip this step
   Select a number from the menu [1]:
   ```

   See Username-Password Plug-In and GSSAPI Plug-In for details about these choices. In this example, select username/password only.

5. Enter a number at the prompt, Which data sent to DB2 should be encrypted?

   Select if or which data sent to DB2 should be encrypted. This step is optional.

   ```
   [1] Nothing
   [2] The username and their password
   [3] All data going to the server
   [4] Encrypt and compress all data going to the server
   [5] Skip this step
   ```

   In this example, select [1] Nothing. Selecting [2], [3], or [4] changes the SRVCON_AUTH to Server_ Encrypt. Selecting [5] Skip this step exits the plug-in setup program.

6. Type y or n at the prompt, Use the CentrifyDC group plugin?

   Specify whether to use the CentrifyDC group plug-in. See Group Plug-In for details about this choice.

   Install the Group plug-in centrifydc_db2group, to retrieve the list of groups to which a user belongs for authorization. The group plug-in is called automatically after user authentication by DB2.

   The group information retrieved is used by DB2 to check a user's access rights and determine whether the user has privilege to do specific tasks. For example: connect, query, db management, and so forth.

   The Group plug-in queries Active Directory first for the groups to which the user belongs and then it looks in the local groups on the host. The two lists are then merged with duplicates removed and returned to DB2.

   In this example, select yes.

7. Enter a number at the prompt, Do you want to configure the instance user db2inst1 as a service account?

   Specify whether to configure the instance user as a service account.

   You must do this step if you want to use the GSS-Plugin. If you already did this step for this instance, select the option to indicate the keytab file name.

   ```
   [1] Use`adkeytab` to create a service account in Active Directory and `keytab`file`.
   NOTE: You need to specify a user name with administrator privileges on the domain to use adkeytab.
   [2] Provide the name of an already existing`keytab`file.
   [3] Skip this step
   ```

   Generally, if you are starting from nothing, enter 1, otherwise enter 2.

   If you are setting up the GSSAPI plug-in (that is, if you selected a single sign-on option in Step 5) and you have not yet configured the instance user as a service account, you must select option 1, Use adkeytab to create a service account in Active Directory and keytab file. You will be prompted later for the Active Directory Administrator password.

If you have already configured the instance user as a service account, the necessary keytab file already exists. If this is the case, select option 2, "Provide the name of an already existing keytab file," and provide the full path and file name of the keytab file.

If you are not setting up the GSSAPI plug-in, you can optionally skip this step.

In this example, even though the GSSAPI plug-in is not being set up (that is, a single sign-on option was not selected in Step 5), you can still choose to configure the instance user as a service account. To do so, select option 1.

8. Enter a filename or press return to accept the default, at the prompt, What is the file name thatadkeytabshould use when creating thekeytabfile?

   Choose the default or specify any location.

   Full path please.

   Note: the file needs to be accessible to the db2inst1 user.

   [/home/db2inst1/db2inst1.keytab]

9. Enter at the prompt, Enter the password for db2inst1.

   Provide the password for the database instance that you specified in Step 2.

   Create a new password for db2inst1 or enter an existing password (if configured earlier).

10. Enter at the prompt, Enter a user name that has administrator privileges for the domain.

    Specify a user name (for example, flast@company.com). The username must be a SamAccount, and must have administrator privileges for the domain (that is, Active Directory Administrator privileges).

11. Enter at the prompt, Enter the container where to store the db2inst1 user.

    Specify the container object in which to create the service account.

    [CN=Users]:

    The default OU is CN=Users

    PAM setup not required for AIX. Skipping...

    If a service account name other than the DB2 instance name is chosen to adopt and build the Kerberos keytab file, this service account needs to meet the following two requirements:

    - The account name must be 8 characters long at most. This is required by the DB2 server.
    - This account must have the same permission granted as the instance owner in DB2 server

    The setupdb2.sh script can use only the container objects in the domain to which the computer is currently joined. You cannot specify another domain for the container object when you use the setupdb2.sh script to install and configure plug-ins. If you want to specify a different domain, you must install the plug-ins manually without using the setupdb2.sh script. See Step 2 in Set up for the GSSAPI plug-in for details about specifying a different domain.

    Type the name of the container object in relative DN format (that is, do not specify the domain portion of the DN). For example, if you wanted to create the service account in the users container in the currently joined domain, you would type the following:

    CN=users

12. Enter at the prompt, What group should be used as the group owner of this file?

    Specify the group name or select the default.

    All DB2 instances that you want to use the username/password plugin must be in this group.[db2iadm1]:

    You are prompted for more information depending on which plug-ins you are setting up:

    - The group that owns the /usr/share/centrifydc/bin/ db2userpass_checkpwd file. You are prompted for this information if you are setting up the username/password plug-in.
    - The password for the user with Active Directory Administrator privileges that you specified in Step 11. You are prompted for this information if you are setting up the GSSAPI plug-in.

    Example return output from this step.

********** `adkeytab` setup (required for GSS-plugin) **********

Using /home/db2inst1/db2inst1.keytab for the `keytab` file for instance: db2inst1

NOTE:`adkeytab`will prompt you for the password of the Active Directory admin user: rsriniva.

#`adkeytab`-n -c CN=Users -u rsriniva -K /home/db2inst1/ db2inst1.keytab -P db2inst1/vaix61-2.corp.contoso.com db2inst1 rsriniva@CORP.CONTOSO.COM's password:

Success: New Account: db2inst1

NOTE:`adkeytab`will prompt you for the password of the Active Directory admin user: rsriniva again.

#`adkeytab`-C db2inst1 -u rsriniva -w XXX-PASS-NOT-DISPLAYED- XXX -K /home/db2inst1/db2inst1.keytab rsriniva@CORP.CONTOSO.COM's password:

Success: Change Password: db2inst1

chmod 600 /home/db2inst1/db2inst1.keytab

chown db2inst1 /home/db2inst1/db2inst1.keytab # db2set DB2ENVLIST=KRB5_KTNAME

adkeytab setup successfully!

********** username/password plugin setup **********

chmod 750 /usr/share/centrifydc/bin/db2userpass_checkpwd

chown root:db2iadm1 /usr/share/centrifydc/bin/ db2userpass_checkpwd

chmod u+s /usr/share/centrifydc/bin/db2userpass_checkpwd username/password setup successfully

cp /usr/share/centrifydc/lib64/libcentrifydc_db2group.so sqllib/security64/plugin/group/centrifydc_db2group.so

******* Updating settings for DB2 instance: db2inst1 ******

Old configuration (You may want to copy these settings down in case you need to revert to the old settings):

Group Plugin (GROUP_PLUGIN) =

GSS Plugin for Local Authorization (LOCAL_GSSPLUGIN) = Server List of GSS Plugins (SRVCON_GSSPLUGIN_LIST) = Server Userid-Password Plugin (SRVCON_PW_PLUGIN) = Server Connection Authentication (SRVCON_AUTH) =

NOT_SPECIFIED

Database manager authentication (AUTHENTICATION) = SERVER The DB2 configuration will be updated to:

LOCAL_GSSPLUGIN = centrifydc_db2gsskrb5 SRVCON_GSSPLUGIN_LIST = centrifydc_db2gsskrb5 SRVCON_PW_PLUGIN = centrifydc_db2userpass SRVCON_AUTH = GSS_SERVER_ENCRYPT AUTHENTICATION = SERVER

GROUP_PLUGIN = centrifydc_db2group

13. Review the script displayed content.

From this point the script stops the DB2 instance: db2inst1, updates the configuration, and then restarts the instance.

System information displays as files are configured. When the setupdb2.sh script finishes the configuration, a completion message displays.

Examples output when the instance is stopped.

```
Stopping instance: db2inst1
# db2stop
SQL1064N DB2STOP processing was successful.
# db2 update dbm config using LOCAL_GSSPLUGIN centrifydc_db2gsskrb5
DB20000I The UPDATE DATABASE MANAGER CONFIGURATION command completed successfully.
# db2 update dbm config using SRVCON_GSSPLUGIN_LIST centrifydc_db2gsskrb5
DB20000I The UPDATE DATABASE MANAGER CONFIGURATION command completed successfully.
# db2 update dbm config using SRVCON_PW_PLUGIN centrifydc_db2userpass
DB20000I The UPDATE DATABASE MANAGER CONFIGURATION command completed successfully.
# db2 update dbm config using SRVCON_AUTH GSS_SERVER_ENCRYPT DB20000I The UPDATE DATABASE MANAGER CONFIGURATION command completed successfully.
# db2 update dbm config using AUTHENTICATION SERVER DB20000I The UPDATE DATABASE MANAGER CONFIGURATION command completed successfully.
# db2 update dbm config using GROUP_PLUGIN centrifydc_db2group DB20000I The UPDATE DATABASE MANAGER CONFIGURATION command completed successfully.
New configuration:
Group Plugin (GROUP_PLUGIN) = centrifydc_db2group
GSS Plugin for Local Authorization (LOCAL_GSSPLUGIN) = centrifydc_db2gsskrb5
Server List of GSS Plugins (SRVCON_GSSPLUGIN_LIST) = centrifydc_db2gsskrb5
Server Userid-Password Plugin (SRVCON_PW_PLUGIN) = centrifydc_db2userpass
Server Connection Authentication (SRVCON_AUTH) = GSS_SERVER_ENCRYPT
Database manager authentication (AUTHENTICATION) = SERVER
Starting Instance # db2start
SQL1063N DB2START processing was successful.
The plugins for DB2 instance: db2inst1 were setup successfully!
```

14. Verify if the setup completed properly or not by running the command as the DB2 instance user:

    ```
    db2 get dbm config |egrep -i "auth|gss|group|srvcon"
    ```

    Example of return output from the command for a scenario where all three DirectControl for DB2 security plug-ins have been configured as shown below. The lines of interest are in **bold**.

    ```
    SYSADM group name (SYSADM_GROUP) = DB2GRP1
    SYSCTRL group name (SYSCTRL_GROUP) = SYSMAINT group name (SYSMAINT_ GROUP) =
    SYSMON group name (SYSMON_GROUP) =
    __Group Plugin (GROUP_PLUGIN) = centrifydc_db2group__
    __GSS Plugin for Local Authorization (LOCAL_GSSPLUGIN) = centrifydc_ db2gsskrb5__
    __Server List of GSS Plugins (SRVCON_GSSPLUGIN_LIST) = centrifydc_ db2gsskrb5__
    __Server Userid-Password Plugin (SRVCON_PW_PLUGIN) = centrifydc_ db2userpass__
    __Server Connection Authentication (SRVCON_AUTH) = SERVER_ENCRYPT__
    __Database manager authentication (AUTHENTICATION) = SERVER Cataloging allowed without authority (CATALOG_NOAUTH) = NO Trusted client authentication (TRUST_CLNTAUTH) = CLIENT__
    Bypass federated authentication (FED_NOAUTH) = NO
    ```

This completes the automated installation on the DB2 server. If you selected single sign-on and username/password or single sign-on only, you need to install the GSSAPI client on every client computer. Go to Set up the GSSAPI DB2 Client for information about that procedure.

If you selected username/password only, you are done with the installation. Go to Test the Installation to finish.

Install Manually

Perform the following steps if you want to install Authentication Service for IBM DB2 manually without using the setupdb2.sh script. If you already installed Authentication Service for IBM DB2, skip this section and go to Set up the GSSAPI DB2 Client.

- Perform the procedures described in Unzip and Restore the Authentication Service for DB2 package and Install Authentication Service for DB2 Using the Platform Install Program
- Copy the Authentication Service for IBM DB2 shared libraries to the appropriate DB2 locations. See Copy the plug-ins.
- If you plan to use username/password for authentication, configure the operating system to load the username/password plug libraries. See Set Up for the Username-Password Plug-in
- If you plan to use single sign-on, configure the operating system to use the GSSAPI plug-in and set up the key table. See Set up for the GSSAPI plug-in
- Configure DB2 to use the three plug-ins. See Configure the DB2 instance
- Confirm that the DB2 configuration is correct. See Verify the Setup

  Note: The Authentication Service for IBM DB2 Group plug-in requires no setup.

Copy the plug-ins

Use the following commands to copy the Authentication Service for IBM DB2 shared libraries from the installation directory to the proper DB2 directory for each instance—db2inst1 in the commands that follow.

The libcentrifydc_db2userpass.so that you use is version-dependent.

Copy Commands for 64-bit Instances:

```
cp /usr/share/centrifydc/lib64/libcentrifydc_db2userpass.so ~db2inst1/sqllib/security64/plugin/server/centrifydc_db2userpass.so
cp /usr/share/centrifydc/lib64/libcentrifydc_db2gsskrb5.so ~db2inst1/sqllib/security64/plugin/server/centrifydc_db2gsskrb5.so
cp /usr/share/centrifydc/lib64/libcentrifydc_db2gsskrb5.so ~db2inst1/sqllib/security64/plugin/client/centrifydc_db2gsskrb5.so
cp /usr/share/centrifydc/lib64/libcentrifydc_db2group.so ~db2inst1/sqllib/security64/plugin/group/centrifydc_db2group.so
cp /usr/share/centrifydc/lib/libcentrifydc_db2gsskrb5.so ~db2inst1/sqllib/security32/plugin/client/centrifydc_db2gsskrb5.so
```

Copy Commands for 32-bit Instances:

```
cp /usr/share/centrifydc/lib/libcentrifydc_db2userpass.so ~db2inst1/sqllib/security32/plugin/server/centrifydc_db2userpass.so
cp /usr/share/centrifydc/lib/libcentrifydc_db2gsskrb5.so ~db2inst1/sqllib/security32/plugin/server/centrifydc_db2gsskrb5.so
cp /usr/share/centrifydc/lib/libcentrifydc_db2gsskrb5.so ~db2inst1/sqllib/security32/plugin/client/centrifydc_db2gsskrb5.so
cp /usr/share/centrifydc/lib/libcentrifydc_db2group.so ~db2inst1/sqllib/security32/plugin/group/centrifydc_db2group.so
```

Setup for the Username-Password Plug-In

The username/password plug in library, centrifydc_db2userpass.so is now in place. Three more procedures are required to finish Authentication Service for IBM DB2 username/password plug-in installation and configuration:

- Configure the instance's Linux computer(s) to use the Authentication Service for IBM DB2 library for PAM authentication.

  Note: The Authentication Service for IBM DB2 username/password security plug-in uses PAM to authenticate users. This step is required only for DB2 servers running on Linux platforms. On AIX-based computers, the Authentication Service for IBM DB2 username/password plug-in uses the native LAM authentication framework which is already configured for authentication against Active Directory accounts.
- Set parameters in the /etc/centrifydc/centrifydc.conf file.
- Assign permissions for the program that checks the password for local users.

1. Configure Linux-based Computers:

Note: This operation requires root user privileges.

You need to tell the PAM service to use Authentication Service for IBM DB2 plug-in for authentication and account management. The name of the Authentication Service for IBM DB2 username/password plug-in is centrifydc_db2userpass.

Each PAM service has its own configuration file in the /etc/pam.d directory. To add the Authentication Service for IBM DB2 username/password plug-in on a Red Hat Linux computer, create the file

/etc/pam.d/centrifydc_db2userpass

with the following contents:

```
# Delinea PAM service for DB2 username/password support
# %PAM-1.0
auth required pam_stack.so service=system-auth
auth required pam_nologin.so
account required pam_stack.so service=system-auth
########################################
```

If you are configuring a SUSE Linux 10 computer, the contents of /etc/pam.d/centrifydc_db2userpass should be as follows:

```
auth include common-auth
account include common-account
```

If you are configuring a SUSE Linux 8 or 9 computer, the contents of /etc/pam.d/centrifydc_db2userpass should be as follows:

```
auth required pam_unix2.so
auth required pam_nologin.so
auth required pam_env.so
account required pam_unix2.so
account required pam_nologin.so
```

2. Set /etc/centrifydc/centrifydc.conf parameters

The following configuration options require you to edit the /etc/centrifydc/centrifydc.conf file on the DB2 server.

- If you want to allow users who are already logged in to the DB2 server to log in to the database instance without entering their user name and password, add the following line to /etc/centrifydc/centrifydc.conf:

  ```
  db2.userpass.allow.localnopasswd.db2_instance_name: true
  ```

  The default value is false, meaning that users already logged in to the server must enter their user name and password to access the database instance.

- If you have an environment in which the user name case used for database authentication differs from user name case stored in /etc/passwd, you need to add the following parameter to the /etc/centrifydc/centrifydc.conf file:

  ```
  db2.userpass.username.lower: true
  ```

  When this parameter is present and set to true, the DB2 username/password plug-in converts the user name to lowercase before attempting authentication. When this parameter is set to false, it leaves the case as-is.

- By default, the Delinea DB2 agent authenticates all Active Directory users even if the Active Directory user is not in the zone. To optionally constrain the authentication to zone enabled Active Directory users only, add the following parameter to the /etc/centrifydc/centrifydc.conf file:

  ```
  db2.user.zone_enabled.db2_instance_name: true
  ```

  After you add this parameter, restart the DB2 instance to pick up the new setting.

  Stop and start the agent after you modify centrifydc.conf to enable the conversion.

Set up for the GSSAPI PlugIn

This section describes how to configure the server to use the Authentication Service for IBM DB2 GSSAPI plug-in.

1. As root, use the adjoin command to join the UNIX DB2 server machine and each UNIX DB2 client using GSSAPI to the same Active Directory domain. See the *Administrator's Guide for Windows* for the adjoin command options. Be careful to join the appropriate Active Directory organizational unit and Delinea zone for your configuration.

   > **Note**: You must have the account name and password for an Active Directory user that has administrator privileges on the Active Directory domain controller to use adjoin. If you do not specify the account name in the adjoin command line you will be prompted to enter the administrator password.

2. As root, use the adkeytab command to create a Kerberos service account for the DB2 instance and generate a keytab file. (The adkeytab tool is included in the Delinea Server Suite package; see /usr/sbin.)

   The following example creates the account for the database instance db2inst1 in the Users container in the currently joined domain. The account resides on a DB2 server with host name (not fully-qualified) hostname, and generates a keytab file (db2inst1.keytab) in the $INSTHOME directory. Substitute your own instance, host, and keytab file names as appropriate.

   ```
   adkeytab -n -c CN=Users -u Administrator -K \
   $INSTHOME/db2inst1.keytab -P db2inst1/hostname db2inst1
   ```

   If you had wanted to create the account in a different domain than the currently joined domain, you would have used the adkeytab -d option.

   This example uses the domain controller's Administrator account to generate the keytab file and requires root to know the administrator password. If you do not know the administrator password, use the -u option to specify any user with administrator privileges on the Active Directory domain controller.

   The adkeytab command always sets the password of the domain account to a random value regardless of whether the account already exists. Use the following command to change the Active Directory password. This example uses db2inst1 for the DB2 instance name and password for the password string for the instance user's account in Active Directory. Substitute your own instance and password as appropriate.

   ```
   adkeytab -C db2inst1 -w password
   ```

   > **Note**: If there is a local user (for example, in /etc/passwd or /etc/shadow) with the same account name as the instance user, the adkeytab command does not change the local password.

   In both examples, you are prompted for the Active Directory Administrator password before the command is executed.

   After you have generated the keytab file with the adkeytab command, do not move or delete it. If you do, the agent will not renew the keytab.

   In addition, set the service account password in Active Directory to *never expire*.

3. Open the file /etc/centrifydc/user.ignore and add the instance user to the end of the file. (This file contains user names that are always treated as local—for example, root, mail, and daemon—when looking up user information.) This allows the instance user to log in as a local user to perform maintenance tasks.

4. Set appropriate permissions to protect the keytab file generated in Step 2.

   For the GSSAPI plug-in to work, the keytab file must be made readable by the DB2 instance owner. In addition, because the keytab file contains sensitive information such as the secret key associated with the DB2 instance service account, it should be properly protected. Execute the following commands as root to achieve this. The following example uses db2inst1 for the DB2 instance name and db2grp1 for the primary group of the instance user. Substitute your own instance and group names as appropriate.

   ```
   chmod 600 $INSTHOME/db2inst1.keytab
   chown db2inst1:db2grp1 $INSTHOME/db2inst1.keytab
   ```

5. Set up the DB2 environment variables to use the new keytab file. By default, DB2 uses the keytab file defined in the KRB5_KTNAME environment variable for authentication. The default is /etc/krb5.keytab. The following procedures describe how to set the variable for different UNIX shells. Perform the action as the DB2 instance owner, and replace db2inst1 with your actual instance name.

   For Bourne, Korn and bash shell users, add the following lines to $INSTHOME/sqllib/userprofile:

   ```
   KRB5_KTNAME=$INSTHOME/db2inst1.keytab
   export KRB5_KTNAME
   ```

   For C shell users, add the following line to $INSTHOME/sqllib/usercshrc:

```
setenv KRB5_KTNAME $INSTHOME/db2inst1.keytab
```

By default, DB2 filters out all user environment variables except for those prefixed with DB2 or db2. To pass the value stored in KRB5_KTNAME to the DB2 instance, the variable must be added to the DB2ENVLIST parameter. To do so, run the following command as the DB2 instance user: db2set DB2ENVLIST=KRB5_KTNAME

Note: Before executing db2set, you must either:

- Log out after updating the userprofile and usercshrc files to set the KRB5_KTNAME environment and log back in again; or
- Set the environment variable in your shell before issuing the command.

6. On some platforms, the DB2 server may not be able to start due to the Kerberos library conflict between the system and Delinea DirectControl.

   The centrifydc_db2gsskrb5 plugin has to be linked against the one from DirectControl.

   To work around this issue, Delinea recommends that you add the library search path and make it readable by DB2 server. Please revise the changes above and do the modification as below:

   Note: The environment variable name and value for library search path is platform specific, and the example below is for Linux x86_64.

   For Bourne, Korn and bash shell users, add the following lines to $INSTHOME/sqllib/userprofile:

   ```
   KRB5_KTNAME=$INSTHOME/db2inst1.keytab
   export KRB5_KTNAME
   LD_LIBRARY_PATH=/usr/share/centrifydc/lib64:/usr/share/centrifydc/kerberos/lib64:$LD_LIBRARY_PATH
   export LD_LIBRARY_PATH
   ```

   For C shell users, add the following line to $INSTHOME/sqllib/usercshrc:

   ```
   setenv KRB5_KTNAME $INSTHOME/db2inst1.keytab
   setenv LD_LIBRARY_PATH=/usr/share/centrifydc/lib64:/usr/share/centrifydc/kerberos/lib64:$LD_LIBRARY_PATH
   ```

Run the following command as the DB2 instance user:

```
db2set DB2ENVLIST="KRB5_KTNAME LD_LIBRARY_PATH"
```

Configure the DB2 Instance

Enter the following commands to modify each DB2 instance's configuration parameters to use the Authentication Service for IBM DB2 plug-ins for authentication and authorization.

All of the following commands should be executed as an instance user.

Case 1: Use the username/password plug-in only:

```
db2 update dbm cfg using SRVCON_PW_PLUGIN centrifydc_db2userpass
db2 update dbm cfg using SRVCON_AUTH NOT_SPECIFIED
db2 update dbm cfg using AUTHENTICATION SERVER
```

Note: If you select the SRVCON_AUTH option, the user name and password are transmitted in the clear. This library also includes the following options to encrypt different parts of the message:

- SERVER_ENCRYPT: The user name and password are encrypted in messages sent from DB2 client to DB2 server.
- DATA_ENCRYPT: User data as well as the authentication data (user name and password) are encrypted in messages sent from DB2 client to DB2 server.
- DATA_ENCRYPT_CMP: DATA_ENCRYPT with backwards compatibility to older versions of the DB2 client. (If you have an older version of the DB2 client that does not support the DATA_ENCRYPT option, only the authentication data is encrypted unless you select the DATA_ENCRYPT_CMP option.)

For example, to set the username/password plug-in to encrypt all data going to the server you would use the following command:

```
db2 update dbm cfg using SRVCON_AUTH DATA_ENCRYPT
```

Case 2: Use the GSSAPI plug-in only:

```
db2 update dbm cfg using SRVCON_PW_PLUGIN NULL
db2 update dbm cfg using SRVCON_GSSPLUGIN_LIST centrifydc_db2gsskrb5
db2 update dbm cfg using LOCAL_GSSPLUGIN centrifydc_db2gsskrb5
db2 update dbm cfg using SRVCON_AUTH GSSPLUGIN
db2 update dbm cfg using AUTHENTICATION SERVER
```

Case 3: Use the username/password plug-in and the GSSAPI plug-in together:

```
db2 update dbm cfg using SRVCON_PW_PLUGIN centrifydc_db2userpass
db2 update dbm cfg using SRVCON_GSSPLUGIN_LIST centrifydc_db2gsskrb5
db2 update dbm cfg using LOCAL_GSSPLUGIN centrifydc_db2gsskrb5
db2 update dbm cfg using SRVCON_AUTH GSS_SERVER_ENCRYPT
db2 update dbm cfg using AUTHENTICATION SERVER
```

For all cases: Run the following command as the DB2 instance user to configure the instance to use the Authentication Service for IBM DB2 group plug-in:

```
db2 update dbmcfg using GROUP_PLUGIN centrifydc_db2group
```

This completes the Authentication Service for IBM DB2 package manual installation and configuration. Next, verify that the configuration parameters are set properly.

Verify the Setup

Execute the following command as the DB2 instance user to verify the setup:

```
db2 get dbm config legrep -i "authlgsslgrouplsrvcon"
```

A sample output of this command for a scenario where all three Authentication Service for IBM DB2 security plug-ins have been configured is as follows. The lines of interest are in **bold**.

```
SYSADM group name (SYSADM_GROUP) = DB2GRP1
SYSCTRL group name (SYSCTRL_GROUP) =
SYSMAINT group name (SYSMAINT_GROUP) =
SYSMON group name (SYSMON_GROUP) =
**Group Plugin (GROUP_PLUGIN) = centrifydc_db2group**
__GSS Plugin for Local Authorization (LOCAL_GSSPLUGIN) = centrifydc_ db2gsskrb5__
__Server List of GSS Plugins (SRVCON_GSSPLUGIN_LIST) = centrifydc_ db2gsskrb5__
__Server Userid-Password Plugin (SRVCON_PW_PLUGIN) = centrifydc_ db2userpass__
**Server Connection Authentication (SRVCON_AUTH) = GSS_SERVER_ENCRYPT**
**Database manager authentication (AUTHENTICATION) = SERVER**
Cataloging allowed without authority (CATALOG_NOAUTH) = NO
Trusted client authentication (TRUST_CLNTAUTH) = CLIENT
Bypass federated authentication (FED_NOAUTH) = NO
```

After installing the plug-ins, the database instance needs to be stopped and restarted. Enter the `db2stop` and `db2start` commands as the instance user.

Upgrade from an Earlier Release

If you are upgrading from an earlier release of Authentication Service for IBM DB2, you have to stop the DB2 instance before the upgrade by using the `db2stop` command. After stopping the DB2 instance, you can upgrade using the `setupdb2.sh` script, or manually by copying the new plug-ins into their corresponding DB2 directories.

Upgrade Using the setupdb2.sh Script

1. Ensure that you have stopped the DB2 instance.

2. Remove the Authentication Service for IBM DB2 software as described in Uninstall DB2 Plug-ins
3. Install the new release of the Authentication Service for IBM DB2 package as described in Install and Configure Server

Upgrade Manually

1. Ensure that you have stopped the DB2 instance.
2. Remove the Authentication Service for IBM DB2 software as described in Uninstall DB2 Plug-ins
3. Perform the procedures described in Install Manually.
4. Restart the DB2 instance after the files are in place using db2start.

   If you are currently using a Beta version of the software, refer to Delinea Knowledge Base article KB-0938 for information about how to perform the upgrade.

If an Installation Attempt Fails

If you attempt to install the Authentication Service for IBM DB2 package and the installation fails, before retrying the installation you must uninstall any files that were installed by performing the procedures described in Uninstall DB2 Plug-ins

Next Step:

Set Up the GSSAPI Client

The Authentication Service for IBM DB2 GSSAPI security plug-in has a client component that must be installed on each DB2 UNIX-based client computer accessing the DB2 server.

DB2 Client Installation on a UNIX Computer

Copy the Delinea for DB2 package to each client. Unzip, restore, and install the package as described in Install and Configure Server.

Just like the DB2 server, you can use either use the setupdb2.sh setup script or manually install and configure the software. The following sections describe these procedures.

Install on UNIX Using the

To install the Delinea for DB2 package using the setupdb2.sh script, perform the steps described in Install and Configure Plug-ins Using the setupdb2.sh Script

> **Note**: The setupdb2.sh script may wrongly identify a DB2 version 8 client as a DB2 server. If this happens, when the script prompts you to confirm the detection, answer **no**. The script will then install the GSSAPI plug-in for DB2 client.

Install on UNIX Manually

Perform the following steps to install the Delinea for DB2 package manually.

To install the Authentication Service for IBM DB2 manually:

1. Copy the shared libraries. Run the following commands as the instance user to copy the shared libraries to the target directories where db2inst1 is the instance name:
   - For a 64-bit DB2 instance:

```
cp /usr/share/centrifydc/lib64/libcentrifydc_db2gsskrb5.so
~db2inst1/sqllib/security64/plugin/client/centrifydc_db2gsskrb5.so
cp /usr/share/centrifydc/lib/libcentrifydc_db2gsskrb5.so
~db2inst1/sqllib/security32/plugin/client/centrifydc_db2gsskrb5.so
```

   - For 32-bit instances, run:

```
cp /usr/share/centrifydc/lib/libcentrifydc_db2gsskrb5.so
~db2inst1/sqllib/security32/plugin/client/centrifydc_db2gsskrb5.so
```

2. Set up the DB2 configuration variables. As the DB2 instance user, run the following commands to tell DB2 to use server authentication schemes:

```
db2 update dbm cfg using LOCAL_GSSPLUGIN centrifydc_db2gsskrb5
db2 update dbm cfg using AUTHENTICATION SERVER
```

3. On some platforms, the DB2 client may not be able to run due to the Kerberos library conflict between the system and Delinea DirectControl.

   The centrifydc_db2gsskrb5 plugin has to be linked against the one from DirectControl.

   To work around the issue, Delinea recommends that you add the library search path. Please do the modification as below:

   > **Note**: The environment variable name and value for library search path is platform-specific, and the example below is for Linux x86_64.

   For Bourne, Korn and bash shell users, add the following lines to $INSTHOME/sqllib/userprofile:

```
LD_LIBRARY_PATH=/usr/share/centrifydc/lib64:/usr/share/centrifydc/kerberos/lib64:$LD_LIBRARY_PATH
export LD_LIBRARY_PATH
```

   For C shell users, add the following line to $INSTHOME/sqllib/usercshrc:

```
setenv LD_LIBRARY_PATH=/usr/share/centrifydc/lib64:/usr/share/centrifydc/kerberos/lib64:$LD_LIBRARY_PATH
```

This section describes how to test the Authentication Service for IBM DB2 security plug-ins after installation. The test can be performed on the DB2 server or from a computer with DB2 client software installed.

The procedure described below shows how an Active Directory user accesses a DB2 instance. The user joe is the Active Directory user in the same zone as the DB2 computer from which the test is executed. The DB2 database instance name is db2inst1, and sample is the database.

1. Grant the user joe access to select from a table. Log in as the instance user and run the following commands to grant user joe the right to select from the PROJECT table in the sample database:

   ```
   db2 connect to sample
   db2 GRANT SELECT on PROJECT to USER joe
   db2 terminate
   ```

2. After joe logs in, he should set up the environment variables before connecting to the database. From the shell prompt:
   - Set the INSTHOME environment variable to the home directory of the instance user. For example, if you are using Bourne shell or equivalent, type:

     ```
     eval export INSTHOME=~db2inst1
     ```

   - Set up the database environment using the following commands.

     Bourne shell or equivalent:

     ```
     . $INSTHOME/sqllib/db2profile
     ```

     C-shell or equivalent:

     ```
     source $INSTHOME/sqllib/db2cshrc
     ```

   These commands can also be added to joe's login script such as

   .cshrc or .profile

3. Connect to the sample database as joe using the following commands:
   - To test single sign-on, type:

     ```
     db2 connect to sample
     ```

   - To test connecting using user name and password, type:

     ```
     db2 connect to sample user joe
     ```

     You should see output similar to the following:

     ```
     Database Connection Information
     Database server = DB2/Linux 9.0
     SQL authorization ID = JOE
     Local database alias = SAMPLE
     ```

4. Verify that the database is functioning by querying the PROJECT table:

   ```
   db2 select '*' from db2inst1.project
   ```

Perform the uninstallation procedures described in the following sections on each instance from which you want to remove the Authentication Service for IBM DB2 plug-in software. You must perform these procedures before you upgrade to a new Authentication Service for IBM DB2 release, or to remove a partially installed Authentication Service for IBM DB2 release after a failed installation attempt.

The uninstallation procedures are as follows. Unless otherwise noted, each procedure is required.

- **Execute the uninstalldb2.sh Script** on DB2 clients and servers to revert DB2 to the settings that existed before the Authentication Service for IBM DB2 package was installed.
- **Manually Reset DB2 Configuration Variables**. This procedure is optional. In most situations, the uninstalldb2.sh script automatically resets DB2 configuration variables to their default values, or to the values that they had before the Authentication Service for IBM DB2 package was installed.

Execute the uninstalldb2 Script

The uninstallation script /usr/share/centrifydc/bin/uninstalldb2.sh will undo the Authentication Service for IBM DB2 installation and revert DB2 to its previous settings. The uninstalldb2.sh script can be run on a DB2 client and a DB2 server. The following table lists the uninstalldb2.sh options.

inst	Yes	A string value	The name of a DB2 database instance.
verbose	No	0 or 1 The default is 1	If the value is 0, only the basic questions are asked. All 3 Authentication Service for IBM DB2 plug-ins are uninstalled. If the value is 1, the script prompts for different options, such as which plug-ins to remove.
debug	No	0 or 1 The default is 0	If the value is 0, uninstallation is performed. If the value is 1, the script displays the steps without actually performing them. Each command is displayed with a "#" prefix. Use this option to preview what commands are executed in an actual invocation.

Because the inst option is required, you must know the name of the instance from which you are removing the Authentication Service for IBM DB2 plug-in software. The following section describes how to determine the instance name.

Determine the Instance Name

You can determine the instance name in one of these ways:

- By reviewing the DB2 log in this location:

  $INSTHOME/sqllib/db2dump/

- By executing one of the following commands:

On AIX:

```
/opt/IBM/db2/V9.5/instance/db2ilist
/opt/IBM/db2/V9.5/instance/db2ilist
```

On Linux:

```
/opt/ibm/db2/V9.5/instance/db2ilist
/opt/ibm/db2/V9.7/instance/db2ilist
```

Run the uninstalldb2.sh Script

The format for script options is *option= value*. In the following example, db2inst1 is the name of a DB2 database instance, the verbose option is selected, and the debug mode is not invoked:

```
uninstalldb2.sh inst=db2inst1 verbose=1
```

Execute the `uninstalldb2.sh` script now using options that are appropriate for your DB2 server or client.

Manually Reset DB2 Configuration Variables

> **Note**: This procedure is optional, as configuration variables are typically reset by the `uninstalldb2.sh` script.

Perform the procedure described in this section to manually set the DB2 configuration variables back to the values they had before the plug-ins were installed. If you know the original plug-in values, reset them accordingly.

If you do not know the original values, use the following commands to reset the variables to their default values. Run these commands as the instance owner:

```
db2 update dbm cfg using SRVCON_AUTH NOT_SPECIFIED
db2 update dbm cfg using AUTHENTICATION SERVER
db2 update dbm cfg using GROUP_PLUGIN NULL
db2 update dbm cfg using LOCAL_GSSPLUGIN NULL
db2 update dbm cfg using SRVCON_GSSPLUGIN_LIST NULL
db2 update dbm cfg using SRVCON_PW_PLUGIN NULL
```

> **Note**: These commands work for both a DB2 client and a DB2 server.

References

For further information about setting up DB2, see the following documentation:

- Quick Beginnings for DB2 Servers
- DB2 DB2 UDB Security Part 1: Understand how user and group accounts interact with DB2 UDB

This section describes how to adopt a service account and the permission required depends on the option chosen.

In a Kerberized environment, there are times when a service account needs to obtain a Kerberos credential and infinitely renew that credential for a long running process.

Another scenario configuring a clustered environment where a virtual host account needs to provide services using an additional ServicePrincipalName (SPN).

One way to achieve goals such as, but not limited to, the above scenarios, is to use the Delinea command adkeytab to adopt a service account and build a keytab file.

Option 1: Reset the Service Account Password

Let the adkeytab command reset this service account's password while adopting the account. The current password of the service account is not required.

With this option, the account adopting the service account needs to have reset password and change password permission of the service account. For example:

```
adkeytab --adopt -u svcadmin -K /etc/svcacct.keytab svcacct
```

From the example, the account svcadmin is performing the adoption so it must have permission to reset password and change password for the adopted account svcacct. After the adoption, the password of this service account, svcacct, is reset to a randomly generated password.

Option 2: Provide the Existing Service Account Password

Provide this service account's current password with adkeytab command while adopting the account. The current password for this service account is required.

With this option, the account adopting the service account does not need any extra permission; the default read permission is enough. With this option, the -local and -w flags are required to adopt this account. For example:

```
adkeytab --adopt -u svcadmin --local -w password> -K /etc/ svcacct.keytab svcacct
```

where <password> is replaced by account svcacct's current password. After the adoption, the password of this service account is not changed or reset.

See the adkeytab main page for a complete list of options and description.

The *Delinea-enabled PuTTY User's Guide* describes how to install and configure the Delinea-enabled PuTTY program on Windows computers. PuTTY is open-source client software that enables you to open telnet, secure shell, rlogin and raw TCP sessions on remote computers. The PuTTY client available in Server Suite has been modified to support Kerberos-based authentication on remote computers that are managed by Server Suite software.

Intended Audience

This guide is intended for users who want to use the Delinea-enabled PuTTY client to open sessions on remote computers and have their identity authenticated using their Kerberos credentials. This guide assumes that you are familiar with Server Suite components and that you have sufficient privileges to perform administrative tasks on your managed computers.

PuTTY is free open-source software that enables you to connect to remote computers using network protocols such as telnet, ssh, rlogin or raw TCP. The version of PuTTY that is widely available, however, does not support Kerberos authentication. The version of PuTTY that is available in Server Suite has been modified to enable users to be authenticated using their Kerberos credentials before establishing a remote connection.

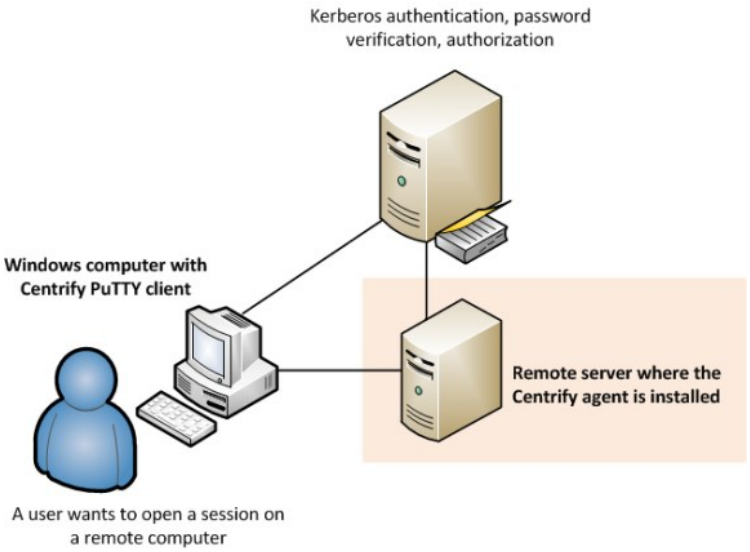
Accessing Remote Server Suite-Managed Computers

You can use the Centrify version of the PuTTY client with any supported protocol and to remotely access any Linux, UNIX, or Windows computer on your network, including computers that are not managed by the Server Suite Agent. However, the most common reason for using the Delinea PuTTY client is to open secure shell (ssh) sessions on remote Server Suite-managed computers. If you have the Server Suite Agent and Centrify OpenSSH installed on a remote computer, you can securely access that computer using your Active Directory credentials and take full advantage of centralized Kerberos authentication and consistent password policies across platforms.

If you use the Delinea PuTTY client to access Server Suite-managed computers through SSH, the Server Suite Agent can determine the UNIX login name to use from the user principal name (UPN) in Active Directory, making it possible for you to connect to any managed computers with a single Active Directory identity.

The Server Suite Agent is also responsible for setting up and managing the Kerberos environment on Server Suite-managed computers. You are not required to configure any DNSto-realm mapping because the agent already knows the relationship between the host computers and their service principal names (SPNs).

Because the Server Suite Agent automatically manages the Kerberos authentication and policy enforcement on Server Suite-managed computers, you can use the Delinea PuTTY client to connect to those computers using a secure and well-established authentication, authorization, and policy enforcement infrastructure.



If you use the Delinea PuTTY client with other protocols or to access remote computers that are not managed by the Server Suite Agent, the program operates in the same way as the standard PuTTY client. You can configure connections for other protocols and set other configuration options as you would for the open-source PuTTY client.

> **Note**: The Delinea PuTTY client is based on PuTTY version 0.64. This version of the Delinea PuTTY client is compatible with the Server Suite Agent, version 4.x and later, and with Centrify OpenSSH, version 4.x, and later.

Installing Delinea PuTTY

The Delinea PuTTY client software is only supported on Windows computers. Before installing, you should verify that you have a supported version of one of the Windows operating system product families. For example, you can use Windows 7 or Windows 8. Alternatively, you can install on computers in the Windows Server product family—such as Windows Server 2008 R2 or Windows Server 2012—if you want your computer to be configured with additional server roles.

For more detailed and most up-to-date information about supported operating system versions, see the Centrify website.

You can install the Delinea PuTTY client by selecting it when you install other Server Suite components or as a standalone executable using its own setup program. If you downloaded the Delinea PuTTY client as a separate software package from the Centrify website, the package includes the standalone setup program for installing the PuTTY client outside of Server Suite.

To install the Delinea PuTTY client from its standalone setup program

1. Double click on the putty-*version*.msi file to start the PuTTY client setup program.

   If another version of the software is installed on the local computer, you are prompted to remove it before you can proceed.

2. On the Welcome page, click **Next**.

3. Select a folder where the software should be installed by accepting the default location or clicking **Browse** to select a different location and specify who can use the PuTTY client on this computer. then click **Next**.

4. On the Confirm installation page, click **Next** to start the installation.

5. If you see a User Account Control warning, click Yes to continue.

6. Click **Finish** upon successful completion of the installation.

In addition to the PuTTY client (putty.exe), the following PuTTY-related programs are installed:

- pageant.exe is a secure shell (ssh) authentication agent for the PuTTY, PSCP, and Plink programs.
- plink.exe is a command-line interface to the PuTTY backend.
- pscp.exe is a command-line secure file copy (SCP) client.
- psftp.exe is a secure file transfer (SFTP) client.
- puttygen.exe is an RSA and DSA key generation utility.
- puttytel.exe is a Telnet-only client.

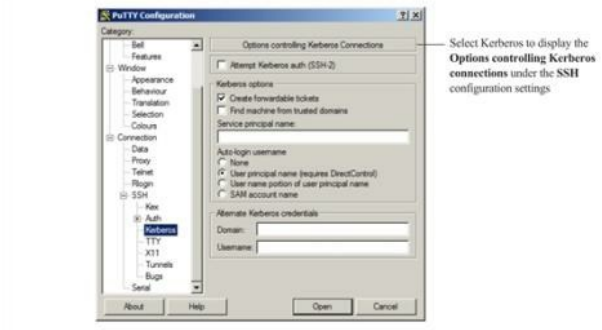
For more information about using these programs, see the official PuTTY documentation. For references to the official PuTTY documentation, see Getting More Information.

Configuring the Delinea PuTTY Client

The Centrify-enabled version of the open-source PuTTY client adds Kerberos authentication for accessing remote computers using secure shell (ssh) network connections. To enable you to configure Kerberos authentication for secure shell sessions, the Delinea PuTTY client adds its own SSH Kerberos configuration page to the standard Windows PuTTY client. All other functionality in the Delinea PuTTY client is the same as in the official PuTTY client, version 0.64.

Starting the Delinea PuTTY Client

After installation, you can start the Delinea PuTTY client from the Start menu or by opening the putty.exe executable in the file location you specified during installation. By default, the **Basic options for your PuTTY session** are displayed. These options are the same in the Delinea PuTTY client as they are in the open-source PuTTY client. For example:

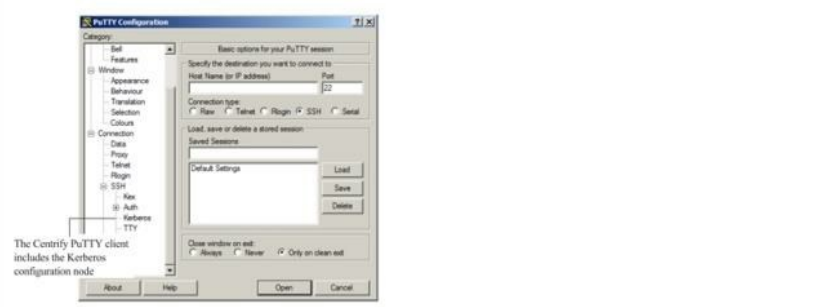


Configuring Kerberos Authentication for Secure Shell Connections

The Kerberos configuration options that have been added to the Centrify version of the PuTTY client are available under the Connection and SSH configuration settings.

To configure Kerberos settings:

1. Expand SSH under the Connection configuration settings. For example:



2. Select **Kerberos** to display the Options for controlling Kerberos connections. For example:

3. Set the appropriate options to configure Kerberos authentication for secure shell remote connections.
    - Select **Attempt Kerberos Auth (SSH-2)** if you want the Delinea PuTTY client to attempt to use Kerberos authentication before any other authentication method when opening a new secure shell session.

      If you do not select this option or select this option and Kerberos authentication fails, the authentication options you have defined in Connection > SSH > Auth are used. The number of times you can type the wrong password before Kerberos authentication fails and other authentication options are used can be configured by group policy settings. For more information about the group policies for configuring Delinea PuTTY, see Configuring Group Policies for Delinea PuTTY.

    - Select **Create forwardable tickets** if you want to allow the same Kerberos credentials used for authentication when connecting to other Kerberos-authenticated services.

      The option is selected by default to enable single sign-on, allowing you to be authenticated silently on other servers without providing a password. If you deselect this option, you are prompted to provide a password any time you connect to another Kerberos-authenticated service.

    - Select **Find machine from trusted domains** if you want the Delinea PuTTY client to look for computers in external trusted domains if it cannot locate a target computer in the local Active Directory forest or a trusted forest.

      If you select this option and the Delinea PuTTY client cannot locate a target computer, the program will attempt an LDAP connection to the domain controller in the trusted domains using your login credentials. The LDAP connection can only succeed if the domain controller is accessible and you have Read access in Active Directory. You can control the LDAP connection setting by using Delinea PuTTY group policies. For more information about the group policies for configuring Delinea PuTTY, see Configuring Group Policies for Delinea PuTTY.

        - Type a specific **Service principal name** if a target computer is in a different forest or if the Delinea PuTTY client cannot access the Kerberos Distribution Center (KDC) for the computer.

- You might have to specify the service principal name if a computer is located in an external trusted domain that is not accessible. For example, if firewall settings prevent the Delinea PuTTY client from making an LDAP connection to the domain controller in the trusted domains, you can explicitly identify the computer by its service principal name.

4. Select an **Auto-login username** option to specify how the Delinea PuTTY client determines the UNIX user account name to use for authentication when opening a secure shell connection.
   - Select **None** if you want to be prompted to specify the user name for Kerberos authentication or if you want to set a default auto-login user name as a Connection > Data configuration option.

     If you select this option, the Delinea PuTTY client does not automatically generate the UNIX user account name.
   - Select **User principal name (requires DirectControl)** if you want the Delinea PuTTY client to use your user principal name (UPN) as the UNIX account name.

     This option requires the Centrify Agent to be installed. With this option, the agent automatically maps the UPN in the Kerberos ticket to the UNIX profile for the Active Directory user name presented in the ticket.
   - Select **User name portion of user principal name** if you want the Delinea PuTTY client to use the user name portion of the UPN as the UNIX user name.

     If you select this option and the UPN is jdoe@xyz.com, the Delinea PuTTY client would use jdoe as the UNIX user name for authentication.
   - Select **SAM account name** if you want the Delinea PuTTY client to look up the sAMAccountName attribute in Active Directory and use it as the UNIX user name.

     If you select this option, the Delinea PuTTY client will initiate an LDAP connection to the currently logged-in domain controller. If the connection or lookup request fails, the Delinea PuTTY client will prompt you to enter the UNIX user name.
5. Type a **Domain** and **Username** if you do not want to use the Kerberos credentials for the account you used to log on to the Windows computer where you are running the Delinea PuTTY client.

   By default, your current Kerberos credentials for your Windows account are used for authentication on the remote computer. If you want to use a different user name and password, specify the domain and user name for the alternate Kerberos credentials you want to use. When the Delinea PuTTY client opens the secure shell session on the remote computer, it will prompt you to provide the password for your alternate credentials.

   The ability to use alternate Kerberos credentials can be configured by group policy settings. For more information about the group policies for configuring Delinea PuTTY, see Configuring Group Policies for Delinea PuTTY.

Saving and Managing Passwords for Remote Sessions

By default, the Kerberos credentials for the Active Directory account you used to log on to the Windows computer are used for authentication on remote computers. If the remote computer is found and authentication is successful, you are not prompted to provide a password.

If you open a secure shell session using alternate Kerberos credentials or the Delinea PuTTY client cannot locate the target computer using the Kerberos credentials you provided, it will prompt you to provide the new credentials.

If you are prompted for a password, you can select **Remember my password** to have your password stored in the Windows credential cache the password so that you are not prompted for again the next time you access the same remote computer. By saving your password or your user name and password in the Windows credential cache, you can have single sign-on (SSO) access to remote UNIX and Linux computers using your Active Directory user credentials.

If the Delinea PuTTY client cannot find the computer you specify using your own or the alternate Kerberos credentials you have specified, you can try other credentials or other configuration options, such as **Find machine from trusted domains**. If the new credentials or configuration options are successful, you can then select Remember my password to access that computer the next time you open a connection to it. After saving your information, you can use single sign-on to access computers in external or untrusted forests or in disjointed domains.

You can manage cached passwords by using the Credential Manager Control Panel or by opening a Command Prompt window and typing control keymgr.dll.

The number of times you can type the wrong password before Kerberos authentication fails and other authentication options are used can be configured by group policy settings. For more information about the group policies for configuring Delinea PuTTY, see Configuring Group Policies for Delinea PuTTY.

Configuring Group Policies for Delinea PuTTY

Centrify provides group policy administrative templates that allow you to centrally manage the configurable PuTTY settings for Kerberos authentication using secure shell connections. The group policy administrative templates are available in both admx and xml file formats.

- The admx template, centrify_putty_settings.admx, is installed by default in the C:\Windows\PolicyDefinitions directory.
- The xml file, centrify_putty_settings.xml, is installed by default in the same directory as the Delinea PuTTY program. For example, if you used the default location in the setup program, the file is located in C:\Program Files (x86)\Centrify\Centrify PuTTY.

To use group policies to configure Delinea PuTTY settings, an administrator must copy either the admx file or the xml file to the appropriate domain controller. If your organization centrally manages Delinea PuTTY settings through these group policies, you do not have to configure them manually for individual secure shell sessions.

By default, all group policies are set to **Not Configured**. Individual policies must be set to **Enabled** to activate a setting. Policies can also be set to **Disabled** to explicitly disable a setting. For details about how policies with Enabled or Disabled settings are inherited or overridden based on where they are applied, see the *Group Policy Guide* and Microsoft documentation for group policies.

Most group policy settings are equivalent to the configuration settings described in Configuring the Delinea PuTTY client. For more information about the opensource PuTTY client configuration settings, see the standard PuTTY documentation. For information about specific group policies, select the group policy, right-click to select **Properties**, then click the **Explain** tab.

Using Other Centrify-Enabled PuTTY Programs

In addition to the main PuTTy client (putty.exe), Centrify has modified the standard versions of the pscp.exe, psftp.exe, and plink.exe programs to support Kerberos authentication.

The modified pscp.exe program supports the following command formats:

```
pscp [options] [user@]host:source target
pscp [options] source [source...] [user@]host:target
pscp [options] -ls [user@]host:filespec
```

The modified psftp.exe program supports the following command formats:

```
psftp [options] [user@]host
```

The modified plink.exe program supports the following command formats:

```
plink [options] [user@]host [command]
```

Many of the PuTTY settings can be provided as options to the command line tools. You can also save command line settings into sessions and load them when executing commands using the –load option. If the settings in a saved session conflict with those specified when invoking the command, the specified options take precedence.

In addition to the standard PuTTY command line options, Delinea PuTTY provides the following options:

-k	Use Kerberos authentication and provide a UNIX user account name during login. This option is equivalent to selecting **Attempt Kerberos auth (SSH-2)** and **None** for the Auto-login username in the Delinea PuTTY Kerberos configuration page.
-K	Use Kerberos authentication and do auto login. This option is equivalent to selecting both **Attempt Kerberos auth (SSH-2**) and the **User principal name (requires DirectControl)** for the Auto-login username in the Delinea PuTTY Kerberos configuration page.
-spn	Specify the service principal name (SPN) of the target computer. This option takes effect only when the –k or –K option is used. This option is equivalent to specifying the computer's service principal name for the **Service principal name** in the Delinea PuTTY Kerberos configuration page.

The other Kerberos settings—such as Create forwardable tickets and Find machine from trusted domains—are not exposed as options to the pscp.exe, psftp.exe and plink.exe programs. You can configure these settings using the Delinea PuTTY client user interface, save them in a session, then load the session using the –load option.

The following example illustrates how to use Delinea PuTTY command line options to facilitate administrative tasks. In this example, the pscp.exe program is used to retrieve the file /etc/group from a remote Linux computer named RedHatLinux with the current user's login name and Kerberos credentials for

authentication on the remote computer:

```
pscp –K RedHatLinux:/etc/group c:\temp
```

Because this command uses the -K option, you don't need to specify a user name in the command line or be prompted for password during runtime. Therefore, the command can be embedded in a batch file for administrative use. However, this command would require the remote RedHatLinux computer to have the Server Suite Agent installed and be joined to an Active Directory domain.

Getting More Information

For more information about the open-source version of PuTTY and standard PuTTY documentation, see the following resources:

- PuTTY website: http://www.chiark.greenend.org.uk/~sgtatham/putty/
- PuTTY documentation: http://www.chiark.greenend.org.uk/~sgtatham/putty/docs.html

Once you have installed and finished setting up your Delinea product and the RSA SecurID authentication agent, you can configure settings so that user authentication can occur for locally defined UNIX users or for Active Directory users who have UNIX profiles in the appropriate zone. In addition, specific groups of Active Directory users can be prompted for password authentication or two factor authentication.

The installation process for each agent does not interfere with or touch any configuration file used by the other product. Follow the standard installation steps for each product.

You can install the products in either order. After the DirectControl agent is installed, you need to join the computer to a domain and place it in a DirectControl Zone.

You can configure the Delinea Authentication Service and RSA SecurID to work together in either of two ways:

- Configure the PAM modules to work with the Authentication Service and RSA SecurID
- Configure SecurID for use with Server Suite zone-based role and privilege execution

If you're using an older version of authentication service or using a version that does not include multi-factor authentication (MFA) support, you can configure the PAM modules to work with authentication service and RSA SecurID. If you've configured role definitions or command rights to require MFA, you can rename a file and create a symlink to configure RSA SecurID to work with your authentication service deployment.

You need to have authentication service installed, with an agent on your UNIX/Linux computer.

You need to also have the RSA SecurID authentication agent installed and configured. This guide shows you how to configure the authentication service to prompt for a SecurID token.

RSA Installation Prerequisites

This guide assumes that you've already installed the RSA SecurID authentication agent. You can get more information about the RSA authentication agent at the following link:

https://www.rsa.com/en-us/products-services/identity-access-management/securid/authentication-agents/authentication-agents-for-pam

Installing the RSA Authentication agent includes but is not limited to the following tasks (consult the RSA documentation for a complete list):

- RSA Secure Console is set up for use
- In the RSA Secure Console, you've added your users, computers, and generated the sdconf.rec file.
- You've successfully installed the RSA authentication agent on your Linux and UNIX computers (this includes installing the sdconf.rec file).
- You've successfully tested the user authentication with the RSA acetest command.

If you have installed the RSA Authentication agent for PAM and successfully performed a test authentication for each user, then you're ready to configure DirectControl to work with the RSA agent and SecurID token.

The installation process for each agent does not interfere with or touch any configuration file used by the other product. Follow the standard installation steps for each product.

You can install the products in either order. After you install the Server Suite Agent, you need to join the computer to Active Directory and place it in a DirectControl Zone.

Installation Overview

To install and configure authentication service and RSA SecurID (an overview):

1. Install the DirectControl agent for *NIX.

   For details, see the Server Suite documentation.

2. Install and set up the RSA SecurID agent.

   For details, see the RSA document, "*RSA Authentication Agent 7.1 for PAM--Installation and Configuration Guide for RHEL*." The document is included in the agent download package.

3. Run the RSA acetest command to verify that the user login credentials work.

   For details, see the RSA documentation.

4. If you have configured role definitions or command rights to require multi-factor authentication (MFA), you create a symlink to point to the RSA SecurID authentication file instead of the file for DirectControl. For details, see Configuring SecurID for use with Server Suite zone-based role and privilege execution.

   With MFA enabled for role definitions or command right definitions, you don't have to manually configure each authentication module to use RSA SecurID.

5. If you use Authentication Service but you don't use role definitions or command right definitions configured for MFA:

   1. Modify the PAM authentication files for Linux, Solaris, or AIX:

      1. For Linux: Configure the /etc/pam.d/system-auth file:

         For details, see Configuring the /etc/pam.d/system-auth File for Linux.

      2. For Solaris and AIX: Configure the pam.conf file:

         For details, see Configuring the pam.conf File for Solaris and AIX.

   2. (Optional) Configure the system to use the SecurID for authentication for specific users or groups.

      Tip: It may be a good idea to disable SecurID authentication for the root user, at least initially, so that you don't get locked out of the computer entirely.

   3. (Optional, as needed) Configure SSH or other authentication services to use SecurID. For details on configuring SSH, see Configuring the pam.conf file for Solaris and AIX.

Configure the /etc/pam.d/system-auth File for Linux

After you've installed both the RSA SecurID and Server Suite Agents on a Linux computer, you'll also need to insert a line in the /etc/pam.d/system.auth file. This change will make it so that the system prompts users for their SecurID token.

Just so that you know, this file will already have some lines at the top that were inserted by the authentication service.

To configure the Linux system authentication file so that users are prompted for the RSA token:

- Add the following line to the beginning of the /etc/pam.d/system.auth file:

  auth required pam_securid.so

  You should restart any services that you plan to use with RSA. For example, if you're using SSH, you should restart the SSH service.

Configure the pam.conf File for Solaris and AIX

For Solaris and AIX computers, you need to edit the /etc/pam.conf file.

To configure the Solaris or AIX system authentication file so that users are prompted for the RSA token:

In the /etc/pam.conf file, add the following code snippet to the end of the file:

```
# Support for Kerberos V5 authentication and example configurations can
# be found in the pam_krb5(5) man page under the "EXAMPLES" section. sshd-kbdint auth required pam_securid.so
sshd-kbdint auth sufficient pam_centrifydc.so unix_cred
sshd-kbdint auth requisite pam_centrifydc.so deny sshd-kbdint account sufficient pam_centrifydc.so unix_cred
sshd-kbdint account requisite pam_centrifydc.so deny
sshd-kbdint session required pam_centrifydc.so
sshd-kbdint password sufficient pam_centrifydc.so ry_first_pass
sshd-kbdint auth requisite pam_authtok_get.so.1
sshd-kbdint auth required pam_dhkeys.so.1
sshd-kbdint auth required pam_unix_cred.so.1
sshd-kbdint auth required pam_unix_auth.so.1
sshd-kbdint account requisite pam_roles.so.1
sshd-kbdint account required pam_unix_account.so.1
sshd-kbdint session required pam_unix_session.so.1
sshd-kbdint password required pam_dhkeys.so.1
sshd-kbdint password requisite pam_authtok_get.so.1
sshd-kbdint password requisite pam_authtok_check.so.1
sshd-kbdint password required pam_authtok_store.so.1
```

You should restart any services that you plan to use with RSA. For example, if you're using SSH, you should restart the SSH service.

Require Token Authentication for Specific Groups or Local Users

RSA supports the ability to require RSA token authentication for specific groups of users. This feature is supported when using the Authentication Service. You can specify Active Directory groups as the required group. Local groups work as well.

You can also configure the agent so that specific groups are not prompted to authenticate with the RSA SecurID token. Group members excluded from SecurID authentication can authenticate using UNIX credentials or by way of another PAM module; you can configure this

Note: The ability to require RSA SecurID token authentication for specific groups does **not** work with AIX. There is a bug in the AIX OS that prevents the SecurID agent from iterating Active Directory groups.

Note: Be sure to exclude any users that you do not want to authenticate with the RSA SecurID token. Once you've enabled users or groups for token authentication, then all users will be challenged for a token even if they weren't assigned on. This situation can cause some users to be locked out of the computer that they're trying to log in to. When you are testing this functionality, it's a good practice to exclude the root user to avoid any complications.

To require SecurID token authentication for specific groups or users:

1. Edit the sd_pam.conf file and add the following lines:

   ```
   #VAR_ACE :: the location where the sdconf.rec, sdstatus.12 and securid files will go
   VAR_ACE=/opt/RSA
   ```

2. To specify specific groups to authenticate using the RSA token, first enable group support by setting the ENABLE_GROUP_SUPPORT parameter to 1, as shown below:

   ```
   #ENABLE_GROUP_SUPPORT :: 1 to enable; 0 to disable group support
   ENABLE_GROUP_SUPPORT=1
   ```

3. To specify the list of groups that will use the RSA token, include them in the LIST_OF_GROUPS parameter, as shown below:

   ```
   #LIST_OF_GROUPS :: a list of groups to include or exclude...Example
   #LIST_OF_GROUPS=other:wheel:eng:othergroupnames
   LIST_OF_GROUPS=sampleadgroup
   ```

4. To exclude groups from requiring the RSA token, include them in the INCL_EXCL_GROUPS parameter, as shown below:

   ```
   #INCL_EXCL_GROUPS :: 1 to always prompt the listed groups for securid
   # authentication (include)
   # :: 0 to never prompt the listed groups for securid
   # authentication (exclude) INCL_EXCL_GROUPS=1
   ```

5. (Optional) To configure what happens when an excluded user tries to authenticate, modify the PAM_IGNORE_SUPPORT parameter, as shown below:

   ```
   #PAM_IGNORE_SUPPORT :: 1 to return PAM_IGNORE if a user is not SecurID
   # authenticated due to their group membership
   # :: 0 to UNIX authenticate a user that is not SecurID
   # authenticated due to their group membership
   PAM_IGNORE_SUPPORT=1
   ```

6. To specify specific users to authenticate using the RSA token, first enable user support by setting the ENABLE_USERS_SUPPORT parameter to 1, as shown below:

   ```
   #ENABLE_USERS_SUPPORT :: 1 to enable; 0 to disable users support
   ENABLE_USERS_SUPPORT=1
   ```

7. To specify the list of users that will use the RSA token, include them in the LIST_OF_USERS parameter, as shown below:

   ```
   #LIST_OF_USERS :: a list of users to include or exclude...Example
   LIST_OF_USERS=localuser1:aduser2
   ```

8. To exclude users from requiring the RSA token, include them in the INCL_EXCL_USERS parameter, as shown below:

   ```
   #INCL_EXCL_USERS :: 1 to always prompt the listed users for securid
   # authentication (include)
   # :: 0 to never prompt the listed users for securid
   # authentication (exclude) INCL_EXCL_USERS=1
   ```

9. (Optional) To configure what happens when an excluded user tries to authenticate, modify the PAM_IGNORE_SUPPORT_FOR_USERS parameter.

You can also consult the RSA SecurID documentation for more details about configuring token authentication for groups, users, excluding users, and so forth. There are more configurations available than are presented in this document.

Configure SSH to Require SecurID

When setting up the SecurID product you must make some configuration changes to the sshd configuration files.

If you are using the Delinea openSSH product you must make some configuration changes to support token authentication. The Delinea openSSH is configured to attempt Kerberos single sign-on whenever a user logs in. This means that the user is not prompted for their user name or password. This capability must be disabled if you want to prompt users for token authentication.

To configure SSH to require a SecurID token:

1. Edit the /etc/centrifydc/ssh/ssh_config file and comment out the lines for the following items:
    - GSSAPIAuthentication
    - GSSAPIKeyExchange
    - GSSAPIDelegateCredentials

    For example:

    # Configuration for DirectControl: Host *
    #GSSAPIAuthentication yes
    #GSSAPIKeyExchange yes
    #GSSAPIDelegateCredentials yes
2. Edit the /etc/centrifydc/ssh/sshd_config file and comment out the lines for the following items:
    - GSSAPIKeyExchange
    - GSSAPIAuthentication
    - GSSAPICleanupCredentials
3. In the /etc/centrifydc/ssh/sshd_config file, be sure that the PrintMotd and UsePam settings are set as followings:

    PrintMotd no
    UsePAM yes
4. Restart sshd to ensure the changes take effect.

For the users that you want to use the SecurID pass code for login, you modify the affected role definitions to require multi-factor authentication. For the commands where you want users to provide a SecurID pass code, you configure the command right for re-authentication using multi-factor authentication.

To configure RSA SecurID for use with Server Suite zone-based role definitions and command rights:

1. In Access Manager, configure your role definitions to use multi-factor authentication:
    1. In Access Manager, locate the role definitions for which you want to require use of the SecurID pass code.

       For example, navigate to your zone, then go to **Authorization** › **Role Definitions**, and then select the rights definition in the right pane.
    2. For each role definition, right-click the role definition and select **Properties**.
    3. Click the **Authentication** tab.
    4. Select **Require multi-factor authentication for login**.
    5. Click **OK** to save the changes.
2. In Access Manager, configure your command rights to use multi-factor authentication:
    1. In Access Manager, locate the command rights definitions for which you want to require use of the SecurID pass code.

       For example, navigate to your zone, then go to **Authorization** › **UNIX Right Definitions** › **Commands**, and then select the rights definition in the right pane.
    2. For each command right, right-click the command right and select **Properties**.
    3. Click the **Attributes** tab.
    4. Select **Re-authenticate current user**.
    5. Select **Require multi-factor authentication**.
    6. Click **OK** to save the changes.
3. Make sure that you've installed the DirectControl agent for *NIX on the UNIX or Linux computer where you want users to use the RSA SecurID pass code.
4. On the Linux or UNIX computer where you want users to use the SecurID pass code, locate the pam_centrifydc_cloud.so file.
5. Rename the pam_centrifydc_cloud.so file.
6. Create a symlink for the pam_centrifydc_cloud.so file to point to the pam_securid.so file instead.

   For the affected users on the affected UNIX or Linux computers, those users will now need to enter their RSA SecurID pass code in order to log in to those computers.

To verify the authentication service and SecurID setup:

1. On the RSA Administration Server, add and configure a UNIX user.
2. Confirm that the local UNIX user can log in using the SecurID token by running the RSA acetest command.
3. In Access Manager, create a UNIX profile for a user in the zone where the UNIX machine is registered.
4. On the RSA Administration Server, register the UNIX profile user and assign them a SecurID token.
5. On the UNIX computer, log in with the new user.

   Tip: Use the UNIX login user name, not the Active Directory user name, when logging in to the UNIX computer.

If you need to disable a user's access to a particular computer, you can do so by one of three ways:

- Disable the user's Active Directory Account.
- Remove the user from the Server Suite Zone.
- Deselect the "Enable user access to this zone" option in the user's Centrify Profile tab.

- For sshd_config, you should explicitly set the following parameter to Yes. Even though the parameter is defaulted to this value, it sometimes is not correctly set. Without this parameter, you will not receive prompts for events like New Pin, and so forth.

  ChallengeResponseAuthentication Yes

- Even though the user authenticates with their SecurID token, they may be prompted to reset their Active Directory password if it has expired in the domain. After the user logs in, they will be presented with the “Change Password” prompts from Active Directory.
- When a user authenticates with a SecurID token, they are granted access to the UNIX machine, but they are not authenticated to the Active Directory Domain. As a result, they will not have Kerberos Credentials or single sign-on capability to other systems. After signing on, the user may type the following and then enter their Active Directory password to authenticate to Active Directory.

  >kinit

Server Suite centrally secures cross-platform data centers through Active Directory-based identity and access management for a wide range of heterogeneous systems, hypervisors and applications.

Built on an integrated architecture that leverages patented technology, the Server Suite of solutions help centralize ID, access privilege delegation and policy management to reduce the organization's IT expense and complexity, improve end-user productivity, strengthen security and enhance regulatory compliance initiatives. Key components of audit and monitoring service include integrated authentication, access control, role-based privilege management, user-level auditing and server protection solutions.

This book describes how to integrate the Samba open source file and print sharing program on a Linux or UNIX computer that has the DirectControl agent already installed.

> **Note**: Beginning in calendar year 2016, Centrify no longer supports the Centrify-enabled version of Samba that was available for use with earlier Server Suite releases. If you are currently using Centrify-enabled Samba with Server Suite 2013.3 or later, you must uninstall Centrify-enabled Samba, install open-source Samba, and install the latest version of the adbindproxy package. Those steps are described in Installing the Centrify Samba integration components. After you perform those steps, Server Suite (2013.3 or later) is integrated with open-source Samba.

Intended Audience

This book is written for an experienced system administrator familiar with the unpacking and installation of programs on Linux or UNIX computers. In addition, the instructions assume that you have a working knowledge of Samba and how to perform common administrative tasks for creating and maintaining Samba shares.

This book also requires you to have a working knowledge of Server Suite and how to perform common administrative tasks using the Access Manager console and the Active Directory Users and Computers administration tool. If you are unfamiliar with Server Suite, see the Administrator's Guide for Linux and UNIX and other documentation.

Using this Guide

The book guides you through the installation and configuration of the components necessary to integrate Server Suite and Samba. It is organized as follows:

- Using Server Suite Technology with Samba provides a brief overview of Samba, and how Samba, Centrify Authentication Service, and Active Directory work together to provide a secure, integrated environment.
- Installing the Centrify Samba Integration Components describes how to unpack and install the Centrify adbindproxy package.
- Migrating Existing Samba Users to Server Suite describes how to migrate your existing Samba users to Active Directory for use with Server Suite.
- Configuring the Samba Integration describes how to use the Samba configuration file and test your integration of Samba, Centrify Authentication Service, and Active Directory.
- Using adbindproxy.pl describes the adbindproxy.pl utility, which enables you to configure Samba for interoperability with Centrify Authentication Service.

Using Server Suite technology with Samba

These topics describe how Samba integrates with Server Suite, and highlights some integration issues that you might encounter.

What is Samba?

Samba is an open source file and printer sharing program that allows a Linux or UNIX host to participate as an Active Directory services domain member. When Samba is installed, Windows users can share files and printers on the Linux or UNIX computers.

Samba.org distributes the Samba files and expects users to download and build their own packages. All major Linux and free UNIX distributions have Samba as a native package. For a native install of Samba on your system, see your distributor's package or port system.

Also, the https://samba.plus web site offers Samba packages for Red Hat Enterprise Linux (RHEL), SuSE Linux Enterprise Server (SLES), and Debian systems. The http://en.opensuse.org/Samba web site offers Samba packages for all SuSE Linux products, including SLES.

What is Server Suite-enabled Samba?

Server Suite-enabled Samba is an adbindproxy module and PERL configuration script that enables Server Suite and Samba to work together without UID, GID, or Active Directory conflicts.

In previous releases, Server Suite would modify the Samba package and provide a unique, Server Suite version of Samba for different operating systems. In this release, Server Suite provides a couple of components that work with the stock Samba packages.

Server Suite is an integrated set of commercial identity management products that enable a Linux, UNIX, or Mac host to participate as an Active Directory domain member. When you install Server Suite products, you can manage the Server Suite-managed computer's user and group accounts and privileges entirely through Active Directory.

When open-source Samba is configured as an Active Directory domain member and the DirectControl agent is installed together with Samba on the same Linux or UNIX host, two problems can arise:

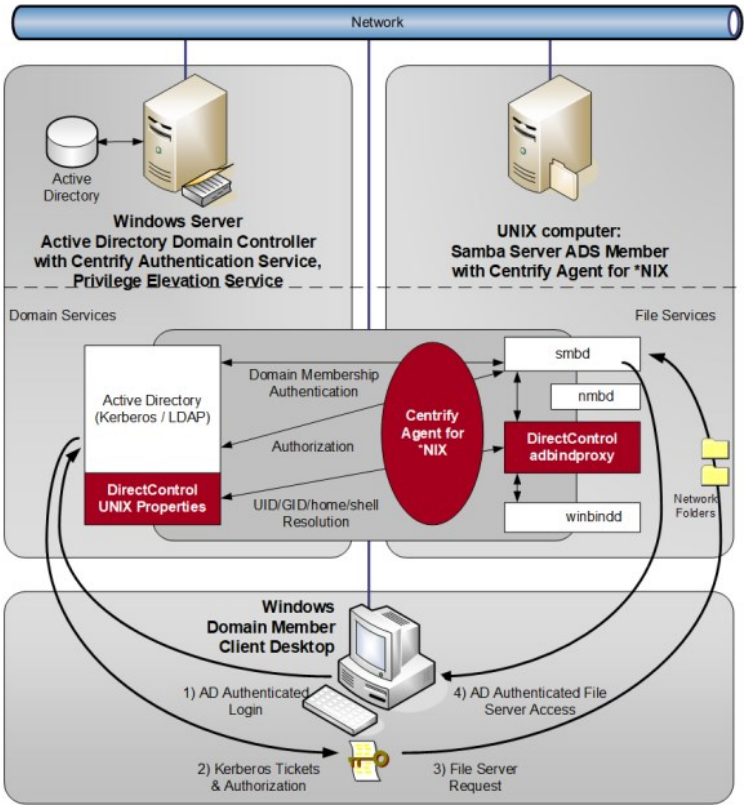
- Samba and the DirectControl agent both attempt to create and manage the same Active Directory computer account object, causing one of the products to stop working.
- Conflicting UIDs and GIDs are generated by Samba and the Server Suite Management Services tools for the same Active Directory users and groups. However, the two programs use different algorithms for generating these values. The result is file ownership conflicts and access control problems.

To resolve these issues, Server Suite provides the following components:

- **adbindproxy (adbindd) module:** The adbindproxy module uses the adbindd daemon. Unless otherwise noted, "adbindproxy" and "adbindd" are used interchangeably in the documentation. The adbindproxy (adbindd) module intercepts Samba UNIX ID mapping requests and reroutes them to the DirectControl agent for processing. This module ensures that Samba and DirectControl agent agree on the UNIX attribute values.
- **adbindproxy.pl PERL configuration script:** Automates most of the setup process and designates the DirectControl agent as the manager of the shared computer object.

Server Suite-Enabled Samba Architecture

The following figure provides a conceptual view of the complete solution architecture using Active Directory, Samba, and Server Suite for Samba components.



If you have not been using Samba up to this point, or if you have been using an older Samba security method (such as user or server), the integration process makes it easy to configure Samba as an Active Directory member.

On the other hand, if you have already been using Samba as an Active Directory domain member and have assigned UIDs and GIDs to Active Directory users and groups, the PERL configuration script helps to resolve conflicts when Samba and Server Suite are integrated.

The integrated solution, composed of the DirectControl agent (installed separately), open-source Samba, and adbindproxy, provides the following:

- Samba and the DirectControl agent use the same Active Directory computer object without conflicts.
- Consistent user and group attributes are applied on files across Windows, Linux and UNIX computers.
- All UNIX user identity attributes, including the UID, GID, home directory, and login shell in UNIX profiles, are centrally stored and managed in Active Directory.
- Both Kerberos and NTLM Samba authentication methods are supported.
- Standard Samba access-control features are implemented and augmented by the Server Suite zones technology.

Installing the Centrify Samba Integration Components

This section explains how to install the Server Suite adbindproxy package. You install the adbindproxy package on your Linux and UNIX computers so that the DirectControl agent works with Samba.

Installation Process Overview

Your Linux or UNIX computer can be in one of three main states regarding Samba and Server Suite:

- New to both Server Suite and Samba:

  Samba is not in use and the computer does not have the DirectControl agent installed. The Samba packages might already be installed but you haven't configured Samba yet. For details, see Installation Overview for Computers New to both Server Suite and Samba.

- Using Samba, new to Server Suite:

  Samba is in use but the computer doesn't have the DirectControl agent installed. For details, see Installation Overview for Computers New to Server Suite.

- Using the previous Centrify-enabled version of Samba:

  Samba is in use and the DirectControl agent is installed, and you're using the previous release of Centrify-enabled Samba. For details, see Upgrade overview for Computers with Centrify-Enabled Samba.

The installation process varies slightly depending on what kind of environment you're currently using.

Installation Overview for Computers New to both Server Suite and Samba

If you're configuring a computer that does not yet have either Samba working nor the DirectControl agent, here's an overview of what you need to do.

Make sure that you have the software you need.	Make sure that you have the latest version of the DirectControl agent, the Centrify adbindproxy package, and the open source Samba files.
Install the DirectControl agent.	Refer to the Server Suite documentation for instructions.
Install open source Samba.	All major UNIX and Linux distributions have Samba as a native package. See your distributor's package or port system for a native install of Samba on your system. You can also visit https://samba.plus/ which offers Samba packages for Red Hat Linux, SUSE Linux Enterprise Server, and Debian.
Install the Server Suite adbindproxy package.	See Installing the adbindproxy Components
Run the adbindproxy.pl script.	See Configuring the Samba Integration
Modify the Samba configuration file, as needed.	See Modifying the Samba smb.conf Configuration File.
Test and verify the configuration.	See Verifying the Samba Integration

Installation Overview for Computers New to Server Suite

If you're configuring a computer that has Samba configured but that does not yet have the DirectControl agent installed, here's an overview of what you need to do.

Make sure that you have the software you need.	Make sure that you have the latest version of the DirectControl agent, the Centrify adbindproxy package, and the open source Samba files.
Install the DirectControl agent.	Refer to the Server Suite documentation for instructions.
Make a backup copy of your smb.conf file.	
Install the Centrify adbindproxy package.	See Installing the adbindproxy Components
Migrate Samba users to Active Directory.	See Migrating Existing Samba Users to Server Suite **Note**: If you're using Auto Zone or Server Suite Express, user migration is not supported.
Run the adbindproxy.pl script.	See Configuring the Samba Integration
Modify the Samba configuration file, as needed.	See Modifying the Samba smb.conf Configuration File.
Test and verify the configuration.	See Verifying the Samba Integration

Upgrade Overview for Computers with Server Suite-Enabled Samba

Beginning in calendar year 2016, we neither provide nor support the Server Suite-enabled version of Samba that was available earlier. Instead, we now provide a standalone adbindproxy package containing the components that are necessary for Server Suite to integrate with open-source Samba.

If you are currently using Server Suite-enabled Samba with Server Suite 2013.3 or later (Server Suite), not only do you need to upgrade to the latest DirectControl agent but there are some additional steps to migrate your users and settings. Below is an overview of what you need to do on each agent-controlled Linux and UNIX computer that was integrated with Samba.

Make sure that you have the software you need.	Make sure that you have the latest version of the DirectControl agent, the Centrify adbindproxy package, and the open source Samba files.
Make a backup copy of your smb.conf file.	
Uninstall Server Suite-enabled Samba.	For example, on most Linux variants you would issue the following command: `rpm -e CentrifyDC-samba`
Upgrade the DirectControl agent so that it's either the latest version or a version later than 2013.3.	Refer to the Server Suite documentation for instructions.
Install open source Samba.	All major UNIX and Linux distributions have Samba as a native package. See your distributor's package or port system for a native install of Samba on your system. You can also visit https://samba.plus/ which offers Samba packages for Red Hat Linux, SUSE Linux Enterprise Server, and Debian.
Install the Server Suite adbindproxy package.	See Installing the adbindproxy Components

Migrate Samba users to Active Directory.	See Migrating Existing Samba Users to Server Suite **Note**: If you're using Auto Zone or Server Suite Express, user migration is not supported.
Run the adbindproxy.pl script.	See Configuring the Samba Integration
Modify the Samba configuration file, as needed.	See Modifying the Samba smb.conf Configuration File.
Test and verify the configuration.	See Verifying the Samba Integration.

What's in the adbindproxy Package

After you download and extract the Centrify adbindproxy package, you'll see the following files: ./Centrify-Adbindproxy-Release-Notes.html ./CentrifyDC-adbindproxy-*release*-rhel5-x86_64.rpm

The software bundle has a name in this format: centrify-adbindproxy-*release*-rhel5-x86_64.rpm and it contains these components:

- **adbindproxy (adbindd) module:** The adbindproxy module uses the adbindd daemon. Unless otherwise noted, adbindproxy and adbindd are used interchangeably in the documentation. The adbindproxy (adbindd) module intercepts Samba UNIX ID mapping requests and reroutes them to the DirectControl agent for processing. This module ensures that Samba and the DirectControl agent agree on the UNIX attribute values.
- **adbindproxy.pl PERL configuration script**: This script automates most of the setup process and designates the DirectControl agent as the manager of the shared computer object.

Installing the adbindproxy Components

Perform the following steps to install the integration components from the adbindproxy package. In these steps, the file name CentrifyDC-adbindproxy-*.rpm is used in place of the full file name. You can use the wildcard symbol (*) to substitute for a portion of the file name if there are no conflicting files in the directory.

> **Note**: If you are upgrading from a previous version of Server Suite-enabled Samba, see Upgrade overview for computers with Centrify-enabled Samba before proceeding.

Be sure to enter the full path name in the command line if multiple versions of the same file exist in the same directory.

To install the Centrify Samba integration components

1. Run the appropriate command for your platform to install the centrifydc-adbindproxy package.

   The following table shows sample commands using the common package installers for each platforms.

Linux-based computers Red Hat Enterprise Linux	For 64-bit systems: rpm -Uvh CentrifyDC-adbindproxy-*release*-rhel5.x86_64.rpm For PowerPC systems: rpm -Uvh CentrifyDC-adbindproxy-*release*-rhel5.ppc64.rpm For Little-endian PowerPC systems (PPCLE): rpm -Uvh CentrifyDC-adbindproxy-*release*-rhel7.ppc64le.rpm
Sun Solaris	On SPARC systems, for example: gunzip centrifydc-adbindproxy-*release*-sol10-sparc-local.tgz tar -xf centrifydc-adbindproxy-*release*-sol10-sparc-local.tar pkgadd -d CentrifyDC-adbindproxy For other Solaris versions and platforms, the commands are the same but the filenames are different. For example, on a 64-bit system: centrifydc-adbindproxy-*release*-sol10-x86-local.tgz
	For HP-UX 11.31 on PA-RISC: gunzip centrifydc-adbindproxy-*release*-hp11.31-pa.depot.gz

HP-UX	swinstall -s /path/centrifydc-adbindproxy-*release*-hp11.31-pa.depot CentrifyDC-adbindproxy For other HP-UX versions and platforms the commands are the same but the file names are different. For example on HP-UX 11.31 Itanium 64-bit systems: centrifydc-adbindproxy-*release*-hp11.31-ia64.depot.gz
IBM AIX	For AIX 7.1 or later: gunzip centrifydc-adbindproxy-*release*-aix7.1-ppc-bff.gz inutoc installp -aY -d centrifydc-adbindproxy-*release*-aix7.1-ppc-bff CentrifyDC.adbindproxy
Debian Linux Ubuntu Linux	Check that you have libcupsys2-gnutls10 (1.1.23-1 or later) installed If you have the required libraries, run the following command to install: dpkg –i centrifydc-adbindproxy-*release*-deb8-x86_64.deb
SuSE Linux OpenSuSE Linux	For 64-bit systems: rpm -ivh CentrifyDC-adbindproxy-*release*-suse11.x86_64.rpm

2. (Optional) Join the computer to a zone using the adjoin command.

   This concludes the installation of the adbindproxy package.

   If you have existing Samba users to migrate, go to Migrating Existing Samba Users to Server Suite. Otherwise, go to Configuring the Samba Integration to continue.

Updating the Samba Files

After you've installed the Server Suite adbindproxy package, you might need to update your version of Samba. When you update the Samba files, the update will replace smb.conf and also restart Samba with its own startup script instead of the adbindd script.

Before you update your version of Samba, it's a good practice to make a backup copy of your smb.conf file.

After you update your version of Samba, perform the following tasks so that you can keep the Server Suite adbindproxy package working.

To keep the Server Suite adbindproxy package working after updating Samba:

- Do one of the following:
  - Run adbindproxy.pl to reconfigure the centrifydc-samba service (Recommended)

    After adbindproxy.pl finishes the setup, you may want to add back the customized settings from the smb.conf backup to the new smb.conf file. Restart the centrifydc-samba service after the change. Note that the commands to restart the service are different on different platforms.
  - Manually replace the smb.conf with the backup.

    After replacing the smb.conf file, restart the centrifydc-samba service. Note that the commands to restart the service are different on different platforms.

    This method may not work because the Samba upgrade may affect the configurations of the centrifydc-samba service and the Samba service itself.

Migrating Existing Samba Users to Server Suite

This section describes how to migrate an existing user population from Samba servers to the integrated Server Suite.

> **Note**: The information in this section is relevant to computers with the core Server Suite components installed and for which you created a Server Suite zone. These instructions do not apply to computers with Server Suite Express installed or computers that are joined through Auto Zone. If you are using Server Suite Express or if you have joined a computer using workstation mode, it is not possible to migrate existing Samba UID and GID settings.

Migrating UNIX Profiles to Active Directory

If your current environment includes Samba servers that are joined to the Active Directory domain as member servers and existing Windows users access the data on those servers, you may want to migrate those existing users to Server Suite to rationalize UIDs and GIDs and manage all of your network's conflicting identities in a single, centralized ID repository.

> **Note**: Migrate your Samba users to Active Directory, as explained in this section, **before** integrating Samba and Authentication Service as explained in Running the adbindproxy.pl Script.

There are two ways to migrate your UNIX profiles to Active Directory:

- If winbind is currently configured in your /etc/nsswitch.conf file, you need to run the getent command to retrieve the user information.
- If you do not have winbind configured in your /etc/nsswitch.conf file, then run the adbindproxy perl script to migrate the users. See the instructions below.

Migrating Users if Winbind is Configured in /etc/nsswitch.conf

To save the winbind information to a file:

1. If winbind is currently configured in your /etc/nsswitch.conf file, run the following commands to save the information to a file before installing the adbindproxy package:

   ```
   getent passwd | grep -v -f /etc/passwd > /tmp/passwd.winbind
   ```

   ```
   getent group | grep -v -f /etc/group > /tmp/group.winbind
   ```

2. Move the exported files to a computer where you have installed the Access Manager console.
3. In the Access Manager console, use the **Import from UNIX** wizard to import the users and groups (with their existing UID and GID mappings) into the zone.

   For more information on importing existing user and group information and mapping information to Active Directory, see the "Importing existing users and groups" chapter in the *Administrator's Guide for Linux and UNIX*.

Migrating Users with the adbindproxy perl Script

If winbind is not currently configured in your /etc/nsswitch.conf file, follow the steps below after you've installed the adbindproxy package.

This script gets the UID andGID files from Samba. You then import them into Active Directory.

To migrate UNIX user profiles to Active Directory using the adbindproxy.pl script:

1. Identify the Samba servers you want to update to integrate with Server Suite.
2. On each of the Samba servers to be updated, locate the winbindd_idmap.tdb file and create a backup copy of the file.
   1. To locate the winbindd_idmap.tdb file, you can run a command similar to the following to view details about the Samba build:

      ```
      /CurrentSambaBInaryPath/smbd -b |grep -i lockdir
      ```

   2. In the output, you should see a line similar to the following that indicates the location of the winbind_idmap.tdb file:

      ```
      LOCKDIR: /var/lib/samba
      ```

3. Make a backup copy of the winbindd_idmap.tdb file.

   For example:

```
cp /var/lib/samba/winbind_idmap.tdb /tmp/winbind_idmap.tdb.pre_adbindproxybackup
```

4. Run the adbindproxy.pl script with the following options to generate the export files.

   ```
   perl /usr/share/centrifydc/bin/adbindproxy.pl --export --groupFile filename --userFile filename --tdbFile filename
   ```

   See Using adbindproxy.pl for details about the command-line parameters for adbindproxy.pl.

   When you run these adbindproxy.pl options it generates export files for the users and the groups that are currently known by the Samba server. By default, these files are created as:

   ```
   /var/centrify/samba/passwd
   ```

   ```
   /var/centrify/samba/group
   ```

5. Move the exported files to a computer where you have installed the Access Manager console.
6. In the Access Manager console, use the **Import from UNIX** wizard to import the users and groups (with their existing UID and GID mappings) into the zone.

   For more information on importing existing user and group information and mapping information to Active Directory, see the "Importing existing users and groups" chapter in the *Administrator's Guide for Linux and UNIX*.

Migrating Samba Servers to Server Suite Zones

Samba generates UIDs and GIDs based on a range of values that have been defined for a specific server. In most cases, a user who has accessed two different Samba servers is likely to have two different UIDs: for example, a user could have UID 6003 on the server mission and UID 9778 on the server dolores.

Therefore, in an initial migration of existing users, each Samba server must join the Active Directory domain in separate Server Suite Zones to accommodate the different UIDs and GIDs users and groups may have.

If you want users to have consistent GIDs and UIDs, then you need to put the Samba servers in the same zone.

Configuring the Samba integration

This section describes how to configure the DirectControl agent and Samba to work together properly after you have installed the integration components from the adbindproxy package and joined agent-controlled computers to a zone.

Running the adbindproxy.pl Script

This section describes how to configure Samba using the adbindproxy.pl script.

> **Note**: If your current environment has Windows users accessing data on Samba member servers that are joined to the Active Directory domain, you may want to migrate those users to Server Suite. This way, you can use Server Suite zones to manage conflicting identities and rationalize UIDs and GIDs. For details on how to migrate those users, see Migrating existing Samba users to Server Suite Complete the migration **before** integrating Samba and the Authentication Service.

The adbindproxy.pl script performs the following tasks:

- Determines the computer's operating system and adjusts accordingly.
- Confirms that the DirectControl agent is installed.
- Confirms that open-source Samba has been installed.
- Determines if you are joined to an Active Directory domain and, if you are, displays the domain name and Server Suite Zone.
- Asks if you want to join Samba to the current Active Directory domain or another. If you choose another, the script guides you through the current domain leave and new domain join processes.

  > **Note**: If you want to modify or set advanced join settings (for example, update PAM or NSS config, use DES for encryption, or use a computer alias), either run adleave before you run adbindproxy.pl or select a different domain when prompted in the script. Otherwise, the script does NOT prompt you to enter advanced join settings.

- If you have a previous Samba installation, asks if you want to keep the smb.conf settings or use new ones. adbindproxy.pl automatically saves the existing copy.

  > **Note**: The script automatically looks for an existing smb.conf file using the smbd -b command. If your current version of smbd does not support the -b option or you have smb.conf in a custom directory the script will not find it. If you want to use your existing smb.conf, move it to /etc/samba before you run the script.

- Removes old state files from previous instances of Samba, including any existing winbind entries from the /etc/nsswitch.conf file.
- Restarts the necessary clients (nmbd, winbindd, adbindd and smbd).
- Installs scripts to automatically start the correct Samba and Server Suite services each time the computer boots.
- Optionally can pass additional options for adjoin and adleave.
- Can generate a response file so that you can run the adbindproxy.pl script without any user interaction.

Before you run adbindproxy.pl, read through the prompts described below to make sure you're prepared with the answers. For example, before you run the script be sure you know the path where Samba is installed.

To begin, log on and switch to the root user and proceed with the following steps:

To run the adbindproxy.pl script

1. To start the script, from root enter the following:

   ```
   perl /usr/share/centrifydc/bin/adbindproxy.pl
   ```

2. Specify the path to the Samba installation:

   1. If Samba is not installed in the default location (/usr), enter the Samba path.
   2. If Samba is installed in /usr, press **Enter** to accept the default. Otherwise, enter your path.

3. Specify the domain to join.

   You proceed based on whether the computer is already joined to a domain or not:

   - If you **are already joined** to a domain when you initiated the script, the script displays the domain name and zone and asks you the following:

     ```
     Do you want to leave or join to another domain? [N]
     ```

To continue to join the current joined Active Directory domain press Enter and skip ahead to Step 6.

If you want to leave the current domain and join another OR change any advanced options (see the list below) in your current domain enter Y and then continue to Step 4.

- If you **are not joined** to a domain, the script displays the following message:

  ```
  Not joined to any domain. Make sure you enter the correct domain and zone information in the next steps
  ```

  This initiates a set of prompts that ask you for the Active Directory domain name, the Centrify Zone and advanced options.

  Continue to Step 4.

4. Join the new Active Directory domain.

   You arrive at this step if you are not joined to an Active Directory Domain when you started adbindproxy.pl or if you decided to leave that domain OR you decided to change advanced options in your current join. If none of these conditions apply to you, skip to Step 6.

   1. At this prompt, enter the domain name:

      ```
      Enter the Active Directory domain to join:
      ```

   2. At the DNS health prompt, press **Enter** to verify that the domain exists.

      ```
      Check DNS health for [domain]? Note: this may take several minutes [Y]:
      ```

   3. At the next prompt, enter the following domain properties:

      Note: If you are running Server Suite in Express Mode or need to join the domain through Auto Zone, enter NULL_AUTO for the zone name.

      1. Server Suite zone on the target Active Directory domain
      2. Computer name on which the adbindproxy package is installed
      3. Active Directory authorized user (default is Administrator)

5. (Optional) Specify advanced join options.

   The script prompts you with the following message:

   ```
   Do you wish to specify advanced join options? [N]:
   ```

   The options are listed below. The defaults are in brackets.

   1. If do not need any advanced join options, enter N. Otherwise, enter Y and make your selections.

      ```
      Canonical name of Active Directory Computer Container
      Preferred Domain Server to use (press Enter for none)
      Update PAM and NSS Config [Y]
      Trust computer for delegation? [N]
      Use DES encryption only? [N]
      Run adjoin in verbose mode? [N]
      Addition computer alias (press Enter for none)
      ```

      The script then displays the selections you made and asks if you want to proceed.

   2. Enter Y to proceed or N to abort adbindproxy.pl.

      If you were not joined to an Active Directory domain when you started the script, you are prompted to enter your password once.

   3. Enter the password for the Active Directory Domain, computer and authorized user specified in the prompts.

      Note: If you choose to proceed **AND** you are leaving the current Active Directory domain to join another, the script prompts you **twice** to enter your password.

   4. In response to the first prompt, enter the current Active Directory domain account password to leave that domain.

   5. In response to the second prompt, enter the password for the Active Directory Domain, computer and authorized user specified in the prompts to join the new domain.

6. Enter the Samba winbindd path.

   At the next prompt, if the samba winbindd listen path is not in /run/samba/winbindd, enter the path or press **Enter** to accept the default.

7. If there is an existing smb.conf file, continue to Step 8.

   Otherwise, if there is no existing smb.conf file (which is true for new installations of Samba), the adbindproxy script searches for existing smb.conf files. If it **does not** find an existing smb.conf file, it automatically creates a new one, stores it in /etc/samba, and displays the following message:

   ```
   Updating smb.conf with recommended settings ...
   ```

   and finishes the script.

   This new smb.conf file has minimal global settings and a samba-test share.

   > **Note**: Regardless of whether you update an existing smb.conf or create a new one, you will need to modify the /etc/samba/smb.conf file to have the [global] section settings and the appropriate shares for your environment. See Modifying the Samba smb.conf configuration file for instructions. The file created by adbindproxy.pl should be used for verifying the Samba integration only.

If you do have at least one existing smb.conf file, continue to Step 8.

8. Specify existing or new smb.conf settings:

   If you have an existing smb.conf file, you next specify whether to update the settings in the existing smb.conf file or create a new, skeletal smb.conf file. If you choose to use the existing settings, you can also choose to do a backup of the existing smb.conf file.

   If the script **does** find an existing smb.conf file, the script copies the smb.conf file to /etc/samba and asks the following question:

   ```
   Do you want to keep the original samba settings? [Y]:
   ```

   > **Note**: If the script finds more than one smb.conf, it displays the list and asks you to select one. After you make the selection, it copies that one to /etc/samba and continues.

   > **Note**: Regardless of whether you update an existing smb.conf or create a new one, you will need to modify the /etc/samba/smb.conf file to have the [global] section settings and the appropriate shares for your environment. See Modifying the Samba smb.conf configuration file for instructions. The file created by adbindproxy.pl should be used for verifying the Samba integration only.

- **Don't keep the original Samba settings**: Enter N to not keep the original Samba settings and instead create the new, basic smb.conf.

  The script creates a backup copy of your smb.conf in /etc/samba. The backup filename is in this format: smb.conf.yyyy-mm-dd-hh-mm. This new smb.conf file has minimal global settings and a samba-test share, if no shares exist.

  Continue to Finishing Up.

- **Keep the original Samba settings**: Enter Y to modify the existing file and continue to Step 9.

9. If you've chosen to keep the original Samba settings, the script displays the following prompt about backing up the existing settings:

   ```
   Backup existing /etc/samba/smb.conf and add recommended settings? [Y]
   ```

   - Enter Y to create a backup in the form, smb.conf.yyyy-mm-dd-hh-mm.
   - Enter N to use the existing smb.conf without making a backup.

     > **Note**: If the existing smb.conf has Security = ADS and the workgroup and realm are set, the script does NOT modify the existing file; the original is left unchanged.

10. For ubuntu and Suse computers where AppArmor exists, the script displays the following prompt about updating the AppArmor policy profiles:

    ```
    Update AppArmor policy profiles? [Y]
    ```

    Use the default [Y], unless you don't want to update the AppArmor profiles now.

    If you don't update the AppArmor profiles now, be sure to update them manually later. Otherwise, winbindd might fail to start and you won't be able to access the samba share. For ubuntu systems, the profiles aren't updated because the winbind policy profile doesn't exist.

11. If you're configuring a Linux system that has SELinux enabled and Samba supports your system's version of samba_selinux, the script checks the

configurations and, if needed, displays the following prompt:

```
Update SELinux policy to allow r/w on non samba_share_t types? [Y]
```

Use the default [Y] unless you have labeled all the share folders with the type samba_share_t.

If you don't update the SELinux policy, Samba cannot read or write to the shared folder is not labeled with the samba_share_t type.

For more information about samba_selinux, see the samba_selinux man page.

12. If you've chosen to keep the original Samba settings, the script displays the following prompt about resetting the Samba cache for user and group IDs.

    ```
    Reset the Samba User/Group ID Cache (Server Suite Samba may create conflicting mappings) [Y]
    ```

    Unless you have created custom mappings, use the default [Y]. This flushes the cache and displays the following message:

    ```
    This prompt is only pertinent to the small set of Samba administrators who created custom user and group ID mappings. If you do have custom mappings, use the default to flush the cache and prevent potential conflicts. After adbindproxy.pl completes, re-add your mappings as necessary.
    ```

    If you entered Y, the script creates new mappings in the Samba User/Group ID cache, which may result in conflicts if there are any mappings in place already.

Finishing Up

To complete the configuration, adbindproxy.pl stops any running versions of smbd, adbindd, winbindd and nmbd, starts the required Server Suite processes, and displays a set of progress and configuration messages. You should see the following messages:

```
Init Samba start script ...
Restarting Samba daemons ...
Reloading systemd: [ OK ]
Restarting centrifydc-samba (via systemctl): [ OK ]
Current DirectControl Configuration:
...
Current Samba Configuration:
...
```

The adbindproxy script displays the following:

```
Press ENTER to continue ...
Notes: If you need to join another domain, please re-run this script and enter the new domain name!
Done.
```

Note: If any service fails to start, you should run one of the following after the adbindproxy.pl script completes its execution.

On Linux or Solaris computers, run:

```
/etc/init.d/centrifydc-samba restart
```

On HP-UX computers, run:

```
/sbin/init.d/centrifydc-samba restart
```

On AIX computers, run:

```
stopsrc -g samba && startsrc -g samba
```

On Linux computers that support systemd, run:

```
systemctl restart centrifydc-samba
```

As a quick test, log off as the root user and log on with an Active Directory user account that has been granted access to the local computer's zone. If this is the first time that you are logging on with this user account, check that the user's home directory is created, which is created automatically by the Authentication Service the first time you log on.

Verifying the Samba Integration

To verify that Samba and Server Suite are working together correctly, you test if you can access Samba shares. If you upgraded existing shares, then you can test those; otherwise, you can verify the connection using the test share.

There are two key scenarios for testing whether Samba is configured properly for integration with the Authentication Service and Active Directory:

- Accessing Samba from a UNIX Client Session
- Accessing Samba Shares from a Windows Desktop

Accessing Samba from a UNIX Client Session

To test access to Samba shares on a Linux or UNIX computer, users should do the following:

To access Samba from a UNIX client session:

1. Log on to the Linux or UNIX computer using the Active Directory account that has been granted access to the local computer's zone.
2. Run the following command:

   ```
   smbclient -k -L host_name
   ```

   The smbclient program displays information about Samba and the SMB shares that are available on the local computer. For example, you should see a listing similar to the following (where s.s.s is the Samba version):

```
OS=[Unix] Server=[Samba s.s.s]

 Sharename Type Comment
 --------- ---- -------
 samba-test Disk
 IPC\$ IPC IPC Service (Samba-CDC)
 sara Disk Home directories

OS=[Unix] Server=[Samba s.s.s]

 Server Comment
 --------- -------
 Workgroup Master
 -------- -------
 ARCADE MAGNOLIA
```

If you are able to see the Samba shares as an Active Directory user logged on to the Linux or UNIX computer that is acting as the Samba server, you should next test accessing the Samba shares from a Windows desktop. For information about performing this test, see Accessing Samba shares from a Windows desktop.

Purging and Reissuing Kerberos Tickets on UNIX Computers

If you see an error such as NT_STATUS_LOGIN_FAILURE instead of the expected results when you run the smbclient program, you may need to purge your existing Kerberos tickets and have them reissued. Try running the following command to remove all of your Kerberos tickets:

```
/usr/share/centrifydc/kerberos/bin/kdestroy
```

Then run the following command to reissue tickets after you provide your Active Directory password:

```
/usr/share/centrifydc/kerberos/bin/kinit
```

You can then run the following command to list the Kerberos tickets that have been issued to you:

```
/usr/share/centrifydc/kerberos/bin/klist
```

After verifying the Kerberos tickets you have been issued, try running the smbclient program again.

Verifying the Version of Samba You Are Using

If purging and reissuing tickets does not resolve the problem, confirm the version of the smbstatus that is currently running using the following command:

```
smbstatus | grep version
```

The command should display the Samba version you have installed. For example:

Samba version s.s.s

(where s.s.s is the installed Samba version)

If the correct version of Samba is installed, run smbstatus again and note the names of any *.tdb files that do not exist, and try restoring them from your backup, then try running the smbclient program again.

If You Don't See the Correct Samba Shares

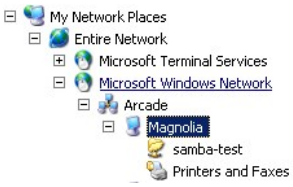
If the smbclient program does not display the Samba shares you have defined in the configuration file, you should review the settings in the smb.conf file and then restart the DirectControl agent and run the adflush command.

Accessing Samba Shares from a Windows Desktop

To test access to Samba shares on a Linux or UNIX computer from a Windows desktop:

1. Log on to a Windows computer that is joined to the domain with an Active Directory user account.
2. Click **Start › Windows Explorer**, then navigate to the domain.

   For example, open **My Network Places › Entire Network › Microsoft Windows Network › Arcade** to view the Arcade.net domain.
3. Select the Linux or UNIX computer that is integrated with Samba to view its Samba shares. For example:



4. Click samba-test or browse other available Samba shares to verify that you can open existing files and create new files.
5. Confirm from both Windows and the managed computer that the files in the share directories are owned by the correct users.

If you cannot browse the shares on the Linux or UNIX computer from the Windows desktop, you should:

- Verify that there is network connectivity between the two systems.
- Confirm that you do not have a firewall running on the managed computer that is blocking access to the SMB ports.
- Make sure there are no stale Kerberos tickets on your Windows system. The tools to remove stale Kerberos tickets may already be installed on your system—see this site for more information about klist and kerbtray programs.

Modifying the Samba smb.conf Configuration File

The Samba configuration file, /etc/samba/smb.conf, defines important parameters for Samba-based file sharing. After you have verified the Samba integration with the Authentication Service and Active Directory using a sample configuration file and the test share, you need to modify the smb.conf file so that it accurately represents your environment.

This smb.conf file must include the [global] section that defines the Active Directory domain, authentication methods, and other parameters. The file should also include a section for each directory you are making accessible as a SMB share.

At the beginning of a line, both the hash symbol (#) and the semi-colon (;) indicate lines to ignore. By convention, in this file, the hash indicates a comment and the semi-colon indicates a parameter you may wish to enable.

If you specify multiple users in valid users, user names can be separated by a comma or by white space.

The settings in the [global] section are required whether you use the sample configuration file or create your own smb.conf file. The settings in the [homes] section indicate that you want to share home directories, and the [samba-test] section describes the samba-test share as a publicly-writable share mapped to the /samba-test directory. For more information about editing the Samba configuration file and the supported parameters, see the Samba documentation.

A sample Samba smb.conf Configuration File

The adbindproxy script tests to determine what operating system is running on the host and generates an smb.conf file appropriate to that platform.

In the following sample file, it runs on a CentOS computer in the arcade.net domain and the Samba share is called MyShare.

```
#
# This file was generated by ADBindProxy Utility
#
[global]
    security = ADS
    realm = ARCADE.NET
    workgroup = ARCADE
    netbios name = centos-6
    auth methods = guest, sam, winbind, ntdomain
    machine password timeout = 0
    passdb backend = tdbsam:/var/lib/samba/private/passdb.tdb
    #
    # Samba versions 3.4.0 and newer have replaced "use kerberos keytab"
    # with "kerberos method".  The directive "kerberos method = secrets and keytab"
    # enables Samba to honor service tickets that are still valid but were
    # created before the Samba server's password was changed.
    #
    kerberos method = secrets and keytab
    #
    # Setting "client use spnego principal" to true instructs SMB client to
    # trust the service principal name returned by the SMB server. Otherwise,
    # client cannot be authenticated via Kerberos by the server in a different
    # domain even though the two domains are mutually trusted.
    #
   #  client use spnego principal = true
    #
    # Setting send spnego principal to yes .
    # Otherwise, it will not send this principal between Samba and Windows 2008
    #
   #  send spnego principal = Yes
    # If your Samba server only serves to Windows systems, try server signing = mandatory.
    server signing = auto
    client ntlmv2 auth = yes
    client use spnego = yes
    template shell = /bin/bash
    winbind use default domain = Yes
    winbind enum users = No
    winbind enum groups = No
    winbind nested groups = Yes
    idmap cache time = 0
   #  ignore syssetgroups error = No
    idmap config * : backend  = tdb
    idmap config * : range = 1000 - 200000000
    idmap config * : base_tdb = 0
    enable core files = false
    #  Disable Logging to syslog, and only write log to Samba standard log files.
    #syslog = 0
[samba-test]
    path = /samba-test
    public = yes
    #  if set  public = No, we should  set parameter valid users .
    #  and when the user or group is in AD , the setting syntaxes is:
    #  valid users = CPUBS\username +CPUBS\group
```

```
   writable = yes
[MyShare]
  path = /samba-test
  browsable = yes
  writable = yes
  guest ok = yes
  read only = no
[homes]
   comment = Home directories
   read only = No
   browseable = No
```

SMB.conf File Variations for Different Platforms

Some platforms will have slight variations in the smb.conf file, as follows:

- On HP-UX computers, the following line is added:

  ```
  guest account = smbnull
  ```

- On SuSE computers, the following lines are added:

```
# Suse 11 CUPS printing appears to crash at start up
# So we disable printing on this platform for now
printing = BSD
```

- On AIX computers, the following comments are added:

```
#
# On AIX, the service NMBD may fail to start because Samba
# cannot determine the correct IP subnet mask.
# In this case, you can manually specify the correct subnet mask.
# For example if you have the following configuration:
#
# Interface     = eth0
# IP Address    = 192.168.97.199
# Subnet mask   = 255.255.252.0
#
# then set the interfaces keyword as follows:
#
# interfaces = eth0 192.168.97.199/255.255.252.0
#
```

Testing Changes to the smb.conf File

When you make changes to the smb.conf file, you should run the Samba utility `testparm` to make sure there are no errors in your smb.conf file before putting it into production use. When you run the `testparm` utility, you should see output similar to the following:

```
Load smb config files from /etc/samba/smb.conf
Processing section "[homes]"
Processing section "[printers]"
Processing section "[samba-test]"
Loaded services file OK.
Server role: ROLE_DOMAIN_MEMBER
Press enter to see a dump of your service definitions

[global]
 workgroup = ARCADE
 realm = ARCADE.NET
   security = ADS
 auth methods = guest, sam, winbind, ntdomain
 passdb backend = tdbsam:/etc/samba/private/passdb.tdb
 syslog = 0
 enable core files = No
 server signing = auto
 machine password timeout = 0
 adbindproxy backend = cdc:/usr/share/centrifydc/lib/libcapi.so
 adbindproxy standard mappers = No
 template shell = /bin/bash
 winbind use default domain = Yes

[homes]
 comment = Home Directories
 read only = No
 browseable = No

[printers]
 comment = All Printers
 path = /usr/spool/samba
 printable = Yes
```

```
 browseable = No

[samba-test]
 path = /samba-test
 read only = No
 guest ok = Yes
```

Using adbindproxy.pl

This section describes the options available for the adbindproxy command-line tool. The adbindproxy.pl utility is used to configure Samba and Authentication Service to work together and provides specific functions, such as exporting UIDs and GIDs, creating symbolic links to Samba binaries and libraries, and restoring backed-up Samba files.

> **Note**: For step-by-step instructions about running adbindproxy.pl to configure Samba and the Authentication Service to work together, see Running the adbindproxy.pl Script.

Synopsis

```
adbindproxy.pl [--help] [--info] [--restore] [--unconfig] [--adjoinExtraOptions] [--adleaveExtraOptions] [--version] [--verbose]
adbindproxy.pl [--export] [--groupFile filename] [--userFile filename] [--tdbfile filename]
adbindproxy.pl [--record] [--responseFile filename]
adbindproxy.pl [--nonInteractive] [--responseFile filename]
adbindproxy.pl [--service start|stop|restart|status]
```

adbindroxy.pl Options

You can use the following options with this command:

-c --test filename	Generate a test target Samba configuration file. With this option, the script generates a target Samba configuration file with the filename for review. This option is a review option and does not change any configuration or make any changes.
-E, --export	Export user IDs (UIDs) and group IDs (GIDs) that are stored in Samba's winbindd_idmap.tdb file. Use the--groupFile and --userFile options to specify the export files for the GIDs and UIDs. Use the --tdbfile option to specify the .tdb file that contains the GIDs and UIDs. After export, you can use the Access Manager Console to import the users and groups with their existing UID and GID mappings into a zone.
-f, --responseFile filename	The filename specifies the response file for recording with the -x option or for non-interactive mode with the -n option. If you don't specify a filename, the default is /var/centrify/samba/adbindproxy.pl.rsp.
-g, --groupFile filename	Specify the file in which to write the Samba-created Active Directory group to GID mappings. Use this option with the export option. By default, the file is: /etc/group
-h, --help	Display the adbindproxy.pl usage information.
-i, --info	Display Samba interoperability information.
-j, --adjoinExtraOptions adjoinoptions	The adjoinoptions are the additional options to be used for the adjoin command. Do not specify the domain or the following options with adjoinExtraOptions, because they're already handled in the response file: -u / --user -c / --container -V / --verbose -n / --name -s / --server -T / --trust -k / --des -z / --zone -a / --alias
	The adleaveoptions are the additional options to be used for the adleave command.

-l, --adleaveExtraOptions adleaveoptions	Do not specify the domain or the following options with adleaveExtraOptions, because they're already handled in the response file: -u / --user -f / --force
-n, --nonInteractive	Run adbindproxy.pl in non-interactive mode using the response file. It is recommended to have the machine joined to the Active Directory domain before running this script in non-interactive mode. Otherwise, adbindproxy.pl needs to obtain the Active Directory authorized user password from the command line with the -j/-l option, or interactively from the terminal. **WARNING**: Typing the password in the command line NOT secure, do NOT do that unless you know what you are doing.
-r, --restore	Restore files backed up from the first time you configured Samba for interoperability with the Authentication Service. Typically, you run adbindproxy.pl with the restore option to restore Samba files before uninstalling the integration components that were provided in adbindproxy.
-S, --symbol	Force the creation of symbolic links to Server Suite for Samba binaries and libraries without asking for confirmation.
--s, --service <start|stop|restart|status>	Control the CentrifyDC Samba service. If you haven't configured the CentrifyDC Samba service yet, this option has no effect. If you specify --service status, there will be a return value of 0 if the service is running and a return value of 1 if the service isn't running.
-T, --noTestShare	Specify to not create the test folder "/samba-test" and not add the "samba-test" share when updating the smb.conf file.
-t, --tdbFile filename	Specify the location of the winbindd_idmap.tdb file that contains Samba UID and GID information. This option is used during the UID and GID export process. If you omit this option, the default file to export from is: /var/lib/samba/winbindd_idmap.tdb
-u, --userFile filename	Specify the file in which to write Samba-created Active Directory user to UID mappings. Use this option with the -exports option. By default, the file is /etc/passwd.
-v, --version	Display version information for the installed software.
-V, --verbose	Display detailed information for each operation.
-x, --record	Record the user input into the response file which can be used later in non-interactive mode.

Examples

To display basic information about the configuration of the Samba integration and interoperability with authentication service and Active Directory, you could type a command line similar to the following:

```
adbindproxy.pl --info
```

This command displays information similar to the following (where v.v.v is the Server Suite version number and s.s.s is the Samba number):

```
The Samba base path is: /usr
CentrifyDC version = CentrifyDC v.v.v
CentrifyDC Architecture = 64-bit
CentrifyDC Realm = ARCADE.NET
CentrifyDC NTLM Domain = ARCADE
CentrifyDC Host = magnolia.arcade.net
CentrifyDC Short Host = magnolia

Samba Version = s.s.s
Samba Architecture = 64-bit
Samba Realm = ARCADE.NET
Samba NetBIOS Name = MAGNOLIA
```

```
Samba Version Supported = yes
Samba and CDC in same Realm = yes
Samba and CDC share machine account = yes
Password sync using libtdb = <not specified>
```

To export existing Samba GID and UID information that you want to import into a Server Suite Zone, and to show details about the operation performed, type a command line similar to the following:

```
adbindproxy.pl --export --verbose
```

This command displays information similar to the following:

```
The existing UID mappings have been exported to
/var/centrify/samba/passwd.

The existing GID mappings have been exported to
/var/centrify/samba/group.
```

To record the user input to a response file:

```
# adbindproxy.pl -x
```

To run adbindproxy.pl in non-interactive mode with the response file that was generated previously at the default location:

```
# adbindproxy.pl -n
```

Developer Tools

- Adedit Command Reference and Scripting Guide
- PowerShell Scripting
- Windows API

This guide describes ADEdit for UNIX administrators who want to manage Server Suite and Active Directory from a Linux, UNIX, or Mac computer through CLI commands or scripts. It assumes that you are well-versed in Active Directory's architecture and management, and that you're equally well-versed in Server Suite access control and privilege management features. For more complete information about Server Suite software and management tasks, see the *Administrator's Guide for Linux and UNIX*.

This *ADEdit Command Reference and Scripting Guide* describes how to use the DelineaADEdit command-line interface to manage Delineaobjects stored in Microsoft Active Directory. ADEdit is a Tool command language (Tcl) application that enables administrators to run commands and write scripts that modify data in Active Directory directly from their Linux or UNIX console.

Intended Audience

This guide describes ADEdit for UNIX administrators who want to manage Delineaand Active Directory from a Linux, UNIX, or Mac computer through CLI commands or scripts. It assumes that you are well-versed in Active Directory's architecture and management, and that you're equally well-versed in Delineaaccess control and privilege management features. For more complete information about Delineasoftware and management tasks, see the *Administrator's Guide for Linux and UNIX*.

Using this Guide

This guide describes how to use ADEdit and provide reference information for all ADEdit commands and the ADEdit library. It does not describe how to write Tcl scripts using ADEdit commands. For a comprehensive explanation of Tcl and its use, see *Tcl and the Tk Toolkit* by John K. Ousterhout and Ken Jones (published by Addison-Wesley).

The chapters provide the following information:

- Getting Started with ADEdit describes the basics of ADEdit command syntax and the logical flow of commands that you need to be familiar with before you begin executing interactive ADEdit sessions or writing ADEdit scripts.
- ADEdit Commands Organized by Type assembles the ADEdit commands into logical groups, corresponding to their usage, and summarizes each command.
- Using the Demonstration Scripts provides script samples for a series of common tasks that you can incorporate into your scripts.
- ADEdit Command Reference provides full command descriptions in alphabetical order.
- ADEdit Tcl Procedure Library Reference describes the Tcl procedures available in the ade_lib Tcl library that use ADEdit commands to perform common administrative tasks.
- Timebox Value Format describes the format of the timebox value used to set hours of the week when a role is enabled and disabled.
- Using ADEdit with Classic Zones summarizes the differences between working with classic and hierarchical zone and lists the commands that are specifically for managing authorization in classic zones.
- Quick Reference for Commands and Library Procedures provides a summary of all ADEdit commands and procedures, including the command syntax and abbreviations.

Viewing Command Help

ADEdit provides brief help text for each command. To view the help, enter help command_name from the ADEdit command prompt. For example, to see the help for the validate_license command you would enter the following:

```
>help validate_license
```

You can also display the general help text for ADEdit by entering man adedit from the shell.

Introduction

Centrify ADEdit is a command-line interface (CLI) utility that enables UNIX administrators to manage Centrify objects—such as zones, rights, and roles—in Microsoft Active Directory. This chapter introduces you to ADEdit's main features and architecture.

How ADEdit uses Tcl

ADEdit is implemented as a Tcl application. Tcl (Tool Command Language) is a powerful but easy to learn programming language that provides full scripting ability. With Tcl, administrators can write simple management scripts that perform complex tasks with a single execution. Experienced Tcl programmers can also include ADEdit commands in their own Tcl applications to add Centrify management capabilities and GUI interfaces for ADEdit operations to those applications.

Administrators who aren't familiar with Tcl can use ADEdit as a scripting tool on their Linux or UNIX computer to manage Centrify directly from the command line or by combining commands into scripts.

What ADEdit Provides

The purpose of ADEdit is to let an administrator with the proper Active Directory permissions fully manage Centrify objects from a UNIX console. By using ADEdit, for example, an administrator working on a Linux computer can perform common administrative tasks such as create a new user account, add a user to a new group, or assign a user to a new role. That same administrator might also query Active Directory for information about zones, groups, roles, or any other Centrify objects.

Because ADEdit is a more powerful and flexible tool, it is intended to replace some of Centrify's previous-generation UNIX command line programs such as adupdate and adquery. Those previous-generation tools limited the operations administrators could perform to a computer's currently joined zone and domain. With ADEdit, administrators can manage objects in any zone or domain and perform operations on many more features than were possible using its predecessors.

To give administrators additional flexibility for performing administrative tasks, ADEdit also allows for multiple modes of execution and provides its own accompanying library of predefined scripts for common tasks.

Administration Across Domains and Forests

ADEdit offers complete control of Centrify objects and properties from a Linux or UNIX console. Administrators with the proper permissions on the Active Directory domain controller can modify every aspect of operation that the Access Manager offers. For example, administrators can use ADEdit to create zones, add groups, delegate permissions, define roles, and modify user properties, group membership and role assignments.

ADEdit can operate on any domain in any forest. Its host computer does not need to be joined to a domain to work with that domain. As long as the administrator has the necessary authentication and rights to work on a domain, ADEdit can bind to the domain and work on it. ADEdit can also work simultaneously on multiple domains in multiple forests.

ADEdit enables you to manage all aspects of the access control and privilege management features of multiple Centrify software from a single CLI tool. For example, it can replace adupdate and adquery and offers the features of LDAP clients such as ldapsearch, without the limitations of those command line programs.

Options for Execution

ADEdit offers multiple modes of execution:

- **Interactive mode**. In interactive mode, ADEdit executes single CLI commands in real time. You can enter a series of commands within a shell to perform simple administrative tasks. ADEdit offers command history that is persistent from session to session. You can use the up arrow and Enter keys to review and re-enter commands instead of retyping complete commands from scratch.
- **Script execution**. ADEdit can accept and execute a Tcl script file that includes ADEdit commands. The Tcl scripting language includes full programming logic with variables, logical operators, branching, functions (called procedures in Tcl), and other useful program-flow features. As the script executes, ADEdit keeps the Active Directory objects that it is working on in internal memory. It does not require repeated queries to Active Directory as it works on an object.
- **Executable file**. You can set up any ADEdit Tcl script as an executable file that can run by itself on a UNIX platform.

Scripting makes ADEdit a very flexible administration tool. You can use a single script to handle hundreds or thousands of repetitive tasks that would take a very long time to perform through the console. And you can write a set of scripts to quickly and easily check on and respond to current conditions. A script could, for example, create a new zone, read etc/passwd files on UNIX computers in that zone, and migrate all existing UNIX users it finds there into new zone

user accounts. Another script could find users in specified groups and then assign a new role to all users in those groups.

With that power comes responsibility. It's quite possible for an ADEdit script—or even a single ADEdit command—to completely erase Active Directory's contents if used incorrectly. There are, for the most part, no warnings and there is no undo feature if this happens. Only knowledgeable users should use ADEdit, and it is important to test scripts in sample environments before deploying them to the enterprise.

Library of Predefined Procedures

ADEdit installs with an accompanying library of utility procedures called the ade_lib Tcl library. These procedures use ADEdit commands to perform standard administrative operations such as adding zone users to a zone group or creating a new Active Directory user. The procedures in the library also provide examples of how to use ADEdit commands efficiently in Tcl scripts. From these examples, administrators can learn how to use and adapt ADEdit commands in their own custom scripts.

How ADEdit Works with Other Centrify Components

ADEdit is part Centrify Server Suite and works with specific Windows and UNIX components of the Centrify architecture. As described in the Administrator's Guide for Linux and UNIX, Centrify uses Active Directory, which runs in a Windows network, to stores Centrify-specific data such as zone information. To make computers part of an Active Directory domain, administrators deploy a platform-specific Server Suite Agent. After the agent is deployed and the computer joins an Active Directory domain, the computer is a Centrify-managed computer and ADEdit can define, retrieve, modify, and delete Active Directory and Centrify information for that computer.

Active Directory and ADEdit

Active Directory uses multi-master data storage. It replicates directory data on multiple domain controllers throughout a domain. Changes in data on one domain controller are replicated to the other domain controllers in the domain.

To perform virtually any operation, ADEdit must bind to one or more Active Directory domain controllers. ADEdit can then query Active Directory for data within bound domains, retrieve Active Directory objects, modify retrieved objects, create new objects, and delete existing objects. Those objects include all Centrify-specific objects such as zone objects, zone user objects, role objects, and more.

> **Note**: ADEdit is not limited in scope to Centrify-specific information. An administrator with full privileges could define, retrieve, modify, and delete information for any object or attribute in Active Directory.

Managed Computers and ADEdit

For computers to be managed by Centrify, they must have the Server Suite Agent installed and must be joined to an Active-Directory domain. The Server Suite Agent includes the following components that work directly with ADEdit:

- **adclient** is a Centrify process running on a managed computer. The adclient process communicates with Active Directory to make its host computer part of the Active Directory domain. Applications that require authentication and authorization or other services then use adclient to query Active Directory for that information. In most cases, ADEdit connects directly to Active Directory without using adclient. However, there are some commands that use adclient to get information more efficiently than from Active Directory directly.
- **Centrify command line programs** are commands administrators can run on managed computers to control adclient operations and work with the Centrify data stored in Active Directory. ADEdit replaces some of these commands, but occasionally works in conjunction with other commands such as adflush, especially when executing ADEdit commands that work through adclient. For more information about using command line programs, see the Administrator's Guide for Linux and UNIX.

Other Administrative Options

ADEdit is intended to the primary tool for administrators who want to perform administrative tasks directly from a command line or in scripts on Linux, UNIX, and Mac OS X computers. However, there are two other administrative options for performing the same tasks outside of ADEdit:

- The **Access Manager** console runs on a Windows computer and provides a graphical user interface that you can use for complete control of Centrify-related information and some Active Directory features.
- The **Centrify Server Suite SDK for Windows** provides application programming interfaces (API) that you can use to control all of the same features provided the **Access Manager** console.

It's important to realize when using any of these tools that an instance of one of these tools has no knowledge of other tool instances and acts as if it's the only administrative tool at work. For example, if one administrator uses the Access Manager console to modify a zone object at the same time as another administrator uses ADEdit to modify the same zone object, their changes might clash. For example, if the changes are first saved by the administrative using

Access Manager, those change might be overridden by changes saved by ADEdit. The last tool to save object data has the final say.

This is true as well for different instances of ADEdit. If two administrators both use different ADEdit instances simultaneously to work on the same object, the administrator who last saves the object is the only one whose work will have an effect on the object.

It's important when using ADEdit in an environment with multiple administrators to retrieve an object, make changes, and check it back in efficiently to avoid conflicts. ADEdit object changes are not atomic.

It helps to bind all administration tools to the same domain controller within a domain to further minimize conflicts. If tools work on different domain controllers, one tool's changes may take time to replicate to the other domain controllers, so other tools connected to other domain controllers won't be able to see those changes immediately.

ADEdit Components

ADEdit has two components: the ADEdit application and the ade_lib Tcl library. They are both installed when the Server Suite Agent is installed on a Linux, UNIX, or Mac OS X computer to be managed.

A user can access ADEdit through a CLI in a shell or through an executing Tcl script or Tcl application. ADEdit's Tcl interpreter executes the commands it receives from the CLI using the ADEdit commands and Tcl commands that are part of ADEdit. It may also use ade_lib Tcl library commands if specified. Tcl scripts and applications use ADEdit's commands and ade_lib Tcl library commands directly. ADEdit binds to an Active Directory domain controller, with which it exchanges data. ADEdit may also (in a few cases) get data from Active Directory through the adclient process.

The ADEdit Application

ADEdit uses Tcl as its scripting language. Tcl is a long-established extensible scripting language that offers standard programming features and an extension named Tk that creates GUIs simply and quickly. Tcl is described in the authoritative book Tcl and the Tk Toolkit by John K. Ousterhout and Ken Jones (Addison-Wesley, 2010).

ADEdit includes a Tcl interpreter and the Tcl core commands, which allow it to execute standard Tcl scripts. ADEdit also includes a set of its own commands designed to manage Centrify and Active Directory information.

ADEdit will execute individual commands in a CLI (in interactive mode) or sets of commands as an ADEdit script.

The ade_lib Tcl Library

The ade_lib Tcl library is a collection of Tcl procedures that provide helper functions for common Centrify-related management tasks such as listing zone information for a domain or creating an Active Directory user. You can include ade_lib in other ADEdit scripts to use its commands.

To use ade_lib in a Tcl script or in an ADEdit session, begin the script or session with: `package require ade_lib`

ADEdit Context

When ADEdit commands work on Active Directory objects, they don't specify a domain and the object to work on as part of each command. ADEdit instead maintains a context in memory that defines what commands work on.

ADEdit's context has two types of components:

- **A set of one or more bindings that connect ADEdit to domains in the forest**. Each binding uses an authentication to connect to an Active Directory domain controller. The authentication must have enough rights to perform ADEdit's administrative actions on the domain controller. Each binding binds ADEdit to a single domain; multiple bindings bind ADEdit to multiple domains at one time.
- **A set of zero, one, or more selected Active Directory objects that ADEdit works on**. A selected object is typically a Centrify object such as a zone, zone user, role, or NIS map, but can also be any generic Active Directory object. ADEdit stores each selected object with all of its attributes (called fields within ADEdit). ADEdit stores no more than one type of each selected object: one zone object, for example, one PAM application object, one generic Active Directory object, and so on.

An ADEdit session or script typically starts by binding to one or more domains. If ADEdit isn't bound to a domain, none of its commands that work with Active Directory (which is most of them) have any effect. Once bound, ADEdit commands work within the scope of all currently bound domains.

An ADEdit session or script then typically selects an object to work on: it specifies an object such as a zone user object that ADEdit retrieves from Active Directory and stores in memory as part of the context. All subsequent zone user commands then work on the zone user object in memory, not the zone user object as it is stored in Active Directory.

When finished with a selected object, the session or script can simply ignore the object (if nothing has changed in it) or it can save the object back to Active Directory (if the object has been modified and modifications need to go back to Active Directory, overwriting the object there). The selected object remains stored in ADEdit's context until the session or script selects a new object of the same type, which replaces the previous object.

By maintaining a context with selected objects, ADEdit avoids constant Active Directory queries for successive object management commands: A selection command queries Active Directory to retrieve an object. Reading or modifying object fields occurs internally and doesn't require Active Directory queries. If the object is saved, a final Active Directory query returns the modified object to Active Directory.

Context Persistence

ADEdit's context persists for the duration of an ADEdit interactive session. The context in an ADEdit script persists only until the end of the script's execution.

Pushing and Popping Contexts

ADEdit can save and retrieve contexts using push and pop commands that use a stack to store successive levels of context. Pushing and popping contexts is useful within Tcl scripts when jumping to a procedure. The script can push the current context to the stack, create an entirely new context for the procedure, then pop the original context back when exiting the procedure.

Context Cautions

Working with ADEdit's context requires some thought. Commands that affect objects don't explicitly specify an object, so you must be careful to ensure that the correct object is specified before executing commands that affect the object. ADEdit has context reporting commands that help by showing current domain bindings and selected objects.

It's important to realize that any modifications to a selected object have no effect until the object is saved back to Active Directory. If you forget to save an object, you lose all modifications.

If you keep an object in context a long time between selecting the object and saving the object, be aware—as noted earlier—that another administration tool may alter the object in Active Directory during that time and you won't know about those alterations.

Logical Organization for ADEdit Commands

The commands you can execute with ADEdit fall into the following logical categories:

- **General-purpose commands** that control ADEdit operation and provide information about ADEdit. For example, you use these commands to view usage help, set the LDAP query time-out interval, and quit ADEdit.
- **Context commands** that set up and control the ADEdit domain context. For example, you use these commands to bind to a domain before subsequent object management commands, view current bindings, and change the context.
- **Object management commands** that enable you to perform all of the same tasks as you can with Active Directory Users and Computers and Access Manager. For example, you use these commands to create, select, and manage zones, users, groups, computers, rights, roles and role Assignments.
- **Utility commands** that perform useful data retrieval and data conversion tasks. For example, you use these commands to convert domain names and security principal names from one format to another.
- **Security descriptor commands** that modify security descriptors and make them readable.

For example, you use these commands to convert security descriptors strings from one format to another.

For more information about the commands each category, see ADEdit commands Organized by Type.

For details about specific commands, see ADEdit Command Reference.

Getting Started with ADEdit

This chapter describes ADEdit's basic syntax, shows the typical logic flow used to handle Server Suite objects, and describes in detail the steps in that logic flow using simple examples.

Starting ADEdit for the First Time

The ADEdit application (adedit) and accompanying library of Tcl procedures (ade_lib) are installed automatically when you install the Server Suite Agent on a UNIX, Linux, or Mac OS X computer. Therefore, both the application and the library are immediately available on any Server Suite-managed computer. You are not required to join the domain before using ADEdit for the first time.

To start a new interactive ADEdit session, type adedit in a standard shell after logging on to your computer. A new angle bracket (>) prompt indicates that you are in an interactive ADEdit session. For example:

```
[myprompt]$ adedit >
```

Anyone can launch ADEdit. However, only users who have sufficient privileges can modify Active Directory objects and Server Suite-specific data.

Basic Command Syntax

ADEdit includes a Tcl interpreter and uses Tcl syntax. However, ADEdit commands have their own syntax within the Tcl syntax. Like other Tcl commands, ADEdit commands are always completely lowercase. ADEdit does not recognize commands with uppercase characters.

Arguments and Options

An ADEdit command works very much like a UNIX command. Depending on the command, you might be required to specify one or more arguments. An argument is typically a variable that follows the command name to provide data that controls the operation to be performed. In some cases, values for the variables are required for a command to execute. In other cases, variables might be optional. The reference information for individual commands indicates whether arguments are required or optional. In most cases, however, arguments must be entered in the order specified for the command.

In addition to arguments, ADEdit commands may or may not have options. Options must precede a command's arguments. Each option is a single word preceded by a hyphen (-) such as -write. Options can also have their own arguments. If an option takes an argument, it must immediately follow the option.

Options are used to control specific operations of ADEdit commands. For example:

```
>bind -gc acme.com administrator #3gEgh^&4
```

In this example, the bind command has an option -gc that specifies a global catalog domain controller. Three arguments follow the option. The first argument is required and specifies the domain to which to bind. The second and third arguments are optional and provide a use name and password to be used for binding.

Command Execution and Results

Like most UNIX commands, ADEdit produces no output or return value if a command executes successfully. Only commands that are defined to return a result produce output when an operation completes successfully. If a command fails, however, ADEdit notifies you of an error in execution and reports the general reason for failure. For example, you might see an error message indicating the wrong number of arguments or a connection problem.

Some commands return results as a Tcl list that other commands in a Tcl script can use. Other commands output results directly to standard output (stdout) where the results are displayed in the shell. You can redirect a command's stdout output to a file or other destination, if desired.

Commands that return Tcl lists start with get followed by an object type (get_zone_users, for example) and return the list of the objects matching the specified object type that are stored in Active Directory. Because other commands can use the Tcl list to act on the returned data, the get commands are especially useful for writing scripts.

Commands that send data to stdout start with list followed by an object type (list_zone_groups, for example) and return the list of the objects matching the specified object type that are stored in Active Directory for the currently selected context. Because the list goes to stdout, the list commands are especially useful for displaying data in interactive sessions as a script executes.

Using Command Abbreviations

Most ADEdit commands have an abbreviation that you can use in place of the full command name. For example, the command list_zone_users has the abbreviation lszu. You can use either the full command name or the abbreviation for any command.

Using the Command History

ADEdit in an interactive session retains a history of previously entered commands. You can visit the command history by pressing the up arrow key to go back in the history and the down arrow key to go forward. Press Enter to run the current command.

ADEdit retains its command history across sessions, so if you quit ADEdit and restart it, you can still visit commands entered in the previous session. The command history has a 50command capacity. Once full, the history drops old commands as you enter new commands.

Using the Help Command

The ADEdit `help` command provides brief information about ADEdit commands. If you enter `help` in ADEdit followed by a command or command abbreviation, `help` returns information about that command, including its syntax.

You can use the wildcard character `*` to specifying any number of variable characters or `?` to specify a single variable character within a command string following the help command. The `help` command returns `help` text for all commands that match the wildcard string. For example, the following command returns help for all commands that start with `get`.

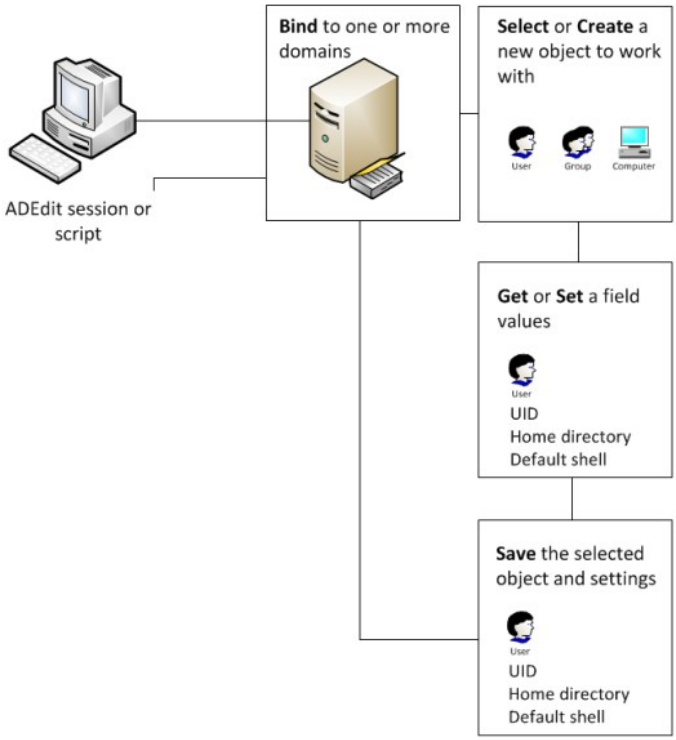
```
> help get*
```

Learning to Use ADEdit

You can use ADEdit interactively to run individual commands or to execute scripts directly. You can use ADEdit commands in scripts that you convert into executable files that can be execute outside of ADEdit sessions. Because scripts can automate and simplify many administrative tasks, it is important for you to know how to combine ADEdit commands in the proper sequence to get the results you are looking for.

Before you begin writing scripts that use ADEdit commands, you should be familiar with the most common logical flow for managing Server Suite-specific and Active Directory objects.

The following illustration provides an overview of the logical process.



As illustrated, the typical logic flow in a ADEdit script follows these steps:

1. **Bind** ADEdit to one or more domains within a forest.

   The domains to which you bind will define the logical boundaries within which all subsequent commands work.

2. **Select** an existing Active Directory object or create a **new** object with which to work.

   You can use select commands to retrieve existing object from Active Directory and store them in memory. You can use new commands to create new objects of a specified type and store them in the ADEdit context as the currently selected object.

   There are also create commands that create a new objects in Active Directory without putting the object in the ADEdit context. You must explicitly select objects that are created with create commands.

3. **Get** or **set** values for a selected object.

   After you select an object to work with and it is stored in memory—that is, the object is in the ADEdit context—you can read field values to see their current settings or write field values to change their current state.

4. **Save** the selected object and any settings you changed.

   If you modify an object in memory or you have created a new object in memory, you must save it back to Active Directory for your changes to have any effect.

As these steps suggest, ADEdit is very context-oriented. The bindings you set and the objects you select determine the ADEdit current context. All commands work within that context. If you select a zone, for example, subsequent commands use the selected zone as the context in which to add new zone users, zone computers, and zone groups.

Outside of scripts that perform the most common administrative tasks, you might use ADEdit commands differently and without following these steps. For example, you might use ADEdit to convert data from one format to another, view help, or get information about the local computer without following the typical logic flow, but those tasks would be exceptions to the general rule.

Binding to a Domain and Domain Controller

ADEdit must bind to one or more domains before any ADEdit commands that affect Active Directory objects will work. When you execute the bind command, you specify the domain to which to bind. You can also specify a user name and password for the bind operation to provide authentication.

The domain can be any domain in the current forest. The ADEdit host computer does not have to be joined to a domain to bind to and work with a domain. A binding command can be as simple as:

```
>bind acme.com
```

If you specify a domain with no options, ADEdit automatically finds the domain's closest, fastest domain controller. Options can narrow down the choice of domain controllers. The -write option, for example, specifies that you want ADEdit to choose a writable domain controller. The -gc option specifies that ADEdit use the global catalog (GC) domain controller. You can use both options to choose a writable GC domain controller, for example:

```
>bind -write -gc acme.com
```

Alternatively, you can name a specific domain controller as a part of the domain name:

```
>bind dcserv1@acme.com
```

> **Note**: Active Directory is a multi-master LDAP system. Changes made at any one domain controller eventually propagate to all other domain controllers in the domain (if they're universal changes). If any administration tools—such as Active Directory Users and Computers, Access Manager, or other instances of ADEdit—bind to the same domain controller, changes made by any one of the tools are immediately available to the other tools without waiting for propagation.

Authentication

If no credentials are provided with a bind command, ADEdit gets its authentication data from the Kerberos credentials cache if one exists. Alternatively, you can provide a user name or both a user name and password. For example:

```
>bind acme.com administrator {e$t86&CG}
```

Notice that the password is enclosed in braces ({}) to ensure that Tcl handles it correctly. Without the braces, Tcl syntax will automatically substitute for some characters such as the $ used in the password. For example, a dollar sign specifies the contents of a variable in Tcl. Enclosing a string in braces guarantees that Tcl will not try to substitute for any of the characters in the string. Tcl drops the braces when it passes the string on.

You can also use the credentials of the ADEdit's host computer by using the -machine option:

```
>bind -machine acme.com
```

> **Note**: Whatever credentials you use, they must be for an account on the Active Directory domain controller with enough authority to read from and make changes to Active Directory objects in the domain. Without the proper authority, ADEdit commands that use Active Directory won't work.

Binding Scope and Persistence

Binding to a single domain allows ADEdit commands to work on Active Directory in that domain. You can bind to multiple domains to allow ADEdit commands to work on more than one domain. To bind to multiple domains, you simply use multiple bind commands, one for each domain.

Once bound to a domain, ADEdit remains bound to that domain until another binding occurs to the same domain (possibly using a different authentication or specifying a different domain controller) or until the current interactive session or executing script ends. Binding might also end if the current context is popped and ADEdit reverts to an earlier context without the binding.

Binding and Join Differences

The ADEdit bind operation is not the same as having the ADEdit host computer join an Active Directory domain. A join is the adclient connection to Active Directory for the host computer. A computer is only allowed to join one domain. A bind is an ADEdit connection to Active Directory, and it can be to more than one domain in the forest. The binding is completely independent of the host computer's joined domain.

> **Note**: A few ADEdit commands that start with joined_* use adclient to retrieve data from Active Directory. Those commands are affected by the host computers's joined domain because they require adclient to be connected to Active Directory and can only get data from the joined domain.

Controlling Binding Operation

You can control the way ADEdit's binding to Active Directory operates. The set_ldap_timeout command sets a time interval for ADEdit's LDAP queries to execute by Active Directory. ADEdit considers a query that doesn't execute by the time-out interval as failed.

Selecting an Object

ADEdit manages Server Suite information by working with the objects in Active Directory. The Server Suite-specific object types are:

- Zones
- Zone users
- Zone computers
- Zone groups
- Roles
- Role assignments
- Privileged UNIX command rights
- PAM application rights
- NIS maps

However, you are not limited to using ADEdit only for managing Server Suite-specific object types. You can also use ADEdit commands to work with generic Active Directory objects, including computers, users, groups, and other classes.

Selection Commands

The ADEdit object select commands have the form select_xxx where xxx is an object type. When you select an object (select_zone, for example), ADEdit looks for the object specified in Active Directory and retrieves it to store the object in the current context.

Each select command is tailored to the type of object it retrieves. As an example, after binding to acme.com, you can use a get_zones command to list the zones in the bound domain, then use a select_zone command to select the zone you want to work with:

```
>get_zones acme.com
{CN=default,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com}
{CN=cz1,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com}
{CN=cz2,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com}
{CN=global,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com}
>select_zone {CN=global,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com}
```

As this example illustrates, each zone is list by its distinguished name (DN) and you use the distinguished name to identify the zone you want to use.

Selection as Part of Context

Once an object is selected, it resides in memory (context) with all attendant field values. Further ADEdit commands can examine and modify the object in context.

ADEdit keeps only one selected object of each type in context at a time. If you select or create another object of the same type, the new object replaces the old object in memory without saving the old object to Active Directory. ADEdit can and does keep multiple objects in context, but each object must be a different type.

> **Note**: A currently selected object often affects work on other objects types, especially the currently selected zone. For example, if you select a zone user, you must first select a zone so that ADEdit knows in which zone to look for the zone user. If you don't first select a zone, you can't select and work on various zone objects such as zone users, zone computers, and zone groups. Knowing your context as you work on objects is important.

Persistence

A selected object stays selected until another object of the same type replaces it or until the current interactive session ends or executing script ends. When an ADEdit session ends, all selected objects are removed from ADEdit's memory. In most cases, you must explicitly save changes to objects in memory to ensure the changes are stored in Active Directory.

Creating a New Object

You can use ADEdit new_xxx commands, where xxx is the object type, to create new objects to work on instead of selecting existing objects. When you use new_xxx commands, commands, ADEdit creates an object of the specified type and stores the object as the currently selected object of that type in ADEdit's current context.

In most cases, ADEdit does not provide default values for a new object's fields. If you create a new object, its fields are empty. You can use the ADEdit set_xxx commands to set values for the fields that are specific to each object type.

Here are some notes about creating objects in ADEdit:

- Creating a new zone works differently than all other object types: ADEdit does not create a new zone in memory. ADEdit creates new zones directly in Active Directory and fills in zone fields with default values. After you create a zone, you must then select it to examine and modify it.
- ADEdit cannot create AIX extended attributes in a Microsoft Services for UNIX (SFU) zone (Ref: CS-25392c).
- Some non-alphanumeric characters are valid for Windows user or group names and are converted to underscore ("_") when changed to be UNIX names in the Access Manager, but cannot be used in adedit. (Ref: IN-90001) The following characters cannot be used in adedit: \ ( ) + ; " , < > =

Examining Objects and Context

The ADEdit context is a combination of current bindings and currently selected objects. You can examine the properties of currently selected objects using ADEdit get_xxx or list_xxx commands, where xxx is an object type. For example, you can use the get_roles or list_roles command to see a list of roles in the current zone.

Getting Field Values for Objects

You can also use get_xxx_field commands to retrieve field values for different types of objects. For example:

```
>select_zone_user adam.avery@acme.com
>get_zone_user_field uname
adam
```

In this example, ADEdit retrieves the value of the field uname—in this case, the UNIX user name field—for the currently selected zone user adam.avery@acme.com.

Getting Current Context Information

You can examine ADEdit's current context at any time using two different commands: the show command and the get_bind_info command.

The show command returns all bindings and selected objects in the current context. For example:

```
>show
Bindings:
    acme.com: calla.acme.com
```

```
Current zone:
    CN=global,CN=Zones,CN=ACME,CN=Program Data,DC=acme,DC=com
Current nss user:
    adam.avery@acme.com:adam:10001:10001:%{u:samaccountname}:%{home}/%{user}:%{shell}:
```

You can use optional arguments to limit the information the show command returns.

The get_bind_info command returns information about a bound domain. When you use this command, you specify the information you want to retrieve, such as the domain's forest, the name of the current domain controller, the domain's security identifier (SID), the functional level of the domain, or the functional level of the domain's forest. For example:

```
>get_bind_info acme.com server
adserve02.acme.com
```

In this case, ADEdit returns the name of the bound server for the domain acme.com.

Modifying or Deleting Selected Objects

Once an object is selected and residing in the ADEdit context, you can modify its fields using the ADEdit set_xxx_field commands, where xxx is the object type. These commands allow you to specify a field name and a field value. For example:

```
>select_zone_user adam.avery@acme.com
>set_zone_user_field uname buzz
```

This example selects the zone user adam.avery@acme.com and sets the uname field for the zone user—the UNIX user name—to buzz. The field is set to the new value only in memory., however. You must save the object before the new field value is stored in Active Directory and takes effect within the object's domain. For example:

```
>save_zone_user
```

Deleting an Object

You can delete a currently selected object using the ADEdit delete_xxx commands, where xxx is the object type. When you delete an object, it is deleted from both memory *and* Active Directory. For example:

```
>select_zone_user adam.avery@acme.com
>delete_zone_user
```

This example deletes the currently selected zone user, adam.avery@acme.com, from the he ADEdit context so there's no longer a selected zone user. The command also deletes the zone user object associated with the user adam.avery@acme.com so there's no longer a zone user by that name in Active Directory.

> **Note**: There is no undo for a delete command. Once the object is deleted from Active Directory, you must recreate it if you want it back. Be especially careful if you set up an ADEdit script to delete multiple objects.

Saving Selected Objects

Any new or modified object in ADEdit's context has no effect until you save the object back to Active Directory. You do so using a save_xxx command where xxx is the object type. For example:

```
>save_zone
```

This example saves the currently selected zone object back to Active Directory along with any field values that have been modified since the zone was selected.

Saving an object does not deselect the object. It remains the selected object in memory so that you can further read and modify it.

Pushing and Popping Context

There are times when you may want to save ADEdit's current context, change it to a new context to work on different objects in different domains, and then revert back to the original context. This is particularly true when writing Tcl scripts with subroutines, where you may want to feel free to complete a completely new context without altering the context of the calling code.

ADEdit offers a push and a pop command to save and retrieve contexts to a stack maintained in memory. push saves the complete current context—all of its bindings and selected objects—to the stack. Subsequent push commands save more contexts to the top of the stack, pushing the older contexts further down the stack, allowing for nested subroutines.

pop reads the context from the top of the stack and restores it to memory as the current context. pop also removes the restored context from the stack. Subsequent pop commands pop more contexts off the stack until the stack is empty, at which point pop returns an error.

Creating ADEdit Scripts

You can combine ADEdit commands into scripts that perform many common administrative tasks, such as creating new zones, adding users to zones, or pre-creating computer accounts. After you create a script, you can execute it from a shell that calls adedit or convert it to an executable file that can run directly from the command line.

Starting with a Simple Script

If you are new to scripting, Tcl, or both, you might want to experiment first with a few simple commands before trying to develop scripts that perform administrative tasks. The steps in this section are intended to help you get started.

If you are already familiar with scripting languages or with using Tcl, you might want to skip ahead to the discussion of the sample scripts or directly to the command reference.

To write a simple ADEdit script:

1. Open a new file—for example, my_adedit_script—in a text editor.
2. Type the following line to set up the adedit environment and include the ADedit Tcl library:

   ```
   #!/bin/env adedit
   package require ade_lib
   ```

   If your version of Linux or UNIX has the env command in a location other than the /bin directory, modify the first line to specify that directory. For example, another common location for the env command is /usr/bin. In this case, you would type:

   ```
   #!/usr/bin/env adedit
   ```

3. Type an appropriate bind command to identify the Active Directory domain or domains to use.

   ```
   bind pistolas.org maya.garcia {$m1l3s88}
   ```

   Depending on whether you are going to run this script interactively or as an executable file, you might include or exclude authentication information.

4. Type the appropriate commands to create and select a new zone.

   ```
   `create_zone` tree “cn=sample,cn=zones,ou=acme,dc=acme,dc=com” std
   select_zone “cn=sample,cn=zones,ou=acme,dc=acme,dc=com”
   ```

5. Type the command to list the current zones to stdout to verify the new zone.

   ```
   list_zones pistolas.org
   ```

6. Type the command to save the zone and quit.

   ```
   save_zone
   quit
   ```

7. Save the text file and execute it using ADEdit or as an executable file.

   After you have tested the basic script, you edit it to create new zones, make a zone a child zone, add new zone computers, groups, or users. for example, you might add lines similar to these:

   ```
   new_zone_user AD_user_UPN
   set_zone_user_field field value
   save_zone_user
   list_zone_users
   ```

   If your sample script creates and selects a zone successfully, you should delete or rename the zone each time you iterate through the execution.

The following is a sample of what the simple script might look like:

```
#! /bin/env adeditpackage require ade_lib
bind pistolas.org maya.garcia {$m1l3s88}
`create_zone` tree "cn=test6,cn=zones,ou=acme,dc=pistolas,dc=org" std
select_zone "cn=test6,cn=zones,ou=acme,dc=pistolas,dc=org"
`set_zone_field` parent "cn=US-HQ,cn=zones,ou=acme,dc=pistolas,dc=org"
```

```
list_zones pistolas.org
save_zone
new_zone_user tim@pistolas.org
set_zone_user_field uname tim
set_zone_user_field uid 81000
set_zone_user_field gid 81000
set_zone_user_field gecos "Tim Jackson, Accounting"
save_zone_user
list_zone_users
quit
```

Executing an ADEdit Script using ADEdit

You can execute ADEdit script by invoking ADEdit on the command line or by making the script an executable file and invoking the script itself directly from the command line.

To execute an ADEdit script by invoking ADEdit on the command line

1. Open a shell.
2. Type adedit followed by the name of the script

   For example, if the name of the script is my_adedit_scipt and it is the current working directory, type:

   ```
   adedit my_adedit_script
   ```

   If the script isn't in the current working directory, specify the path to the script and any arguments if the script requires any.

Running an ADEdit Script as an Executable from the Command Line

You can run an ADEdit script without invoking ADEdit first by making the script an executable file.

To run an ADEdit script as a UNIX-executable file

1. Verify the script begins with the following lines:

   ```
   #!/bin/env adedit
   package require ade_lib
   ```

   The script reads it as a comment, however UNIX or Linux will use it to find and execute ADEdit and then execute the rest of the script.

2. Use chmod to make the file executable.

   For example, if the name of the script is my_adedit_scipt and it is the current working directory, type:

   ```
   chmod +x my_adedit_script
   ```

3. Make sure the file's directory is listed in your PATH environment variable if you want to be able to execute the file from any directory.

   Alternatively, modify the script to include the full path to adedit. For example:

   ```
   #!/bin/env /usr/bin/adedit
   ```

   Once set up this way, you can simply enter the script's file name in a shell and have the script execute as a command.

   ```
   /my_adedit_script
   ```

Running an ADEdit Script as a Shell Script

You can also run the script as a shell script. In this case, the script file would have the .sh suffix and would contain the following lines at the beginning of the file:

```
#!/bin/sh
# \
exec adedit "$0" ${1+"$@"}
package require ade_lib
```

ADEdit Commands Organized By Type

As discussed in *Logical Organization for ADEdit Commands*, there are different types of ADEdit commands that can be organized into logical categories. This chapter provides a brief introduction to the ADEdit commands in each of those logical categories. For detailed information about individual commands, see ADEdit Command Reference.

General Purpose Commands

You can use the following general purpose commands to control overall ADEdit operation or return general information about ADEdit or its host computer.

help	Returns information about a specified ADEdit command or all ADEdit commands.
get_adinfo	Returns information about the joined domain, the joined zone, or the name the local computer is joined under.
quit	Quits ADEdit.
set_ldap_timeout	Sets the time-out value used by ADEdit's LDAP commands that perform read and write operations on Active Directory through a binding.

Context Commands

You can use the following context commands set the current domain bindings, report on the current bindings and selected object, and save and retrieve the ADEdit context (which includes both bindings and currently selected objects).

bind	Binds to one or more Active Directory domains to define the ADEdit context for subsequent commands.
get_bind_info	Returns information about the domains to which ADEdit is bound.
pop	Restores the context from the top of the ADEdit context stack.
push	Saves the current context to the ADEdit context stack.
show	Displays the current context of ADEdit, including its bound domains and currently selected objects.
validate_license	Determines whether there is a valid license and stores an indicator in the ADEdit context.

Object Management Commands

You can use object management commands to retrieve, modify, create, and delete Active Directory objects of any kind, including Centrify-specific objects such as zones, rights, and roles. The command set for each object type is similar to the command sets for the other object types.

Zone Object Management Commands

You can use the following zone object management commands to create, select, save, and delete zones and manage zone properties.

create_zone	Creates a new zone in Active Directory.
delegate_zone_right	Delegates a zone administrative task to a specified user or group.
delete_zone	Deletes the selected zone from Active Directory and memory.

get_child_zones	Returns a Tcl list of child zones, computer roles, or computer-specific zones associated with the current zone.
get_zone_field	Returns the value for a specified field from the currently selected zone.
get_zone_nss_vars	Returns the NSS substitution variable for the selected zone.
get_zones	Returns a Tcl list of all zones within a specified domain.
save_zone	Saves the selected zone with its current settings to Active Directory.
select_zone	Retrieves a zone from Active Directory and stores it in memory as the currently selected zone.
set_zone_field	Sets the value for a specified field in the currently selected zone.

Zone User Object Management Commands

You can use the following zone user commands to create, select, save, and delete zone user objects and manage user properties in the currently selected zone.

delete_local_user_profile	Deletes a local user (that is not an Active Directory user) that has a profile defined in the current zone.
delete_zone_user	Deletes the zone user from Active Directory and from memory.
get_local_user_profile_field	Returns the value of a profile field for the currently selected local user (that is not an Active Directory user) that has a profile defined in the current zone.
get_local_users_profile	Returns a Tcl list of profiles for local users (that are not Active Directory users) that are defined in the currently selected zone.
get_zone_user_field	Returns the value for a specified field from the currently selected zone user.
get_zone_users	Returns a Tcl list of the Active Directory names of zone users in the current zone.
list_local_users_profile	Returns a list of local users (that are not Active Directory users) that have a profile defined in the current zone.
list_zone_users	Lists all zone users with NSS data for each user in stdout.
new_local_user_profile	Creates an object for a local user (that is not an Active Directory user) in the currently selected zone.
new_zone_user	Creates a new zone user and stores it in memory as the currently selected zone user.
save_local_user_profile	Saves the object for the currently selected local user (that is not an Active Directory user) after you create the local user object or edit profile field values for the local user object.
save_zone_user	Saves the selected zone user with its current settings to Active Directory.
select_local_user_profile	Selects a local user (that is not an Active Directory user) object for viewing or editing.
select_zone_user	Retrieves a zone user from Active Directory and stores it in memory as the selected zone user.
set_local_user_profile_field	Sets the value of a field for the currently selected local user (that is not an Active Directory user) that has a profile defined in the current zone.

set_zone_user_field	Sets the value for a specified field in the currently selected zone user.

Zone Group Object Management Commands

You can use the following zone group commands to create, select, save, and delete zone group objects and manage group properties in the currently selected zone.

delete_local_group_profile	Deletes a local group (that is not an Active Directory group) that has a profile defined in the current zone.
delete_zone_group	Deletes the zone group from Active Directory and from memory.
get_local_group_profile_field	Returns the value of a profile field for the currently selected local group (that is not an Active Directory group) that has a profile defined in the current zone.
get_local_groups_profile	Returns a Tcl list of profiles for local groups (that are not Active Directory groups) that are defined in the currently selected zone.
get_zone_group_field	Returns the value for a specified field from the currently selected zone group.
get_zone_groups	Return a Tcl list of Active Directory names of all zone groups in the current zone.
list_local_groups_profile	Returns a list of local groups (that are not Active Directory groups) that have a profile defined in the current zone.
list_zone_groups	Lists all zone groups with object data for each group in stdout.
new_local_group_profile	Creates an object for a local group (that is not an Active Directory group) in the currently selected zone.
new_zone_group	Creates a new zone group and stores it in memory as the currently selected zone group.
save_local_group_profile	Saves the object for the currently selected local group (that is not an Active Directory group) after you create the local group object or edit profile field values for the local group object.
save_zone_group	Saves the selected zone group with its current settings to Active Directory.
select_local_group_profile	Selects a local group (that is not an Active Directory group) object for viewing or editing.
select_zone_group	Retrieves a zone group from Active Directory and stores it in memory as the selected zone group.
set_local_group_profile_field	Sets the value of a field for the currently selected local group (that is not an Active Directory group) that has a profile defined in the current zone.
set_zone_group_field	Sets the value for a specified field in the currently selected zone group.

Zone Computer Object Management Commands

You can use the following zone computer commands to create, select, save, and delete zone group objects and manage computer properties in the currently selected zone.

delete_zone_computer	Deletes the zone computer from Active Directory and from memory.

get_zone_computer_field	Returns the value for a specified field from the currently selected zone computer.
get_zone_computers	Returns a Tcl list of Active Directory names of all zone computers in the current zone.
list_zone_computers	Lists all zone computers along with object data for each computer in stdout.
new_zone_computer	Creates a new zone computer and stores it in memory as the currently selected zone computer.
save_zone_computer	Saves the selected zone computer with its current settings to Active Directory.
select_zone_computer	Retrieves a zone computer from Active Directory and stores it in memory as the selected zone computer.
set_zone_computer_field	Sets the value for a specified field in the currently selected zone computer.

Computer Role Object Management Commands

You can use the following computer role commands to create, select, save, and delete computer role objects and manage computer role properties in the currently selected zone.

create_computer_role	Creates a new computer role in Active Directory.
delete_zone	Deletes the selected computer role from Active Directory and memory.
get_role_assignments	Returns a Tcl list of user role assignments associated with the selected computer role.
get_zone_field	Retrieves the computer group associated with the computer role.
list_role_assignments	Lists user role assignments associated with the selected computer role.
new_role_assignment	Creates a new role assignment and associates it with the selected computer role.
save_zone	Saves the selected computer role with its current settings to Active Directory.
select_zone	Retrieves a computer role from Active Directory and stores it in memory as the selected zone for subsequent commands.
set_zone_field	Sets the computer group which is associated with the computer role.

Role Object Management Commands

You can use the following role object commands to create, select, save, and delete role objects and manage role properties in the currently selected zone.

add_command_to_role	Adds a privileged command to the currently selected role.
add_pamapp_to_role	Adds a PAM application right to the currently selected role.
delete_role	Deletes the selected role from Active Directory and from memory.
get_role_apps	Returns a Tcl list of the PAM applications associated with the currently selected role.
get_role_commands	Returns a Tcl list of the privileged commands associated with the currently selected role.

get_role_field	Returns the value for a specified field from the currently selected role.
get_roles	Returns a Tcl list of roles in the current zone.
list_role_rights	List all privileged commands and PAM applications associated with the currently selected role in stdout.
list_roles	Lists all roles in the currently selected zone along with object data for each role in stdout.
new_role	Creates a new role and stores it in memory as the currently selected role.
remove_command_from_role	Removes a privileged command from the currently selected role.
remove_pamapp_from_role	Removes a PAM application from the currently selected role.
save_role	Saves the selected role with its current settings to Active Directory.
select_role	Retrieves a role from Active Directory and stores it in memory as the selected role.
set_role_field	Sets the value for a specified field in the currently selected role.

Role Assignment Object Management Commands

You can use the following role assignment object commands to create, select, save, and delete role assignment objects and manage role assignment properties in the currently selected zone.

delete_role_assignment	Deletes the selected role assignment from Active Directory and from memory.
get_role_assignment_field	Returns the value for a specified field from the currently selected role assignment.
get_role_assignments	Returns a Tcl list of role assignments in the current zone.
list_role_assignments	Lists all role assignments along with object data for each role assignment in stdout.
new_role_assignment	Creates a new role assignment and stores it in memory as the currently selected role assignment.
save_role_assignment	Saves the selected role assignment with its current settings to Active Directory.
select_role_assignment	Retrieves a role assignment from Active Directory and stores it in memory as the selected role assignment.
set_role_assignment_field	Sets the value for a specified field in the currently selected role assignment.

PAM Application Object Management Commands

You can use the following PAM application commands to create, select, save, and delete PAM application objects and manage PAM application properties in the currently selected zone.

delete_pam_app	Deletes the selected PAM application from Active Directory and from memory.
get_pam_apps	Returns a Tcl list of PAM applications in the current zone.

get_pam_field	Returns the value for a specified field from the currently selected PAM application.
list_pam_apps	List all PAM applications along with object data for each PAM application in stdout.
new_pam_app	Creates a new PAM application and stores it in memory as the currently selected PAM application.
save_pam_app	Saves the selected PAM application with its current settings to Active Directory.
select_pam_app	Retrieves a PAM application from Active Directory and stores it in memory as the selected PAM application.
set_pam_field	Sets the value for a specified field in the currently selected PAM application.

Command (dz) Object Management Commands

You can use the following privileged authorization commands to create, select, save, and delete privileged UNIX command and manage command properties in the currently selected zone.

delete_dz_command	Deletes the selected command from Active Directory and from memory.
get_dz_commands	Return a Tcl list of commands in the current zone.
get_dzc_field	Returns the value for a specified field from the currently selected command.
list_dz_commands	List all privileged commands along with object data for each command in stdout.
new_dz_command	Creates a new command and stores it in memory as the currently selected command.
save_dz_command	Saves the selected command with its current settings to Active Directory.
select_dz_command	Retrieve a privileged command from Active Directory and stores it in memory as the selected command.
set_dzc_field	Sets the value for a specified field in the currently selected command.

NIS Map Object Management Commands

You can use the following NIS map commands to create, select, save, and delete NIS maps and manage NIS map entries and properties in the currently selected zone.

add_map_entry	Adds an entry to the currently selected NIS map.
add_map_entry_with_comment	Adds an entry with comments to the currently selected NIS map.
delete_map_entry	Removes an entry from the currently selected NIS map.
delete_nis_map	Deletes the selected NIS map from Active Directory and from memory.
get_nis_map	Returns a Tcl list of the entries in the currently selected NIS map.
get_nis_map_field	Returns the value for a specified field from the currently selected NIS map.

get_nis_map_with_comment	Returns a Tcl list of the entries with their comments in the currently selected NIS map.
get_nis_maps	Returns a Tcl list of NIS maps in the current zone.
list_nis_map	Lists the NIS map entries from the currently selected NIS map in stdout.
list_nis_map_with_comment	Lists the NIS map entries and comments from the currently selected NIS map in stdout.
list_nis_maps	List all NIS maps in the currently selected zone in stdout.
new_nis_map	Creates a new NIS map and stores it in memory as the currently selected NIS map.
save_nis_map	Saves the selected NIS map with its current entries to Active Directory.
select_nis_map	Retrieves a NIS map from Active Directory and stores it in memory as the selected NIS map.

Active Directory Object Management Commands

You can use the following Active Directory commands to create, select, save, and delete NIS maps and manage NIS map entries and properties in the currently selected zone.

add_object_value	Adds a value to a multi-valued field attribute of the currently selected Active Directory object.
delete_object	Deletes the selected Active Directory object from Active Directory and from memory.
delete_sub_tree	Deletes an Active Directory object and all of its children.
get_object_field	Returns the value for a specified field from the currently selected Active Directory object.
get_object_field_names	Returns a Tcl list of the field names for each of the fields attributes associated the currently selected Active Directory object.
get_objects	Performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of matching objects.
new_object	Creates a new Active Directory object and stores it in memory as the currently selected Active Directory object.
remove_object_value	Removes a value from a multi-valued field attribute of the currently selected Active Directory object.
save_object	Saves the selected Active Directory object with its current settings to Active Directory.
select_object	Retrieves an object with its attributes from Active Directory and stores it in memory as the selected Active Directory object.
set_object_field	Sets the value for a specified field in the currently selected Active Directory object.

Utility Commands

You can use the following utility commands retrieve and convert data from format to format, manipulate distinguished names, and manage group membership and user passwords.

dn_from_domain	Converts a domain's dotted name to a distinguished name (DN) format.
dn_to_principal	Searches Active Directory for a DN and, if found, returns the corresponding UPN.

domain_from_dn	Converts a domain's distinguished name (DN) to a dotted name format.
get_group_members	Returns a Tcl list of members in a group.
get_parent_dn	Returns the parent of an LDAP path (a distinguished name): it removes the first element of the DN and returns the rest.
get_pwnam	Searches the etc/passwd file for a UNIX user name and, if found, returns a Tcl list of the passwd profile values associated with the user.
get_rdn	Returns the relative DN of an LDAP path: it returns only the first element of the supplied DN.
get_schema_guid	finds a class or attribute in Active Directory and returns its globally unique identifier (GUID)
getent_passwd	Returns a Tcl list of all entries in the local /etc/passwd file.
joined_get_user_membership	Uses adclient to query Active Directory and returns a Tcl list of groups that a user belongs to.
joined_name_to_principal	Uses adclient to search for a UNIX name and return the security principal associated with that UNIX name.
joined_user_in_group	Uses adclient to check Active Directory to see if a user is in a group.
move_object	Moves the selected object to the specified location.
principal_from_sid	Searches Active Directory for an SID and returns the security principal associated with the SID.
principal_to_dn	Searches Active Directory for a user principal name (UPN) and, if found, returns the corresponding DN.
rename_object	Renames the selected object.
set_user_password	Sets an Active Directory user's password.
sid_to_escaped_string	Converts an Active Directory security identifier (SID) to an escaped string.
sid_to_uid	Converts an Active Directory SID to a user ID (UID).

Security Descriptor Commands

You can use the following security descriptor commands modify SDs and make them readable by humans.

add_sd_ace	Adds an access control entry to a security descriptor.
explain_sd	Converts a security description in SDDL format to a human-readable form.
remove_sd_ace	Removes an access control entry (ACE) from a security descriptor.
set_sd_owner	Sets the owner of a security descriptor.

Using the Demonstration Scripts

This chapter describes the ADEdit sample scripts provided in the package. The scripts are listed in the following table. The corresponding source files are in the /usr/share/centrifydc/samples/adedit directory. The source file name is shown in the table and each script header.

You have a couple of different ways to invoke scripts from the command line (see Creating ADEdit scripts under Getting Started with ADEdit). The sample scripts demonstrate two of them.

Reading command line input	These scripts illustrate two different methods for using the Tcl argv, argc, and argv0 variables.	MktDept.sh getopt-example
Create a parent zone	This script illustrates how to create a Delineaparent zone.	CreateParentZone
Create child zones	This script illustrates how to create two child zones in a parent zone.	CreateChildZones
Create privileged commands and roles	These scripts illustrate how to create new privileged commands and new roles that include those commands.	MakeRole ApacheAdminRole
Add and provision UNIX users	This script and input file illustrate how to add users to Active Directory and copy them to the Active Directory UNIX Users group. If you have the Zone Provision Agent configured and running, you can use this script or one similar to it to automatically provision user profiles when users are added to Active Directory.	AddUnixUsers users.txt
Simple tools	These scripts demonstrate how you can list the computers in a zone, extract field attributes from user objects, and list the users in a zone.	computers-report useracc-report user-report GetComputers
Run a script from a script	These scripts illustrate how you can call a script (setenv) from within another script to perform different queries based on the values entered.	setenv GetChildZones GetGroups GetUsers GetZones

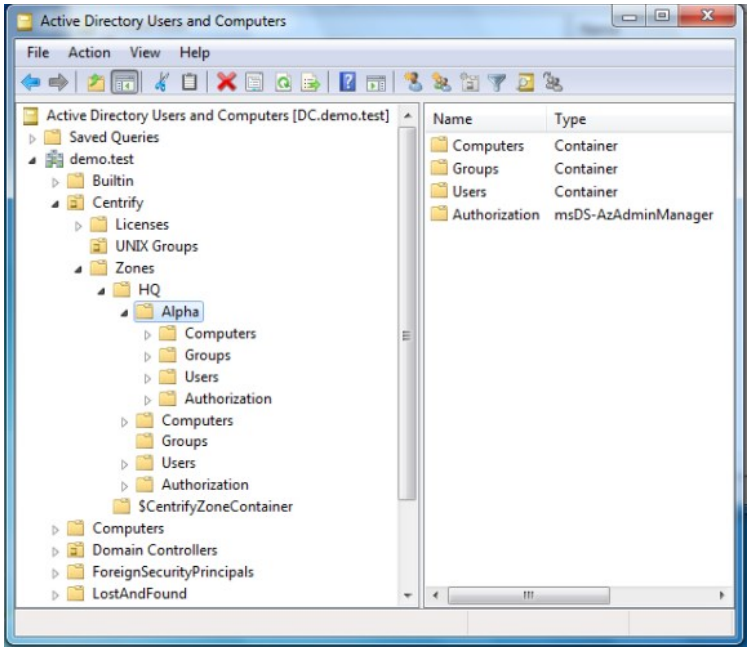
Zone Containers and Nodes

Many ADEdit commands require you to specify the zone container. This container is the root container used by Delineato store the zone information for the users, groups, computers and child zones. This container can have any name and can be anywhere in Active Directory. This container can also be an organizational unit.

Before you proceed, you need to know the location of the zone containers in Active Directory and the distinguished names you use to specify the zone container and its objects.

This section illustrates some sample cases with different locations for the zone container and the distinguished name for commonly used variables in the scripts.

In this example, the installer defined a base organizational unit called Delinea. This architecture is often used because it puts all the UNIX-related information in a single branch. The container with the zone information is called Zones.



In addition to the Zones container location, the installation script requires the installer to specify a location for a container to store the Delinea software licenses. In this figure, the node—Licenses—is in the base organizational unit. However, it does not need to be there.

In this figure, the installer also created another organizational unit called UNIX Groups for the Active Directory groups used for the UNIX users. Keeping all of the groups recreated for the UNIX users in a single node simplifies managing them and the privileges assigned to each user. (With few exceptions, the UNIX users get their rights from the role assigned to the group in which they are a member.) Often, more organizational units are created for managing different classes of UNIX user and UNIX services.

There are two zones in this figure: the parent zone HQ and a child zone named Alpha. Each zone contains nodes labeled Computers, Groups, Users, and Authorization. When you specify a zone, computer, user, or group in an ADEdit command you must use the distinguished name. The following table illustrates the distinguished names.

Domain	demo.test	dc=demo,dc=test
Base organizational unit	Delinea	ou=Acme,dc=demo,dc=test
Zone container	Zones	cn=Zones,ou=Acme,dc=demo,dc=test
Parent zone	HQ	cn=HQ,cn=Zones,ou=Centrity,dc=demo,dc=test
Child zone	Alpha	cn=Alpha,cn=HQ,cn=Zones,ou=Centrity,dc=demo,dc=test
Organizational unit	UNIX Groups	“ou=UNIX Groups,ou=Acme,dc=demo,dc=test”
UNIX group	ApacheAdmins	“cn=ApacheAdmin,ou=UNIX Groups,ou=Acme,dc=demo, dc=test”
Computer in Alpha zone	RHEL	cn=RHEL,cn=Computers,cn=Alpha,cn=HQ,cn=Zones,ou=Centrity,dc=demo,dc=test

You should note that distinguished names can contain space, as illustrated by the UNIX Groups organizational unit. To prevent Tcl from interpreting a space as new element in a list, you can enclose the distinguished name with double quotes (“ “) or using braces (). When specifying distinguished names, you should also be sure to use ou and cn correctly. Commands will fail if you refer to an organizational unit using cn.

Create Tcl Procedures

The following example demonstrates how to create procedures using the Tcl proc command. These two procedures create a new Active Directory user and Active Directory group, respectively, but first check to see if that object already exists in Active Directory.

This example uses the Tcl catch and if commands to determine if the account already exists. catch takes a Tcl script (in this case, the select_object command) and returns a 1 if an error (in this case, the account does NOT exist) occurs. Inside the if command, a non-zero result of the expression causes the body commands (puts and create_aduser or create_adgroup) to be executed. Otherwise, if select_object is successful (the account exists) it does not create the new account.

> **Note**: See the AddUnixUsers script for a similar example that uses the catch and if commands to determine whether a user exists.

Create Active Directory Group Procedure

```
# The following procedure creates an Active Directory group if a
# group with the same distinguished name does not already exist.
proc my_create_adgroup {dn sam gtype} {
        if { [catch {select_object \$dn}] } {
     # If we fail to select the object, the group
     # does not exist. So we create it here.
     puts "Creating \$dn"
     create_adgroup \$dn \$sam \$gtype
  } else {
     puts "\$dn exists. Do not create."
  }
 }
```

Create Active Directory User Procedure

```
# The following procedure creates an Active Directory user if an
# account with the same distinguished name does not already exist.
proc my_create_aduser {dn upn sam pw} {
         if { [catch {select_object \$dn}] } {
     # If we fail to select the object, the account
     # does not exist. So we create it here.
     puts "Creating \$dn"
     create_aduser \$dn \$upn \$sam \$pwd
   } else {
     puts "\$dn exists. Do not create."
   }
 }
```

Reading Command Line Input

In general, Tcl reads the arguments following the script name as a list and creates the following three variables:

- argv: a Tcl list containing all of the arguments in the command line
- argc: a count of the number of arguments in the lists
- argv0: the script name.

For example, the following script uses all three variables. This is a simple command in the form

```
>/bin/sh MktDept.sh name name name
```

where *name* is a person's name, such as Mary or Joe. If you want to use first and last name, surround the name with quotes, for example "Jane Smith".

> **Note**: This code sample demonstrates starting ADEdit from a shell script. The subsequent examples use the executable file model.

MktDept.sh

```
#!/bin/sh
# This script takes a list of names and displays it
#
# \
exec adedit "$0" ${1+"$@"}
package require ade_lib
if { $argc == 0 } {
        puts "Command format: $argv0 name name ..."
        exit 1
}
set total $argc
puts "
The following people are in the marketing department"
while {$total > 0} {
```

```
    incr total -1
    puts "[lindex $argv $total]"
    }
```

The first if statement uses the count, argc, to determine if any arguments have been entered. If the argc value is equal to zero, the user did not enter any names and the script displays the command format message. The argc counter is used again to set the total count of names entered for the while loop. Inside the loop, the names are drawn from the argv list.

Another useful command for parsing command line options is getopt. This command derives from, but is different than, the Tcl getopt command. The ADEdit getopt command has the following syntax:

```
getopt _argv name ?-var?
```

where:

- _argv is the Tcl list that contains the command line arguments.
- name is a label for the associated data.
- ?_var? is the variable name for the data.

For example, the following script illustrates the use of getopt to define the user and group variables that will be used later in the script.

This script also demonstrates how to use a procedure, usage, that prompts the user when she doesn't enter all of the arguments. usage first displays the full command syntax and then the missing argument.

> **Note**: The user and password arguments are optional. If the user enters a user name without the password, the bind program automatically prompts for the password. You do not need to include that prompt in the script.

getopt-example

```
#!/bin/env adedit
# This script takes a domain name and optionally user name and password
# and binds the user to the specified domain.
# If the user does not specify a user name or password, she is prompted.
#
package require ade_lib
proc usage {msg} {
            puts {usage: -d <domain> [-u <user>] [-p <password>]}
             puts $msg
             exit 1
}
if {[getopt argv -d domain] == 0} {
            usage "Missing Domain, ex.   centrify.demo"
}
if {[getopt argv -u user] != 0} {
      if {[getopt argv -p password]} {
            bind $domain $user $password
      } else {
        bind $domain $user}
            } else {
    puts "Enter administrator name:"
            gets stdin user
            bind $domain $user
}
puts "
Binding complete to $domain."
```

Create a Parent Zone

This sample script illustrates how you can create a parent zone. This script uses the puts command to display information and to prompt the user to specify variables that will be used to create the parent zone object. The command line syntax is as follows:

```
>./CreateParentZone - z parentZone -u adminName [-p password]
```

where:

- parentZone is the name of the parent zone you want to create.
- adminName is the name of an Active Directory user with administrator privileges on the domain controller.
- password is the administrator's password. If you do not enter the password in the command line, you are prompted to enter it.

Note that this sample script assumes you are using the default deployment structure with the top-level organizational unit. If you are not using the default deployment structure, you should modify the sample script to reflect the structure you are using before testing its operation.

CreateParentZone

```
#!bin/env adedit
# This script creates a tree zone. Use this, for example, to create the
# parent zone for child zones created in other scripts.
package require ade_lib
proc usage {msg} {
        puts {usage: -z >parentZone> -u >user>}
        puts $msg
        exit 1
}
if {[getopt argv -z parentZone] == 0} {
        usage "Missing the name for the new zone"
}
puts "
Enter the domain name for the bind command"
gets stdin domain
if {[getopt argv -u user] != 0} {
        if {[getopt argv -p password]} {
                bind $domain $user $password
                } else {
                bind $domain $user}
        } else {
        puts "Enter administrator name"
        gets stdin user
        bind $domain $user
}
set domaindn [dn_from_domain $domain]
puts "
Enter the name of the Active Directory container that holds the Delineazone data"
gets stdin zonesNode
puts "
Enter the organizational unit with the Delineazone data container"
gets stdin baseOU
puts "Summary:"
puts "Domain is $domain. DN for the domain is $domaindn"
puts "The base OU is $baseOU."
puts "The container for the zone information is $zonesNode"
puts "The new zone is named $parentZone"
#create the parent zone in Active Directory
puts "
Creating Delineazone $parentZone"
create_zone tree "cn=$parentZone,cn=$zonesNode,ou=$baseOU,$domaindn" std
puts "Created new zone: cn=$parentZone,cn=$zonesNode,ou=$baseOU,$domaindn"
```

Create Child Zones

This script creates two child zones in the domain and parent zone specified in the command line. The command line syntax is as follows:

```
>./CreateChildZones -d domain -z parentZone [-u adminName] [-p password]
```

where:

- domain is the domain name
- parentZone is the name of an existing zone
- adminName is the name of an Active Directory user with administrator privileges on the domain controller
- password is the administrator's password. If you do not enter the password in the command line, your are prompted for it

The *password is optional. If you do not type it in the command line, the script prompts you to enter it.

The script binds to the domain you specify using the user name and password you provide. The script then prompts you to enter the name of the organizational unit and container in which you store the zone information. After that, it prompts you to enter names for the two child zones. Note that this sample script assumes you are using the default deployment structure with the top-level organizational unit. If you are not using the default deployment structure, you should modify the sample script to reflect the structure you are using before testing its operation.

To confirm the script ran successfully, open Access Manager and expand the **Child Zones** node under the parent zone you specified in the command line. If the two new child zones are listed, you can right-click each zone name to see its zone properties.

CreateChildZones

```
#!/bin/env adedit
# This script creates 2 child zones in the domain and parent zone
# specified in the command line.
#
package require ade_lib
```

```
proc usage {msg} {
        puts {usage: -d <domain> -z <parentZone> [-u <user>] [-p <password>]}
puts $msg
         exit 1
}
if {[getopt argv -d domain] == 0} {
        usage "Missing Domain, ex. demo.test"
}
if {[getopt argv -z parentZone] == 0} {
        usage "Missing parent zone, ex. HQ"
}
if {[getopt argv -u user] != 0} {
        if {[getopt argv -p password]} {
                bind $domain $user $password
                 } else {
        bind $domain $user}
        } else {
puts "Enter administrator name"
        gets stdin user
        bind $domain $user
}
puts "
Enter the name of the container for the Delineazone data"
gets stdin zoneContainer
puts "
Enter the organizational unit for the Delineazone data"
gets stdin zoneContainerOU
# Define distinguished name for domain
set domaindn [dn_from_domain $domain]
puts "
Summary:"
puts  "Domain is $domain. DN for the domain is $domaindn"
puts  "The base OU is $zoneContainerOU."
puts  "The container for the zone information is $zoneContainer
"
# Create child zones
puts "Enter child zone name"
gets stdin czone1
puts "
Enter another child zone name"
gets stdin czone2
create_zone tree "cn=$czone1,cn=$parentZone,cn=$zoneContainer,ou=$zoneContainerOU,$domaindn" std
create_zone tree "cn=$czone2,cn=$parentZone,cn=$zoneContainer,ou=$zoneContainerOU,$domaindn" std
# link the children to parent
select_zone "cn=$czone1,cn=$parentZone,cn=$zoneContainer,ou=$zoneContainerOU,$domaindn"
set_zone_field parent "cn=$parentZone,cn=$zoneContainer,ou=$zoneContainerOU,$domaindn"
save_zone
select_zone  "cn=$czone2,cn=$parentZone,cn=$zoneContainer,ou=$zoneContainerOU,$domaindn"
set_zone_field parent "cn=$parentZone,cn=$zoneContainer,ou=$zoneContainerOU,$domaindn"
save_zone
puts "
Child zones $czone1 and $czone2 created in $parentZone"
```

Create Privileged Commands and Roles

Users get the rights necessary to run privileged commands and access applications from their role assignments. The predefined UNIX Login role gives users basic access to UNIX computers without any elevated privileges. The scripts in this section illustrate how you can create roles with additional rights. The first sample script uses a separate text file to define a new role and the commands users in that role are allowed to execute. The second sample script illustrates how to define the commands and the role within the script after prompting for bind credentials and the target zone.

Both scripts create the same commands and role.

Privileges and Role Defined in a File

For the first sample script, a single role and its privileged commands are defined in the file Role_apacheAdmin.txt. This sample text file defines the role name and a few sample commands that you might assign to an Apache server administrator. For example:

```
ApacheAdminRole
vi /etc/httpd/conf/httpd.conf
apachectl *
htpasswd *
```

The first line in the Role_apacheAdmin.txt file specifies the new role name. The subsequent lines specify the commands to add to the role. You can edit the text file to suit your environment. For example, you might want add or remove commands or modify the path to the Apache configuration file. To create the role and commands, you can then run the MakeRole sample script and specify the Role_apacheAdmin.txt file name as a commandline argument. The MakeRole sample script then prompts you to enter the domain name, account, and password for the bind command and to type the name of the parent zone where the sample role will be created.

Note that you must specify a parent zone for this sample script. The second sample ApacheAdminRole script, shown in the **Privileges and Roles Defined in the Script** section below, displays the list of zones in the domain to illustrate how you can create a role in a child zone. In addition, this sample script assumes you are using the default deployment structure with the top-level organizational unit. If you are not using the default deployment structure, you should modify the sample script to reflect the structure you are using before testing its operation.

MakeRole

The MakeRole sample script creates a role with the set of privileged commands defined in the sample Role_apacheAdmin.txt file.

```
#!/bin/env adedit
# This script creates a role consisting of a
# set of privileged commands
# The role name and commands are specified
# in a separate file.
#
# The first line in the input file should be
# the new role name.
# The subsequent lines are the names of the
# privileged commands to
# add to the role.
# For example:
#     audit_admin_cmds
#     /usr/bin/vi /etc/security/audit/config
#     /usr/bin/vi /etc/security/audit/objects
package require ade_lib
if { $argc != 1 } {
    puts "usage: $argv0 file"
    exit 1
}
if {[catch {set fp [open [lindex $argv 0] r]} errmsg]}
    {
    puts "Cannot open [lindex $argv 0]."
    exit 1
}
# Get domain and bind
puts "Enter domain name"
gets stdin domain
set domaindn [dn_from_domain $domain]
puts "Enter account name with administrator privileges"
gets stdin administrator
puts "Enter $administrator password"
gets stdin APWD
bind $domain $administrator "$APWD"
# Select the target zone and base organizational unit
puts "Enter the target zone name for the new role"
gets stdin zonename
puts "
Enter the name of the Active Directory container that holds the Delineazone data"
gets stdin zonesNode
puts "
Enter the organizational unit with the Delineazone data container"
gets stdin baseOU
select_zone "cn=$zonename,cn=$zonesNode,ou=$baseOU,$domaindn"
if {[gets $fp line] == -1} {
            puts "Cannot read [lindex $argv 0]."
             exit 1
}
# Create role
puts "Creating role...$line"
set role $line
new_role "$role"
save_role "$role"
set count 0
while {[gets $fp line] >= 0} {
   incr count
# Create command. Each command will be named
# based on the role defined in the first line
# and the command's line number in the file
   set cmd_name $role$count
   new_dz_command "$cmd_name"
   # set the command fields
   set cmd_path $line
   set_dzc_field cmd "$cmd_path"
   set_dzc_field dzdo_runas root
   set_dzc_field umask 077
   # prevent nested execution
   set_dzc_field flags 1
   # save the command
   save_dz_command
   # Add the command to the Role
   add_command_to_role "$cmd_name"
```

```
 }
close $fp
save_role "$role"
```

Privileges and Roles Defined in the Script

In this sample script, you create the same Apache administrator commands and role as the previous script. However, this script displays a list of the zones in the domain and lets you select in which zone to create the commands and role.

ApacheAdminRole

```
#!/bin/env adedit
puts "This script creates privileged commands and the ApacheAdminRole in the zone entered"
package require ade_lib
puts "
Enter the domain name"
gets stdin domain
puts "
Enter the account name to use to modify Active Directory"
gets stdin acctName
bind $domain $acctName
set domaindn [dn_from_domain $domain]
set zonelist [get_zones $domain]
set numberZones [llength $zonelist]
set row 1
set zonenum 0
puts "
This domain contains the following zones"
while {$numberZones != 0} {
        puts "$row. [lindex $zonelist $zonenum]"
        incr zonenum
        incr row
        incr numberZones -1
}
puts "
Enter the row number of the target zone"
gets stdin rowSelect
set zone [lindex $zonelist [incr rowSelect -1]]
select_zone "$zone"
puts "
Creating command-level Apache admin rights in $zone"
puts "
Creating web_edit_httpd_config"
new_dz_command web_edit_httpd_config
set_dzc_field cmd "vi /etc/httpd/conf/httpd.conf"
set_dzc_field description "edit httpd config file"
set_dzc_field dzdo_runas root
set_dzc_field dzsh_runas root
set_dzc_field path /usr/local/apache2/bin
set_dzc_field flags 1
save_dz_command
puts "
Creating web_apachectl"
new_dz_command web_apachectl
set_dzc_field cmd "apachectl *"
set_dzc_field description "Web Apache Server Control"
set_dzc_field dzdo_runas root
set_dzc_field dzsh_runas root
set_dzc_field path /usr/local/apache2/bin
save_dz_command
puts "
Creating web_htpasswd"
new_dz_command web_htpasswd
set_dzc_field cmd "htpasswd *"
set_dzc_field description "Web Apache Manage user files"
set_dzc_field dzdo_runas root
set_dzc_field dzsh_runas root
set_dzc_field path /usr/local/apache2/bin
save_dz_command
#-------------------------------------------------------------------------
# Create ApachedAdminRights role
# The new_role command creates the role in the currently selected zone.
puts "
Creating the ApacheAdminRole with these rights"
# In each role you need to set the sysrights with the set_role_field
# to the following binary values
# password_login = 01
# sso = 02
# ignore_disabled = 04
# full_shell = 08
new_role ApacheAdminRights
add_command_to_role web_edit_httpd_config
```

```
add_command_to_role web_apachectl
add_command_to_role web_htpasswd
set_role_field sysrights [expr 0x0000000b] #full_shell | sso | password_login
save_role
save_zone
```

Add and Provision UNIX Users

It is difficult to provision a lot of UNIX users and ensure that the UID is unique in the domain. To assist you with the process, Delineaprovides a set of features called the Zone Provisioning Agent. The Zone Provisioning Agent includes a service that automatically assigns a unique UID and other UNIX profile attributes, such as the home directory, default shell, and primary GID, based on rules you define.

This script demonstrates how you could use the Zone Provisioning Agent to add and provision users. For this sample script, the list of UNIX users is defined in the source file named users.txt and the Active Directory source group is Unix Users.

> **Note**:To learn more about the Zone Provisioning Agent and automated provisioning, see the *Planning and Deployment Guide*.

users.txt

You specify the names to be added in a text file in which each name is on a separate line. Be sure to use line feed only as the end-of-line; do not use CR-LF. The sample file in the distribution package contains the following names:

```
Amy.Adams
Brenda.Butler
Dennis.Day
Eric.Edwards
```

AddUnixUsers

In the following script, you specify the file name with the user names in the command line. The script then prompts you for the additional information required. The target Active Directory group—Unix Users—is hard-coded into the script.

This script uses the Tcl catch command three times to control processing when an error occurs.

- In the first case, it is used to exit gracefully if the specified file cannot be opened.
- In the second case, catch is used to determine if the user already exists. An error here indicates that the user does not exist and, rather than exiting, the else statement creates the user. (If the user already existed, you would not want to create another Active Directory account.)
- In the third case, catch is used to exit gracefully if the user is already a member of the Unix Users group.

```
#!/bin/env adedit
# This script creates an Active Directory account
# for each user the specified
# and adds the user to UNIX Users group.
# This automatically fills in their UNIX profile.
# Command line input: file name w/ user names in
# format ffff.llll only
# Prompted input: domain, administrator
#name, default password
package require ade_lib
if { $argc != 1 } {
    puts "usage: $argv0 file"
    exit 1
}
if {[catch {set users [open [lindex $argv 0] r]}
      errmsg]} {
    puts "Cannot open [lindex $argv 0]."
    exit 1
}
# Get domain and bind
puts "Enter domain name"
gets stdin domain
set domaindn [dn_from_domain $domain]
puts "Enter account name with administrator privileges"
gets stdin administrator
puts "Enter $administrator password"
gets stdin APWD
bind $domain $administrator "$APWD"
puts "
Define password to be used for all accounts"
gets stdin pwd
# Now start creating accounts from users
# example: "cn=Ellen Edwards,cn=Users,$domaindn"
# "Ellen.Edwards@$domain" ellen.edwards pwd
while {[gets $users sam] >= 0} {
```

```
    set name [split $sam .]
    set dn "cn=[lindex $name 0] [lindex $name 1],
          cn=Users,$domaindn"
    set upn $sam@$domain
    if { [catch { select_object $dn }] } {
        # If we fail to select the object,
        # most probably it
        # does not exist. So we create it here.
        puts "Creating $dn"
        create_aduser $dn $upn $sam $pwd
    } else {
        puts "$dn exists. Skip creating."
    }
# Because we already installed and started ZPA,
# this provisions the
# Active Directory account
    catch { add_user_to_group $sam@$domain
          "UNIX Users@$domain" }
  }
close $users
```

Simple Tools

The following scripts are simple "utilities" for getting information from Active Directory about the managed computers and users accounts:

- computers-report: Lists the managed computers in the zone.
- useracc-report: List the Active Directory users in the domain and several account properties.
- user-report: Lists the users in a zone.
- GetComputers: Lists all of the managed computers in the specified domain and the zone to which each computer is joined.

Following these scripts are sample scripts that demonstrate how you can use a script that calls, for example, commonly-used commands in other scripts. For more information, see **Run a Script from a Script** below.

computers-report

Use this command to list managed computers in the zone. The command line arguments are as follows:

-domain	required	Domain name.
-m	optional	Bind using the ADEdit host computer's credentials (see bind). You can use either the computer credentials (-m) or the user account credentials (-u).
-u	optional	Administrator's account name.
-p	optional	Administrator's account password. **Note**: If you do not enter the password in the command line you will be prompted to enter it.
-sep	optional	Separator used between data. The default is separator is the pipe (|) character.

```
#!/bin/env adedit
# This script lists the managed computers on the zone.
# Command line input is the domain, the
# administrator account name and
# the separator to use between computer's field
# values in the output
package require ade_lib
# Lists all of the managed computers and the zone
proc usage {msg} {
     puts {usage: -domain <domain> [-m] [-u <user>]
       [-p <password>] [-sep csv | tab | <char>]}
     puts $msg
     exit 1
}
if {[getopt argv -domain domain] == 0} {
    usage "Missing domain"
}
set verbose 0
if {[getopt argv -v]} {
```

```
    set verbose 1
}
set sep "|"
getopt argv -sep sep
if {$sep == "csv"} {set sep ","}
if {$sep == "tab"} {set sep "\t"}
if {[getopt argv -m]} {
     bind -gc -machine $domain
} else {
   if {[getopt argv -u user]} {
      if {[getopt argv -p password]} {
          bind -gc $domain $user $password
       } else {
        bind -gc $domain $user}
     } else {
    bind -gc $domain
  }
}
# this code runs entirely off the GC
cache on
set scps [get_objects -gc -depth sub [dn_from_domain $domain] {(&amp;(displayName=$CimsComputerVersion*)(objectClass=serviceConnectionPoint))}]
foreach scp $scps {
    select_object -gc $scp
    set name [get_object_field name]
    set parent ""
    # first look for parentLink
    foreach k [get_object_field keywords] {
       set bits [split $k ':']
       if {[lindex $bits 0] == "parentLink"} {
          set sid [lindex $bits 1]
          #ok we got it
          # make sure it exists
        catch {set parent [principal_from_sid $sid]}
        }
     }
     # if we didn't then try by managed By (DC3)
     if {$parent == ""} {
        set mb [get_object_field managedBy]
        if {$mb != ""} {
           set parent $mb
           }
        }
         set orphan 0
         if {$parent == ""} {set orphan 1}
           set path [get_parent_dn [get_parent_dn
               [get_object_field dn]]]
           set zone [string range [get_rdn $path] 3 end]
           puts $name$sep$zone$sep$orphan
     }
```

useracc-report

Use this command to list all users and their Active Directory account control values. The command line arguments are as follows:

-domain	required	Domain name
-m	optional	Bind using the ADEdit host machine's credentials (see bind) Note: If you use -m you do not need to enter -u
-u	optional	Administrator's account name.
-p	optional	Administrator's account password. Note: If you do not enter the password in the command line you will be prompted to enter it.
-sep	optional	Separator used between data. Default is |

```
#!/bin/env adedit
# This script lists all the users and their Active Directory account control values
package require ade_lib
# List users and the following field
proc usage {msg} {
            puts {usage: -domain <domain> [-m] [-u <user>] [-p <password>] [-sep csv | tab | <char>]}
            puts $msg
            exit 1
```

```
}
if {[getopt argv -domain domain] == 0} {
        usage "Missing domain"
}
set verbose 0
if {[getopt argv -v]} {
        set verbose 1
}
set sep "|"
getopt argv -sep sep
if {$sep == "csv"} {set sep ","}
if {$sep == "tab"} {set sep "\t"}
if {[getopt argv -m]} {
        bind -machine $domain
} else {
   if {[getopt argv -u user]} {
      if {[getopt argv -p password]} {
        bind $domain $user $password
       } else {
        bind $domain $user}
        } else {
    bind $domain
  }
}

user-report

Use this command to lists the users in the specified zone. The command line arguments are as follows:

-z	required	The distinguished name of the zone
-m	optional	Bind using the ADEdit host machine's credentials (see bind) Note: If you use -m you do not need to enter -u
-u	optional	Administrator's account name.
-p	optional	Administrator's account password. Note: If you do not enter the password in the command line you will be prompted to enter it.

```
#!/bin/env adedit
# This script lists the users in the zone you specify in the command line.
# On the command line use either -m or -u
package require ade_lib
proc usage {msg} {
        puts {usage: -z <zoneDN> [-m] [-u <user>] [-p <password>]}
```

```
            puts $msg
            exit 1
}
if {[getopt argv -z zoneDN] == 0} {
            usage "Missing input zone. Enter full distinguished name"
}
if {[catch {domain_from_dn $zoneDN} domain]} {
            usage "Invalid input zone name. Enter full distinguished name"
}
set verbose 0
if {[getopt argv -v]} {
            set verbose 1
}
if {[getopt argv -m]} {

             } else {
    bind $domain
  }
}
select_zone $zoneDN
list_zone_users
```

GetComputers

Use this command to list all the Centrify-managed computers in the specified domain. Enter the domain name in the command line.

```
#!/bin/env adedit
# GetComputers
# Purpose: Retrieves a listing of all UNIX computers in all DelineaZones.
package require ade_lib
puts "
This script retrieves a listing of all UNIX computers in the specified domain"
puts "and shows the zone to which it is joined"
if { $argc == 0 } {
            puts "
            Command format: $argv0 domain name"
            exit 1
 }
set domain [lindex $argv 0]
# Use lindex command because argv is a list and bind requires a string
puts "
Enter administrator name for bind command"
gets stdin admin
bind $domain $admin
foreach ZONE [get_zones $domain] {
            select_zone $ZONE
            foreach COMPUTER [get_zone_computers] {
                        puts -nonewline $COMPUTER:; puts $ZONE;
            }
}
```

Run a Script from a Script

The following scripts illustrate the use of the Tcl source command to run the script in a specified file. In this example, the source file is setenv, which prompts the user to enter environment variables such as the domain and zone.

> **Note** You may find repeated use of setenv to be maddening since it prompts you for all of the environment variables regardless of whether the command actually needs them. This is done for demonstration purposes only. In a production environment, you would eliminate the prompts you don't need by tailoring setenv specifically to your environment. Feel free to remove or comment out parts when you've had enough.

The subsequent scripts in this section call the setenv script and then run a short script that does simple queries, such as get the child zones, get the computers in the zone, and get the groups.

setenv

This script prompts you to enter data that can be used in the calling script. This example is intended as a demonstration only. Not all of the information is relevant to the calling script. Note that this sample script assumes you are using the default deployment structure with a top-level organizational unit. If you are not using the default deployment structure, you should modify the sample script to reflect the structure you are using before testing its operation.

```
# Setenv file contents
```

```
# Purpose: Sets up a common environment for the following Active Directory
# tools, selecting the Active Directory Domain, binding the user, and
# defining commonly used variables.
# Other Active Directory tools:
# GetZones
# GetUsers
# GetGroups
# GetChildZones
# GetComputers
puts "
This portion of the script prompts you to enter the domain and account name for the bind command."
# If you are always using the same domain, comment out the puts and gets and use the set command instead
puts "
Enter the domain name"
gets stdin domain
# get the distinguished name for the domain.
set domaindn [dn_from_domain $domain]
puts "
Enter administrator account name for bind command"
gets stdin admin
bind $domain $admin
puts "
bind to $domain complete"
puts "
The next two prompts ask you to enter the OU and container for your zone information"
puts "
Enter the name of the Active Directory container that holds the Delineazone-related data"
gets stdin zonesContainer
# If you are always using the same zone, comment out the puts and gets and use the set command instead
# set zonesContainer <Active Directory container with zones data>
puts "
Enter the name of the organizational unit that has the zone container."
gets stdin zonesContainerOU
# If you are always using the same OU for the zone container, comment out the puts and gets and use the set command instead
# set zonesContainerOU <Active Directory OU with zones container>
puts "
Enter the base organizational unit with the Delineamanaged computers data"
gets stdin baseOU
# If you are always using the same base OU, comment out the puts and gets commands and use the set command instead
# set baseOU <base OU name>
puts "
The next prompt asks for the parent zone."
# If you are always using the same zone, comment out the puts and gets and use the set command instead
# set parentZone <parent zone name>
puts "
Enter the parent zone name"
gets stdin parentZone
```

GetZones

Use this script to get a list of all the zones in a domain.

```
#!/bin/env adedit
# GetZones
# Purpose: Performs a recursive listing of all Delineazones in the specified
# domain
package require ade_lib
source setenv
puts "
This script retrieves a recursive listing of all Delineazones in the $domain domain"
puts "
The Active Directory folder with the Delineazone data is named $zonesContainer"
puts "
That container is in organizational unit $zonesContainerOU"
puts "
The parent zone is $parentZone"
foreach ZONE [get_zones $domain] {
        puts $ZONE;
}
```

GetUsers

Use this script to get a list of all users in a zone.

```
# GetUsers
# Purpose: Operates on a recursive listing of all UNIX users in all
# DelineaZones, and retrieves the administered UNIX attribute values
# for each user object in each zone.
package require ade_lib
puts "
This script retrieves the UNIX attributes for each user in each zone in the specified domain"
source setenv
```

```
foreach ZONE [get_zones $domain] {
    select_zone $ZONE
    foreach USER [get_zone_users] {
        save_zone_user $USER
        puts  -nonewline "[get_zone_user_field uname]:[gzuf uid]:[gzuf gid]:[gzuf gecos]:[gzuf home]:[gzuf shell]"; puts :$USER:$ZONE
    }
}
```

GetGroups

Use this script to get the UNIX group attribute values for the groups in the managed computers.

```
#!/usr/bin/env adedit
# GetGroups
# Purpose: Retrieves the UNIX group attribute values for each UNIX
# group administered in the parent zone specified in setenv.
# To select a different zone, change the DN in the select_zone command
package require ade_lib
puts "
This script retrieves the group attribute values for each UNIX group in the specified parent zone"
source setenv
select_zone "CN=$parentZone,CN=$zonesContainer,OU=$zonesContainerOU,$domaindn"
foreach GROUP [get_zone_groups] {
    select_zone_group $GROUP
    puts  -nonewline "[get_zone_group_field name]:[gzgf gid]"; puts :$GROUP
}
```

GetChildZones

Use this command to get a list of the child zones for the specified parent.

```
#!/bin/env adedit
# # GetChildZones
# Purpose: Retrieves a recursive listing of all new hierarchical Delineachild
# zones administered underneath the parent zone specified in setenv
#
package require ade_lib
source setenv
puts "
This script retrieves a recursive listing of all child zones in $parentZone"
puts "
The Active Directory folder with the Delineazone information is $zonesContainer"
select_zone "CN=$parentZone,CN=$zonesContainer,OU=$zonesContainerOU,$domaindn"
foreach ZONE [get_child_zones -tree] {
    puts $ZONE;
}
```

ADEdit Command Reference

This chapter describes each ADEdit command in alphabetical order. Each command description includes details about the options and arguments you can specify and the values returned, if applicable.

Inn, addition, some ADEdit commands can only be used when you are working with hierarchical zones. Other commands can be used in classic or hierarchical zones, but require you to specify the zone type. For each command, the **Zone type** section indicates whether there are any zonerelated constraints as follows:

- **Hierarchical only**: You must have a hierarchical zone selected for the command to work.
- **Classic and hierarchical**: You can use the command in both classic zones and hierarchical zones. Options in the command let you specify whether you are working with a classic or hierarchical zone. In most cases, commands that work in both classic and hierarchical zones, require the classic zone to be a classic4 zone. The classic3 zone type is intended for backward compatibility with older agents and only commands where the zone type is not applicable are supported.
- **Classic only**: You must have a classic4 zone selected for the command to work.
- **Not applicable**: You can use the command because the zone type does not matter.

In addition to the zone type, syntax, and return values, each command description includes at least one usage example and a summary of related commands, if appropriate.

add_command_to_role

Use the add_command_to_role command to add a privileged UNIX command to the currently selected role that is stored in memory. The command must already exist. You can create privileged UNIX commands using new_dz_command.

The add_command_to_role command does *not* change the role as it is stored Active Directory. Running the command changes the role only in memory. You must save the role before the added command takes effect in Active Directory. If you select another role or quit ADEdit before saving the role, any commands you've added since the last save won't take effect.

Zone Type

Classic and hierarchical

Syntax

add_command_to_role command[/zonename]

Abbreviation

acr

Options

This command takes no options.

Arguments

This command takes the following argument:

command[*/zonename*]	string	Required. Specifies the name of an existing UNIX command to add to the currently selected role. If the UNIX command right that you want to add is defined in the current zone, the *zonename* argument is optional. If the UNIX command right is defined in a zone other than the currently selected zone, the *zonename* argument is required to identify the specific UNIX command right to add.

Return Value

This command returns nothing if it runs successfully.

Examples

```
add_command_to_role basicshell/global
```

This example adds the command basicshell, defined in the global zone, to the currently selected role.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select a role to work with:

- get_role_commands returns a Tcl list of the UNIX commands for the role.
- new_role creates a new role.
- select_role retrieves a role from Active Directory.

The following commands enable you to work with a currently selected role:

- add_pamapp_to_role adds a PAM application to the role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM applications for the role.
- get_role_field reads a field value from the role.
- list_role_rights lists of all privileged commands and PAM application rights for the role.
- remove_command_from_role removes a UNIX command from the role.
- remove_pamapp_from_role removes a PAM application from the role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the role.

add_map_entry

Use the add_map_entry command to add an entry to the currently selected NIS map stored in memory. This command does not support a comment field. If you want to add a comment along with the entry use add_map_entry_with_comment instead.

To change an existing entry in a NIS map, use delete_map_entry to remove the entry, then add the revised version using add_map_entry.

The add_map_entry` command changes the NIS map in memory and in Active Directory. You do not need to save the NIS map for the added entry to take effect in Active Directory.

Zone Type

Not applicable

Syntax

```
add_map_entry key value
```

Abbreviation

```
ame
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

key	string	Required. Specifies the key of the NIS map entry.
value	string	Required. Specifies the value of the NIS map entry.

Return Value

This command returns nothing if it runs successfully.

Example

add_map_entry Finance “Hank@acme.com,Sue@acme.com”

This example adds the NIS map entry Finance with the value Hank@acme.com,Sue@acme.com to the currently selected NIS map.

Related Commands

The following commands enable you to view and select the NIS map you want to work with:

- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps lists to stdout of all NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use additional commands to work with that map's entries or use the following commands to delete or save the currently selected NIS map:

- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.

add_map_entry_with_comment

Use the add_map_entry_with_comment command to add an entry to the currently selected NIS map stored in memory and lets you include a comment. The comment can be up to 2048 characters and does not support new line syntax.

To change an existing entry in a NIS map, use delete_map_entry to remove the entry, then add the revised version using add_map_entry_with_comment.

The add_map_entry_with_comment command changes the NIS map in memory and in Active Directory. You do not need to save the NIS map for the added entry to take effect in Active Directory.

Zone Type

Not applicable

Syntax

add_map_entry_with_comment key value comment

Abbreviation

amewc

Options

This command takes no options.

Arguments

This command takes the following arguments:

key	string	Required. Specifies the key of the NIS map entry.

value	string	Required. Specifies the value of the NIS map entry.
comment	string	Required. Specifies the comment for the NIS map entry.

Return Value

This command returns nothing if it runs successfully.

Example

```
add_map_entry_with_comment Finance “Hank@acme.com,Sue@acme.com” “new Finance staff”
```

This example adds the NIS map entry Finance, with the value Hank@acme.com,Sue@acme.com and comment new Finance staffto the currently selected NIS map.

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and select a NIS map to work with:

- get_nis_maps returns a Tcl list of NIS maps in the current zone.
- list_nis_maps lists to stdout the NIS maps in the current zone.
- new_nis_map creates a new NIS map.
- select_nis_map retrieves a NIS map from Active Directory.

The following commands enable you to work with a currently selected NIS map:

- add_map_entry adds an entry to the NIS map.
- delete_map_entry removes an entry from the NIS map.
- get_nis_map_field reads a field value from the NIS map.
- get_nis_map and get_nis_map_with_comment return a Tcl list of NIS map entries.
- list_nis_map and list_nis_map_with_comment lists NIS map entries to stdout.

add_object_value

Use the add_object_value command to add a value to a multi-valued field (attribute) of a specified Active Directory object in Active Directory. This command only works on the object in Active Directory, not on the currently selected Active Directory object in memory (if there is one).

If the added value isn't valid, Active Directory will report an error and add_object_value won't save the value.

This command is useful for fields that may be very large—members of a group, for example.

Zone Type

Not applicable

Syntax

```
add_object_value dn field value
```

Abbreviation

aov

Options

This command takes no options.

Arguments

This command takes the following arguments:

dn	string	Required. Specifies the distinguished name (DN) of the Active Directory object in which to add a value.
field	string	Required. Specifies the name of a multi-valued field in the currently selected Active Directory object to which to add the value. This can be any field that is valid for the type of the currently selected Active Directory object.
value		Required. Specifies the value to add to the field. The type of value depends on the field specified by the *field* argument.

Return Value

This command returns nothing if it runs successfully.

Examples

```
add_object_value cn=groups,dc=acme,dc=com users adam.avery
```

This example adds the value adam.avery to the users field of the groups object specified by the DN.

Related Commands

The following commands enable you to work with Active Directory objects:

- delete_object deletes the Active Directory object from Active Directory.
- delete_sub_tree deletes the Active Directory object and all of its children.
- get_object_field reads a field value from the Active Directory object.
- remove_object_value removes a value from a multi-valued attribute of the Active Directory object.
- save_object saves the Active Directory object.
- set_object_field sets a field value in the Active Directory object.

add_pamapp_to_role

Use the add_pamapp_to_role command to add a PAM application right to the currently selected role stored in memory. The PAM application right must already exist. You can create PAM application rights using new_pam_app.

The add_pamapp_to_role command does *not* change the role as it is stored Active Directory. The command only changes the role stored in memory. You must save the role using save_role before the added PAM application takes effect in Active Directory. If you select another role or quit ADEdit before saving the role, any PAM application rights you've added since the last save won't take effect.

You can only use the add_pamapp_to_role if the currently selected zone is a classic4 or hierarchical zones. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
add_pamapp_to_role app[/zonename]
```

Abbreviation

```
apr
```

Options

This command takes no options.

Arguments

This command takes the following argument:

app[*/zonename*]	string	Required. Specifies the name of an existing PAM application right to add to the currently selected role. If the PAM application right that you want to add is defined in the current zone, the *zonename* argument is optional. If the PAM application right is defined in a zone other than the currently selected zone, the *zonename* argument is required to identify the specific PAM application right to add.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example adds the PAM application login-all, which is defined in the currently selected zone, to the currently selected role:

```
add_pamapp_to_role login-all
```

The following example adds the PAM application access right oracle-admin from the emea zone to the currently selected role:

```
add_pamapp_to_role oracle-admin/emea
```

Related Commands

The following commands enable you to view and select the role you want to work with:

- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.
- get_roles returns a Tcl list of roles in the current zone.
- list_roles displays a list to stdout of all roles in the currently selected zone.

After you have a role stored in memory, you can use additional commands to work with that role's fields, commands, and applications or use the following commands to delete or save the currently selected role:

- save_role saves the selected role with its current settings to Active Directory.
- delete_role deletes the selected role from Active Directory and from memory.

add_sd_ace

Use the add_sd_ace command to add an access control entry (ACE) in ACE string form to a security descriptor (SD) in SDDL (security descriptor description language) form.

The command takes an ACE string and an SDDL string. The command writes the ACE string there. The command returns an SDDL string that includes the added ACE string.

Zone Type

Not applicable

Syntax

```
add_sd_ace sddl_string ace_string
```

Abbreviation

```
ase
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

sddl_string	string	Required. Specifies a security descriptor in SDDL format.
ace_string	string	Required. Specifies an access control entry in ACE string form (which is always enclosed in parentheses)

Return Value

This command returns a security descriptor string in SDDL format if it runs successfully.

Examples

This example adds an ACE string (A;;SDRCWDWOCCDCLCSWRPWPDTLOCR;;;SY) to an SDDL at the end of the command.

```
add_sd_ace O:DAG:DAD:AI(A;;RCWDWOCCDCLCSWRPWPLOCR;;;DA)(OA;;CCDC;bf967aba-0de6-11d0-a285-00aa003049e2;;AO)

```

Related Commands

The following commands enable you to work with security descriptor strings:

- explain_sd converts security descriptor in SDDL format to a human-readable form.
- remove_sd_ace removes an access control entry (ACE) from a security descriptor.
- set_sd_owner sets the owner of a security descriptor.

bind

Use the bind command to bind ADEdit to a domain. Multiple bind commands can bind ADEdit to multiple domains in multiple forests. ADEdit must be bound to at least one domain before its commands have any effect on Active Directory or Delineaobjects. When ADEdit is bound to multiple domains, its commands can work on any of those domains.

You can use bind to bind to any domain for which the DNS can resolve a name and for which you have log-in permission. ADEdit's host computer does not need to be joined to a domain for ADEdit to bind to and work on that domain.

You can optionally specify a server in the domain to bind to, in which case ADEdit binds to that domain controller. If you don't specify a server, ADEdit automatically binds to the closest, fastest domain controller. You can use options to request automatic binding to a global catalog (GC) domain controller or to a writable domain controller.

You can authorize the bind connection to a domain controller in the following ways:

- If you provide no user or password arguments, bind uses the user name and password stored in the current Kerberos credential cache on the ADEdit host computer.
- If you provide a user argument without the password argument, bind in interactive mode prompts you for a password, then uses the user argument along with your entered password for authorization.
- If you provide a user argument and password argument, bind uses the user and password arguments for authorization.
- If you specify the -machine option, ADEdit authenticates using the credentials for the ADEdit host computer. You cannot provide user or password arguments if you specify the -machine option. Note that you must have read permission on the host's credential files to use this option, so you must typically have root permissions to use the option.

Zone Type

Not applicable

Syntax

bind [-gc] [-write] [-machine] [*server*@]*domain* [*user* [*password*]]

Abbreviation

None

Options

This command takes the following options:

-gc	Requests an automatic binding to a global catalog (GC) domain controller. This option has no effect if there's a domain controller specified using the *server* argument.
-write	Requests an automatic binding to a writable domain controller. This option has no effect if there's a domain controller specified using the *server* argument.
-machine	Binds using the credentials for the ADEdit host computer. Note that most computer accounts have only read permission, not write permission for Active Directory. To use this option, you must have read permission on the local computer's keytab file and credentials cache. In most cases, only the root user has this right.

Arguments

This command takes the following arguments:

[*server*]@domain	string	Required. Specifies the domain to bind to. If you want to specify a domain controller to connect to, precede the domain with the name of the domain controller's server followed by the "@" symbol. If you don't specify a domain controller, bind performs an automatic binding to the domain controller that ADEdit determines is most optimal for binding.

[*user*]	string	Optional. Specifies the user name for logging on to the domain controller. If you don't specify this argument and the -machine option is also not present, ADEdit attempts to log on using your current account credentials. If you specify the -machine option, you cannot use this argument.
[*password*]	string	Optional. Requires the *user* argument. Specifies the password to use when logging on to the domain controller as *user*.

Return Value

This command returns no value.

Examples

The following example binds ADEdit to the domain acme.com, logging in as administrator with the password #3gEgh^&4:

```
bind acme.com administrator #3gEgh^&4
```

Note that a password that includes Tcl-special characters such as $ might trigger character substitution that modifies the password. To ensure that a password isn't altered by the Tcl interpreter, enclose the password in braces {}. For example:

```
bind acme.com maya,garcia {$m1l3s88}
```

Related Commands

The following commands perform actions related to the bind command:

- get_bind_info returns information about a domain to which ADEdit is bound.
- pop restores the context from the top of ADEdit's context stack to ADEdit.
- push saves ADEdit's current context to ADEdit's context stack.
- show returns the current context of ADEdit: its bound domains and its currently selected objects.

clear_rs_env_from_role

Use the clear_rs_env_from_role command to remove the restricted shell environment from the currently selected role that is stored in memory.

The clear_rs_env_from_role command does not modify the information stored in Active Directory for the role. If you run this command using ADEdit without saving the role to Active Directory, the change will have no effect on the restricted shell environment stored in Active Directory.

You can only use the clear_rs_env_from_role command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

```
clear_rs_env_from_role
```

Abbreviation

```
crse
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
clear_rs_env_from_role
```

This example removes the restricted shell environment from the current role.

Related Commands

The following commands perform actions related to this command:

- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.
- set_rs_env_for_role assigns a restricted shell environment to the current role.

After you have a restricted shell environment stored in memory, you can use the following commands to work with that: restricted shell environment:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.

create_computer_role

Use the create_computer_role command to create a new computer role in Active Directory. The command does *not* store the new computer role in memory nor set it as the currently selected ADEdit computer role. To manage the computer role, you must select it using select_zone and then use zone commands to work with the computer role's fields.

ADEdit requires a valid license before the computer role is created. The create_computer_role command does an implicit search. The first place it looks is the ADEdit context for a valid license indicator (see the validate_license command) for the forest. If an indicator is not in the context, the command checks for a valid license as follows:

- Bind to the global catalog (GC) domain controller, search the forest for the license container and validate the license.
- Bind to the current domain, search for the license container and validate the license.

If it finds a valid license, it stores an indicator in the current context and creates the new computer role. If it does not find a valid license, create_computer_role reports "No valid license found" and exits. If the command fails, use validate_license to validate the license container explicitly.

To associate role assignments with the new computer role, you must select the computer role, then use new_role_assignment.

Zone Type

Hierarchical only

Syntax

```
create_computer_role computer_role_path group_upn
```

Abbreviation

```
ccr
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

computer_role_path	string	Required. Specifies a path to the new computer role. The path consists of the hosting zone's distinguished name followed by a slash and the name of the new computer role.
group_upn	string	Required. Specifies the user principal name (UPN) of a computer group in Active Directory to associate with this computer role. This computer group defines the set of computers in which this computer role functions. The computer group must be available within the computer role's host domain.

Return Value

This command returns no value if it runs successfully.

Examples

The following example creates a new computer role named LinuxComputers in the global zone of acme.com:

```
create_computer_role {CN=global,CN=Zones,CN=Acme,DC=acme,DC=com/LinuxComputers} linux_computers@acme.com
```

The scope of the computer role is defined by the group named linux_computers which is an Active Directory groups defined in acme.com. To work with the new computer role, you must select it as a zone:

```
select_zone "CN=global,CN=Zones,CN=Acme,DC=acme,DC=com/LinuxComputers"
```

Related Commands

The following command retrieves the computer role from Active Directory and stores it in memory so you can use other commands to work with it.

- select_zone retrieves the computer role and stores it in memory.

After you have a computer role selected as a zone, you can use the following commands to view and manage the computer role:

- new_role_assignment creates a new role assignment for the selected computer role.
- list_role_assignments lists user role assignments for the selected computer role.
- get_role_assignments returns a Tcl list of user role assignments for the selected computer role.
- get_zone_field retrieves what computer group is associated with the computer role.
- set_zone_fieldsets what computer group is associated with the computer role.
- delete_zone deletes the selected computer role from Active Directory and memory.

create_zone

Use the create_zone command to create a new zone in Active Directory. The command does *not* store the new zone in memory nor set it as the currently selected ADEdit zone. To manage the zone, you must select it using select_zone and then use zone commands.

This command can create different types of zones and the zones can use different types of schemas, depending on the schema you are using for Active Directory. Before the zone is created, however, ADEdit checks for a valid license.

The create_zone command first checks the ADEdit context for a valid license indicator for the forest. If an indicator is not found in the context, the command checks for a valid license as follows:

- Bind to the global catalog (GC) domain controller, search the forest for the license container and validate the license.
- Bind to the current domain, search for the license container and validate the license.

If the command finds a valid license, it stores an indicator in the current context and creates the new zone. If it does not find a valid license, create_zone reports "No valid license found" and exits. If the command fails, use the validate_license command to validate the license container explicitly.

> **Note**: When this command creates a zone, the zone contains predefined roles such as "sftp" and "UNIX Login." The zone does not, however, contain the role "Windows Login" because ADEdit does not support Windows rights.

Zone Type

Classic and hierarchical

Syntax

create_zone [-ou] [-nonisserversgroup] [-notdelegateanyright] zone_type path [schema_type]

Abbreviation

cz

Options

This command takes the following options:

-nonisserversgroup	Creates the new zone without the zone_nis_servers group.
-notdelegateanyright	Creates the new zone but does not set the zone permissions. If you use this option, be sure to set the zone permissions later.
-ou	Creates the new zone as an organizational unit object. If not present, the new zone is created as a container object. Note that the parent container determines what type of object the zone can be. If the parent container is a generic container object, the zone must be a container object. If the parent container is an organizational unit object, the zone can be either an organizational unit object or a container object.

Arguments

This command takes the following arguments:

zone_type	string	Required. The possible values are: **tree** specifies a hierarchical zone that can be a parent or child zone. **classic3** specifies a classic zone that is compatible with agent version 3 and later. **classic4** specifies a classic zone that is compatible with agent version 4 and later. **computer** specifies a computer-level zone that consists of a single computer in a hierarchical zone. This zone type is used to support computer-level overrides for user and group profiles and role assignments. It is not applicable in classic zones. **classic-computer** specifies a computer-level zone that consists of a single computer in a classic zone. This zone type is used to enable you to assign a role to a specific computer in classic zones. It is not applicable in hierarchical zones.
path	string	Required. Specifies a path to the new zone. The path consists of the new zone's distinguished name (DN) and (if a computer override) the name of the computer.
schema_type	string	Optional. Specifies the type of schema to use for the new zone. The possible values are: **sfu** specifies the Microsoft Services For UNIX schema. This setting can be used for tree, classic3, and classic4 zone types. If it's used for a hierarchical zone, it can only be the root of the zone hierarchy. **std** specifies the dynamic schema. This setting can be used for all zone types. This is the default schema unless ADEdit detects the RFC2307 schema. **rfc** specifies the RFC2307 schema.This setting can be used for all zone types. This is the default schema if ADEdit detects that RFC2307 is installed and the domain is at Windows Server 2003 functional level. If none of these values is present, the default is either **std** or **rfc** as described above.

Return Value

This command returns no value if it runs successfully.

Examples

The following examples illustrate how to create a classic zone, hierarchical zone, and computer-specific zone in Server Suite 2012 and later.

Classic Zone

The following command creates a classic zone named finance in the Acme organizational unit in the acme.com domain that uses the dynamic schema (std):

```
create_zone classic4 “CN=finance,OU=Acme,DC=acme,DC=com” std
```

Hierarchical Zone

The following command creates a new hierarchical parent zone named finance in the Zones container in the Acme organizational unit in the acme.com domain:

```
create_zone tree “CN=finance,CN=Zones,OU=Acme,DC=acme,DC=com” std
```

To make the finance zone a child zone within a global zone already created in the same container, OU, and domain, you would next select finance to make it the currently selected zone, then use set_zone_field (szf) to specify the global zone as its parent, and the save finance. For example:

```
select_zone “CN=finance,CN=Zones,OU=UNIX,DC=acme,DC=com”  szf parent “CN=global,CN=Zones,OU=UNIX,DC=acme,DC=com”  save_zone
```

Computer-specific Zone

The following command creates a computer-specific zone for the computer srv1 in the apache zone, which is a child of the global zone, in the Zones container in the Acme organizational unit in the acme.com domain.

```
create_zone computer svr1.acme.com@CN=apache,CN=global,CN=Zones,OU=Acme,DC=acme,DC=com
```

Related Commands

Before you use this command, you must bind to one or more Active Directory domains. The following command enables you to store a newly created zone in memory:

- select_zone retrieves a zone from Active Directory and stores it in memory.

After you have created a new zone and stored it in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_field reads a field value from the currently selected zone.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.
- set_zone_field sets a field value in the currently selected zone.

delegate_zone_right

Use the delegate_zone_right command to delegate an administrative right for the currently selected zone to a security principal (user or group). Zone rights allow a user or group to use and manage zone properties, including computer-specific zone properties and computer roles.

Zone Type

Classic and hierarchical

Syntax

```
delegate_zone_right right principal_upn
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes the following arguments:

right	string	Required. Specifies the right to delegate. Possible values: **add_computer_role**: The right to add computer roles to the zone. **add_computer_zone**: The right to add computer-specific zones. **add_group**: The right to add groups to the zone.
		add_nismap: The right to add NIS maps to the zone. **add_remove_nismap_entry**: The right to add or remove NIS map entries. **add_user**: The right to add users to the zone.
		add_user_group_to_computer_zone: The right to add user and group overrides to the selected computer-specific zone. **change_user**: The right to modify user profiles in the zone. **change_group**: The right to modify group profiles in the zone.
		change_computer: The right to modify computer profiles in the zone. **change_zone**: The right to change zone properties. **delegate_permission_for_computer_zone**: The right to delegate permissions to other users for computer-specific zones.
right (continued)	string (continued)	**delete_computer**: The right to remove computers from the zone. **delete_computer_role**: The right to delete computer roles in the zone. **delete_computer_zone**: The right to delete computer-specific zones.
		delete_group: The right to remove groups from the zone. **delete_user**: The right to remove users from the zone. **delete_user_group_from_computer_zone**: The right to delete user and group overrides from the selected computer-specific zone.
		delete_zone: The right to remove the zone. **enable_dz**: The right to initialize authorization (privilege elevation service) data. This right is only applicable in classic zones. **import**: The right to import users and groups into the zone.
		join: The right to join computers to the zone. **manage_role_assignments**: The right to modify the roles assigned in zones, computer-specific zones, and computer roles. **manage_roles_and_rights**: The right to modify role definitions and access rights.
		modify_computer_role: The right to modify computer role entries. This right is not applicable in classic zones. **modify_nismap_entry**: The right to modify NIS map entries. **modify_user_group_in_computer_zone**: The right to modify user and group overrides in the selected computer-specific zone.
right (continued)	string (continued)	**nisservers**: The right to allow computers to respond to NIS client requests. **remove_nismap**: The right to remove NIS maps.
principal_upn	string	Required. Specifies the user principal name (UPN) of a user or group in Active Directory to delegate the specified right to.

Return Value

This command returns no value if it runs successfully.

Examples

```
delegate_zone_right add_user adam.avery@acme.com
```

This example delegates the right to add users to the currently selected zone to the Active Directory user Adam Avery.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone to work with:

- `create_zone` creates a new zone in Active Directory.
- `get_zones` returns a Tcl list of all zones within a specified domain.
- `select_zone` retrieves a zone from Active Directory and stores it in memory.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_field reads a field value from the currently selected zone.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.
- set_zone_field sets a field value in the currently selected zone.

delete_dz_command

Use the `delete_dz_command command to delete the currently selected privileged command from Active Directory and from memory. You cannot use other commands to manage privileged commands after deletion because there will be no currently selected command in memory.

Zone Type

Classic and hierarchical

Syntax

delete_dz_command

Abbreviation

dldzc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_dz_command

This example deletes the currently selected command from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a UNIX command to work with:

- get_dz_commands returns a Tcl list of UNIX commands in the current zone.
- list_dz_commands lists to stdout the UNIX commands in the current zone.
- new_dz_command creates a new UNIX command and stores it in memory.
- select_dz_command retrieves a UNIX command from Active Directory and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- get_dzc_field reads a field value from the currently selected command.
- save_dz_command saves the selected command with its current settings to Active Directory.
- set_dzc_field sets a field value in the currently selected command.

delete_local_group_profile

Use the delete_local_group_profile command to delete a local UNIX or Linux group that has a profile defined in the current zone. When you delete a group, the group's zone object is deleted, but the group's entry in the local /etc/group file is retained.

Zone Type

Hierarchical only.

Syntax

delete_local_group_profile group_name

Abbreviation

dllgp

Options

This command takes no options.

Arguments

This command takes the following argument:

group_name	string	Required. Specifies the UNIX name of the local group to delete from the zone.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_local_group_profile marketing

This example deletes the zone object for the local group marketing. The entry for marketing in the local /etc/group file is retained.

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

delete_local_user_profile

Use the delete_local_user_profile command to delete a local UNIX or Linux user that has a profile defined in the current zone. When you delete a user, the user's zone object is deleted, but the user's entry in the local /etc/passwd file is retained.

Zone Type

Hierarchical only.

Syntax

```
delete_local_user_profile user_name
```

Abbreviation

```
dllup
```

Options

This command takes no options.

Arguments

This command takes the following argument:

user_name	string	Required. Specifies the UNIX name of the local user to delete from the zone.

Return Value

This command returns nothing if it runs successfully.

Examples

```
delete_local_user_profile anton.splieth
```

This example deletes the zone object for the local user anton.splieth. The entry for anton.splieth in the local /etc/passwd file is retained.

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.

- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

delete_map_entry

Use the delete_map_entry command to delete an entry from the currently selected NIS map stored in memory. The delete_map_entry command changes the NIS map in memory and in Active Directory. You do not need to save the NIS map for the deleted entry to take effect in Active Directory.

Zone Type

Not applicable

Syntax

delete_map_entry key:index

Abbreviation

dlme

Options

This command takes no options.

Arguments

This command takes the following argument:

key:index	string	Required. Specifies the key of the NIS map entry to delete followed by a colon : and the index number of the key.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_map_entry calla:1

This example deletes the NIS map entry with the key value "calla" and index number 1 from the currently selected NIS map.

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and select the NIS map to work with:

- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps lists to stdout all of the NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map's entries:

- get_nis_map or get_nis_map_with_comment returns a Tcl list of the map entries in the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- list_nis_map or list_nis_map_with_comment lists to stdout the map entries in the currently selected NIS map.
- add_map_entry or add_map_entry_with_comment adds an map entry to the currently selected NIS map.

delete_nis_map

Use the delete_nis_map command to delete the currently selected NIS map from Active Directory and from memory. You cannot use other commands to

manage the NIS map after deletion because there will be no currently selected map in memory.

Zone Type

Not applicable

Syntax

delete_nis_map

Abbreviation

dlnm

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_nis_map

This example deletes the currently selected NIS map from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and select the NIS map to work with:

- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps lists to stdout of all NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map's entries:

- add_map_entry or add_map_entry_with_comment adds an entry to the currently selected NIS map.
- delete_map_entry removes an entry from the currently selected NIS map.
- get_nis_map or get_nis_map_with_comment returns a Tcl list of the entries in the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- list_nis_map or list_nis_map_with_comment lists to stdout of the entries in the currently selected NIS map.

delete_object

Use the delete_object command to delete the currently selected Active Directory object from Active Directory and from memory. You cannot use other commands to manage the object after deletion because there will be no currently selected Active Directory object in memory.

> **Note**:Do NOT use the delete_object command to delete an Active Directory user or group that has been provisioned. If you use delete_object to delete a provisioned user or group, you create orphan user or group UNIX data objects. Instead, use the delete_zone_user or delete_zone_group command. In addition, you would use the select_zone_user and select_zone_group rather than select_object to select the user or group. For information about displaying orphan accounts, see the list_zone_users and list_zone_groups.

Zone Type

Not applicable

Syntax

delete_object

Abbreviation

dlo

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_object

This example deletes the currently selected Active Directory object from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected Active Directory object stored in memory. The following commands enable you to view and select the object to work with:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of matching objects.
- new_object creates a new Active Directory object and stores it in memory.
- select_object retrieves an object with its attributes from Active Directory and stores it in memory.

After you have an Active Directory object stored in memory, you can use other commands to work with that object's attributes, or the following commands to delete or save information for the object:

- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- save_object saves the selected Active Directory object with its current settings to Active Directory.

delete_pam_app

Use the delete_pam_app command to delete the currently selected PAM application from Active Directory and from memory. You cannot use other commands to manage the PAM application after deletion because there will be no currently selected PAM application in memory.

Zone Type

Classic and hierarchical

Syntax

delete_pam_app

Abbreviation

dlpam

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
delete_pam_app
```

This example deletes the currently selected PAM application from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. After you have a zone stored in memory, you can use the following commands to view and select the PAM application to work with:

- `get_pam_apps` returns a Tcl list of PAM application rights in the current zone.
- `list_pam_apps` lists to `stdout` all PAM application rights in the current zone.
- `new_pam_app` creates a new PAM application right and stores it in memory.
- `select_pam_app` retrieves a PAM application right from Active Directory and stores it in memory

After you have a PAM application stored in memory, you can use the following commands to work with that PAM application's attributes, delete the PAM application, or save information for the PAM application:

- `delete_pam_app` deletes the selected PAM application right from Active Directory and from memory.
- `get_pam_field` reads a field value from the currently selected PAM application right.
- `save_pam_app` saves the selected PAM application right with its current settings to Active Directory.
- `set_pam_field` sets a field value in the currently selected PAM application right.

delete_role

Use the `delete_role` command to delete the currently selected role from Active Directory and from memory. You cannot use other commands to manage the role after deletion because there will be no currently selected role in memory.

Zone Type

Classic and hierarchical

Syntax

```
delete_role
```

Abbreviation

```
dlr
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
delete_role
```

This example deletes the currently selected role from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- `get_roles` returns a Tcl list of roles in the current zone.
- `list_roles` lists to `stdout` all roles in the currently selected zone.
- `new_role` creates a new role and stores it in memory.
- `select_role` retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

- `add_command_to_role` adds a UNIX command to the currently selected role.
- `add_pamapp_to_role` adds a PAM application to the currently selected role.
- `get_role_apps` returns a Tcl list of the PAM applications associated with the role.
- `get_role_commands` returns a Tcl list of the UNIX commands associated with the role.
- `get_role_field` reads a field value from the currently selected role.
- `list_role_rights` lists to `stdout` all UNIX commands and PAM applications associated with the role.
- `remove_command_from_role` removes a UNIX command from the currently selected role.
- `remove_pamapp_from_role` removes a PAM application from the currently selected role.
- `save_role` saves the selected role with its current settings to Active Directory.
- `set_role_field` sets a field value in the currently selected role.

delete_role_assignment

Use the `delete_role_assignment` command to delete the currently selected role assignment from Active Directory and from memory. You cannot use other commands to manage the role assignment after deletion because there will be no currently selected role assignment in memory.

Zone Type

Classic and hierarchical

Syntax

```
delete_role_assignment
```

Abbreviation

```
dlra
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
delete_role_assignment
```

This example deletes the currently selected role assignment from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected role assignment stored in memory. The following commands enable you to view and select the role assignment to work with:

- get_role_assignments returns a Tcl list of role assignments in the current zone.
- list_role_assignments lists to stdout all role assignments in the currently selected zone.
- new_role_assignment creates a new role assignment and stores it in memory.
- select_role_assignment retrieves a role assignment from Active Directory and stores it in memory.

After you have a role assignment stored in memory, you can use other commands to work with that role assignment's fields, or the following commands to save information for the role assignment:

- save_role_assignment saves the selected role assignment with its current settings to Active Directory.
- write_role_assignment saves the selected role assignment to a file.

delete_rs_command

Use the delete_rs_command command to delete the currently selected restricted shell command from Active Directory and from memory. After you run this command, you cannot run subsequent ADEdit commands for restricted shell commands because there will be no currently selected restricted shell command available in memory.

Zone Type

Classic only

Syntax

delete_rs_command

Abbreviation

dlrsc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_rs_command

This example deletes the currently selected restricted shell command from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- get_rs_commands returns a Tcl list of restricted shell commands in the current zone.
- list_rs_commands lists to stdout the restricted shell commands in the current zone.
- new_rs_command creates a new restricted shell command and stores it in memory.

- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell:

- get_rsc_field reads a field value from the currently selected command.
- save_rs_command saves the selected command with its current settings to Active Directory.
- set_rsc_field sets a field value in the currently selected command.

delete_rs_env

Use the delete_rs_env command to delete the currently selected restricted environment from Active Directory and from memory. After you run this command, you cannot run subsequent ADEdit commands for a restricted shell environment because there will be no currently selected restricted shell environment available in memory.

Zone Type

Classic only

Syntax

delete_rs_env

Abbreviation

dlrse

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_rs_env

This example deletes the currently selected RSE from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with restricted shell environments:

- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.
- set_rse_field sets a field value in the current restricted shell environment.

delete_sub_tree

Use the delete_sub_tree command to delete an object and all of its child objects from Active Directory. Only child objects that are in the same container as the specified parent object are deleted. Child objects in other containers are not deleted.

WARNING: This is a very powerful command, and can cause a lot of damage if used incorrectly. It's similar to running rm -rf * in UNIX.

In interactive mode, ADEdit prompts you for confirmation before executing this command. If you use this command in a script, ADEdit does not prompt for confirmation. You should use caution before using this command in a script.

This command can be used on any Active Directory object, including a container, OU, computer object, group or user. However, it is especially useful for deleting a corrupted zone. You'd normally use select_zone and then delete_zone to delete a zone. If the zone is damaged, though, select_zone might not work. In that case, delete_sub_tree will do the job.

If the zone is a hierarchical zone, this command deletes only the child zones in the same container as the parent zone. If there are any child zones in other containers, they are not deleted.

Zone Type

Classic and hierarchical

Syntax

```
delete_sub_tree dn
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes the following argument:

dn	DN	Required. Specifies the distinguished name of the object (with all of its children) to remove from Active Directory.

Return Value

This command returns nothing if it runs successfully.

Examples

```
delete_sub_tree "CN=marketing,CN=Zones,CN=Acme,DC=acme,DC=com"
```

This example deletes the currently selected "marketing" zone with all of its children from Active Directory.

Related Commands

The following commands enable you to view and manage the Active Directory object to work with:

- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of matching objects.
- new_object creates a new Active Directory object and stores it in memory.
- save_object saves the selected Active Directory object with its current settings to Active Directory.
- select_object retrieves an object with its attributes from Active Directory and stores it in memory.

The following commands enable you to view and manage Active Directory object attributes:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- get_object_field reads a field value from the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- set_object_field sets a field (attribute) value in the currently selected Active Directory object.

delete_zone

Use the delete_zone command to delete the currently selected zone from Active Directory and from memory. After you run this command, you cannot run subsequent ADEdit commands for zones because there will be no currently selected zone available in memory.

This command performs an LDAP sub-tree deletion operation. Only child zones that are in the same container as the specified parent zone are deleted. Child zones that are located in other containers are not deleted. Child zones that are based on pointers defined in the child zone are not deleted. For more information about deleting sub-tree objects, see delete_sub_tree.

In interactive mode, ADEdit prompts you for confirmation before executing this command. If you use this command in a script, ADEdit does not prompt for confirmation. You should use caution before using this command in a script.

Zone Type

Classic and hierarchical

Syntax

delete_zone

Abbreviation

dlz

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_zone

This example deletes the currently selected zone or computer role from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the zone to work with:

- create_zone creates a new zone in Active Directory.
- get_zones returns a Tcl list of all zones within a specified domain.
- select_zone retrieves a zone from Active Directory and stores it in memory as the currently selected zone.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates an administrative right to a specified user or group.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones for the current zone.
- get_zone_field reads a field value from the currently selected zone.
- set_zone_field sets a field value in the currently selected zone.

- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.

delete_zone_computer

Use the delete_zone_computer command to delete the currently selected zone computer profile from Active Directory and from memory. After you run this command, you cannot run subsequent ADEdit commands for zone computer profiles because there will be no currently selected zone computer profile available in memory. This command only deletes the zone profile for the computer. It does not delete the Active Directory computer account.

Zone Type

Classic and hierarchical

Syntax

```
delete_zone_computer [-all]
```

Abbreviation

```
dlzc
```

Options

This command takes the following option:

-all	Removes the corresponding computer-specific zone profile if the selected computer is a computer-specific override zone.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
delete_zone_computer
```

This example deletes the currently selected zone computer profile from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected zone computer profile stored in memory. The following commands enable you to view and select the zone computer profile to work with:

- get_zone_computers returns a Tcl list of the Active Directory names of all zone computer profiles in the current zone.
- list_zone_computers lists to stdout all zone computer profiles in the current zone.
- new_zone_computer creates a new zone computer profile and stores it in memory.
- select_zone_computer retrieves a zone computer profile from Active Directory and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- get_zone_computer_field reads a field value from the currently selected zone computer profile.
- set_zone_computer_field sets a field value in the currently selected zone computer profile.
- save_zone_computer saves the selected zone computer profile with its current settings to Active Directory.

delete_zone_group

Use the delete_zone_group command to delete the currently selected zone group profile from Active Directory and from memory. After you run this command, you cannot run subsequent ADEdit commands for zone groups because there will be no currently selected zone group available in memory.

Zone Type

Classic and hierarchical

Syntax

```
delete_zone_group
```

Abbreviation

dlzg``

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
delete_zone_group
```

This example deletes the currently selected zone group from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected zone group stored in memory. The following commands enable you to view and select the zone group to work with:

- get_zone_groups returns a Tcl list of the Active Directory names of all zone groups in the current zone.
- list_zone_groups lists to stdout all zone groups in the current zone.
- new_zone_group creates a new zone group and stores it in memory.
- select_zone_group retrieves a zone group from Active Directory and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- get_zone_group_field reads a field value from the currently selected zone group.
- save_zone_group saves the selected zone group with its current settings to Active Directory.
- set_zone_group_field sets a field value in the currently selected zone group.

delete_zone_user

Use the delete_zone_user command to delete the currently selected zone user profile from Active Directory and from memory. After you run this command, you cannot run subsequent ADEdit commands for zone users because there will be no currently selected zone user available in memory.

Zone Type

Classic and hierarchical

Syntax

```
delete_zone_user
```

Abbreviation

dlzu

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

delete_zone_user

deletes the currently selected zone user from Active Directory and from memory.

Related Commands

Before you use this command, you must have a currently selected zone user stored in memory. The following commands enable you to view and select the zone user to work with:

- get_zone_users returns a Tcl list of the Active Directory names of all zone users in the current zone. * list_zone_users lists to stdout all zone users in the current zone.
- new_zone_user creates a new zone user and stores it in memory.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- get_zone_user_field reads a field value from the currently selected zone user.
- save_zone_user saves the selected zone user with its current settings to Active Directory.
- set_zone_user_field sets a field value in the currently selected zone user.

dn_from_domain

Use the dn_from_domain command to convert a specified domain name in dotted form (acme.com, for example) to a distinguished name (DN). This conversion doesn't require lookup in Active Directory. The command performs a simple text conversion.

Zone Type

Not applicable

Syntax

dn_from_domain domain_name

Abbreviation

dnfd

Options

This command takes no options.

Arguments

This command takes the following argument:

domain_name	string	Required. Specifies a dotted domain name (acme.com, for example)

Return Value

This command returns a domain name as a distinguished name.

Examples

```
dn_from_domain acme.com
```

This example returns the domain name in this form: `dc=acme,dc=com`

Related Commands

The following commands convert information from one format to another:

- `domain_from_dn` converts a domain's distinguished name (DN) to a dotted name.
- `dn_to_principal` returns the sAMAccount@domain name or user principal name (UPN) for a security principal.

dn_to_principal

Use the `dn_to_principal` command to specify the distinguished name (DN) of a security principal (user, computer, or group). The command searches Active Directory for the principal, and if the principal is found, the command returns the `sAMAccount@domain` name of the principal. Optionally, you can also use this command to return the user principal name (UPN) for the principal.

Zone Type

Not applicable

Syntax

```
dn_to_principal [-upn] principal_dn
```

Abbreviation

```
dntp
```

Options

This command takes the following option:

-upn	Returns the principal name in user principal name (UPN) format, not the default sAMAccount@domain format.

Arguments

This command takes the following argument:

principal_dn	string	Required. Specifies the distinguished name (DN) of a security principal.

Return Value

This command returns the sAMAccount@domain name or (optionally) the user principal name (UPN) of a security principal. If the command doesn't find the specified security principal in Active Directory, it presents a message that it didn't find the principal.

Examples

```
dn_to_principal cn=brenda butler,cn=users,dc=acme,dc=com
```

This example returns: brenda.butler@acme.com

Related Commands

The following commands search for security principals in Active Directory:

- principal_to_dn searches Active Directory for a user principal name (UPN) and, if found, returns the corresponding distinguished name (DN).
- principal_from_sid searches Active Directory for an SID and returns the security principal associated with the SID.

domain_from_dn

Use the `domain_from_dn`` command takes a distinguished name (DN) that contains a domain and returns the domain name in dotted form (acme.com, for example). This conversion doesn't require lookup in Active Directory. The command performs a simple text conversion.

Zone Type

Not applicable

Syntax

```
domain_from_dn dn
```

Abbreviation

```
dfdn
```

Options

This command takes no options.

Arguments

This command takes the following argument:

dn	string	Required. Specifies a distinguished name that contains a domain.

Return Value

This command returns a domain name in dotted form such as acme.com. If the distinguished name doesn't contain domain component (DC) values, the command returns a notice that the DC values are missing.

Examples

```
dfdn cn=johndoe,cn=users,dc=acme,dc=com
```

This example returns: acme.com

Related Commands

The following command converts information from one format to another:

- dn_from_domain converts a domain's dotted name to a distinguished name.

explain_sd

Use the explain_sd command to specify a security descriptor (SD) in security descriptor description language (SDDL) form and returns a human-readable form of the security descriptor.

Zone Type

Not applicable

Syntax

```
explain_sd sddl_string
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes the following argument:

sddl_string	string	Required. Specifies a security descriptor in SDDL format.

Return Value

This command returns text that describes the supplied security descriptor in humanreadable form.

Examples

```
explain_sd O:DAG:DAD:AI(A;;SDRCWDWOCCDCLCSWRPWPDTLOCR;;;SY)(A;;RCWDWOCCDCLCSWRPWPLOCR;;;DA)
(OA;;CCDC;bf967aba-0de6-11d0-a285-00aa003049e2;;AO)(OA;;CCDC;bf967a9c-0de6-11d0-a285-00aa003049e2;;AO)

Related Commands

The following commands enable you to work with security descriptor strings:

- remove_sd_ace removes an access control entry (ACE) from a security descriptor.
- add_sd_ace adds an access control entry to a security descriptor.
- set_sd_owner sets the owner of a security descriptor.

forest_from_domain

Use the forest_from_domain command to retrieve the forest name based on the domain name. The command also stores the retrieved forest name in memory.

Zone Type

Not applicable

Syntax

```
forest_from_domain [-nocache] <domain>
```

Abbreviation

ffd

Options

This command takes the following option:

nocache	Use this option to force fetch the forest name from Active Directory instead of reading the forest name from in memory.

Arguments

This command takes the following argument:

domain	string	Required. Specifies the domain for which you want to retrieve the forest.

Return Value

This command returns the forest name (in upper case text).

Examples

```
>forest_from_domain 5027f1d2.test
```

5027F1D1.TEST

>ffd 5027f1d2.test

5027F1D1.TEST

get_adinfo

Use the get_adinfo command to return information about the current join state for the ADEdit host computer. The command returns information about the joined domain, the joined zone, or the name the host computer is joined under.

Zone Type

Not applicable

Syntax

get_adinfo domain|zone|host

Abbreviation

adinfo

Options

This command takes no options.

Arguments

This command takes the following argument:

domain|zone|host	string	Required. The possible values are: **domain** returns the name of the currently joined domain. **zone** returns the distinguished name of the currently joined zone. **host** returns the name under which the ADEdit host computer is joined.

Return Value

This command returns a domain name, zone name, or computer name depending on the provided argument.

Examples

get_adinfo domain

This example returns the joined domain. For example: acme.com

get_adinfo zone

This example returns the path to the joined zone. For example:

CN=default,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com

Related Commands

None.

get_bind_info

Use the get_bind_info command to return information about one of ADEdit's currently bound domains. The command can return the name of the domain's forest, the name of the server bound within the domain, the security identifier (SID) of the domain, and the functional level of the domain or the domain's forest.

Zone Type

Not applicable

Syntax

get_bind_info domain forest|server|sid|domain_level|forest_level

Abbreviation

gbi

Options

This command takes no options.

Arguments

This command takes the following arguments:

domain	string	Required. Specifies the name of the domain for which to get information.
forest | server | sid | domain_level | forest_level	string	Required. The possible values are: **forest** returns the name of the forest that contains the bound domain. **server** returns the name of the domain server to which ADEdit is bound in the domain. **sid** returns the SID (security identifier) of the bound domain. **domain_level** returns the functional level of the bound domain, represented by an integer value: -1: unknown functional level 0: Windows 2000 Server 1: Windows Server 2003, interim level 2: Windows Server 2003 3: Windows Server 2008 4: Windows Server 2008 R2 5: Windows Server 2012 6: Windows Server 2012 R2 7: Windows Server 2016, preview **forest_level** returns the functional level of the forest that contains the bound domain.

Return Value

This command returns a forest name, server name, security identifier, or functional level depending on the provided argument.

Examples

get_bind_info acme.com server

This example returns the name of the domain controller: adserve02.acme.com

Related Commands

The following commands perform actions related to this command:

- bind binds ADEdit to a domain for subsequent ADEdit commands.
- pop restores the context from the top of ADEdit's context stack to ADEdit.
- push saves ADEdit's current context to ADEdit's context stack.
- show returns the current context of ADEdit, including its bound domains and its currently selected objects.

get_child_zones

Use the get_child_zones command to return a Tcl list of the child zones, computer roles, and computer zones for the currently selected zone stored in memory. The options to return child zones and computer roles are only applicable when you are working with hierarchical zones.

In classic zones, you can use this command to return a Tcl list of classic-computer zones under the currently selected classic zone. A classic-computer zone is a special zone type that contains a single computer to enable computer-level role assignments. The classic zone must have the corresponding computer object and that computer must be identified as a classic-computer zone to support computer-specific role assignments.

Because classic zones do not have child zones or computer roles, executing get_child_zones with the -crole or -tree option without the computer option returns an empty list.

Zone Type

Classic and hierarchical

Syntax

get_child_zones [-tree] [-crole] [-computer]

Abbreviation

gcz

Options

This command takes any of the following options:

-tree	Returns a Tcl list of the current zone's child zones. If the currently selected zone is a classic zone, this option is ignored.
-crole	Returns a Tcl list of the current zone's hosted computer roles. If the currently selected zone is a classic zone, this option is ignored.
-computer	Returns a Tcl list of the current zone's computer-specific zones. For classic zones, this option returns a list of classic-computer zones.

If you don't specify an option and the currently selected zone is a hierarchical zone, get_child_zones returns the complete list of child zones including computer roles and computerspecific "zones" that enable computer-specific overrides. If you don't specify an option and the currently selected zone is a classic zone, get_child_zones returns the list of classic-computer zones.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of child zones, computer roles, or computer-specific zones depending on the options used.

Examples

get_child_zones

This example returns:

```
{CN=cz1,CN=Zones,CN=Acme,CN=Program Data,DC=eel,DC=nest}
{CN=cz2,CN=Zones,CN=Acme,CN=Program Data,DC=eel,DC=nest}
{CN=global,CN=Zones,CN=Acme,CN=ProgramData,DC=eel,DC=nest/oracleServers}
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the zone to work with:

- create_zone creates a new zone in Active Directory.
- get_zones returns a Tcl list of all zones within a specified domain.
- select_zone retrieves a zone from Active Directory and stores it in memory as the currently selected zone.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates administrative rights to a specified user or group.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_zone_field reads a field value from the currently selected zone.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.

- save_zone saves the selected zone with its current settings to Active Directory.
- set_zone_field sets a field value in the currently selected zone.

get_dz_commands

Use the get_dz_commands command to check Active Directory and return a Tcl list of UNIX command objects defined within the currently selected zone. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed. Use the list_dz_commands command to output to stdout.

You can only use the get_dz_commands command if the currently selected zone is a classic4 or hierarchical zones. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

get_dz_commands

Abbreviation

gdzc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of UNIX commands defined in the currently selected zone.

Examples

get_dz_commands

This example returns the list of commands: root_any

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a UNIX command to work with:

- list_dz_commands lists to stdout the UNIX commands in the current zone.
- new_dz_command creates a new UNIX command and stores it in memory.
- select_dz_command retrieves a UNIX command from Active Directory and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- delete_dz_command deletes the selected command from Active Directory and from memory.
- get_dzc_field reads a field value from the currently selected command.
- save_dz_command saves the selected command with its current settings to Active Directory.
- set_dzc_field sets a field value in the currently selected command.

get_dzc_field

Use the get_dzc_field command to return the value for a specified field from the currently selected command object that is stored in memory.

The get_dzc_field command does *not* query Active Directory for the command. If you change field values using ADEdit without saving the command to Active Directory, the field value you retrieve using get_dzc_field won't match the same field value for the command stored in Active Directory.

You can only use the get_dzc_field command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
get_dzc_field field
```

Abbreviation

gdzcf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve. The possible values are: **description**: Returns text describing the UNIX command. **cmd**: Returns the restricted shell command string or strings. **path**: Returns the path to the command's location. **form**: Returns an integer that indicates whether the cmd and path strings use wild cards (0) or a regular expression (1). **dzdo_runas**: Returns a list of users and groups that can run this command under dzdo version of sudo. Users may be listed by user name or user ID (UID). **dzsh_runas**: Returns a list of users and groups that can run this command in a restricted shell environment (dzsh). Users can be listed by user name or UID. You cannot get this field value if the selected zone is a classic4 zone. **keep**: Returns a comma-separated list of environment variables from the current user's environment to keep. **del**: Returns a comma-separated list of environment variables from the current user's environment to delete. **add**: Returns a comma-separated list of environment variables to add to the final set of environment variables. **pri**: Returns an integer that specifies the command priority for the restricted shell command object. **umask**: Returns an integer that defines who can execute the command. **flags**: Returns an integer that specifies a combination of different properties for the command. **createTime**: Returns the time and date this command was created, returned in generalized time format. **modifyTime**: Returns the time and date this command was last modified, returned in generalized time format. **dn**: Returns the command's distinguished name. **selinux_role**: Returns the SELinux role used when constructing a new security context for command execution (tree zone only). **selinux_type**: Returns the SELinux type used when constructing a new security context for command execution (tree zone only). **digest**: Returns the SHA-2 digest to verify the file checksum before command execution. Note that selinux_role and selinux_type are only supported on Red Hat Enterprise Linux systems and effective only on systems with SELinux enabled and joined to a hierarchical zone.

Getting the cmd and path field values

If you specify the cmd and path fields, the return value can be a string that uses wild cards (*, ?, and !), or a regular expression. If the cmd and path strings use wild cards, an asterisk (*) matches zero or more characters, a question mark (?) matches exactly one character, and the exclamation mark (!) negates matching of the specified string.

For both the cmd and path fields, the form field indicates whether the specified string is interpreted as a regular expression or as a string that includes wild cards.

Getting environment variable field values

If you specify the keep, del, or add field, the return value is a comma-separated list of environment variables. The keep, del, and add fields control the environment variables used by the commands specified by the cmd string. The keep and del settings are mutually exclusive:

- The keep field only takes effect if the flag 16 is included in the setting for the flag field.
- The del field only takes effect if the flag 16 is not included in the setting for the flag field.

Any environment variables kept or deleted are in addition to the default set of the user's environment variables that are either retained or deleted. The default set of environment variables to keep is defined in the dzdo.env_keep configuration parameter in the centrifydc.conf file. The default set of environment variables to delete is defined in the dzdo.env_delete configuration parameter in the centrifydc.conf file.

The add field returns the environment variables added to the final set of environment variables resulting from the keep or del fields.

Getting the command priority field value

If you specify the pri field, the return value indicates the command priority when there are multiple matches for command strings in a command object. If there are multiple commands specified by this command object, the pri field specifies the specifies their relative priority. The higher the value returned by this field, the higher the command's priority.

Getting the umask field value

If you specify the umask field, the return value is a 3-digit octal value that defines who can read, write, and execute the selected command object. The three digits of the umask field specify the read, write, or execute permission for the file owner, group, and other users. The left digit defines the owner execution rights, the middle digit defines the group execution rights, and the right digit defines execution rights for other users. Each digit is a combination of binary flags, one flag for each right as follows:

- 4 is read
- 2 is write
- 1 is execute

These values are added together to define the rights available for each entity. For example, a umask value of 600 indicates read and write permission (4+2) for the owner, but no permissions for the group or other users. Similarly, a umask value of 740 indicates read, write, execute permissions (4+2+1) for the owner, read permissions for the group, but no permissions for other users.

Getting command properties from the flags field value

If you specify the flags field, the return value is an integer that defines a combination of binary flags, with one flag for each of the following properties:

1—Prevents nested command execution. If this flag value is not set, nested command execution is allowed.

2—Requires authentication with the user's password.

4—Requires authentication with the run-as user's password.

8—Preserves group membership. If this flag value is not set, group membership is not preserved.

16—Resets environment variables for the command, deleting the variables specified in the dzdo.env_delete parameter and keeping the variables specified in the keep field. If this flag is not set, the command removes the unsafe environment variables specified in the dzdo.env_delete parameter along with any additional environment variables specified by the del field.

32—Requires multi-factor authentication to execute the command.

64—Prevents navigation up the path hierarchy when executing the command.

These values are added together to define the value for the flags field. For example, a flags field value of 11 indicates that nested command execution is not allowed (1), the command requires authentication using the user's password (2), and the user's group membership should be preserved (8). The value returned is the sum of these flags (1+2+8).

Return Value

This command returns a field value, which varies in type depending on the data type stored by the field.

Examples

```
get_dzc_field dzdo_runas
```

returns: root

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a UNIX command to work with:

- get_dz_commands returns a Tcl list of UNIX commands in the current zone.
- list_dz_commands lists to stdout the UNIX commands in the current zone.
- new_dz_command creates a new UNIX command and stores it in memory.
- select_dz_command retrieves a UNIX command from Active Directory and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- delete_dz_command deletes the selected command from Active Directory and from memory.
- save_dz_command saves the selected command with its current settings to Active Directory.
- set_dzc_field sets a field value in the currently selected command.

get_group_members

Use the get_group_members command to check the Active Directory group membership for a specified group. You can use this command to return a Tcl list of the users in a specified group in one of two ways:

- With the -ad option to return a simplified list of the distinguished names that are members of the specified group. The -ad option lists the users and groups that are members of the specified group without recursively expanding the group membership of any nested group.
- Without the -ad option to return a complete list of users that are members of the specified group. If you don't specify the -ad option, the command recursively expands the groups that are members of the specified group to identify all of the users in any nested group.

Zone Type

Not applicable

Syntax

```
get_group_members [-ad | -upn] group_UPN
```

Abbreviation

ggm

Options

This command takes the following options:

-ad	Returns the distinguished names for the users and groups that are members of the specified group. This option does not expand the group membership to list users who are members of nested groups.
-upn	Returns user names in user principal name (UPN) format for all of the users that are members of the specified group. This option expands the group membership of the specified group to include users who are members of nested groups. If you don't specify this option, a complete list of user names is returned using the default sAMAccount@domain format.

Arguments

This command takes the following argument:

group_UPN	string	Required. Specifies the user principal name (UPN) of the group to for which you want to return user membership.

Return Value

This command returns a Tcl list of group members.

Examples

```
get_group_members poweradmins@acme.com
```

This example returns the complete list of users who are members of the poweradmin@acme.com group, including users who are members of any nested groups, using the sAMAccountName@domain.name format. For example:

```
martin.moore@acme.com rachel.roberts@acme.com frank.smith@acme.com
```

The following example returns the distinguished names of the users and groups that are members of the demo-qa-lab@acme.com group without listing the members of any nested groups.

```
get_group_members -ad demo-qa-lab@acme.com
```

For example, this command returns the list of users and groups without expanding the group membership for the LabAdmins and QA groups:

```
CN=LabAdmins,CN=Users,DC=acme,DC=com {CN=Chris Howard,CN=Users,DC=acme,DC=com} CN=QA,CN=Users,DC=acme,DC=com CN=frank.smith,CN=UsersDC=acme,DC=com
```

Related Commands

The following commands perform actions related to this command:

- joined_get_user_membership checks Active Directory through adclient and returns a Tcl list of groups that a user belongs to.
- joined_user_in_group checks Active Directory through adclient to see if a user is in a group.
- get_effective_groups checks Active Directory and returns a Tcl list of groups a user belongs to.

get_local_group_profile_field

Use the get_local_group_profile_field command to display the value of the specified field for the currently selected local UNIX or Linux group that has a profile defined in the current zone. Before executing this command, you must select a local group by executing the select_local_group_profile command.

Zone Type

Hierarchical only.

Syntax

```
get_local_group_profile_field field_name
```

Abbreviation

```
glgpf
```

Options

This command takes no options.

Arguments

This command takes the following argument:

field_name	Required. Specifies the local group field to retrieve. The data type depends on the field. The possible values are: **gid**: The numeric group identifier. **name**: The UNIX name of the group. **member**: The UNIX name of at least one group member. **profileflag**: The value of the group's profile flag as set in the group object in the zone. For the group to be managed by the agent, the profile flag must be set to 1 or 3.If set to 1, the group profile is enabled. If the group profile is complete and the profile flag is set to 1, the profile will be installed or updated in /etc/group at the next local account refresh interval. If set to 3, the group profile is removed from /etc/group at the next local account refresh interval. **dn**: The distinguished name of the group. **createTime**: The creation time of the group profile.

modifyTime: The most recent modification time of the group profile. You can also specify AIX extended attributes as the field to get an extended attribute value for a group. Extended attribute fields start with the aix. prefix. For example, the admin extended attribute can be retrieved by specifying aix.admin as the field.

Return Value

This command returns the value of the specified field.

Examples

The following example returns the GID of the currently selected local group in the zone.

```
get_local_group_profile_field gid
```

The following example returns the value of the profile flag for the currently selected local group. In this example, the profile flag is 1, meaning that the group profile in /etc/group will be updated with the latest settings from the local account zone object at the next local account refresh interval.

```
get_local_group_profile_field profileflag

1
```

If the current group is on AIX, you can get group extended attributes and values. For example, to find out if the current group is an administrative group, you can get the admin extended attribute:

```
get_local_group_profile_field aix.admin

true
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

get_local_groups_profile

Use the get_local_groups_profile command to return a TCL list of profiles for local groups that are defined in the currently selected zone.

Zone Type

Hierarchical only.

Syntax

```
get_local_groups_profile
```

Abbreviation

glgp

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

If you run this command from the command line, it returns a TCL list of profiles for local groups that are defined in the currently selected zone. The list is sorted by group UNIX name.

If you run this command in a script, no output is returned to stdout, and no output appears in the shell where the script is executed. To return output to stdout from a script, use the list_local_groups_profile command.

Examples

The following example shows a TCL list of profiles for local groups that are defined in the current zone.

```
get_local_groups_profile
lg001 lg002 lg003 lg005 lg006 lg007
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

get_local_user_profile_field

Use the get_local_user_profile_field command to display the value of the specified field for the currently selected local UNIX or Linux user that has a profile defined in the current zone. Before executing this command, you must select a local user by executing the select_local_user_profile command.

Zone Type

Hierarchical only.

Syntax

```
get_local_user_profile_field field_name
```

Abbreviation

glupf

Options

This command takes no options.

Arguments

This command takes the following argument:

field_name	string	Required. Specifies the local user profile field to retrieve. The possible values include: **uid**: The user's numeric identifier. **gid**: The GID of the user's primary group. **shell**: The local user's default shell on the local computer. Possible values are: /bin/bash, /bin/csh, /bin/ksh, /bin/sh, /bin/tcsh, %. **home**: The local user's default home directory on the local computer. **gecos**: General information about the local user account. **uname**: The UNIX name of the user. **dn**: The distinguished name of the user. **createTime**: The creation time of the user profile. **modifyTime**: The most recent modification time of the user profile. **profileflag**: The value of the user's profile flag as set in the user object in the zone. For the user to be managed by the agent, the profile flag must be set to 1 , 2, or 3. You can also specify AIX extended attributes as the field to get an extended attribute value for a user. Extended attribute fields start with the aix. prefix. For example, the admin extended attribute can be retrieved by specifying aix.admin as the field.

Return Value

This command returns the value of the specified field.

Examples

The following example returns the UID of the currently selected local user in the zone.

```
get_local_user_profile_field uid
```

The following example returns the value of the profile flag for the currently selected local user. In this example, the profile flag is 2, meaning that the user profile in /etc/passwd will be updated with the latest settings from the local account zone object at the next local account refresh interval, but the password entry in /etc/passwd will be set to !! so that the user cannot log into the local computer.

```
get_local_user_profile_field profileflag
```

```
2
```

For more information about the meaning of the profile flag value, see set_local_user_profile_field.

You can also specify AIX extended attributes as the field to get an extended attribute value for a user. Extended attribute fields start with the aix. prefix. For example, the admin extended attribute can be retrieved by specifying aix.admin as the field.

```
get_local_user_profile_field aix.admin
```

```
false
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.

- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

get_local_users_profile

Use the get_local_users_profile command to return a TCL list of profiles for local users that are defined in the currently selected zone.

Zone Type

Hierarchical only.

Syntax

```
get_local_users_profile
```

Abbreviation

```
glup
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

If you run this command from the command line, it returns a TCL list of profiles for local users that are defined in the currently selected zone. The list is sorted by user UNIX name.

If you run this command in a script, no output is returned to stdout, and no output appears in the shell where the script is executed. To return output to stdout from a script, use the list_local_users_profile command.

Examples

The following example shows a TCL list of profiles for local users that are defined in the current zone.

```
get_local_users_profile
db2011 db2012 lu001 lu002 lu003 lu004 lu006 lu007 lu008 lu009 lu012 lu013
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the

group object.

- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

get_nis_map

Use the get_nis_map command to return a Tcl list containing the entries for the currently selected NIS map stored in memory. This command does not return the contents of the comment field. If you want to retrieve the comment, use get_nis_map_with_comment instead.

The get_nis_map command does *not* query Active Directory for this NIS map, but changing map entries using add_map_entry and delete_map_entry changes both selected NIS map in memory and the corresponding NIS map in Active Directory so their contents should match.

Zone Type

Not applicable

Syntax

get_nis_map

Abbreviation

gnm

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of NIS map entries. Each entry contains:

- The key
- The instance number of the key (there may be multiple entries with the same key)
- The value

Each entry component is separated from the next by a colon (:).

Examples

get_nis_map

This example returns the list of map entries. For example:

{Finance:1: Hank@acme.com,jane@acme.com,joe@acme.com} {Mktg:1: Mike@acme.com,Sue@acme.com}

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and manage NIS maps:

- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps lists to stdout all NIS maps in the currently selected zone.

- new_nis_map creates a new NIS map and stores it in memory.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map's entries:

- add_map_entry or add_map_entry_with_comment adds an entry to the currently selected NIS map.
- delete_map_entry removes an entry from the currently selected NIS map.
- get_nis_map_with_comment returns a Tcl list of the entries in the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- list_nis_map or list_nis_map_with_comment lists to stdout of the entries in the currently selected NIS map.

get_nis_map_field

Use the get_nis_map_field command to return the value for a specified field from the currently selected NIS map stored in memory. The get_nis_map_field command does *not* query Active Directory for the NIS map. If you've changed field values using ADEdit without saving the NIS map to Active Directory, the field value you retrieve using get_nis_map_field won't match the same field value for the NIS map stored in Active Directory.

Zone Type

Not applicable

Syntax

```
get_nis_map_field field
```

Abbreviation

gnmf

Options

This command takes no options.

Arguments

This command takes the following argument, which is case-sensitive:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve. The possible values are: **createTime**: Specifies the time and date this NIS map was created, returned in generalized time format **modifyTime**: Specifies the time and date this NIS map was last modified, returned in generalized time format **dn**: Specifies the NIS map's distinguished name

Return Value

This command returns a field value, which varies in type depending on the data type stored by the field.

Examples

```
get_nis_map_field createTime
```

This example returns the value of the createTime field. For example: 20110525163718.0Z

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and manage NIS maps:

- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.

- list_nis_maps lists to stdout all NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map's entries:

- add_map_entry or add_map_entry_with_comment adds an entry to the currently selected NIS map.
- delete_map_entry removes an entry from the currently selected NIS map.
- get_nis_maps or get_nis_map_with_comment returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_map or list_nis_map_with_comment lists to stdout of the entries in the currently selected NIS map.

get_nis_map_with_comment

Use the get_nis_map command to return a Tcl list containing the entries for the currently selected NIS map stored in memory. This command includes the comment field for map entries. The get_nis_map_with_comment command does *not* query Active Directory for this NIS map, but changing map entries using add_map_entry and delete_map_entry changes both selected NIS map in memory and the corresponding NIS map in Active Directory so their contents should match.

Zone Type

Not applicable

Syntax

get_nis_map_with_command``

Abbreviation

gnmwc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of NIS map entries. Each entry contains:

- The key
- The instance number of the key (there may be multiple entries with the same key)
- The value
- The comment

Each entry component is separated from the next by a colon (:).

Examples

get_nis_map_with_comment

This example returns the map entries including comments:

{Finance:1: Hank@acme.com,jane@acme.com,joe@acme.com: Finance dept staff}{Mktg:1: Mike@acme.com,Sue@acme.com: Marketing dept staff}

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and manage NIS maps:

- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps lists to stdout all NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map's entries:

- add_map_entry or add_map_entry_with_comment adds an entry to the currently selected NIS map.
- delete_map_entry removes an entry from the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_map or list_nis_map_with_comment lists to stdout of the entries in the currently selected NIS map.

get_nis_maps

Use the get_nis_maps command to check Active Directory and return a Tcl list of NIS maps defined within the currently selected zone. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed. Use list_nis_maps to output the list of NIS maps to stdout.

Zone Type

Not applicable

Syntax

get_nis_maps

Abbreviation

gnms

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of NIS maps defined in the currently selected zone.

Examples

get_nis_maps

This example returns the list of NIS maps: Aliases Printers Services

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and manage NIS maps:

- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- list_nis_maps lists to stdout all NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the other commands to work with that map's entries.

get_object_field

Use the get_object_field command to return the value of a specified field from the currently selected Active Directory object stored in memory. The get_object_field command does *not* query Active Directory for the object. If you change field values using ADEdit without saving the object to Active Directory, the field value you retrieve using get_object_field won't match the same field value for the object stored in Active Directory.

Zone Type

Not applicable

Syntax

get_object_field field

Abbreviation

gof

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve. The possible values include any attribute that can be defined for the type of object currently selected. Special values are: **sid**: The object's security identifier. **guid**: The object's globally unique identifier. **sd**: The object's security descriptor. **createTime**: The time and date this object was created, returned in generalized time format. **modifyTime**: The time and date this object was last modified, returned in generalized time format. **dn**: The object's distinguished name.

Return Value

This command returns a field value, which varies in type depending on the data type stored by the field.

Examples

get_object_field guid

This example returns the globally unique identifier for an object. For example:

44918ee7-80bc-4741-95d3-dd189e235ab8

Related Commands

Before you use this command, you must have a currently selected Active Directory object stored in memory. The following commands enable you to view and select the object to work with:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of matching objects.
- new_object creates a new Active Directory object and stores it in memory.
- select_object retrieves an object with its attributes from Active Directory and stores it in memory.

After you have an Active Directory object stored in memory, you can use the following commands to work with that object's attributes, delete the object, or save information for the object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.

- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field_names returns a Tcl list of the field names (attributes) for the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- save_object saves the selected Active Directory object with its current settings to Active Directory.
- set_object_field sets a field value in the currently selected Active Directory object.

get_object_field_names

Use the get_object_field_names command to return a Tcl list of the field names for each of the fields—the object attributes—of the currently selected Active Directory object. The get_object_field_names command does not query Active Directory for the object's field names but looks at the selected object as it is stored in ADEdit memory.

Zone Type

Not applicable

Syntax

get_object_field_names

Abbreviation

gofn

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of field names.

Examples

select_object "cn=amy adams,cn=users,dc=ajax,dc=com" get_object_field_names

This example returns the field names associated with the selected user Amy Adams:

_SID _dn _objectCategory _server accountExpires cn codePage countryCode distinguishedName
gidNumber instanceType lastLogonTimestamp loginShell msDS-MembersForAzRoleBL msSFU30NisDomain
nTSecurityDescriptor name objectCategory objectClass objectGUID objectSid primaryGroupID
pwdLastSet sAMAccountName sAMAccountType uSNChanged uSNCreated uid uidNumber unixHomeDirectory
userAccountControl userPrincipalName whenChanged whenCreated

Related Commands

Before you use this command, you must have a currently selected Active Directory object stored in memory. The following commands enable you to view and select the object to work with:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of objects that match the search criteria.
- new_object creates a new Active Directory object and stores it in memory.
- select_object retrieves an object and its attributes from Active Directory and stores it in memory.

After you have an Active Directory object stored in memory, you can use the following commands to work with that object's attributes, delete the object, or save information for the object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- delete_object deletes the selected Active Directory object from Active Directory and from memory.

- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field reads a field value from the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- save_object saves the selected Active Directory object with its current settings to Active Directory.
- set_object_field sets a field value in the currently selected Active Directory object.

get_objects

Use the get_objects command to perform an LDAP search of Active Directory and return a Tcl list of the distinguished names (DNs) of the objects that match the search criteria. You specify a container in Active Directory where the search begins and a standard LDAP filter that defines the objects you're searching for.

You can control the nature of the search through options that specify whether to use the global catalog (GC) for a forest-wide search, the number of levels deep for the search to go below the beginning container of the search, and the maximum number of objects for the get_objects command to return.

Zone Type

Not applicable

Syntax

get_objects [-gc] [-depth one|sub] [-limit limit] [-f forest] base filter

Abbreviation

go

Options

This command takes the following options:

-gc	Requests a forest-wide search using a global catalog. For this option to work, ADEdit must be bound to a global catalog domain controller using the bind command with the -gc option. If you don't specify this option, the search is only within the currently bound domains.
-depth one | sub	Specifies how deep to search. This option must be followed by one of two values: **one**: Specifies that the search will search only through objects immediately below the container specified by the argument *base*. **sub**: Specifies that the search will be full-depth, starting at the container specified by *base* and continuing through all sub-containers below that level. If you don't specify this option, the search defaults to the value **one**.
-limit *limit*	Limits the number of objects returned by the search to the positive integer specified by *limit*. If you don't specify this option, the search returns all matching objects without limit.
-f *forest*	Specifies the forest to search. If you bind ADEdit to multiple forests, you can use this option to identify a specific forest to search for objects matching the criteria you specify.

Arguments

This command takes the following arguments:

base	DN	Required. Specifies the distinguished name of an Active Directory container in which to start the search. If you want to perform a forest-wide search using the global catalog option but do not specify the forest to search, use an empty string as the base argument. For example: get_objects -gc -depth sub "" (cn=demo). You should not use an empty string as the starting point for a search if you bind to multiple forests. If you bind to multiple forests, you should always specify the forest to search.
filter	LDAP filter	Required. A string that uses standard LDAP filter syntax to specify criteria for the search.

Return Value

This command returns a Tcl list of the distinguished names of the objects matching the search criteria.

Examples

```
get_objects “cn=users,dc=acme,dc=com” (objectclass=*)
```

This example returns a list of distinguished name matching the objectclass filter:

```
CN=Builtin,DC=acme,DC=com CN=Computers,DC=acme,DC=com {OU=Domain Controllers,DC=acme,DC=com} CN=ForeignSecurityPrincipals,DC=acme,DC=com
CN=Infrastructure,DC=acme,DC=com CN=LostAndFound,DC=acme,DC=com {CN=NTDS Quotas,DC=acme,DC=com} {CN=Program Data,DC=acme,DC=com} CN=System,DC=acme,DC=com
CN=Users,DC=acme,DC=com
```

Related Commands

The following commands enable you to view and select the object to work with:

- new_object creates a new Active Directory object and stores it in memory.
- select_object retrieves an object and its attributes from Active Directory and stores it in memory.

After you have an Active Directory object stored in memory, you can use the following commands to work with that object's attributes, delete the object, or save information for the object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field reads a field value from the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- save_object saves the selected Active Directory object with its current settings to Active Directory.
- set_object_field sets a field value in the currently selected Active Directory object.

get_pam_apps

Use the get_pam_apps command to check Active Directory and return a Tcl list of plug-in authentication module (PAM) applications defined within the currently selected zone. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed. Use list_pam_apps to output the list of PAM applications to stdout.

You can only use the get_pam_apps command to return information about PAM applications if the currently selected zone is a classic4 or hierarchical zones. The command does not work for other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
get_pam_apps
```

Abbreviation

```
gpam
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of PAM applications defined in the currently selected zone. Each element in the string is the name of a PAM application.

Examples

```
get_pam_apps
```

This example returns all of the PAM application rights for the selected zone:

```
dzssh-all dzssh-direct-tcpip dzssh-exec dzssh-scp dzssh-sftp dzssh-shell dzssh-subsystem dzssh-tcpip-forward dzssh-tunnel dzssh-x11-forwarding loginall ssh sshd
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. After you have a zone stored in memory, you can use the following commands to view and select the PAM application to work with:

- list_pam_apps lists to stdout the PAM application rights in the current zone.
- new_pam_app creates a new PAM application right and stores it in memory.
- select_pam_app retrieves a PAM application from Active Directory and stores it in memory.

After you have a PAM application stored in memory, you can use the following commands to work with that PAM application's attributes, delete the PAM application, or save information for the PAM application:

- delete_pam_app deletes the selected PAM application from Active Directory and from memory.
- get_pam_field reads a field value from the currently selected PAM application.
- save_pam_app saves the selected PAM application with its current settings to Active Directory.
- set_pam_field sets a field value in the currently selected PAM application.

get_pam_field

Use the get_pam_field command to return the value of a specified field for the currently selected plug-in authentication module (PAM) application object stored in memory. The get_pam_field command does *not* query Active Directory for the PAM application. If you change field values using ADEdit without saving the PAM application to Active Directory, the field value you retrieve using get_pam_field won't match the same field value for the PAM application stored in Active Directory.

You can only use the get_pam_field command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
get_pam_field field
```

Abbreviation

```
gpf
```

Options

This command takes no options.

Arguments

This command takes the following argument:

	Required. Specifies the case-sensitive name of the field whose value to retrieve. The possible values are: **application**: The name of

field	string	the application allowed to use adclient's PAM authentication service. The name can be literal, or it can contain ? or * wildcard characters to specify multiple applications. **description**: Text describing the PAM application. **createTime**: The time and date this PAM application was created, returned in generalized time format. **modifyTime**: The time and date this PAM application was last modified, returned in generalized time format. **dn**: the PAM application's distinguished name.

Return Value

This command returns a field value. The data type for this value depends on the field specified.

Examples

```
get_pam_field application
```

This example returns the contents of the application field:

```
ftp
```

The selected PAM application object specifies ftp can authenticate using adclient.

Related Commands

Before you use this command, you must have a currently selected PAM application object stored in memory. The following commands to view and select the PAM application to work with:

- get_pam_apps returns a Tcl list of PAM application rights in the current zone.
- list_pam_apps lists to stdout the PAM application rights in the current zone.
- new_pam_app creates a new PAM application right and stores it in memory.
- select_pam_app retrieves a PAM application right from Active Directory and stores it in memory.

After you have a PAM application stored in memory, you can use the following commands to work with that PAM application's attributes, delete the PAM application, or save information for the PAM application:

- delete_pam_app deletes the selected PAM application right from Active Directory and from memory.
- get_pam_field reads a field value from the currently selected PAM application right.
- save_pam_app saves the selected PAM application right with its current settings to Active Directory.
- set_pam_field sets a field value in the currently selected PAM application right.

get_parent_dn

Use the get_parent_dn command to specify an LDAP path using a distinguished name (DN) and return the parent of the path. This command removes the first element from the distinguished name and returns the rest of the DN.

Zone Type

Not applicable

Syntax

```
get_parent_dn DN
```

Abbreviation

```
gpd
```

Options

This command takes no options.

Arguments

This command takes the following argument:

DN	string	Required. Specifies a distinguished name.

Return Value

This command returns a distinguished name that is the parent of the supplied distinguished name.

Examples

```
get_parent_dn CN=global,CN=Zones,CN=Acme,DC=acme,DC=com
```

This example returns: `CN=Zones,CN=Acme,DC=acme,DC=com`

Related Commands

The following command performs actions related to this command:

- `get_rdn` returns the relative distinguished name of a specified LDAP path.

get_pending_zone_groups

Use the `get_pending_zone_groups` command to check Active Directory and return a Tcl list of pending import groups for the currently selected zone. Pending import groups are group profiles that have been imported from Linux or UNIX computers, but not yet mapped to any Active Directory group. If executed in a script, this command does not output its list to `stdout`, and no output appears in the shell where the script is executed. Use `list_pending_zone_groups` to output the list to `stdout`.

Zone Type

Classic and hierarchical

Syntax

```
get_pending_zone_groups
```

Abbreviation

gpzg

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of pending import group profiles that have been imported into the currently selected zone. Each entry in the list contains the following fields, separated by colons : :

- Distinguished name (DN) of the pending import group as it is stored in Active Directory. The distinguished name for each pending import group includes a prefix that consists of “PendingGroup” and the globally unique identifier (GUID) for the group.
- UNIX group name.
- Numeric group identifier (GID).

Examples

```
get_pending_zone_groups
```

The command returns output in the form of:

```
DN:group_name:gid
```

This sample command might return output similar to the following:

```
CN=PendingGroup_573135e7-edd9-46b9-9cbd-c839570a90c8,CN=Groups, CN=bean_pz,CN=Zones,CN=Acme,DC=win2k3,DC=test:root:0
CN=PendingGroup_7878065a-4d2f-4749-8f3b-6ffe24303f6a,CN=Groups, CN=bean_pz,CN=Zones,CN=Acme,DC=win2k3,DC=test:unixgrp:5000
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following command performs actions related to this command:

- `select_object` retrieves the specified Active Directory object and its attributes from Active Directory and stores the object in memory.
- `get_object_field` enables you to view and work with the pending import group.

get_pending_zone_users

Use the `get_pending_zone_users` command to check Active Directory and return a Tcl list of pending import users for the currently selected zone. Pending import users are user profiles that have been imported from Linux or UNIX computers, but not yet mapped to any Active Directory user. If executed in a script, this command does not output its list to `stdout`, and no output appears in the shell where the script is executed. Use `list_pending_zone_users` to output the list to `stdout`.

Zone Type

Classic and hierarchical

Syntax

```
get_pending_zone_users
```

Abbreviation

```
gpzu
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of pending import user profiles that have been imported into the currently selected zone. Each entry in the list contains the following fields, separated by colons : :

- Distinguished name (DN) of the pending import user as it is stored in Active Directory. The distinguished name for each pending import user includes a prefix that consists of “PendingUser” and the globally unique identifier (GUID) for the user.
- UNIX user name.
- Numeric user identifier (UID).
- Numeric primary group identifier (GID).
- Personal information from the GECOS field.
- Home directory.
- Default login shell.

Examples

```
get_pending_zone_users
```

This sample command might return output similar to the following:

CN=PendingUser_09024f3a-6abc-4666-a127-722f9fe0e0bf,CN=Users,CN=finance, CN=Zones,CN=Acme,DC=win2k3,DC=test:root:0:0:root:/root:/bin/bash
CN=PendingUser_0b9fe038-1325-438f-8529-cb190ab5914a,CN=Users,CN=finance, CN=Zones,CN=Acme,DC=win2k3,DC=test:bean:6001:5000:bean.zhang:/home/bean:/bin/bash

Before you use this command, you must have a currently selected zone stored in memory. The following command performs actions related to this command:

- select_object retrieves the specified Active Directory object and its attributes from Active Directory and stores the object in memory.
- get_object_field enables you to view and work with the pending import group.

get_pwnam

Use the get_pwnam command to look up a UNIX user name in the /etc/passwd file on the ADEdit host computer. If there's an entry for the specified user name, the command returns the profile values of that entry as a Tcl list. The get_pwnam command uses the NSS layer to perform the lookup operation. You can use the command to look up information for any user in the /etc/passwd file, including root.

Zone Type

Not applicable

Syntax

get_pwnam unix_name

Abbreviation

gpn

Options

This command takes no options.

Arguments

This command takes the following argument:

unix_name	string	Required. Specifies the UNIX user name to search for in the /etc/passwd file.

Return Value

This command returns a Tcl list of user profile attributes for a specified user if the specified user name is found in the local /etc/passwd file. If the command doesn't find the specified user, it a "User not found" message.

Examples

get_pwnam adam

This example returns the profile for the UNIX user adam:

adam x 500 500 {Adam Andrews} /home/adam /bin/bash

Related Commands

The following command performs actions related to this command:

- getent_passwd returns a Tcl list of all entries in the local /etc/passwd file.

get_rdn

Use the get_rdn command to specify an LDAP path using a distinguished name (DN) and return the relative distinguished name. This command returns only the first element of the supplied distinguished name.

Zone Type

Not applicable

Syntax

```
get_rdn DN
```

Abbreviation

```
grdn
```

Options

This command takes no options.

Arguments

This command takes the following argument:

DN	string	Required. Specifies a distinguished name.

Return Value

This command returns the first element of the supplied distinguished name.

Examples

```
get_rdn CN=global,CN=Zones,CN=Acme,DC=acme,DC=com
```

This example returns: `CN=global`

Related Commands

The following command performs actions related to this command:

- `get_parent_dn` returns the parent distinguished name of a specified LDAP path.

get_role_apps

Use the `get_role_apps` command to return a Tcl list of PAM application rights associated with the currently selected role.

The `get_role_apps` command does *not* query Active Directory for the role. If you change the PAM applications associated with the current role using ADEdit without saving the role to Active Directory, the PAM applications you retrieve using `get_role_apps` won't match the same PAM applications for the role as stored in Active Directory.

You can only use the `get_role_apps` command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
get_role_apps
```

Abbreviation

grap

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of PAM applications associated with the currently selected role. Each PAM application in the list shows the application name followed by a slash (/) and the zone in which the PAM application is defined.

Examples

```
get_role_apps
```

This example returns the list of PAM applications for the currently selected role: ftp/cz1

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands to view and select the role to work with:

- get_roles returns a Tcl list of roles in the currently selected zone.
- list_roles lists to stdout the roles in the currently selected zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role's attributes, delete the role, or save information for the role:

- add_command_to_role adds a UNIX command to the currently selected role.
- add_pamapp_to_role adds a PAM application to the currently selected role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_commands returns a Tcl list of the UNIX commands associated with the currently selected role.
- get_role_field reads a field value from the currently selected role.
- list_role_rights returns a list of all UNIX commands and PAM applications associated with the currently selected role.
- remove_command_from_role removes a UNIX command from the currently selected role.
- remove_pamapp_from_role removes a PAM application from the currently selected role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the currently selected role.

get_role_assignment_field

Use the get_role_assignment_field command to return the value for a specified field from the currently selected role assignment stored in memory. The get_role_assignment_field command does *not* query Active Directory for the role assignment. If you change field values using ADEdit without saving the role assignment to Active Directory, the field value you retrieve using get_role_assignment_field won't match the same field value for the role assignment stored in Active Directory.

You can only use the get_role_assignment_field command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
get_role_assignment_field field
```

Abbreviation

graf

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve. The possible values are:
		assignee: Returns user display name in format specific to type of logged in user.
		customAttr: Returns the custom text strings set for the role assignment.
		customAttr: Returns the custom text strings set for the role assignment.
		description: Returns the description for the role assignment.
		dn: Returns the role assignment's distinguished name.
		from: Returns the starting date and time for the role assignment. The start and end dates and times are expressed in standard UNIX time. You can use the Tcl clock command to manipulate these values. A value of 0 indicates no date or time is set for the role assignment.
		modifyTime: Returns the time and date this role assignment was last modified, returned in generalized time format.
		ptype: Returns a letter or symbol that indicates the account type associated with a role assignment. You can use the explain_ptype command to translate the returned value into a text string that describes the account type.
		role: Returns the name of the role and the zone in which the role is defined.
		to: Returns the ending date and time for the role assignment.

Return Value

This command returns a field value. The data type depends on the field specified.

Examples

This example returns the role name (root) and the zone where the role is defined (global):

```
get_role_assignment_field role
```

```
root/global
```

This example returns the assignee display name in the appropriate format.

```
get_role_assignment_field assignee
```

- For AD user/group:

  ```
  CN=dc1,CN=Users,DC=sayms,DC=local
  ```

- For trusted forest AD user/group:

  ```
  CN=S-1-5-21-4259971489-770964042-439865176-1106,CN=ForeignSecurityPrincipals,DC=sayms,DC=local
  ```

- For local uid:

  #56789@localhost

- For local user:

  localuser1@localhost

- For local group:

  %localgroup1@localhost

Related Commands

Before you use this command, you must have a currently selected role assignment stored in memory. The following commands to view and select the role assignment to work with:

get_role_assignments

Use the get_role_assignments command to check Active Directory and return a Tcl list of role assignments defined within the currently selected zone. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed. Use list_role_assignments to output the list to stdout.

If you do not specify an option, the command returns the current users and groups in the zone with a role assignment.

You can only use the get_role_assignments command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

get_role_assignments [-upn] [-user] [-group] [-invalid]

Abbreviation

gra

Options

This command takes any one of the following options:

-upn	Returns user names in user principal name (UPN) format, not the default sAMAccount@domain format.
-user	Returns a Tcl list of the current users in the zone with a role assignment.
-group	Returns a Tcl list of the current groups in the zone with a role assignment.
-invalid	Returns a Tcl list of any invalid role assignments in the zone. For example, this option would return role assignment for a group or user that no longer exists.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of role assignments defined in the currently selected zone. Each role assignment includes the sAMAccount@domain name or the

user principal name of the user or group to whom the role is assigned, the name of the role assigned, and the zone in which the role is defined. These three pieces of data are separated from each other by a slash (/).

Examples

```
get_role_assignments
```

This example returns the list of role assignments:

```
poweradmins@acme.com/root/global proj_admins@acme.com/login/global
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. After you have a zone stored in memory, you can use the following commands to view and select the role assignment to work with:

- list_role_assignments lists to stdout the role assignments in the current zone.
- new_role_assignment creates a new role assignment and stores it in memory.
- select_role_assignment retrieves a role assignment from Active Directory and stores it in memory.

After you have a role assignment stored in memory, you can use the following commands to work with that role assignment's attributes, delete the role assignment, or save information for the role assignment:

- delete_role_assignment deletes the selected role assignment from Active Directory and from memory.
- get_role_assignment_field reads a field value from the currently selected role assignment.
- save_role_assignment saves the selected role assignment with its current settings to Active Directory.
- set_role_assignment_field sets a field value in the currently selected role assignment.
- write_role_assignment saves the selected role assignment to a file.

get_role_commands

Use the get_role_commands command to return a Tcl list of UNIX commands associated with the currently selected role. The get_role_commands command does *not* query Active Directory for the role. If you change commands associated with the current role using ADEdit without saving the role to Active Directory, the commands you retrieve using get_role_commands won't match the same commands for the role stored in Active Directory.

You can only use the get_role_commands command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
get_role_commands
```

Abbreviation

```
grc
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of commands associated with the currently selected role. Each command in the list shows the command name followed by a slash (/) and the zone in which the command is defined.

Examples

get_role_commands

This example returns the list of commands:

pwd/global ls/global cd/childzone1

Related commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the current zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role's attributes, delete the role, or save information for the role:

- add_command_to_role adds a UNIX command to the currently selected role.
- add_pamapp_to_role adds a PAM application to the currently selected role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM applications associated with the currently selected role.
- get_role_field reads a field value from the currently selected role.
- list_role_rights returns a list of all UNIX commands and PAM applications associated with the currently selected role.
- remove_command_from_role removes a UNIX command from the currently selected role.
- remove_pamapp_from_role removes a PAM application from the currently selected role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the currently selected role.

get_role_field

Use the get_role_field command to return the value for a specified field from the currently selected role stored in memory. The get_role_field command does *not* query Active Directory for the role. If you change field values using ADEdit without saving the role to Active Directory, the field value you retrieve using get_role_field won't match the same field value for the role stored in Active Directory.

You can only use the get_role_field command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

get_role_field field

Abbreviation

grf

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve.

The possible field values are:

- **allowLocalUser**: Returns true or false depending on whether local users can be assigned to the role. You cannot get this field value if the selected zone is a classic4 zone.
- **AlwaysPermitLogin**: Returns true or false depending on whether "rescue rights" are configured for the role. You cannot get this field value if the selected zone is a classic zone.
- **auditLevel**: Returns the auditing level configured for the role. Roles can be configured without auditing (not requested), to audit if possible, or to have auditing required. You cannot get this field value if the selected zone is a classic4 zone.
- **createTime**: Returns the time and date this role was created in generalized time format.
- **customAttr**: Returns the custom text strings set for the role.
- **description**: Returns the text string that describes the role.
- **dn**: Returns the role's distinguished name.
- **modifyTime**: Returns the time and date this role was last modified in generalized time format.
- **sysrights**: Returns the system rights granted to the role. This value is an integer that represents a combination of binary flags, one for each system right. You cannot get this field value if the selected zone is a classic zone.

  For more information about the value returned for system rights, see the section below, Getting the System Rights Field for a Role.
- **timebox**: Returns the hours and days in the week when the role is enabled. This value is a 42-digit hexadecimal number.

  When represented in binary, each bit represents an hour of the week as described in the Timebox Value Format
- **visible**: Returns true or false depending on whether "User is visible" right is configured for the role. You cannot get this field value if the selected zone is a classic zone.

Getting the system rights field for a role

You can specify the sysrights field to return information about the system rights that have been granted to the currently selected role. This field value is an integer that represents a combination of binary flags, with one flag for each of the following system rights:

1—Password login and non password (SSO) login are allowed.

2—Non password (SSO) login is allowed.

4—Account disabled in Active Directory can be used by sudo, cron, etc.

8—Log in with non-restricted shell.

16—Audit not requested/required.

32—Audit required.

64—Always permit to login.

128—Remote login access is allowed for Windows computers.

256—Console login access is allowed for Windows computers.

512—Require multi-factor authentication through the Delinea Connector to log on.

1024—PowerShell remote access is allowed

These values are added together to define the sysrights field value. For example, a sysrights value of 6 indicates that the role is configured to allow single sign-on

login and to ignore disabled accounts (2+4). A value of 11 indicates that the most common UNIX system rights are enabled (1+2+8). A value of 384 indicates that most common Windows system rights are enabled (128+256).

Return Value

This command returns a field value, which varies in type depending on the data type stored by the field.

Examples

```
get_role_field timebox
```

This example returns the content of the timebox field:

```
00FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF0
```

This return value indicates that the role is enabled during all hours of the weekdays, but none of the weekends.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the currently selected zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role's attributes, delete the role, or save information for the role:

- add_command_to_role adds a UNIX command to the currently selected role.
- add_pamapp_to_role adds a PAM application to the currently selected role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM applications associated with the currently selected role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the currently selected role.
- list_role_rights returns a list of all UNIX commands and PAM applications associated with the currently selected role.
- remove_command_from_role removes a UNIX command from the currently selected role.
- remove_pamapp_from_role removes a PAM application from the currently selected role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the currently selected role.

get_role_rs_commands

Use the get_role_rs_commands command to return a Tcl list of the restricted shell commands associated with the currently selected role.

The get_role_rs_commands command does not query Active Directory for the restricted shell commands. If you change the restricted shell commands associated with the current role using ADEdit without saving the role to Active Directory, the commands you retrieve using get_role_rs_commands won't match the restricted shell commands that are stored in Active Directory.

You can only use get_role_rs_commands if the currently selected zone is a classic4 zone. This command does not work in other types of zones.

Zone Type

Classic only

Syntax

```
get_role_rs_commands
```

Abbreviation

```
grrsc
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of restricted shell commands associated with the currently selected role. Each restricted shell command in the list shows the restricted shell command name followed by a slash (/) and the zone in which the restricted shell command is defined.

Examples

```
get_role_rs_commands
```

This example returns : rse1-id2/c123 rse1-id1/c123

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the currently selected zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with restricted shells:

- get_role_rs_env returns the restricted shell environment from the currently selected role.

get_role_rs_env

Use the get_role_rs_env command to return the restricted shell environment from the currently selected role that is stored in memory.

The get_role_rs_env command does not query the data stored in Active Directory for the role. If you change the restricted shell environment in ADEdit without saving the role to Active Directory, the value you retrieve using get_role_rs_env won't match the same value for the role that is stored in Active Directory.

You can only use the get_role_rs_env command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

```
get_role_rs_env
```

Abbreviation

```
grrse
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns the restricted shell environment of the currently selected role if it runs successfully. If the currently selected role does not require a restricted shell environment, the command returns nothing.

Examples

get_role_rs_env

This example returns the restricted shell environment if it exists for the selected role:

rse1

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the currently selected zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with restricted shells:

- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- save_rs_env saves the restricted shell environment to Active Directory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

get_roles

Use the get_roles command to check Active Directory and return a Tcl list of roles defined within the currently selected zone. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed. Use list_roles to output the list to stdout.

You can only use the get_roles command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

get_roles

Abbreviation

getr

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of roles defined in the currently selected zone.

Examples

get_roles

This example returns the list of roles:

```
{Rescue - always permit login} scp sftp listed {UNIX Login} {Windows Login} winscp
```

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- list_roles lists to stdout the roles in the currently selected zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with role:

- add_command_to_role adds a UNIX command to the currently selected role.
- add_pamapp_to_role adds a PAM application to the currently selected role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM applications associated with the currently selected role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the currently selected role.
- list_role_rights returns a list of all UNIX commands and PAM applications associated with the currently selected role.
- remove_command_from_role removes a UNIX command from the currently selected role.
- remove_pamapp_from_role removes a PAM application from the currently selected role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the currently selected role.

get_rs_commands

Use the get_rs_commands command to return a Tcl list of restricted shell commands that are defined for the currently selected zone. If you want to return a list of restricted shell commands to stdout, use the list_rs_commands command.

Zone Type

Classic only

Syntax

```
get_rs_commands
```

Abbreviation

```
grsc
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of restricted shell commands for the currently selected zone.

Examples

```
get_rs_commands
```

This example returns output similar to this:

```
rse1-id1 rse1-id2 rse2-id1
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- list_rs_commands lists to stdout the restricted shell commands in the current zone.
- new_rs_command creates a new restricted shell command and stores it in memory.
- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- get_rsc_field reads a field value from the currently selected command.
- save_rs_command saves the selected command with its current settings to Active Directory.
- set_rsc_field sets a field value in the currently selected command.

get_rs_envs

Use the get_rs_envs command to check Active Directory and return a list of restricted environments that are defined within the currently selected zone. If you want to return a list of restricted shell environment to stdout, use the list_rs_envs command.

Zone Type

Classic only

Syntax

```
get_rs_envs
```

Abbreviation

```
grse
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of restricted environments in the currently selected zone.

Examples

```
get_rs_envs
rse1 rse2
```

This example returns the list of restricted shell environments.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with restricted shell environments:

- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.
- set_rse_field sets a field value in the current restricted shell environment.

get_rsc_field

Use the get_rsc_field command to return the value of a specified field value from the currently selected restricted shell command that is stored in memory. Delinea-specific fields are similar to Active Directory attributes but are stored within the Active Directory schema.

The get_rsc_field command does not query Active Directory for the restricted shell command. If you change field values using ADEdit without saving the restricted shell command to Active Directory, the field value you retrieve using get_rsc_field won't match the value stored in Active Directory.

You can only use the get_rsc_field command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

get_rsc_field field

Abbreviation

grscf

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the name of the field whose value you want to retrieve. The possible values are: **description**: Returns text describing the restricted shell command. **cmd**: Returns the restricted shell command string or strings. **path**: Returns the path to the command's location. **form**: Returns an integer that indicates whether the cmd and path strings use wild cards (0) or a regular expression (1). **dzsh_runas**: Returns a list of users and groups that can run this command in a restricted shell environment (dzsh). Users can be listed by user name or UID. **keep**: Returns a comma-separated list of environment variables from the current user's environment to keep. **del**: Returns a comma-separated list of environment variables from the current user's environment to delete. **add**: Returns a comma-separated list of environment variables to add to the final set of environment variables. **pri**: Returns a n integer that specifies the command priority for the restricted shell command object. **umask**: Returns an integer that defines who can execute the command. **flags**: Returns an integer that specifies a combination of different properties for the command. **createTime**: The time and date this command was created, returned in generalized time format. **modifyTime**: The time and date this command was last modified, returned in generalized time format. **dn**: The command's distinguished name.

Return Value

This command returns a field value. The data type depends on the field specified. For more information about the field values returned by different fields, see get_dzc_field.

Examples

get_rsc_field description

This example returns the contents of the description field:

This is the RSC description

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- get_rs_commands returns a Tcl list of restricted shell commands in the current zone.
- list_rs_commands lists to stdout the restricted shell commands in the current zone.
- new_rs_command creates a new restricted shell command and stores it in memory.
- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- save_rs_command saves the selected command with its current settings to Active Directory.
- set_rsc_field sets a field value in the currently selected command.

get_rse_cmds

Use the get_rse_cmds command to return a Tcl list of restricted shell commands associated with the currently selected restricted shell environment.

The get_rse_cmds command does not query Active Directory for the restricted shell environment. If you change the restricted shell commands associated with the current restricted shell environment using ADEdit without saving the restricted shell environment to Active Directory, the commands you retrieve using get_rse_cmds won't match those stored in Active Directory.

You can only use the get_rse_cmds command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

get_rse_cmds

Abbreviation

grsec

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of restricted shell commands associated with the currently selected restricted shell environment. Each restricted shell command in the list shows the command name followed by a slash (/) and the zone in which the command is defined.

Examples

get_rse_cmds

The command returns the list restricted commands:

rse1-id2/c123 rse1-id1/c123

Related Commands

Before you use this command, you must have a currently selected restricted shell environment stored in memory. The following commands enable you to view and select the restricted shell environments:

- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- save_rs_env saves the restricted shell environment to Active Directory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following command to work with its fields:

- set_rse_field sets a field value in the current restricted shell environment.

get_rse_field

Use the get_rse_field command to return a field value from the currently selected restricted shell environment stored in memory.

The get_rse_field command does not query Active Directory for the restricted shell environment. If you have changed field values using ADEdit without saving the restricted shell environment to Active Directory, the field value you retrieve using get_rse_field won't match the field value for the restricted shell environment that is stored in Active Directory.

You can only use the get_rse_field command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

```
get_rse_field field
```

Abbreviation

```
grsef
```

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the name of the field whose value to get. The only possible value is: description: Returns a text string describing the restricted shell environment.

Return Value

This command returns a field value, which varies in type depending on the data type stored by the field.

Examples

```
get_rse_field description
```

This command returns the content of the description field. For example:

```
This is the restricted shell environment description
```

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to

work with restricted shell environments:

- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- save_rs_env saves the restricted shell environment to Active Directory.
- set_rse_field sets a field value in the current restricted shell environment.

get_schema_guid

Use the get_schema_guid command to look up a specified class or attribute in Active Directory. If the specified object is found, the command returns the globally unique identifier (GUID) of the class or attribute.

This command is useful for setting a security descriptor (SD) at a class or attribute level.

Zone Type

Not applicable

Syntax

```
get_schema_guid schema_name
```

Abbreviation

gsg

Options

This command takes no options.

Arguments

This command takes the following argument:

schema_name	string	Required. Specifies the name of a class or attribute.

Return Value

This command returns the globally unique identifier (GUID) of the provided schema object (class or attribute).

Examples

```
get_schema_guid MS-DS-Az-Role
```

This example returns the globally unique identifier of MS-DS-Az-Role:

```
8213eac9-9d55-44dc-925c-e9a52b927644
```

Related Commands

None.

get_zone_computer_field

Use the get_zone_computer_field command to return the value of a specified field from the currently selected zone computer stored in memory. The get_zone_computer_field command does *not* query Active Directory for the zone computer. If you change field values using ADEdit without saving the zone computer to Active Directory, the field value you retrieve using get_zone_computer_field won't match the same field value for the zone computer stored in Active Directory.

Zone Type

Classic and hierarchical

Syntax

```
get_zone_computer_field field
```

Abbreviation

gzcf

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve. The possible values are: **addn**: Returns the distinguished name of the Active Directory computer object for the zone computer. For example, if the computer object is created in the default Computers container, this field might return a path similar to CN=firefly-sf,CN=Computers,DC=ajax,DC=org. **agentVersion**: Returns the version of agent currently installed on the zone computer. **cpus**: Returns the number of CPUs in the computer. **createTime**: Returns the time and date this zone computer was created (in generalized time format). **dn**: Returns the distinguished name of the service connection point for the zone computer. If the computer is in a Services for UNIX (SFU) zone, no value is returned for this field. **dnsname**: Returns the domain name service (DNS) name of the zone computer. **enabled**: Returns 1 if the zone computer is enabled in its zone or 0 if it is not. **modifyTime**: Returns the time and date this zone computer was last modified (in generalized time format).

Return Value

This command returns a field value. The data type depends on the field specified.

Examples

```
get_zone_computer_field dnsname
```

This example returns the name of the zone computer as listed in DNS:

```
printserver.acme.com
```

Related Commands

Before you use this command, you must have a currently selected zone computer stored in memory. The following commands enable you to view and manage the zone computers:

- get_zone_computers returns a Tcl list of the Active Directory names of all zone computers in the current zone.
- list_zone_computers lists to stdout the zone computers in the current zone.
- new_zone_computer creates a new zone computer and stores it in memory.
- select_zone_computer retrieves a zone computer from Active Directory and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- delete_zone_computer deletes the zone computer from Active Directory and from memory.
- save_zone_computer saves the zone computer with its current settings to Active Directory.
- set_zone_computer_field sets a field value in the currently selected zone computer.

get_zone_computers

Use the get_zone_computers command to check Active Directory and return a Tcl list of zone computers defined within the currently selected zone. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed. Use list_zone_computers to output the list to stdout.

Zone Type

Classic and hierarchical

Syntax

get_zone_computers

Abbreviation

gzc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of zone computers defined in the currently selected zone. Each entry in the list is the security identifier (SID) of a computer that you can use to look up that computer.

Examples

get_zone_computers

This example returns the security identifier for each computer:

*S-1-5-21-2076040321-3326545908-468068287-1107

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and manage the zone computers:

- list_zone_computers lists to stdout the zone computers in the current zone.
- new_zone_computer creates a new zone computer and stores it in memory.
- select_zone_computer retrieves a zone computer from Active Directory and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- delete_zone_computer deletes the zone computer from Active Directory and from memory.
- get_zone_computer_field reads a field value from the currently selected zone computer.
- save_zone_computer saves the zone computer with its current settings to Active Directory.
- set_zone_computer_field sets a field value in the currently selected zone computer.

get_zone_field

Use the get_zone_field command to return the value for a specified field from the currently selected zone stored in memory. The get_zone_field command does *not*

query Active Directory for this zone. If you change field values using ADEdit without saving the zone to Active Directory, the field value you retrieve using get_zone_field won't match the same field value for the zone stored in Active Directory.

Zone Type

Classic and hierarchical

Syntax

get_zone_field field

Abbreviation

gzf

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve.

The data type depends on the field you return. The possible field values are:

- **availableshells**: Returns the shells available to assign to new users in the zone.
- **block.parent.zgroup**: Returns the value of the block.parent.zgroup field in the zone object's description.
- **cloudurl**: Returns the name of the cloud instance associated with the selected zone.
- **computers**: Returns the computer group UPN that is assigned to the computer role selected as a zone.
- **createTime**: Returns the time and date this zone was created.
- **customAttr**: Returns the custom text strings that have been set for the zone. This field is only applicable for hierarchical zones.
- **defaultgid**: Returns the default primary group to assign to new users.
- **defaultgecos**: Returns the default GECOS data to assign to new users.
- **defaulthome**: Returns the default home directory to assign to new users.
- **defaultshell**: Returns the default shell to assign to new users.
- **description**: Returns the description of the zone.
- **dn**: Returns the zone's distinguished name.
- **gidnext**: Returns the next GID to use when auto-assigning GID numbers to new groups.
- **gidreserved**: Returns the GID number or range of numbers (1-100) that are reserved.
- **groupname**: Returns the default group name used for new groups in the zone.
- **modifyTime**: Returns the time and date this zone was last modified.
- **nisdomain**: Returns the name of the NIS domain if it has been set.
- **parent**: Returns the distinguished name (DN) of the parent zone for the selected zone.
- **schema**: Returns the schema used in this zone, for example, std.
- **sid2iddomainmap**: Returns the domain ID mapping from the selected zone. This field is not supported for auto zones nor classic zones.
- **sfudomain**: Returns the Windows domain name for the SFU zone. Only use this argument if the current zone is a Service for UNIX (sfu) zone.
- **tenantid**: Returns the Delinea Platform tenant ID for the zone. This field is only applicable for hierarchical zones.
- **type**: Returns the type of the zone, for example, classic4 or tree.
- **uidnext**: Returns the next UID to use when auto-assigning UID numbers to new users.
- **uidreserved**: Returns the UID number or range of numbers (1-100) that are reserved.
- **username**: Returns the default user name used for new users in the zone.

For more information about the values returned by these fields, see the Return value section.

Return Value

This command returns the current value for the specified field. The data type depends on the field specified.

availableshells	Returns the list of shells available to choose from when adding new users to the currently selected zone. The value is a list of shell paths, separated by colons :. For example, "/bin/bash:/bin/csh:/bin/ksh"
block.parent.zgroup	Returns the value of the block.parent.zgroup field from the zone object's description for the currently selected zone. This field can be true if you want to prevent groups provisioned in the parent zone from being visible in the child zone if they aren't being used. The default value is false.
cloudurl	Returns the fully-qualified URL of the cloud instance associated with the selected zone.
computers	Returns the computer group UPN that is assigned to the computer role if the currently selected zone is a "computer role" zone.
createTime	Returns the time and date this zone was created (in generalized time format).
defaultgid	Returns the default primary group to assign to new users in the currently selected zone. The value can be a specific GID value or include variables.
defaultgecos	Returns the default GECOS data to assign to new users in the currently selected zone. The value can be a string or include variables.
defaulthome	Returns the default home directory to assign to new users in the currently selected zone. The value can be a string that defines the path or include variables.
defaultshell	Returns the default shell to assign to new users in the currently selected zone. The value can be a string that defines the shell or include variables.
description	Returns the description of the zone. If the currently selected zone is a computer role, this field returns the Active Directory description attribute for the msds-AzScope object.
dn	Returns the zone's distinguished name. If the currently selected zone is a computer role, this field returns the Active Directory distinguished name attribute of the msds-AzScope object.
gidnext	Returns the next GID to use when auto-assigning GID numbers to new groups in the currently selected zone.
gidreserved	Returns the GID number or range of numbers (1-100) that are reserved in the currently selected zone.
groupname	Returns the default group name used for new groups in the currently selected zone. You can only return the value for this field if the current zone is a hierarchical zone.
modifyTime	Returns the time and date this zone was last modified (in generalized time format).
nisdomain	Returns the name of the NIS domain if it has been set. The default value is the zone name.
parent	Returns the distinguished name (DN) of the parent zone for the currently selected zone. You can only return the value for this field if the current zone is a hierarchical zone. You can use the option -raw with this field to return the parentLink attribute in the raw *Guid@Domain* format.
schema	Returns the schema used in this zone, for example, std.
sfudomain	Returns the Windows domain name for the SFU zone. Only use this argument if the current zone is a Service for UNIX (sfu) zone.
sid2iddomainmap	Returns a comma-separated key value pairs string. If an empty string is returned, that means that there's no domain ID mapping for the selected zone.
tenantid	Returns the tenant ID of the cloud instance associated with the selected zone.

type	Returns the type of the currently selected zone. For example, this field returns classic3 or classic4 for a classic zone or tree for a hierarchical zone.
uidnext	Returns the next UID to use when auto-assigning UID numbers to new users in the currently selected zone.
uidreserved	Returns the UID number or range of numbers (1-100) that are reserved in the currently selected zone.
username	Returns the default user name used for new users in the zone. You can only return the value for this field if the current zone is a hierarchical zone.

Examples

get_zone_field type

This example returns the zone type:

tree

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the zone:

- create_zone creates a new zone in Active Directory.
- get_zones returns a Tcl list of all zones within a specified domain.
- select_zone retrieves a zone from Active Directory and stores it in memory.

After you have a zone stored in memory, you can use the following commands to work with that zone computer:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.
- set_zone_field sets a field value in the currently selected zone.

get_zone_group_field

Use the get_zone_group_field command to return the value for a specified field from the currently selected zone group stored in memory. The get_zone_group_field command does *not* query Active Directory for the zone group. If you change field values using ADEdit without saving the zone group to Active Directory, the field value you retrieve using get_zone_group_field won't match the same field value for the zone group stored in Active Directory.

Zone Type

Classic and hierarchical

Syntax

get_zone_group_field field

Abbreviation

gzgf

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the case-sensitive name of the field whose value to retrieve. The possible values are: **addn**: Returns the distinguished name of the Active Directory group object for the zone group. For example, if the group object is created in the default Users container, this field might return a path similar to CN=pubsteam,CN=Users,DC=ajax,DC=org. **createTime**: Returns the time and date this zone group was created (in generalized time format). **dn**: Returns the distinguished name of the service connection point for the zone group. If the zone is a Services for UNIX (sfu) zone, no value is returned for this field. **gid**: Returns the numeric identifier for the group. **modifyTime**: Returns the time and date this zone group was last modified (in generalized time format). **name**: Returns the group name. **required**: Returns 1 if the zone group is required for members in this zone, or 0 if the group is not required. Users assigned to a required group cannot remove the group from their active set of groups. You can also specify AIX extended attributes as the field to get an extended attribute value for a group. Extended attribute fields start with the aix. prefix. For example, the admin extended attribute can be retrieved by specifying aix.admin as the field.

Return Value

This command returns a field value. The data type depends on the field specified.

Examples

The following example returns the group name.

```
get_zone_group_field name
```

```
padmins
```

If the current group is on AIX, you can get AIX group extended attributes and values. For example, to find out if the current group is an administrative group, you can get the admin extended attribute:

```
get_zone_group_field aix.admin
```

```
true
```

Related Commands

Before you use this command, you must have a currently selected zone group stored in memory. The following commands enable you to view and manage the zone groups:

- list_zone_groups lists to stdout the zone groups in the current zone.
- new_zone_group creates a new zone group and stores it in memory.
- select_zone_group retrieves a zone group from Active Directory and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- delete_zone_group deletes the selected zone group from Active Directory and from memory.
- save_zone_group saves the selected zone group with its current settings to Active Directory.
- set_zone_group_field sets a field value in the currently selected zone group.

get_zone_groups

Use the get_zone_groups command to check Active Directory and return a Tcl list of zone groups defined within the currently selected zone. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed. Use list_zone_groups to output the list to stdout.

Zone Type

Classic and hierarchical

Syntax

```
get_zone_groups
```

Abbreviation

gzg

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of zone groups defined in the currently selected zone. Each entry in the list is the user principal name (UPN) of a group that you can use to look up that group.

Examples

```
get_zone_groups
```

This example returns the list of zone groups: poweradmins@acme.com auditors@acme.com

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select zone groups:

- list_zone_groups lists to stdout the zone groups in the current zone.
- new_zone_group creates a new zone group and stores it in memory.
- select_zone_group retrieves a zone group from Active Directory and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- delete_zone_group deletes the selected zone group from Active Directory and from memory.
- get_zone_group_field reads a field value from the currently selected zone group.
- save_zone_group saves the selected zone group with its current settings to Active Directory.
- set_zone_group_field sets a field value in the currently selected zone group.

get_zone_nss_vars

Use the get_zone_nss_vars command to return a Tcl list containing the NSS substitution variables for the currently selected zone stored in memory. This command only works on hierarchical zones and won't return a value for other zone types.

The get_zone_nss_vars command does *not* query Active Directory for this zone. If you change the variables using set_zone_field without saving the zone Active Directory, the variable you retrieve using get_zone_nss_vars won't match the same field variable for the zone stored in Active Directory.

Zone Type

Hierarchical only

Syntax

```
get_zone_nss_vars
```

Abbreviation

gznv

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of strings in the form "A=B".

Examples

```
get_zone_nss_vars
```

This example returns: NSSRANDCOUNT=32000 NSRANDFILE=/params/nssrand.seed

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone:

- `create_zone creates a new zone in Active Directory.
- `get_zones returns a Tcl list of all zones within a specified domain.
- `select_zone retrieves a zone from Active Directory and stores it in memory.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_field reads a field value from the currently selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.
- set_zone_field sets a field value in the currently selected zone.

get_zone_user_field

Use the get_zone_user_field command to return the value for a specified field from the currently selected zone user stored in memory. The get_zone_user_field command does *not* query Active Directory for the zone user. If you change field values using ADEdit without saving the zone user to Active Directory, the field value you retrieve using get_zone_user_field won't match the same field value for the zone user stored in Active Directory.

Zone Type

Classic and hierarchical

Syntax

```
get_zone_user_field field
```

Abbreviation

gzuf

Options

This command takes no options.

Arguments

This command takes the following required argument:

field (string type)

Specifies the case-sensitive name of the field whose value to retrieve.

Argument values

- **addn**: Returns the distinguished name of the Active Directory user object for the zone user. For example, if the user object is created in the default Users container, this field might return a path similar to CN=amy.adams,CN=Users,DC=ajax,DC=org.
- **createTime**: Returns the time and date this zone user was created.
- **dn**: Returns the distinguished name of the service connection point for the zone user. If the zone is a Services for UNIX (sfu) zone, no value is returned for this field.
- **enabled**: Returns 1 if the user is enabled, or 0 if the user is disabled. This field is only applicable for users in classic zones. All other zone types use roles.
- **foreign**: If the zone user comes from another forest, this field returns the user principal name of the zone user. Otherwise, this field returns no value.
- **gecos**: Returns information from the GECOS field.
- **gid**: Returns the primary group identifier (GID) for the user.
- **home**: the Returns user's home directory.
- **modifyTime**: Returns the time and date this zone user was last modified.
- **shell**: Returns the user's shell type.
- **uid**: Returns the numeric identifier for the user.
- **uname**: Returns the user name.

You can also specify AIX extended attributes as the field to get an extended attribute value for a zone user.

Return Value

This command returns a field value. The data type depends on the field specified.

Examples

The following example returns the current zone user's user name:

```
get_zone_user_field uname
adam
```

If the current zone user is on AIX, you can get extended attributes and values. For example:

```
select_zone_user aixu1@acme.com
get_zone_user_field aix.ttys
u1,u2,u3
```

Related Commands

Before you use this command, you must have a currently selected zone user stored in memory. The following commands enable you to view and select a zone user:

- get_zone_users returns a Tcl list of the Active Directory names of all zone users in the current zone.
- list_zone_users lists to stdout the zone users and their NSS data in the current zone.
- new_zone_user creates a new zone user and stores it in memory.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- delete_zone_user deletes the selected zone user from Active Directory and from memory.
- save_zone_user saves the selected zone user with its current settings to Active Directory.
- set_zone_user_field sets a field value in the currently selected zone user.

get_zone_users

Use the get_zone_users command to check Active Directory and return a Tcl list of zone users defined within the currently selected zone. If executed in a script, this command does not output its list tostdout, and no output appears in the shell where the script is executed. Use list_zone_users to output the list to stdout.

Zone Type

Classic and hierarchical

Syntax

```
get_zone_users [-upn]
```

Abbreviation

gzu

Options

This command takes the following option:

-upn	Optional. Returns user names in user principal name (UPN) format rather than the default sAMAccount@domain format.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of zone users defined in the currently selected zone. By default, users are listed by sAMAccountName@domain. You can use the -upn option to return users listed by user principal name (UPN). If a zone user is an orphan user—that is, its corresponding Active Directory user no longer exists—the user is listed by its security identifier (SID) instead of the sAMAccountName or user principal name.

Examples

get_zone_users

This example returns the list of users: adam.avery brenda.butler chris.carter

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone user:

- list_zone_users lists to stdout the zone users and their NSS data in the current zone.
- new_zone_user creates a new zone user and stores it in memory.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- delete_zone_user deletes the selected zone user from Active Directory and from memory.
- get_zone_user_field reads a field value from the currently selected zone user.
- save_zone_user saves the selected zone user with its current settings to Active Directory.
- set_zone_user_field sets a field value in the currently selected zone user.

get_zones

Use the get_zones command to check Active Directory and return a Tcl list of zones within a specified domain. Note that this does not include computer-specific override zones or computer roles.

Zone Type

Classic and hierarchical

Syntax

get_zones domain

Abbreviation

gz

Options

This command takes no options.

Arguments

This command takes the following argument:

domain	string	Required. Specifies the name of the domain for which to return zones.

Return Value

This command returns a Tcl list with the distinguished name for each zone in the specified domain.

Examples

```
get_zones acme.com
```

This example returns the list of zones in the acme.com domain:

```
CN=childzone1,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com CN=childzone2,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com
CN=global,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com
```

Related Commands

The following commands perform actions related to this command:

- create_zone creates a new zone in Active Directory.
- select_zone retrieves a zone from Active Directory and stores it in memory.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_field reads a field value from the currently selected zone.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.
- set_zone_field sets a field value in the currently selected zone.

getent_passwd

Use the getent_passwd command to return a Tcl list of local UNIX users that are defined in the /etc/passwd file on the ADEdit host computer. If the local host is joined to an Active Directory domain, the command also returns information for the Active Directory users who have a profile in the joined domain and zone.

Zone Type

Not applicable

Syntax

```
getent_passwd
```

Abbreviation

```
gep
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a Tcl list of /etc/passwd file entries with all user profile attributes.

Examples

getent_passwd

This example returns the contents of the local /etc/passwd file:

```
{root x 0 0 root /root /bin/bash}{bin x 1 1 bin /bin /sbin/nologin}{daemon x 2 2 daemon /sbin /sbin/nologin}{adm x 3 4 adm /var/adm /sbin/nologin}{lp x 4 7 lp /var/spool/lpd /sbin/nologin}{sync x 5 0 sync /sbin /bin/sync}{shutdown x 6 0 shutdown /sbin /sbin/shutdown}
```

Related Commands

The following command performs actions related to this command:

- get_pwnam searches the /etc/passwd file for a UNIX user name and, if found, returns a Tcl list of the profile attributes associated with the user.

guid_to_id

Use the guid_to_id command to specify a globally unique identifier (GUID) for a user or group and returns a UID or GID that uses the Apple methodology for automatically generated unique identifiers.

Zone Type

Not applicable

Syntax

```
guid_to_id guid
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes the following argument:

guid	string	Required. Specifies the globally unique identifier for a user or group.

Return Value

This command returns UID or GID for the user or group generated using the Apple mechanism for automatically generating identifiers.

Examples

```
guid_to_id 763ddbc8-44cc-4a79-83aa-abc899b46aba
```

This example returns the UID for the user associated with the specified globally unique identifier:

```
1983765448
```

Related Commands

The following command performs actions related to this command:

- principal_to_id returns a unique UID or GID based on either the Apple methodology or the Delinea Auto Zone methodology for generating numeric identifiers.
- sid_to_uid converts a user's security identifier to a numeric identifier (UID).

help

Use the help command to return information about one or more ADEdit commands. It's followed by a command pattern that is either the name of a single ADEdit command or a string with wild cards that specifies multiple possible commands. The command pattern can also be a command abbreviation.

The command pattern wild cards are:

- ? for a single character
- * for multiple characters

Zone Type

Not applicable

Syntax

```
help command_pattern
```

Abbreviation

```
h
```

Options

This command takes no options.

Arguments

This command takes the following argument:

command_pattern	string	Required. Specifies the name of one or more ADEdit commands for which to return information. You can specify a command name, command shortcut or use the ? and * wild cards to specify a single character or multiple characters respectively.

Return Value

This command returns information for the specified command or commands. If there's no match for the *command_pattern* you specify, the command returns nothing.

Examples

```
help explain_sd
```

This example returns information for the explain_sd command.

```
help ?et*
```

This example returns information for the ADEdit commands that start with get or set, such as get_zones, get_zone_field, set_zone_field, and set_role_field.

Related Commands

None.

is_dz_enabled

Use this command to check whether authorization is enabled in a currently selected classic zone.

Zone Type

Classic only

Syntax

```
is_dz_enabled
```

Abbreviation

```
idze
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns 1 if authorization is enabled in a classic or 0 if authorization is not enabled.

Examples

```
create_zone classic4 cn=c125,cn=zones,dc=test,dc=net
select_zone cn=c125,cn=zones,dc=test,dc=net
is_dz_enable
0
manage_dz -on
is_dz_enable
1
```

This code example creates a new classic zone, checks that authorization is disabled by default, then enables authorization for the zone.

Related Commands

The following command performs actions related to this command:

- `manage_dz` enables and disables authorization in classic4 zones.

joined_get_user_membership

Use the `joined_get_user_membership` command to have `adclient` query Active Directory for a list of groups that a specified user belongs to in the domain to which ADEdit's host computer is joined. If the `adclient` query returns groups, this command returns those groups in a Tcl list.

Because this command queries Active Directory through `adclient`, the query might use the `adclient` cache instead of connecting directly to Active Directory. The `adclient` cache isn't guaranteed to be updated with ADedit activity. Therefore, you might need to execute the Delinea UNIX command `adflush` before using `joined_get_user_membership` to ensure you get the most up-to-date results.

Zone Type

Not applicable

Syntax

```
joined_get_user_membership user_UPN
```

Abbreviation

jgum

Options

This command takes no options.

Arguments

This command takes the following argument:

user_UPN	string	Required. Specifies the user principal name (UPN) of the user to check for group membership.

Return Value

This command returns a Tcl list of groups.

Examples

```
joined_get_user_membership liz.lemon@acme.com
```

This example returns group membership for liz.lemon in the joined domain:

```
acme.com/Users/Domain Users
```

Related Commands

The following commands performs actions related to this command:

- joined_user_in_group checks Active Directory through adclient to see if a user is in a group.
- get_effective_groups returns a Tcl list of groups a user belongs to.
- get_group_members returns a Tcl list of members in a group.

joined_name_to_principal

Use the joined_name_to_principal command have adclient query Active Directory for a UNIX name of a specified user. If the specified user is found, the command returns the associated Active Directory user name in the format of sAMAccountName@domain. The command can also optionally return the user principal name (UPN) of the user. This command works only for users within the domain to which ADEdit's host computer is joined through adclient.

Zone Type

Not applicable

Syntax

```
joined_name_to_principal [-upn] UNIX_name
```

Abbreviation

jntp

Options

This command takes the following option:

-upn	Returns the user's Active Directory name in user principal name (UPN) format.

Arguments

This command takes the following argument:

UNIX_name	string	Required. Specifies the UNIX name of a user to look for in Active Directory.

Return Value

This command returns the sAMAccountName@domain form of the user name if the user is found in Active Directory. If you specify the -upn option, this command returns the UPN form of user name.

Examples

```
joined_name_to_principal -upn adam
```

This example returns the sAMAccountName@domain for the UNIX user adam:

```
adam.avery@acme.com
```

Related Commands

The following commands performs actions related to this command:

- principal_to_dn searches Active Directory for a user principal name (UPN) and, if found, returns the corresponding DN.
- dn_to_principal searches Active Directory for a distinguished name and, if found, returns the corresponding UPN.
- principal_from_sid searches Active Directory for a security identifier (SID) and returns the security principal associated with the SID.

joined_user_in_group

Use the joined_user_in_group command to have adclient query Active Directory to see if a specified user belongs to a specified group. This command works only for users and groups within the domain to which ADEdit's host computer is joined through adclient.

Because this command queries Active Directory throughadclient, the query might use adclient's cache rather than connect directly to Active Directory. The adclient cache isn't guaranteed to be updated with ADedit activity. Therefore, you might need to execute the Delinea UNIX command adflush before using joined_user_in_group to ensure you get the most up-to-date results.

Zone Type

Not applicable

Syntax

```
joined_user_in_group user_UPN group_UPN
```

Abbreviation

```
jug
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

user_UPN	string	Required. Specifies the user principal name (UPN) of the user for which you want to check group membership.
group_UPN	string	Required. Specifies the UPN of the group for which you want to check user membership.

Return Value

This command returns 1 if the user is a member of the group, or 0 if the user is not a member of the group.

Examples

```
joined_user_in_group martin.moore@acme.com poweradmins@acme.com
```

This example returns 1 because martin.moore is a member of the poweradmins group.

Related Commands

The following commands performs actions related to this command:

- joined_get_user_membership uses adclient to return a Tcl list of groups that a user belongs to.
- get_effective_groups checks Active Directory directly and returns a Tcl list of groups a user belongs to.
- get_group_members checks Active Directory and returns a Tcl list of members in a group.

list_dz_commands

Use the list_dz_commands command to check Active Directory and return a list of UNIX command objects defined within the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_dz_commands to return a Tcl list.

You can only use the list_dz_commands command to return UNIX command data for classic4 and hierarchical zones.

Zone Type

Classic and hierarchical

Syntax

```
list_dz_commands
```

Abbreviation

```
lsdzc
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of UNIX commands defined in the currently selected zone. Each entry in the list contains the following fields, separated

by colons (:):

- The name of the UNIX command followed by a slash (/) and the name of the zone where the command is defined.
- The properties of the command.
- Text describing the command.

Examples

```
list_dz_commands
```

This example returns commands in the following format:

```
root_any/global : * form(0) dzdo_runas(root) flags(16) : Run any command as root
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a UNIX command:

- `get_dz_commands` returns a Tcl list of UNIX commands in the current zone.
- `new_dz_command` creates a new UNIX command and stores it in memory.
- `select_dz_command` retrieves a UNIX command from Active Directory and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- `delete_dz_command` deletes the selected command from Active Directory and from memory.
- `get_dzc_field` reads a field value from the currently selected command.
- `save_dz_command` saves the selected command with its current settings to Active Directory.
- `set_dzc_field` sets a field value in the currently selected command.

list_local_groups_profile

Use the `list_local_groups_profile` command to display a list of local UNIX and Linux group profiles that are defined in the current zone.

Zone Type

Hierarchical only.

Syntax

```
list_local_groups_profile
```

Abbreviation

```
lslgp
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to `stdout` of the local UNIX and Linux group profiles that are defined in the current zone. Each profile contains the group name, GID, members, and profile flag value.

Examples

The following example returns a local group profile list.

```
list_local_groups_profile lam_grp1:3001:lam_usr1:1 lam_grp2:3002:lam_usr2:1 lam_grp3:3003:lam_usr3:3
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

list_local_users_profile

Use the list_local_users_profile command to display a list of local UNIX and Linux user profiles that are defined in the current zone.

Zone Type

Hierarchical only.

Syntax

```
list_local_users_profile
```

Abbreviation

```
lslup
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of the local UNIX and Linux user profiles that are defined in the current zone. Each profile contains the user name, UID, primary GID, GECOS, home directory, shell, and profile flag value.

Examples

The following example returns a local user profile list.

```
list_local_users_profile
```

```
lam_usr1:2001:2001:lam usr1:/home/lam_usr1:/bin/bash:1
```

lam_usr2:2002:2002:lam usr2:/home/lam_usr2:/bin/bash:2

lam_usr3:2003:2003:lam usr3:/home/lam_usr3:/bin/bash:3

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

list_nis_map

Use the list_nis_map command to return a list of all map entries within the currently selected NIS map. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_nis_map to return a Tcl list of NIS map entries.

Zone Type

Not applicable

Syntax

list_nis_map

Abbreviation

lsnm

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of the map entries for the currently selected NIS map. Each map entry in the list contains the following fields separated by colons (:):

- The key
- The instance number of the key
- The value

Examples

list_nis_map

This example returns map entries similar to the following:

Finance:1:Hank@acme.com,jane@acme.com,joe@acme.com

Mktg:1:Mike@acme.com,Sue@acme.com

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and select a NIS map:

- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps returns a list to stdout of all NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map:

- add_map_entry or add_map_entry_with_comment adds a map entry to the currently selected NIS map.
- delete_map_entry removes an entry from the currently selected NIS map.
- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_map or get_nis_map_with_comment returns a Tcl list of the map entries in the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- list_nis_map_with_comment lists to stdout the map entries in the currently selected NIS map.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.

list_nis_map_with_comment

Use the list_nis_map_with_comment command to return a list of all map entries for the currently selected NIS map and includes the entries' comment. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed.

The command does not return a Tcl list back to the executing script. Use get_nis_map or get_nis_map_with_comment to return a Tcl list of NIS map entries for parsing or further processing within the script.

Zone Type

Not applicable

Syntax

list_nis_map_with_comment

Abbreviation

lsnmwc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of the map entries for the currently selected NIS map. Each map entry in the list contains the following fields separated by colons ':' :

- The key
- The instance number of the key
- The value
- The comment

Examples

list_nis_map_with_comment

This example returns map entries similar to the following:

Finance:1:Hank@acme.com,jane@acme.com,joe@acme.com:Finance dept staff

Mktg:1:Mike@acme.com,Sue@acme.com:Marketing dept staff

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and select a NIS map:

- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps lists to stdout the NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map:

- add_map_entry or add_map_entry_with_comment adds a map entry to the currently selected NIS map.
- delete_map_entry removes an entry from the currently selected NIS map.
- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_map or get_nis_map_with_comment returns a Tcl list of the map entries in the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- list_nis_map lists to stdout the map entries in the currently selected NIS map.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.

list_nis_maps

Use the list_nis_maps command to check Active Directory and return a list of NIS maps defined in the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_nis_maps to return a Tcl list.

Zone Type

Not applicable

Syntax

list_nis_maps

Abbreviation

lsnms

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of NIS maps defined in the currently selected zone.

Examples

list_nis_maps

This example returns the list of NS maps for the zone:

Aliases

Printers

Services

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and select a NIS map:

- get_nis_maps returns a Tcl list of NIS maps in the currently selected zone.
- list_nis_maps lists to stdout the NIS maps in the currently selected zone.
- new_nis_map creates a new NIS map and stores it in memory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map:

- add_map_entry or add_map_entry_with_comment adds a map entry to the currently selected NIS map.
- delete_map_entry removes an entry from the currently selected NIS map.
- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_map or get_nis_map_with_comment returns a Tcl list of the map entries in the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- list_nis_map or list_nis_map_with_comment lists to stdout the map entries in the currently selected NIS map.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.

list_pam_apps

Use the list_pam_apps command to check Active Directory and return a list of PAM application rights defined in the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_pam_apps to return a Tcl list.

You can only use the list_pam_apps command to return PAM application rights for classic4 and hierarchical zones.

Zone Type

Classic and hierarchical

Syntax

list_pam_apps

Abbreviation

lspa

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of PAM application rights defined in the currently selected zone. Each entry contains the following fields, separated by colons : :

- The name of the PAM access right followed by a slash (/) and the zone in which the PAM access right is defined.
- The name of one or more PAM applications to which the right applies.
- Text describing the PAM application object.

Examples

list_pam_apps

This example returns a list of PAM application access rights for the selected zone (the following is a subset of the default predefined rights):

```
dzssh-all/global : dzssh-* : All of ssh services
dzssh-exec/global : dzssh-exec : Command execution
dzssh-scp/global : dzssh-scp : scp
dzssh-sftp/global : dzssh-sftp : sftp
dzssh-shell/global : dzssh-shell : Terminal tty/pty
dzssh-tunnel/global : dzssh-tunnel : Tunnel device forwarding
dzssh-X11-forwarding/global : dzssh-x11-forwarding : X11 forwarding
login-all/global : * : Predefined global PAM permission. Do not delete.
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a PAM application object:

- get_pam_apps returns a Tcl list of PAM applications in the current zone.
- new_pam_app creates a new PAM application and stores it in memory.
- select_pam_app retrieves a PAM application from Active Directory and stores it in memory.

After you have a PAM application object stored in memory, you can use the following commands to work with that PAM application:

- delete_pam_app deletes the selected PAM application from Active Directory and from memory.
- get_pam_field reads a field value from the currently selected PAM application.
- save_pam_app saves the selected PAM application with its current settings to Active Directory.
- set_pam_field sets a field value in the currently selected PAM application.

list_pending_zone_groups

Use the list_pending_zone_groups command to check Active Directory and return a list of pending import groups for the currently selected zone. Pending import groups are group profiles that have been imported from Linux or UNIX computers, but not yet mapped to any Active Directory group. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_pending_zone_groups to return a Tcl list.

Zone Type

Classic and hierarchical

Syntax

list_pending_zone_groups

Abbreviation

lpzg

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of pending import groups for the currently selected zone. Each entry in the list contains the following fields, separated by colons (:) :

- Distinguished name (DN) of the pending import group as it is stored in Active Directory. The distinguished name for each pending import group includes a prefix that consists of "PendingGroup" and the globally unique identifier (GUID) for the group.
- UNIX group name.
- Numeric group identifier (GID).

Examples

```
list_pending_zone_groups
```

This example returns the list of groups similar to this:

```
CN=PendingGroup_573135e7-edd9-46b9-9cbd-c839570a90c8,CN=Groups, CN=bean_pz,CN=Zones,CN=Acme,DC=win2k3,DC=test:root:0   CN=PendingGroup_7878065a-4d2f-4749-8f3b-6ffe24303f6a,CN=Groups, CN=bean_pz,CN=Zones,CN=Acme,DC=win2k3,DC=test:unixgrp:5000
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following command performs actions related to this command:

- get_pending_zone_groups returns a Tcl list of the pending import groups in the current zone.

list_pending_zone_users

Use the list_pending_zone_users command to check Active Directory and return a list of pending import users for the currently selected zone. Pending import users are user profiles that have been imported from Linux or UNIX computers, but not yet mapped to any Active Directory user. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_pending_zone_users to return a Tcl list.

Zone Type

Classic and hierarchical

Syntax

```
list_pending_zone_users
```

Abbreviation

```
lpzu
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of pending import users for the currently selected zone. Each entry in the list contains the following fields, separated by colons (:) :

- Distinguished name (DN) of the pending import user as it is stored in Active Directory. The distinguished name for each pending import user includes a prefix that consists of "PendingUser" and the globally unique identifier (GUID) for the user.
- UNIX user name.
- Numeric user identifier (UID).
- Numeric primary group identifier (GID).

- Personal information from the GECOS field.
- Home directory.
- Default login shell.

Examples

list_pending_zone_users

This example returns the list of groups similar to this:

CN=PendingUser_09024f3a-6abc-4666-a127-722f9fe0e0bf,CN=Users,CN=finance, CN=Zones,CN=Acme,DC=win2k3,DC=test:root:0:0:root:/root:/bin/bash: CN=PendingUser_0b9fe038-1325-438f-8529-cb190ab5914a,CN=Users,CN=finance, CN=Zones,CN=Acme,DC=win2k3,DC=test:bean:6001:5000:bean.zhang:/home/bean:/bin/bash:

Related Commands

The following command performs actions related to this command:

- get_pending_zone_users returns a Tcl list of the pending import users in the current zone.

list_role_assignments

Use the list_role_assignments command to check Active Directory and return a list of role assignments defined within the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_role_assignments to return a Tcl list.

If you do not specify an option, the command returns the current users and groups in the zone with a role assignment using the default sAMAccount@domain format.

You can only use the list_role_assignments command to return role assignments for classic4 and hierarchical zones.

Zone Type

Classic and hierarchical

Syntax

list_role_assignments [-upn] [-visible] [-user] [-group] [-invalid]

Abbreviation

lsra

Options

This command takes the following options:

-upn	Optional. Returns user names in user principal name (UPN) format rather than the default sAMAccount@domain format.
-visible	Returns a list to stdout of the visible role assignments in the zone. Use this option if you only want to return role assignments for the roles that are identified as visible. This option is only applicable in hierarchical zones.
-user	Returns a list to stdout of the current users in the zone with a role assignment. Use this option if you only want to return valid users with a role assignment.
-group	Returns a list to stdout of the current groups in the zone with a role assignment. Use this option if you only want to return valid groups with a role assignment.
-invalid	Returns a list to stdout of any invalid role assignments in the zone. A role assignment is invalid if it specifies a group or user that no longer exists. Use this option if you only want to return invalid role assignments.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of role assignments defined in the currently selected zone. Each entry in the list provides the following information:

- The user or group to whom the role assignment applies by sAMAccount@domain name or user principal name.
- The name of the role assigned followed by a slash (/) and the zone where the role is defined.

Examples

```
>bind pistolas.org

>select_zone “cn=northamerica,cn=zones,ou=acme,dc=pistolas,dc=org”

>list_role_assignments
```

This example returns the role assignments for the northamerica zone: Domain Users@pistolas.org: Window Login/northamerica adm-sf@pistolas.org: UNIX Login/northamerica rey@pistolas.org: UNIX Login/northamerica maya@pistolas.org: SQLAdmin/northamerica

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a role assignment:

- get_role_assignments returns a Tcl list of role assignments in the current zone.
- new_role_assignment creates a new role assignment and stores it in memory.
- select_role_assignment retrieves a role assignment from Active Directory and stores it in memory.

After you have a role assignment stored in memory, you can use the following commands to work with that role assignment:

- delete_role_assignment deletes the selected role assignment from Active Directory and from memory.
- get_role_assignment_field reads a field value from the currently selected role assignment.
- save_role_assignment saves the selected role assignment with its current settings to Active Directory.
- set_role_assignment_field sets a field value in the currently selected role assignment.
- write_role_assignment saves the selected role assignment to a file.

list_role_rights

Use the list_role_rights command to return a list of all UNIX commands and PAM application rights set within the currently selected role. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script.

The list_role_rights command does *not* query Active Directory for the role. If you change commands or PAM applications using ADEdit without saving the role to Active Directory, commands and PAM applications you retrieve using list_role_rights won't match those stored in Active Directory.

You can only use list_role_rights to return role rights for classic4 and hierarchical zones.

Zone Type

Classic and hierarchical

Syntax

```
list_role_rights
```

Abbreviation

```
lsrr
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of the PAM application and UNIX command rights that are defined for the currently selected role.

Each entry lists the name of the application or command right, the attributes of the application or command, and any descriptive text.

Examples

```
list_role_rights
```

This example returns the list of PAM application and UNIX command rights:

```
dzssh-all/northamerica : dzssh-exec : Command execution   login-all/seattle : * : Predefined global PAM permission. Do not delete.   cron-exec/seattle : cron form(0) dzdo_runas(admin) flags(16)
;
```

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select a role:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles returns a list of all roles in the currently selected zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

- add_command_to_role adds a UNIX command right to the current role.
- add_pamapp_to_role adds a PAM application right to the current role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM application rights associated with the current role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- get_role_field reads a field value from the current role.
- remove_command_from_role removes a UNIX command from the current role.
- remove_pamapp_from_role removes a PAM application from the current role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the current role.

list_roles

Use the list_roles command to check Active Directory and return a list of roles defined in the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_roles to return a Tcl list.

You can only use list_roles to return role information for classic4 and hierarchical zones.

Zone Type

Classic and hierarchical

Syntax

```
list_roles
```

Abbreviation

```
lsr
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of roles defined in the currently selected zone.

Examples

```
list_roles
```

This example returns the list of roles for the zone:

```
Rescue - always permit login
listed
scp
sftp
UNIX Login
Windows Login
winscp
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a role:

- get_roles returns a Tcl list of roles in the current zone.
- new_role creates a new role and stores it in memory as the currently selected role.
- select_role retrieves a role from Active Directory and stores it in memory as the selected role.

After you have a role stored in memory, you can use the following commands to work with that role:

- add_command_to_role adds a UNIX command right to the current role.
- add_pamapp_to_role adds a PAM application right to the current role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM application rights associated with the current role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- get_role_field reads a field value from the current role.
- list_role_rights returns a list of all UNIX command and PAM application rights associated with the current role.
- remove_command_from_role removes a UNIX command from the current role.
- remove_pamapp_from_role removes a PAM application from the current role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the current role.

list_rs_commands

Use the list_rs_commands command to print a list of the restricted shell commands that are defined for the currently selected zone. This command retrieves information from Active Directory and to returns the list of restricted shell commands to stdout. If you want to return a Tcl list of restricted shell commands, use get_rs_commands.

Zone Type

Classic only

Syntax

```
list_rs_commands
```

Abbreviation

lsrsc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list of restricted shell commands for the currently selected zone.

Examples

list_rs_commands

This command returns the list of restricted shell commands and attributes similar to this:

rseid1/c123 : id form(0) dzsh_runas($) umask(77) path(USERPATH) flags(0) : rseid2/c123 : id2 form(0) dzsh_runas($) pri(1) umask(77) path(USERPATH) flags(0) : id2

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- get_rs_commands returns a Tcl list of restricted shell commands in the current zone.
- new_rs_command creates a new restricted shell command and stores it in memory.
- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- get_rsc_field reads a field value from the currently selected command.
- save_rs_command saves the selected command with its current settings to Active Directory.
- set_rsc_field sets a field value in the currently selected command.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and manage the restricted shell commands:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- new_rs_command creates a new restricted shell command and stores it in memory.
- save_rs_command saves the selected restricted shell command with its current settings to Active Directory.
- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with its fields:

- get_rsc_field reads a field value from the current restricted shell command.
- set_rsc_field sets a field value in the current restricted shell command.

list_rs_envs

Use the list_rs_envs command to check Active Directory and print a list of restricted shell environments defined within the currently selected zone to stdout. Use the get_rs_envs command to return a Tcl list.

Zone Type

Classic only

Syntax

list_rs_envs

Abbreviation

lsrse

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command prints the list of restricted shell environments to stdout. It has no return value.

Examples

list_rs_envs

This example displays the list of restricted shell environments.

restrict_env1

restrict_env2

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with restricted shell environments:

- get_rs_envs returns a Tcl list of restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.
- set_rse_field sets a field value in the current restricted shell environment.

list_zone_computers

Use the list_zone_computers command to check Active Directory and return a list of zone computers defined within the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_zone_computers to return a Tcl list.

Zone Type

Classic and hierarchical

Syntax

list_zone_computers

Abbreviation

lszc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of zone computers defined in the currently selected zone. Each zone computer entry includes the following fields, separated by colons (:) :

- User principal name (UPN) of the computer.
- Number of CPUs in the computer and the version of Delinea software installed on the computer.
- Name of the computer in DNS.

Examples

```
list_zone_computers
```

This example returns the list of computers similar to this:

```
printserv$@acme.com:cpus (1) agentVersion (CentrifyDC 5.0.0): printserv.acme.com
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone computer:

- get_zone_computers returns a Tcl list of the Active Directory names of all zone computers in the current zone.
- new_zone_computer creates a new zone computer and stores it in memory.
- select_zone_computer retrieves a zone computer from Active Directory and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- delete_zone_computer deletes the zone computer from Active Directory and from memory.
- get_zone_computer_field reads a field value from the currently selected zone computer.
- save_zone_computer saves the zone computer with its current settings to Active Directory.
- set_zone_computer_field sets a field value in the currently selected zone computer.

list_zone_groups

Use the list_zone_groups command to check Active Directory and return a list of zone groups defined in the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_zone_groups to return a Tcl list.

Zone Type

Classic and hierarchical

Syntax

```
list_zone_groups
```

Abbreviation

```
lszg
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of zone groups defined in the currently selected zone. Each entry in the list contains the following fields, separated by colons (:) :

- User principal name of the zone group as it is stored in Active Directory.
- UNIX group name.
- Numeric group identifier (GID).
- The string "Required" if the "Users are required to be members of this group" option is set for the group.

Examples

```
list_zone_groups
```

This example returns the list of groups similar to this:

```
sf-admins@pistolas-org:sfadmins:10F24
sf-apps@pistolas.org:sf-apps:2201
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select zone groups:

- get_zone_groups returns a Tcl list of the Active Directory names of the zone groups in the current zone.
- new_zone_group creates a new zone group and stores it in memory.
- select_zone_group retrieves a zone group from Active Directory and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- delete_zone_group deletes the selected zone group from Active Directory and from memory.
- get_zone_group_field reads a field value from the currently selected zone group.
- save_zone_group saves the selected zone group with its current settings to Active Directory.
- set_zone_group_field sets a field value in the currently selected zone group.

list_zone_users

Use the list_zone_users command to check Active Directory and return a list of zone users defined in the currently selected zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use get_zone_users to return a Tcl list.

Zone Type

Classic and hierarchical

Syntax

```
list_zone_users [-upn]
```

Abbreviation

```
lszu
```

Options

This command takes the following option:

-upn	Optional. Returns user names in user principal name (UPN) format rather than the default sAMAccount@domain format.

Arguments

This command takes no arguments.

Return Value

This command returns a list to stdout of zone users for the currently selected zone. Each entry in the list contains the following user profile fields separated by colons (:) :

- sAMAccountName@domain or the UPN of the zone user as it is stored in Active Directory.

  If the Active Directory user no longer exists for a zone user, the command returns the security identifier (SID) of the orphan user.
- UNIX user name.
- Numeric user identifier (UID).
- Numeric identifier for the user's primary group (GID).

  If the GID has the number 2147483648 (which is 80000000 hex) it means that the UID is being used as the GID. (This can occur in hierarchical zones.)
- Personal information from the GECOS field.
- The user's home directory.
- The user's default login shell.
- Whether the user is enabled or disabled (in classic zones only).

Examples

```
list_zone_users
```

This example returns the list of users similar to this:

```
adam.avery@acme.com:adam:10001:10001:%{u:samaccountname}:%{home}/%{user}:%{shell}:
ben.brown@acme.com:brenda:10002:10002:%{u:samaccountname}:%{home}/%{user}:%{shell}:
chris.cain@acme.com:chris:10003:10003:%{u:samaccountname}:%{home}/%{user}:%{shell}:
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select zone users:

- get_zone_users returns a Tcl list of the Active Directory names of zone users in the current zone.
- new_zone_user creates a new zone user and stores it in memory.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- delete_zone_user deletes the selected zone user from Active Directory and from memory.
- get_zone_user_field reads a field value from the currently selected zone user.
- save_zone_user saves the selected zone user with its current settings to Active Directory.
- set_zone_user_field sets a field value in the currently selected zone user.

manage_dz

Use the manage_dz command to enable or disable authorization in classic zones. In classic zones, authorization-related features are disabled by default, and the authorization store that is required for managing rights, roles, and restricted environment is not available in Active Directory.

To enable authorization in classic zones using ADEdit, you can run the manage_dz``-on command. This command creates the authorization store if it does not exist, and sets the zone property that enables privilege elevation service features.

To disable authorization in a classic zone, you can run the manage_dz –off command. Running this command disables authorization services. The command does not remove any existing authorization data from Active Directory.

Zone Type

Classic only

Syntax

manage_dz [-on l-off]

Abbreviation

mnz

Options

This command takes the following options:

-on	Enables authorization for the currently selected zone and creates the authorization data store if it not currently defined in Active Directory.
-off	Disables authorization for the currently selected zone. This option does not remove any data from the authorization data store if it currently exists.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
create_zone classic4 cn=c125,cn=zones,dc=ross,dc=net
select_zone cn=c125,cn=zones,dc=ross,dc=net
is_dz_enable
0
manage_dz -on
is_dz_enable
1
```

This code example creates a zone, checks that authorization is disabled by default, then enables authorization for the zone.

Related Commands

The following command performs actions related to this command:

is_dz_enabled checks whether authorization is currently enabled for a zone.

move_object

Use the move_object command to move the selected object to the specified location. The new location must be in the same domain. You cannot use this command to move an object to another domain. You do not need to save the object after moving it.

Zone Type

Not applicable

Syntax

move_object destination

Abbreviation

mvo

Options

This command takes no options.

Arguments

This command takes the following argument:

destination	string	Required. Specifies the distinguished name of the new location.

Return Value

This command returns nothing if it runs successfully.

Example

The following commands move the ApacheAdmins group from the Groups container in the Global zone to the Groups container in the US zone.

```
select_object “cn=ApacheAdmins@demo.test,cn=Groups,cn=Global,cn=Zones,CN=Acme,dc=demo,dc=test”  mvo “cn=Groups,cn=US,cn=Zones,ou=Acme,dc=demo,dc=test”
```

Related Commands

The following command performs actions related to this command:

- select_object selects the object you want to move.

new_dz_command

Use the new_dz_command command to create a new UNIX command object for the current zone and sets the new command as the currently selected command in memory. The new command has no field values set. The new_dz_command does *not* save the new command to Active Directory. To save the UNIX command, you must first set at least the “command” field using set_dzc_field, then use save_dz_command. If you don’t save a new UNIX command, it will disappear when you select a new command or when the ADEdit session ends.

You can only use the new_dz_command command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
new_dz_command _name_
```

Abbreviation

newdzc

Options

This command takes no options.

Arguments

This command takes the following argument:

name	string	Required. Specifies the name to assign to the new UNIX command.

Return Value

This command returns nothing if it runs successfully.

Examples

new_dz_command account_manager

This example creates a new UNIX command named account_manager in the current zone.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select UNIX commands:

- get_dz_commands returns a Tcl list of UNIX commands in the current zone.
- list_dz_commands returns a list of all UNIX commands in the currently selected zone.
- select_dz_command retrieves a UNIX command from Active Directory and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- delete_dz_command deletes the selected command from Active Directory and from memory.
- get_dzc_field reads a field value from the currently selected command.
- save_dz_command saves the selected command with its current settings to Active Directory.
- set_dzc_field sets a field value in the currently selected command.

new_local_group_profile

Use the new_local_group_profile command to create an object for a local UNIX or Linux group in the currently selected zone. After you create the group object, it is automatically selected for editing with the set_local_group_profile_field command. That is, you do not need to execute the select_local_group_profile command to select the new group prior to defining profile fields. After you create the new group, save it by executing the save_local_group_profile command.

When the group profile is complete and the profileflag field is set to 1 (enabled), the profile is added to /etc/group on each UNIX and Linux computer in the zone at the next local account refresh interval. A group profile must have the following fields (attributes) to be considered complete:

- A unique numeric identifier (GID).
- A group name.

See the *Administrator's Guide for Linux and UNIX* for more details about creating local group profiles.

Zone Type

Hierarchical only.

Syntax

new_local_group_profile group_name

Abbreviation

newlgp

Options

This command takes no options.

Arguments

This command takes the following argument:

group_name	string	Required. Specifies the UNIX name of the new local group to create in the zone.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example shows a typical sequence of commands to create an object for the local UNIX or Linux group marketing in the currently selected zone. This command sequence creates a complete group profile, and sets the profile flag to 1 (enabled) so that the profile is added to /etc/group at the next local account update interval.

```
new_local_group_profile marketing
set_local_group_profile_field gid 3004
set_local_group_profile_field member lam_usr4
set_local_group_profile_field profileflag 1
save_local_group_profile
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

new_local_user_profile

Use the new_local_user_profile command to create an object for a local UNIX or Linux user in the currently selected zone. After you create the user object, it is automatically selected for editing with the set_local_user_profile_field command. That is, you do not need to execute the select_local_user_profile command to select the new user prior to defining profile fields. After you create the new user, save it by executing the save_local_user_profile command.

> **Note**:Unlike local groups, which are visible by default, you must explicitly assign local users to a visible role. If you do not assign a local user to a visible role, the user profile defined in the zone object is not updated in /etc/passwd on local computers. A predefined visible role for local users, local listed, is provided to make local users visible. After you create a local user profile, you must assign the local user to the local listed role, or to another visible role. You can use the select_role_assignment and new_role_assignment ADEdit commands to make role assignments.

When the user profile is complete and the profileflag field is set to 1 (enabled) or 2 (disabled), the profile is added to /etc/passwd on each UNIX and Linux computer in the zone at the next local account refresh interval.

A user profile must have the following fields (attributes) to be considered complete:

- A user name (the UNIX login name).
- A unique numeric user identifier (UID).
- The user's primary group profile numeric identifier (GID).
- The default home directory for the user.
- The default login shell for the user.

Note that the GECOS field is not required.

See the *Administrator's Guide for Linux and UNIX* for more details about creating local user profiles.

Zone Type

Hierarchical only.

Syntax

```
new_local_user_profile user_name
```

Abbreviation

```
newlup
```

Options

This command takes no options.

Arguments

This command takes the following argument:

user_name	string	Required. Specifies the UNIX name of the new local user to create in the zone.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example shows a typical sequence of commands to create an object for the local UNIX or Linux user `lam_usr4` in the currently selected zone. This command sequence creates a complete user profile, sets the profile flag to `1` (enabled), and adds the user to the `local listed` role so that the profile is added to `/etc/passwd` at the next local account update interval.

```
new_local_user_profile lam_usr4
set_local_user_profile_field uid 2004
set_local_user_profile_field gid 2004
set_local_user_profile_field shell /bin/bash
set_local_user_profile_field home /home/lam_usr4
set_local_user_profile_field profileflag 1
save_local_user_profile
select_role_assignment local listed
new_role_assignment lam_usr4
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- `delete_local_group_profile` deletes a local UNIX or Linux group that has a profile defined in the current zone.
- `delete_local_user_profile` deletes a local UNIX or Linux user that has a profile defined in the current zone.
- `get_local_group_profile_field` displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current

zone.

- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

new_nis_map

Use the new_nis_map command to create a new NIS map for the current zone and set the new NIS map as the currently selected NIS map in memory. The new NIS map has no map entries.

The new_nis_map does *not* save the new NIS map to Active Directory. To save the new map, you must use save_nis_map. If you don't save a new NIS map, it will disappear when you select a new NIS map or when the ADEdit session ends.

Zone Type

Not applicable

Syntax

```
new_nis_map [-automount] map
```

Abbreviation

newnm

Options

This command takes the following option:

-automount	Specifies that the new NIS map is an automount map. For most NIS maps, the map name defines the type of map you are creating. For example, if you create a new NIS map with the name netgroup, it must be a NIS netgroup map and contain valid netgroup entries. However, you can specify any name for NIS automount maps. Use this option to identify automount maps that have a name other than automount.

Arguments

This command takes the following argument:

map	string	Required. Specifies the name of the new NIS map. For most NIS maps, the map name defines the type of map you are creating. For example, if you create a new NIS map with the name netgroup, it must be a NIS netgroup map and contain valid netgroup entries. For information about the type of NIS maps you can create, see the_Network Information Service Administrator's Guide_.

Return Value

This command returns nothing if it runs successfully.

Examples

The following command creates the NIS map “Printers” in the current zone.

```
new_nis_map Printers
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select NIS maps:

- get_nis_maps returns a Tcl list of NIS maps in the current zone.
- list_nis_maps lists to stdout the NIS maps in the current zone.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map:

*add_map_entryOr add_map_entry_with_comment adds an entry to the current NIS map stored in memory.

- delete_map_entry removes an entry from the current NIS map.
- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_map or get_nis_map_with_comment returns a Tcl list of the map entries in the current NIS map.
- get_nis_map_field reads a field value from the current NIS map.
- list_nis_map or list_nis_map_with_comment lists to stdout ` the map entries in the current NIS map.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.

new_object

Use the new_object command to create a new Active Directory object and set the new object as the currently selected Active Directory object in memory. The new object has no field values set. The new_object command does *not* save the new object to Active Directory. To save the new object, you must use save_object. If you don't save a new object, it will disappear when you select a new object or when the ADEdit session ends.

The new_object command does not check to see if the new object conforms to Active Directory's expectations for the new object in the location you specify. Active Directory will report any errors when you try to save the object.

Zone Type

Not applicable

Syntax

```
new_object dn
```

Abbreviation

```
newo
```

Options

This command takes no options.

Arguments

This command takes the following argument:

dn	DN	Required. Specifies the distinguished name for the new object.

Return Value

This command returns nothing if it runs successfully.

Examples

```
new_object "ou=Acme,cn=Program Data,dc=acme,dc=com"
```

This example creates a new organizational unit Delinea in the container Program Data in the domain acme.com and stores it in memory as the currently selected Active Directory object.

Related Commands

The following commands enable you to view and select Active Directory objects:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of objects matching the specified search criteria.
- select_object retrieves an object with its attributes from Active Directory and stores it in memory.

After you have an object stored in memory, you can use the following commands to work with that object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field reads a field value from the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- save_object saves the selected Active Directory object with its current settings to Active Directory.
- set_object_fieldsets a field value in the currently selected Active Directory object.

new_pam_app

Use the new_pam_app command to create a new PAM application right for the current zone and set the new PAM application as the currently selected PAM application in memory. The new PAM application has no field values set.

The new_pam_app does *not* save the new PAM application to Active Directory. To save the PAM application right, you must first set at least the "application" field using set_pam_field, then use save_pam_app. If you don't save a new PAM application, it will disappear when you select a new PAM application or when the ADEdit session ends.

You can only use the new_pam_app to create PAM application rights if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
new_pam_app name
```

Abbreviation

```
newpam
```

Options

This command takes no options.

Arguments

This command takes the following argument:

name	string	Required. Specifies the name to assign to the new PAM application access right.

Return Value

This command returns nothing if it runs successfully.

Examples

```
new_pam_app basic
```

This example creates a new PAM application access right named basic in the current zone.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select PAM application rights:

- get_pam_apps returns a Tcl list of PAM application rights in the current zone.
- list_pam_apps lists to stdout the PAM application rights in the currently selected zone.
- select_pam_app retrieves a PAM application right from Active Directory and stores it in memory.

After you have a PAM application right stored in memory, you can use the following commands to work with that PAM application right:

- delete_pam_app deletes the selected PAM application right from Active Directory and from memory.
- get_pam_field reads a field value from the currently selected PAM application right.
- save_pam_app saves the selected PAM application right with its current settings to Active Directory.
- set_pam_field sets a field value in the currently selected PAM application right.

new_role

Use the new_role command to create a new role for the current zone and set the new role as the currently selected role in memory. The new role has no field values set. The new_role command does *not* save the new role to Active Directory. To save the new role, you must use save_role. If you don't save a new role, it will disappear when you select another role or when the ADEdit session ends.

You can only use the new_role to create a role if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
new_role _name
```

Abbreviation

```
newr
```

Options

This command takes no options.

Arguments

This command takes the following argument:

name	string	Required. Specifies the name to assign to the new role.

Return Value

This command returns nothing if it runs successfully.

Examples

```
new_role customerservice
```

This example creates a new role named customerservice in the current zone.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select roles:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the current zone.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

- add_command_to_roleadds a UNIX command to the current role.
- add_pamapp_to_role adds a PAM application to the current role.
- delete_role deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM applications associated with the currently selected role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- get_role_field reads a field value from the currently selected role.
- list_role_rights returns a list of all UNIX commands and PAM application rights associated with the current role.
- remove_command_from_role removes a UNIX command from the current role.
- remove_pamapp_from_role removes a PAM application from the current role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the currently selected role.

new_role_assignment

Use the new_role_assignment command to create a new role assignment for the current zone and set the new role assignment as the currently selected role assignment in memory. The new role assignment has no field values set.

The new_role_assignment command does *not* save the new role assignment to Active Directory. To save the role assignment, you must first set at least the "role" field using set_role_assignment_field, then use save_role_assignment. If you don't save a new role assignment, it will disappear when you select another role assignment or when the ADEdit session ends.

You can only use the new_role_assignment to create a role assignment if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
new_role_assignment userIAll AD usersIAll Unix users
```

Abbreviation

```
newra
```

Options

This command takes no options.

Arguments

This command takes the following argument:

user | All AD users | All Unix users	string	Required. Specifies the user or group to assign the role to. This argument can be a user principal name (UPN) or a sAMAccountName if you are assigning a role to an Active Directory user or group, a UNIX user name or UID if assigning the role to a local UNIX user, or the UNIX group name if you assigning the role to a local UNIX group. To assign a role to a local UNIX account, use the following format: oracle@localhost To assign the role to a domain user, use the following format: oracle@*domain.name* You can also specify "All AD users" to assign a selected role to all Active Directory users or "All Unix users" to assign the selected role to all local UNIX users. This argument is not supported if the selected zone is a classic4 zone.

Return Value

This command returns nothing if it runs successfully.

Examples

```
new_role_assignment adam.avery@acme.com
```

This example creates a new role assignment for adam.avery@acme.com in the current zone. You must set at least one role assignment field and an available time for the role to be effective.

The following example creates a new role assignment for the local UNIX user oracle in the current zone.

```
new_role_assignment oracle@localhost
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select role assignment to work with:

- get_role_assignments returns a Tcl list of role assignments in the current zone.
- list_role_assignments lists to stdout the role assignments in the current zone.
- select_role_assignment retrieves a role assignment from Active Directory and stores it in memory.

After you have a role assignment stored in memory, you can use the following commands to work with that role assignment's attributes, delete the role assignment, or save information for the role assignment:

- delete_role_assignment deletes the selected role assignment from Active Directory and from memory.
- get_role_assignment_field reads a field value from the currently selected role assignment.
- save_role_assignment saves the selected role assignment with its current settings to Active Directory.
- set_role_assignment_field sets a field value in the currently selected role assignment.
- write_role_assignment saves the selected role assignment to a file.

new_rs_command

Use the new_rs_command command to create a new restricted shell command under the currently selected restricted shell environment and set the new restricted shell command as the currently selected restricted shell command in memory. The umask field for the new restricted shell command is set to a default value of 077 and default priority field (pri) is set to 0. For more information about restricted shell command fields, see the command description for get_rsc_field.

The new_rs_command command does not save the new restricted shell command to Active Directory. To store the new restricted shell command in Active Directory, you must use save_rs_command. If you don't save a new restricted shell command, it will disappear when you select another restricted shell command or when the ADEdit session ends.

You can only use the new_rs_command command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

new_rs_command name

Abbreviation

newrsc

Options

This command takes no options.

Arguments

This command takes the following argument:

name	string	Required. Specifies the name to assign to the new restricted shell command.

Return Value

This command returns nothing if it runs successfully.

Examples

new_rs_command rsc1

This example creates a new restricted shell command named rsc1 in the current zone.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- get_rs_commands returns a Tcl list of restricted shell commands in the current zone.
- list_rs_commands lists to stdout the restricted shell commands in the current zone.
- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- get_rsc_field reads a field value from the currently selected command.
- save_rs_command saves the selected command with its current settings to Active Directory.
- set_rsc_field sets a field value in the currently selected command.

new_rs_env

Use the new_rs_env command to create a new restricted shell environment for the current zone and set the new restricted shell environment as the currently selected restricted shell environment stored in memory. The new restricted shell environment has no field values set.

The new_rs_env command does not save the new restricted shell environment to Active Directory. To save the new restricted shell environment to Active Directory, you must use the save_rs_env command. If you don't save a new restricted shell environment, it will disappear when you select another restricted shell environment or when the ADEdit session ends.

You can only use the new_rs_env command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

new_rs_env name

Abbreviation

newrse

Options

This command takes no options.

Arguments

This command takes the following argument:

name	string	Required. Specifies the name to assign to the new restricted shell environment.

Return Value

This command creates a new restricted shell environment in the currently selected zone.

Examples

new_rs_envs rse3

This example creates a new restricted environment named rse3 in the current zone.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with restricted shell environments:

- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.
- set_rse_field sets a field value in the current restricted shell environment.

new_zone_computer

Use the new_zone_computer command to create a new zone computer in the current zone and set the new zone computer as the currently selected zone computer in memory. The new zone computer has no field values set.

The new_zone_computer command does *not* save the new zone computer to Active Directory. To save the new zone computer, you must use save_zone_computer. If you don't save a new zone computer, it will disappear when you select another zone computer or when the ADEdit session ends.

The new_zone_computer command requires you to specify an Active Directory computer account name. If the computer name you specify is not found in Active Directory, the command does not create the zone computer.

Zone Type

Classic and hierarchical

Syntax

new_zone_computer sAMAccountName@domain

Abbreviation

newzc

Options

This command takes no options.

Arguments

This command takes the following argument:

sAMAccountName @domain	string	Required. Specifies the sAMAccountName of an Active Directory computer followed by @ and the domain name where the computer is located.

Return Value

This command returns nothing if it runs successfully.

Examples

new_zone_computer sales2$@acme.com

This example creates a new zone computer sales2@acme.com in the current zone. Note that Tcl syntax requires $@ to represent an actual ampersand symbol @. You could also enclose the argument in braces: {sales2@acme.com}.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and manage the zone computers:

- get_zone_computers returns a Tcl list of the Active Directory names of all zone computers in the current zone.
- list_zone_computers lists to stdout the zone computers in the current zone.
- new_zone_computer creates a new zone computer and stores it in memory.
- select_zone_computer retrieves a zone computer from Active Directory and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- delete_zone_computer deletes the zone computer from Active Directory and from memory.
- get_zone_computer_field reads a field value from the currently selected zone computer.
- save_zone_computer saves the zone computer with its current settings to Active Directory.
- set_zone_computer_field sets a field value in the currently selected zone computer.

new_zone_group

Use the new_zone_group command to create a new group in the current zone that is based on an existing Active Directory group. If the command is successful, the new zone group becomes the currently selected zone group stored in memory.

The new_zone_group command does not set any field values or save the new zone group to Active Directory. Before you can save the new zone group, you must first set at least one field for the new zone group using the set_zone_group_field command. You can then save the zone group profile using the save_zone_group command.

> **Note**:If the currently selected zone is a classic zone, you must set all fields for the new zone group before saving the group profile.

If you don't save a new zone group, it will disappear when you select another zone group or end the ADEdit session.

The new_zone_group command requires you to specify an Active Directory group name. The command will search for the group first by the supplied UPN in the specified domain, then by the **sAMAccountname** in the specified domain, then by the supplied UPN in any bound domain. If the group name cannot be found, the new zone group is not created.

Zone Type

Classic and hierarchical

Syntax

new_zone_group AD_group_UPN

Abbreviation

newzg

Options

This command takes no options.

Arguments

This command takes the following argument:

AD_group_UPN	string	Required. Specifies the user principal name (UPN) of an Active Directory group.

Return Value

This command returns nothing if it runs successfully.

Examples

new_zone_group poweradmins@acme.com

This example creates a new zone group named poweradmins@acme.com in the current zone.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select zone groups:

- get_zone_groups returns a Tcl list of the Active Directory names of all zone groups in the current zone.
- list_zone_groups lists to stdout the zone groups in the current zone.
- select_zone_group retrieves a zone group from Active Directory and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- delete_zone_group deletes the selected zone group from Active Directory and from memory.
- get_zone_group_field reads a field value from the current zone group.
- save_zone_group saves the selected zone group with its current settings to Active Directory.
- set_zone_group_field sets a field value in the current zone group.

new_zone_user

Use the new_zone_user command to create a new zone user in the current zone based on an existing Active Directory user. If the command is successful, the new zone user becomes the currently selected zone user stored in memory.

The new_zone_user command does not set any field values or save the new zone user to Active Directory. Before you can save the new zone user, you must first set at least one field value using the set_zone_user_field command. You can then save the zone user profile using the save_zone_user command.

Note: If the currently selected zone is a classic zone, you must set all fields for the new zone user before saving the user profile.

If you don't save a new zone user, it will disappear when you select another zone user or end the ADEdit session.

You can create more than one zone user within a zone based on a single Active Directory user. The first zone user you create uses the Active Directory user's user principal name (UPN), for example, martin.moore@acme.com. Any other zone users you create for the same Active Directory user must use aliases. An alias is the Active Directory user's UPN with +n appended where n is a positive integer that is unique for this Active Directory user in this zone. For example, martin.moore@acme.com+1 is an alias, as is martin.moore@acme.com+5. Alias integers need not be consecutive or in order. (Note that SFU zones do not support user aliases.)

The new_zone_user command requires you to specify Active Directory user name. The command will search for the user first by the supplied UPN in the specified domain, then by the **sAMAccountname** in the specified domain, then by the supplied UPN in any bound domain. If the user name cannot be found, the new zone user is not created.

Zone Type

Classic and hierarchical

Syntax

```
new_zone_user AD_user_UPN
```

Abbreviation

```
newzu
```

Options

This command takes no options.

Arguments

This command takes the following argument:

AD_user_UPN	string	Required. Specifies the user principal name (UPN) of an Active Directory user. If you are specifying an alias, append the UPN with "+" followed by a positive integer that is unique for this user and the zone.

Return Value

This command returns nothing if it runs successfully.

Examples

```
new_zone_user adam.avery@acme.com
```

This example creates a new zone user based on the Active Directory user adam.avery@acme.com in the current zone.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone user:

- get_zone_users returns a Tcl list of the Active Directory names of all zone users in the current zone.
- list_zone_users lists to stdout the zone users and their NSS data in the current zone.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- delete_zone_user deletes the selected zone user from Active Directory and from memory.

- get_zone_user_field reads a field value from the currently selected zone user.
- save_zone_user saves the selected zone user with its current settings to Active Directory.
- set_zone_user_field sets a field value in the currently selected zone user.

pop

Use the pop command to retrieve a previously-stored context of bindings and selected objects from the top of the context stack. This command replaces the current ADEdit context with the retrieved context. Popping a context from the context stack removes the context from the stack.

This command is useful for Tcl scripts that use subroutines. A push can save the context before it's altered in the subroutine; a pop can return the saved context when the subroutine returns.

Zone Type

Not applicable

Syntax

```
pop
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully. If the stack is empty, it returns a message stating so.

Examples

```
pop
```

This example retrieves the context from the top of the context stack and uses it as the current ADEdit context.

Related Commands

The following commands perform actions related to this command:

- show returns the current context of ADEdit, including its bound domains and its currently selected objects.
- push saves the current ADEdit context to the ADEdit context stack.

principal_from_sid

Use the principal_from_sid command look up the security principal for a specified security identifier (SID) in Active Directory. If the security identifier is found, the command returns the Active Directory name of the principal.

Zone Type

Not applicable

Syntax

```
principal_from_sid [-upn] sid
```

Abbreviation

pfs

Options

This command takes the following option:

-upn	Returns the user names in user principal name (UPN) format, not the default sAMAccount@domain format.

Arguments

This command takes the following argument:

sid	string	Required. Specifies the security identifier of an Active Directory security principal.

Return Value

This command returns the Active Directory name of the principal if it finds a principal. If it does not find a principal, it returns a message stating so.

Examples

```
principal_from_sid S-1-5-21-2076040321-3326545908-468068287-1159
```

This example returns the principal name: oracle_machines@acme.com

Related Commands

The following commands perform actions related to this command:

- principal_to_dn searches Active Directory for a user principal name (UPN) and, if found, returns the corresponding distinguished name (DN).
- dn_to_principal searches Active Directory for a distinguished name (DN) and, if found, returns the corresponding user principal name (UPN).

principal_to_dn

Use the principal_to_dn command to search Active Directory for the specified user principal name (UPN) of a security principal (user, machine, or group). If a security principal is found for the specified UPN, the command returns the distinguished name (DN) of the principal.

Zone Type

Not applicable

Syntax

```
principal_to_dn principal_upn
```

Abbreviation

ptd

Options

This command takes no options.

Arguments

This command takes the following argument:

principal_upn	string	Required. Specifies the user principal name (UPN) of a security principal.

Return Value

This command returns a distinguished name. If the command doesn't find the specified security principal in Active Directory, it presents a message that it didn't find the principal.

Examples

principal_to_dn brenda.butler@acme.com

This example returns the distinguished name for the specified UPN:

cn=brenda butler,cn=users,dc=acme,dc=com

Related Commands

The following commands perform actions related to this command:

- dn_from_domain converts a domain's dotted name to a distinguished name.
- get_parent_dn returns the parent of an LDAP path as a distinguished name.
- get_rdn returns the relative distinguished name of an LDAP path.
- dn_to_principal searches Active Directory for a distinguished name, and, if found, returns the corresponding user principal name (UPN).
- principal_from_sid searches Active Directory for a security identifier and returns the security principal associated with the security identifier.

principal_to_id

Use the principal_to_id command to search Active Directory for the specified user principal name (UPN) of a user or group security principal. If a security principal is found for the specified UPN, the command returns the numeric identifier for the principal.

Zone Type

Not applicable

Syntax

principal_to_id [-apple] upn

Abbreviation

pti

Options

This command takes the following option:

-apple	Specifies that you want to use the Apple scheme for generating the UID or GID for the specified user or group principal. If you don't specify this option, the UID or GID returned is based on the Delinea Auto Zone scheme.

Arguments

This command takes the following argument:

upn	string	Required. Specifies the user principal name (UPN) of a user or group security principal.

Return Value

This command returns a unique UID or GID based on either the Apple methodology or the Delinea Auto Zone methodology for generating numeric identifiers. If the user or group principal is not found in Active Directory, the command returns an error message indicating that it didn't find the principal.

Examples

```
principal_to_id -apple brenda.butler@acme.com
```

This example returns the UID for the specified user generated using the Apple scheme:

```
1983765448
```

Related Commands

The following commands perform actions related to this command:

- guid_to_id accepts a globally unique identifier (GUID) for a user or group and returns a UID or GID generated using the Apple scheme.
- principal_from_sid searches Active Directory for a security identifier and returns the security principal associated with the security identifier.

push

Use the push command to save the current ADEdit context—its bindings and selected objects in memory—to a context stack. This command leaves the current context in place, so all current bindings and selected objects remain in effect in ADEdit after the push.

This command is useful for Tcl scripts that use subroutines. You can use the push command to save the context before it's altered in the subroutine. You can then use the pop command to retrieve the saved context when the subroutine returns.

Zone Type

Not applicable

Syntax

```
push
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing.

Examples

```
push
```

The example saves the current ADEdit context.

Related Commands

The following commands perform actions related to this command:

- show returns the current context of ADEdit, including its bound domains and currently selected objects.
- pop restores the context from the top of the ADEdit context stack to ADEdit.

quit

Use the quit command to quit ADEdit and return to the shell from which ADEdit was launched. You can also end an interactive ADEdit session by pressing Ctrl-D or entering exit.

> **Note**: If you enter the exit command, understand that it will terminate the session immediately without performing a commit operation.

Zone Type

Not applicable

Syntax

```
quit
```

Abbreviation

```
q
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing.

Examples

```
quit
```

This example ends an ADEdit session.

Related Commands

None.

remove_command_from_role

Use the remove_command_from_role command to remove a UNIX command from the currently selected role stored in memory.

The remove_command_from_role command does not change the role as it is stored in Active Directory. You must save the role before the removed command takes effect in Active Directory. If you select another role or quit ADEdit before saving the role, any UNIX commands you have removed since the last save won't take effect.

You can only use the remove_command_from_role command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

remove_command_from_role command[/zonename]

Abbreviation

rcfr

Options

This command takes no options.

Arguments

This command takes the following argument:

command[*/zonename*]	string	Required. Specifies the name of a UNIX command to remove from the currently selected role. If the UNIX command that you want to remove is defined in the current zone, the *zonename* argument is optional. If the UNIX command right is defined in a zone other than the currently selected zone, the *zonename* argument is required to identify the specific command to remove.

Return Value

This command returns nothing if it runs successfully.

Examples

remove_command_from_role basicshell/global

This example removes the UNIX command named basicshell, which is defined in the global zone, from the currently selected role.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the current zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

- add_command_to_roleadds a UNIX command to the current role.
- add_pamapp_to_role adds a PAM application to the current role. 'delete_role" deletes the selected role from Active Directory and from memory.
- get_role_apps returns a Tcl list of the PAM applications associated with the current role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- list_role_rights returns a list of all UNIX commands and PAM applications associated with the current role.
- remove_pamapp_from_role removes a PAM application from the current role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the current role.

remove_object_value

Use the remove_object_value command to remove a value from a multi-valued attribute of a specified Active Directory object. This command only affects the specified attribute for specified object in Active Directory. The command does not change the currently selected Active Directory object in memory, if there is one.

If the field or value to be removed isn't valid, Active Directory will report an error and remove_object_value won't remove the value.

This command is useful for fields that may be very large—members of a group, for example.

Zone Type

Not applicable

Syntax

```
remove_object_value dn field value
```

Abbreviation

rov

Options

This command takes no options.

Arguments

This command takes the following arguments:

dn	string	Required. Specifies the distinguished name (DN) of the Active Directory object from which to remove a value.
field	string	Required. Specifies the name of a multi-valued attribute in the currently selected Active Directory object from which to remove the value. This argument can be any field that is valid for the type of the Active Directory object you have specified using the *dn* argument. For example, if the Active Directory object specified is a computer object, the *field* argument might be operatingSystem.
value		Required. Specifies the value to remove from the field. The data type of the *value* depends on the *field* you specify.

Return Value

This command returns nothing if it runs successfully.

Examples

```
remove_object_value cn=groups,dc=acme,dc=com users adam.avery
```

This example removes the value adam.avery from the users field of the groups object in Active Directory.

Related Commands

The following commands enable you to view and select the object to work with:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of objects matching the search criteria.
- new_object creates a new Active Directory object and stores it in memory.
- select_object retrieves an object and its attributes from Active Directory and stores it in memory.

After you have an Active Directory object stored in memory, you can use the following commands to work with that object's attributes, delete the object, or save information for the object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field reads a field value from the currently selected Active Directory object.
- save_object saves the selected Active Directory object with its current settings to Active Directory.
- set_object_field sets a field value in the currently selected Active Directory object.

remove_pamapp_from_role

Use the remove_pamapp_from_role command to remove a PAM application access right from the currently selected role stored in memory.

The remove_pamapp_from_role command does not change the role as it is stored Active Directory. To remove the PAM application right from the role stored in Active Directory, you must save your changes using the save_role command. If you select another role or quit ADEdit before saving the role, any PAM applications you've removed since the last save won't take effect.

You can only use the remove_pamapp_from_role command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
remove_pamapp_from_role app[/zonename]
```

Abbreviation

```
rpamfr
```

Options

This command takes no options.

Arguments

This command takes the following argument:

app[*/zonename*]	string	Required. Specifies the name of a PAM application right to remove from the currently selected role. If the PAM application right that you want to remove is defined in the current zone, the *zonename* argument is optional. If the PAM application right is defined in a zone other than the currently selected zone, the *zonename* argument is required to identify the specific PAM application right to remove.

Return Value

This command returns nothing if it runs successfully.

Examples

```
remove_pamapp_from_role ftp-all
```

This example removes the PAM application right named ftp-all defined in the currently selected zone from the currently selected role.

To remove the PAM application right when it is defined in the seattle zone, you would include the zone name:

```
remove_pamapp_from_role ftp-all/seattle
```

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the current zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

*add_command_to_roleadds a UNIX command to the current role.

- add_pamapp_to_role adds a PAM application to the current role. 'delete_role" deletes the selected role from Active Directory and from memory. *get_role_apps returns a Tcl list of the PAM applications associated with the current role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- list_role_rights returns a list of all UNIX commands and PAM applications associated with the current role. *remove_command_from_roleremoves a UNIX command from the current role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the current role.

remove_sd_ace

Use the remove_sd_ace command to remove an access control entry (ACE) in ACE string form from a security descriptor (SD) in SDDL (security descriptor description language) form.

The command looks for the supplied ACE string within the supplied SDDL string. If the command finds the ACE string, it removes it from the SDDL string and returns the SDDL string.

Zone Type

Not applicable

Syntax

remove_sd_ace sddl_string ace_string

Abbreviation

rsa

Options

This command takes no options.

Arguments

This command takes the following arguments:

sddl_string	string	Required. Specifies a security descriptor in SDDL format.
ace_string	string	Required. Specifies an access control entry in ACE string form, which is always enclosed in parentheses.

Return Value

This command returns a modified security descriptor in SDDL format if it runs successfully.

Examples

This example removes the first ACE string from an SDDL. The ACE string to remove is at the end of the command

(A;;SDRCWDWOCCDCLCSWRPWPDTLOCR;;;SY):

Related Commands

The following commands enable you to work with security descriptor strings:

- add_sd_ace adds an access control entry to a security descriptor.
- explain_sd converts an SD in SDDL format to a human-readable form.
- set_sd_owner sets the owner of a security descriptor.

rename_object

Use the rename_object command to rename the selected object. You can replace only the first relative distinguished name in the selected object. You do not need to save the object after you change the name.

Zone Type

Not applicable

Syntax

rename_object name

Abbreviation

rno

Options

This command takes no options.

Arguments

This command takes the following argument:

name	string	Required. Specifies the replacement relative distinguished name for the first relative distinguished name in the selected object.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example selects the user object Lois Lane and changes her name to LoisLane:

select_object “cn=Lois Lane,cn=Users,dc=demo,dc=test” rename_object LoisLane

The following example selects the organizational unit UnixServers an renames it to UNIX Servers:

```
select_object“ou=UnixServers,ou=Acme,dc=demo,dc=test” rno “UNIX Servers”
```

In both examples, quotes are required to preserve spaces in object names.

Related Commands

The following command performs actions related to this command:

- select_object selects the object you want to rename.

save_dz_command

Use the save_dz_command command to save the currently selected UNIX command stored in memory to Active Directory. You must save a UNIX command for any changes you make using ADEdit to take effect in Active Directory. If you select another UNIX command or end the ADEdit session before saving the currently selected UNIX command, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

```
save_dz_command
```

Abbreviation

```
svdzc
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
save_dz_command
```

This example saves the currently selected UNIX command to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a UNIX command:

- get_dz_commands returns a Tcl list of UNIX commands in the current zone.
- list_dz_commands lists to stdout the UNIX commands in the current zone.
- new_dz_command creates a new UNIX command and stores it in memory.
- select_dz_command retrieves a UNIX command from Active Directory and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- delete_dz_command deletes the selected command from Active Directory and from memory.
- get_dzc_field reads a field value from the currently selected command.
- set_dzc_field sets a field value in the currently selected command.

save_local_group_profile

Use the save_local_group_profile command to save the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.

Whenever you execute the new_local_group_profile or select_local_group_profile command, the group continues to be selected until you execute the save_local_group_profile command.

You can save a group object before the group profile is complete. However, the group profile is not added to /etc/group on each UNIX and Linux computer in the zone until the group profile is complete and the profileflag field is set to 1 (enabled). See new_local_group_profile for details about which attributes a group profile must have to be considered complete.

Zone Type

Hierarchical only.

Syntax

save_local_group_profile

Abbreviation

svlgp

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example saves the currently selected object for the local UNIX or Linux group in the currently selected zone.

save_local_group_profile``

For example, earlier you might have executed the following command to select the marketing group object so that you could edit its profile fields:

select_local_group_profile marketing

Executing the following command would save any changes you had made to the marketing group object:

save_local_group_profile

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.

- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

save_local_user_profile

Use the save_local_user_profile command to save the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.

Whenever you execute the new_local_user_profile or select_local_user_profile command, the user continues to be selected until you execute the save_local_user_profile command.

You can save a user object before the user profile is complete. However, the user profile is not added to /etc/passwd on each UNIX and Linux computer in the zone until the user profile is complete, the profileflag field is set to 1 (enabled) or 2 (disabled), and the user is assigned a visible role such as local listed. See new_local_user_profile for details about which attributes a user profile must have to be considered complete.

Zone Type

Hierarchical only.

Syntax

```
save_local_user_profile
```

Abbreviation

```
svlup
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

T`his command returns nothing if it runs successfully.

Examples

The following example saves the currently selected object for the local UNIX or Linux user in the currently selected zone.

```
save_local_user_profile
```

For example, earlier you might have executed the following command to select the object for UNIX user anton.splieth so that you could edit its profile fields:

```
select_local_user_profile anton.splieth
```

Executing the following command would save any changes you had made to the user object for anton.splieth:

```
save_local_user_profile
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

save_nis_map

Use the save_nis_map command to save the currently selected NIS map stored in memory to Active Directory. You must save the NIS map for any changes you make using ADEdit to take effect in Active Directory. If you select another NIS map or end the ADEdit session before saving the currently selected NIS map, your changes will be lost.

Zone Type

Not applicable

Syntax

save_nis_map

Abbreviation

svnm

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_nis_map

This example saves the currently selected NIS map to Active Directory.

Related Commands

Before you use this command, you must have a currently selected NIS map stored in memory. The following commands enable you to view and select a NIS map:

- get_nis_maps returns a Tcl list of NIS maps in the current zone.
- list_nis_maps lists to stdout the NIS maps in the current zone.

- new_nis_map creates a new NIS map and stores it in memory.
- select_nis_map retrieves a NIS map from Active Directory and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map:

*add_map_entryOr add_map_entry_with_comment adds a map entry to the currently selected NIS map.

- delete_map_entry removes an entry from the currently selected NIS map.
- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_map or get_nis_map_with_comment returns a Tcl list of the map entries in the currently selected NIS map.
- get_nis_map_field reads a field value from the currently selected NIS map.
- list_nis_map or list_nis_map_with_comment lists to stdout the map entries in the currently selected NIS map.

save_object

Use the save_object command to save the currently selected Active Directory object stored in memory to Active Directory. You must save the Active Directory object for any changes you make using ADEdit to take effect in Active Directory. If you select another Active Directory object or end the ADEdit session before saving the currently selected object, your changes will be lost.

If an object has invalid attributes or values or is the wrong class for the container where it's being saved, Active Directory will report an error and the object will not be saved.

Zone Type

Not applicable

Syntax

save_object

Abbreviation

svo

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_object

This example saves the currently selected Active Directory object to Active Directory.

Related Commands

The following commands enable you to view and select the object to work with:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of objects matching the specified search criteria.
- new_object creates a new Active Directory object and stores it in memory.
- select_object retrieves an object and its attributes from Active Directory and stores it in memory.

After you have an Active Directory object stored in memory, you can use the following commands to work with that object's attributes, delete the object, or

save information for the object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field reads a field value from the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- set_object_field sets a field value in the currently selected Active Directory object.

save_pam_app

Use the save_pam_app command to save the currently selected PAM application access right stored in memory to Active Directory. You must save the PAM application right for any changes you make using ADEdit to take effect in Active Directory. If you select another PAM application right or end the ADEdit session before saving the currently selected PAM application right, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

save_pam_app

Abbreviation

svpam

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_pam_app

This example saves the currently selected PAM application to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a PAM application object:

- get_pam_apps returns a Tcl list of PAM applications in the current zone.
- list_pam_apps lists to stdout the PAM application rights in the current zone.
- new_pam_app creates a new PAM application right and stores it in memory.
- select_pam_app retrieves a PAM application right from Active Directory and stores it in memory.

After you have a PAM application right stored in memory, you can use the following commands to work with that PAM application:

- delete_pam_app deletes the selected PAM application from Active Directory and from memory.
- get_pam_field reads a field value from the currently selected PAM application.
- set_pam_field sets a field value in the currently selected PAM application.

save_role

Use the save_role command to save the currently selected role stored in memory to Active Directory. You must save the role for any changes you make using ADEdit to take effect in Active Directory. If you select another role or end the ADEdit session before saving the currently selected role, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

save_role

Abbreviation

svr

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_role

This example saves the currently selected role to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select roles:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the current zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

- add_command_to_roleadds a UNIX command to the current role.
- add_pamapp_to_role adds a PAM application right to the current role.
- delete role deletes the selected role from Active Directory and from memory. *get_role_apps returns a Tcl list of the PAM application rights associated with the current role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- get_role_field reads a field value from the current role.
- list_role_rights returns a list of all UNIX commands and PAM application rights associated with the current role. *remove_command_from_roleremoves a UNIX command from the current role.
- remove_pamapp_from_role removes a PAM application right from the current role.
- set_role_field sets a field value in the current role.

save_role_assignment

Use the save_role_assignment command to save the currently selected role assignment stored in memory to Active Directory. You must save the role assignment for any changes you make using ADEdit to take effect in Active Directory. If you select another role assignment or end the ADEdit session before saving the currently selected role assignment, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

```
save_role_assignment
```

Abbreviation

```
svra
```

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

```
save_role_assignment
```

This example saves the currently selected role assignment to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select role assignment to work with:

- `get_role_assignments` returns a Tcl list of role assignments in the current zone.
- `list_role_assignments` lists to `stdout` the role assignments in the current zone.
- `new_role_assignment` creates a new role assignment and stores it in memory.
- `select_role_assignment` retrieves a role assignment from Active Directory and stores it in memory.

After you have a role assignment stored in memory, you can use the following commands to work with that role assignment's attributes, delete the role assignment, or save information for the role assignment:

- `delete_role_assignment` deletes the selected role assignment from Active Directory and from memory.
- `get_role_assignment_field` reads a field value from the current role assignment.
- `save_role_assignment` saves the selected role assignment with its current settings to Active Directory.
- `set_role_assignment_field` sets a field value in the current role assignment.
- `write_role_assignment` saves the selected role assignment to a file.

save_rs_command

Use the `save_rs_command` command to save the currently selected restricted shell command that is stored in memory to Active Directory. You must save the restricted shell command for any changes you make using ADEdit to take effect in Active Directory. If you select another restricted shell command or end the ADEdit session before saving the currently selected restricted shell command, your changes will be lost.

Zone Type

Classic only

Syntax

```
save_rs_command``
```

Abbreviation

svrsc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_rs_command

This example saves the currently selected RSC to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- get_rs_commands returns a Tcl list of restricted shell commands in the current zone.
- list_rs_commands lists to stdout the restricted shell commands in the current zone.
- new_rs_command creates a new restricted shell command and stores it in memory.
- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- get_rsc_field reads a field value from the currently selected command.
- set_rsc_field sets a field value in the currently selected command.

save_rs_env

Use the save_rs_env command to save the currently selected restricted shell environment that is stored in memory to Active Directory. You must save the selected restricted shell environment for any changes you make using ADEdit to take effect in Active Directory. If you select another restricted shell environment or end the ADEdit session before saving the currently selected restricted shell environment, your changes will be lost.

Zone Type

Classic only

Syntax

save_rs_env

Abbreviation

svrse

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_rs_env

This command saves the currently selected restricted shell environment to Active Directory.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with restricted shell environments:

- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- set_rse_field sets a field value in the current restricted shell environment.

save_zone

Use the save_zone command to save the currently selected zone stored in memory to Active Directory. You must save the selected zone for any changes you make using ADEdit to take effect in Active Directory. If you select another zone or end the ADEdit session before saving the currently selected zone, your changes will be lost.

This command only saves fields that are properties in the currently selected zone. The command does not save any users or groups added to a zone. You must save users and groups individually using the save_zone_user and save_zone_group commands.

Zone Type

Classic and hierarchical

Syntax

save_zone

Abbreviation

svz

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_zone

This example saves the currently selected zone or computer role to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone to work with:

- create_zone creates a new zone in Active Directory.
- get_zones returns a Tcl list of all zones within a specified domain.
- select_zone retrieves a zone from Active Directory and stores it in memory.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_field reads a field value from the currently selected zone.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- set_zone_field sets a field value in the currently selected zone.

save_zone_computer

Use the save_zone_computer command to save the currently selected zone computer stored in memory to Active Directory. You must set at least one field value before you can save a zone computer. In classic zones, you must set all field values before you can save a zone computer.

You must save the selected zone computer for any changes you make using ADEdit to take effect in Active Directory. If you select another zone computer or end the ADEdit session before saving the currently selected zone computer, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

save_zone_computer

Abbreviation

svzc

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_zone_computer

This example saves the currently selected zone computer to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and manage the zone computers:

- get_zone_computers returns a Tcl list of the Active Directory names of all zone computers in the current zone.
- list_zone_computers lists to stdout the zone computers in the current zone.
- new_zone_computer creates a new zone computer and stores it in memory.
- select_zone_computer retrieves a zone computer from Active Directory and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- delete_zone_computer deletes the zone computer from Active Directory and from memory.
- get_zone_computer_field reads a field value from the currently selected zone computer.
- save_zone_computer saves the zone computer with its current settings to Active Directory.
- set_zone_computer_field sets a field value in the currently selected zone computer.

save_zone_group

Use the save_zone_group command to save the currently selected zone group stored in memory to Active Directory. You must set at least one field value before you can save a zone group. In classic zones, you must set all field values before you can save a zone group.

You must save the selected zone group for any changes you make using ADEdit to take effect in Active Directory. If you select another zone group or end the ADEdit session before saving the currently selected zone group, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

save_zone_group

Abbreviation

svzg

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_zone_group

This example saves the currently selected zone group to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select zone groups:

- get_zone_groups returns a Tcl list of the Active Directory names of all zone groups in the current zone.
- list_zone_groups lists to stdout the zone groups in the current zone.
- new_zone_group creates a new zone group and stores it in memory.
- select_zone_group retrieves a zone group from Active Directory and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- delete_zone_group deletes the selected zone group from Active Directory and from memory.
- get_zone_group_field reads a field value from the currently selected zone group.
- save_zone_group saves the selected zone group with its current settings to Active Directory.
- set_zone_group_field sets a field value in the currently selected zone group.

save_zone_user

Use the save_zone_user command to save the currently selected zone user stored in memory to Active Directory. You must set at least one field value before you can save a zone user. In classic zones, you must set all field values before you can save a zone user.

You must save the selected zone user for any changes you make using ADEdit to take effect in Active Directory. If you select another zone user or end the ADEdit session before saving the currently selected zone user, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

save_zone_user

Abbreviation

svzu

Options

This command takes no options.

Arguments

This command takes no arguments.

Return Value

This command returns nothing if it runs successfully.

Examples

save_zone_user

This example saves the currently selected zone user to Active Directory.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone user:

- get_zone_users returns a Tcl list of the Active Directory names of all zone users in the current zone.
- list_zone_users lists to stdout the zone users and their NSS data in the current zone.
- new_zone_user creates a new zone user and stores it in memory.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- delete_zone_user deletes the selected zone user from Active Directory and from memory.
- get_zone_user_field reads a field value from the currently selected zone user.
- save_zone_user saves the selected zone user with its current settings to Active Directory.
- set_zone_user_field sets a field value in the currently selected zone user.

select_dz_command

Use the select_dz_command command to retrieve a UNIX command in the currently selected zone from Active Directory. This command stores the selected UNIX command in memory, and makes it the currently selected UNIX command for subsequent ADEdit commands. The UNIX command remains selected until you select another UNIX command or zone, delete the UNIX command, or end the ADEdit session.

If you use ADEdit commands such as set_dzc_field to change settings for the selected UNIX command, you must save the selected UNIX command using the save_dz_command command for your changes to take effect in Active Directory. If you select another UNIX command or end the ADEdit session before saving the currently selected UNIX command, your changes will be lost.

You can only use the select_dz_command command to select UNIX commands if the currently selected zone is a classic4 or hierarchical zone. The command does not work for other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
select_dz_command command
```

Abbreviation

sldzc

Options

This command takes no options.

Arguments

This command takes the following arguments:

command	string	Required. Specifies the name of the UNIX command to select.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_dz_command account_manager
```

This example looks for the UNIX command named "account_manager" in the current zone and, if found, selects it as the current UNIX command.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a UNIX command to work with:

- get_dz_commands returns a Tcl list of UNIX commands in the current zone.
- list_dz_commands lists to stdout the UNIX commands in the current zone.
- new_dz_command creates a new UNIX command and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- delete_dz_command deletes the selected command from Active Directory and from memory.
- get_dzc_field reads a field value from the currently selected command.
- save_dz_command saves the selected command with its current settings to Active Directory.

- set_dzc_field sets a field value in the currently selected command.

select_local_group_profile

Use the select_local_group_profile command to select a local UNIX or Linux group object for viewing or editing. The group that you specify remains selected until you execute the save_local_group_profile command.

You typically use select_local_group_profile to select a group profile before you execute get_local_group_profile_field or set_local_group_profile_field to view or edit profile information.

Zone Type

Hierarchical only.

Syntax

```
select_local_group_profile group_name
```

Abbreviation

sllgp

Options

This command takes no options.

Arguments

This command takes the following argument:

group_name	string	Required. Specifies the UNIX name of the local group to select.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example selects the object for the local UNIX or Linux group marketing.

```
select_local_group_profile marketing
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.

- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

select_local_user_profile

Use the select_local_user_profile command to select a local UNIX or Linux user object for viewing or editing. The user that you specify remains selected until you execute the save_local_user_profile command.

You typically use select_local_user_profile to select a user profile before you execute get_local_user_profile_field or set_local_user_profile_field to view or edit profile information.

Zone Type

Hierarchical only.

Syntax

```
select_local_user_profile user_name
```

Abbreviation

sllup

Options

This command takes no options.

Arguments

This command takes the following argument:

user_name	string	Required. Specifies the UNIX name of the local user to select.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example selects the object for the local UNIX or Linux user anton.splieth.

```
select_local_user_profile anton.splieth
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.

- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

select_nis_map

Use the select_nis_map command to retrieve a NIS map in the currently selected zone from Active Directory. This command stores the NIS map in memory, and makes it the currently selected NIS map for subsequent ADEdit commands. The NIS map remains selected until you select another NIS map or zone, delete the NIS map, or end the ADEdit session.

If you use ADEdit commands such asadd_map_entryto change settings for the selected NIS map, you must save the selected NIS map using the save_nis_map command for your changes to take effect in Active Directory. If you select another NIS map or end the ADEdit session before saving the currently selected NIS map, your changes will be lost.

Zone Type

Not applicable

Syntax

```
select_nis_map map
```

Abbreviation

```
slnm
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

map	string	Required. Specifies the name of the NIS map to retrieve from Active Directory.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_nis_map Printers
```

This example looks for the NIS map named “Printers” in the current zone and, if found, selects it as the current NIS map.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select NIS maps:

- get_nis_maps returns a Tcl list of NIS maps in the current zone.
- list_nis_maps returns a list to stdout of all NIS maps in the current zone.
- new_nis_map creates a new NIS map and stores it in memory.

After you have a NIS map stored in memory, you can use the following commands to work with that map:

- add_map_entryor add_map_entry_with_comment adds an entry to the current NIS map stored in memory.
- delete_map_entry removes an entry from the current NIS map.
- delete_nis_map deletes the selected NIS map from Active Directory and from memory.
- get_nis_map or get_nis_map_with_comment returns a Tcl list of the map entries in the current NIS map.
- get_nis_map_field reads a field value from the current NIS map.
- list_nis_map or list_nis_map_with_comment lists to stdout the map entries in the current NIS map.
- save_nis_map saves the selected NIS map with its current entries to Active Directory.

select_object

Use the select_object command to retrieve the specified Active Directory object and its attributes from Active Directory. This command stores the object in memory and makes it the currently selected Active Directory object. You can use options to retrieve the rootDSE of the object or to list specific attributes to retrieve for the object.

Zone Type

Not applicable

Syntax

```
select_object [-rootdse] [-attrs a1[,a2,...]] dn
```

Abbreviation

slo

Options

This command takes the following options:

-rootdse	Returns the rootDSE of the specified object instead of the object.
-attrs *a1*[,a2,...]	Specifies the attributes to retrieve and store in memory. If you use this option, only the attributes you name (*a1, a2, a3,* and so on) are retrieved. This option is useful if you want to limit the number of attributes returned or want to return attributes not normally returned by Active Directory. If you do not use this option, ADEdit retrieves the attributes normally returned by Active Directory for the selected object type.

Arguments

This command takes the following argument:

dn	DN	Required. Specifies the distinguished name (DN) of an Active Directory object.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_object “cn=users,dc=acme,dc=com”
```

This example returns the container object cn=users,dc=acme,dc=com and its attributes, and stores it in memory as the currently selected Active Directory object.

Related Commands

The following commands enable you to view and select the object to work with:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of objects matching the specified search criteria.
- new_object creates a new Active Directory object and stores it in memory.

After you have an Active Directory object stored in memory, you can use the following commands to work with that object's attributes, delete the object, or save information for the object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field reads a field value from the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- save_object saves the selected Active Directory object with its current settings to Active Directory.
- set_object_field sets a field value in the currently selected Active Directory object.

select_pam_app

Use the select_pam_app command to retrieve a PAM application access right in the currently selected zone from Active Directory. This command stores the PAM application right in memory, and makes it the currently selected PAM application right for subsequent ADEdit commands. The PAM application right remains selected until you select another PAM application right or zone, delete the PAM application right, or end the ADEdit session.

If you use ADEdit commands such as set_pam_field to change settings for the selected PAM application right, you must save the selected PAM application right using the save_pam_app command for your changes to take effect in Active Directory. If you select another PAM application right or end the ADEdit session before saving the currently selected PAM application right, your changes will be lost.

You can only use the select_pam_app command to select PAM applications if the currently selected zone is a classic4 or hierarchical zone. The command does not work for other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
select_pam_app name[/zonename]
```

Abbreviation

slpam

Options

This command takes no options.

Arguments

This command takes the following argument:

name[*/zonename*]	string	Required. Specifies the name of the PAM application right to select. If the PAM application right that you want to select is defined in the current zone, the *zonename* argument is optional. If the PAM application right is defined in a zone other than the currently selected zone, the *zonename* argument is required to identify the specific PAM application right to select.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example retrieves the PAM application right named sftp in the current zone and makes it the currently selected PAM application right:

```
select_pam_app sftp
```

The following example retrieves the PAM application right named sftp defined in the chicago zone and makes it the currently selected PAM application right:

```
select_pam_app sftp/chicago
```

The definition for the PAM application right named sftp might be the same in both zones, but it is not required to be. Specifying the zone ensures you get the definition you expect.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. After you have a zone stored in memory, you can use the following commands to view and select the PAM application to work with:

- get_pam_apps returns a Tcl list of PAM application rights in the current zone.
- list_pam_apps lists to stdout the PAM application rights in the current zone.
- new_pam_app creates a new PAM application right and stores it in memory.
- select_pam_app retrieves a PAM application right from Active Directory and stores it in memory

After you have a PAM application stored in memory, you can use the following commands to work with that PAM application's attributes, delete the PAM application, or save information for the PAM application:

- delete_pam_app deletes the selected PAM application right from Active Directory and from memory.
- get_pam_field reads a field value from the currently selected PAM application right.
- save_pam_app saves the selected PAM application right with its current settings to Active Directory.
- set_pam_field sets a field value in the currently selected PAM application right.

select_role

Use the select_role command to retrieve a role in the currently selected zone from Active Directory. This command stores the role in memory, and makes it the currently selected role for subsequent ADEdit commands. The role remains selected until you select another role or zone, delete the role, or end the ADEdit session.

If you use ADEdit commands such as set_role_field to change settings for the selected role, you must save the selected role using the save_role command for your changes to take effect in Active Directory. If you select another role or end the ADEdit session before saving the currently selected role, your changes will be lost.

You can only use the select_role command to select roles if the currently selected zone is a classic4 or hierarchical zone. The command does not work for other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
select_role role
```

Abbreviation

```
slr
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

role	string	Required. Specifies the name of the role to select.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_role servicerep
```

This example retrieves the role definition named servicerep in the current zone and makes it as the currently selected role.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a role:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the current zone.
- new_role creates a new role and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

*add_command_to_roleadds a UNIX command right to the current role.

- add_pamapp_to_role adds a PAM application right to the current role.
- delete-role deletes the selected role from Active Directory and from memory. *get_role_apps returns a Tcl list of the PAM application rights associated with the current role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- get_role_field reads a field value from the current role.
- list_role_rights returns a list of all UNIX command and PAM application rights associated with the current role. *remove_command_from_roleremoves a UNIX command right from the current role.
- remove_pamapp_from_role removes a PAM application right from the current role.
- save_role saves the selected role with its current settings to Active Directory.
- set_role_field sets a field value in the current role.

select_role_assignment

Use the select_role_assignment command to retrieve a role assignment in the currently selected zone from Active Directory. This command stores the role assignment in memory, and makes it the currently selected role assignment for subsequent ADEdit commands. The role assignment remains selected until you select another role assignment or zone, delete the role assignment, or end the ADEdit session.

If you use ADEdit commands such as set_role_assignment_field to change settings for the selected role assignment, you must save the selected role assignment using the save_role_assignment command for your changes to take effect in Active Directory. If you select another role assignment or end the ADEdit session before saving the currently selected role assignment, your changes will be lost.

You can only use the select_role_assignment command to select role assignments if the currently selected zone is a classic4 or hierarchical zone. The command does not work for other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
select_role_assignment principal/role[/zone]
```

Abbreviation

slra

Options

This command takes no options.

Arguments

This command takes the following argument:

principal/role[/zone]	string	Required. Specifies the user principal name (UPN) of the user or group to whom the role is assigned, followed by a slash (/) and the name of the role to assign to the principal. The *zone* argument is optional if the role is defined in the currently selected zone. If the role is defined in a zone other than the currently selected zone, the */zone* argument is required.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_role_assignment poweradmins@acme.com/root/global
```

This example retrieves the role assignment that assigns the role named root, as defined in the global zone, to the principal named poweradmins@acme.com. The principal is a group.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a role assignment:

- get_role_assignments returns a Tcl list of role assignments in the current zone.
- list_role_assignments lists to stdout the role assignments in the current zone.
- new_role_assignment creates a new role assignment and stores it in memory.
- select_role_assignment retrieves a role assignment from Active Directory and stores it in memory.

After you have a role assignment stored in memory, you can use the following commands to work with that role assignment:

- delete_role_assignment deletes the selected role assignment from Active Directory and from memory.
- get_role_assignment_field reads a field value from the currently selected role assignment.
- save_role_assignment saves the selected role assignment with its current settings to Active Directory.
- set_role_assignment_field sets a field value in the currently selected role assignment.
- write_role_assignment saves the selected role assignment to a file.

select_rs_command

Use the select_rs_command command to retrieve a restricted shell command in the currently selected zone from Active Directory, store it in memory, and set it as the currently selected restricted shell command for other ADEdit commands. After you select the restricted shell command to work with, it remains selected until you select a different restricted shell command, change the currently selected zone, delete the restricted shell command, or end the ADEdit session.

If you use ADEdit commands such as set_rsc_field to change settings for the selected restricted shell command, you must save the restricted shell command using the save_rs_command command for your changes to take effect in Active Directory. If you select another restricted shell command or end the ADEdit session before saving the currently selected restricted shell command, your changes will be lost.

You can only use the select_rs_command if the currently selected zone is a classic zone.The command does not work in other types of zones.

Zone Type

Classic only

Syntax

select_rs_command rs_cmd

Abbreviation

slrsc

Options

This command takes no options.

Arguments

This command takes the following argument:

rs_cmd	string	Required. Specifies the name of the restricted shell command to select.

Return Value

This command returns nothing if it runs successfully.

Examples

select_rs_command rsc1

This command looks for the restricted shell command name rsc1 in the current zone. If rsc1 is found in the current zone, it becomes the currently selected context for subsequent commands.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- get_rs_commands returns a Tcl list of restricted shell commands in the current zone.
- list_rs_commands lists to stdout the restricted shell commands in the current zone.
- new_rs_command creates a new restricted shell command and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell command:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- get_rsc_field reads a field value from the currently selected command.
- save_rs_command saves the selected command with its current settings to Active Directory.
- set_rsc_field sets a field value in the currently selected command.

select_rs_env

Use the select_rs_env command to retrieve a restricted shell environment in the currently selected zone from Active Directory, stores it in memory, and sets it to be the currently selected restricted shell environment for other ADEdit commands. The restricted shell environment remains selected until you select another restricted shell environment, change the currently selected zone, delete the restricted shell environment, or end the ADEdit session.

If you use ADEdit commands such as set_rse_field to change settings for the restricted shell environment, you must save the restricted shell environment using the save_rs_env command for your changes to take effect in Active Directory. If you select another restricted shell environment or end the ADEdit session before saving the currently selected restricted shell environment, your changes will be lost.

You can only use the select_rs_env command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

select_rs_env rse_name

Abbreviation

slrse

Options

This command takes no options.

Arguments

This command takes the following argument:

rse_name	string	Required. Specifies the name of the restricted shell environment to select.

Return Value

This command returns nothing if it runs successfully.

Examples

select_rs_env rse1

This command looks for the restricted shell environment named rse1 in the current zone. If rse1 is found in the current zone, it becomes the currently selected context for subsequent commands.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with restricted shell environments:

- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.
- set_rse_field sets a field value in the current restricted shell environment.

select_zone

Use the select_zone command to retrieve a zone from Active Directory, stores the zone in memory, and make that zone as the currently selected zone for subsequent ADEdit commands. The zone remains selected until you select another zone, delete the zone, or end the ADEdit session.

If you use ADEdit commands such as set_zone_field to change settings for the zone, you must save the zone using the save_zone command for your changes to take effect in Active Directory. If you select another zone or end the ADEdit session before saving the currently selected zone, your changes will be lost.

You should note that ADEdit treats *computer roles* and *computer-specific overrides* as special use-case zones. You can, therefore, use the select_zone command to retrieve a “computer role zone” or a “computer-specific zone” to work with as the currently selected zone. If you specify a zone that is a computer role zone or a computer-specific zone, subsequent ADEdit commands will treat the zone as a computer role or a computer-specific zone instead of a standard zone. You can only work with one zone at a time, regardless of type. Because some ADEdit commands behave differently in different types of

zones, you should verify the type of zone you are working with when you select a zone.

Zone Type

Classic and hierarchical

Syntax

```
select_zone [-nc] path
```

Abbreviation

slz

Options

This command takes the following option:

-nc	Requests a reread of the zone's fields from Active Directory. Use this option after you use the save_zone command to ensure you have the current Active Directory field values in memory. For example, after a save_zone command, the modifyTime field value is updated. If you do not then run select_zone -nc, a gzf modifyTime command returns the previous value.

Arguments

This command takes the following argument:

path	string	Required. Specifies the path to the selected zone or computer role. The path format depends on the type of zone selected: A tree, classic3, classic4, or SFU zone path consists of the zone's distinguished name. Enclose the path in braces or quotes to allow spaces in the distinguished name. A computer role path consists of the host zone's distinguished name followed by a slash (/) and the name of the computer zone. Enclose the path in braces or quotes to allow spaces in the distinguished name. A computer override path consists of the computer name followed by an ampersand (@) and the distinguished name of the host zone.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example selects a standard zone named cz1 in the Zones container in the UNIX organizational unit in the acme.com domain:

```
select_zone "CN=cz1,CN=Zones,OU=UNIX,DC=acme,DC=com”
```

The following example selects the computer role named LinuxComputers in the global zone in the Zones container in the UNIX organizational unit in the acme.com domain:

```
select_zone “CN=global,CN=Zones,OU=UNIX,DC=acme,DC=com/LinuxComputers”
```

The following example selects the computer-specific override zone named server1 in the global zone in the acme.com domain:

```
select_zone "server1.acme.com@CN=global,CN=Zones,OU=Acme,DC=acme,DC=com”
```

Related Commands

The following commands perform actions related to this command:

- create_zone creates a new zone in Active Directory.
- get_zones returns a Tcl list of all zones within a specified domain.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_field reads a field value from the currently selected zone.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.
- set_zone_field sets a field value in the currently selected zone.

select_zone_computer

Use the select_zone_computer command to retrieve a zone computer in the currently selected zone from Active Directory, store it in memory, and make it the currently selected zone computer for subsequent ADEdit commands. The zone computer remains selected until you select another zone computer, delete the zone computer, or end the ADEdit session.

If you use ADEdit commands such as set_zone_computer_field to change settings for the zone computer, you must save the zone computer using the save_zone_computer command for your changes to take effect in Active Directory. If you select another zone computer or end the ADEdit session before saving the currently selected zone computer, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

```
select_zone_computer sAMAccountName$@domain
```

Abbreviation

slzc

Options

This command takes no options.

Arguments

This command takes the following argument:

sAMAccountName	string	Required. Specifies the Active Directory computer's sAMAccountName followed by $@ and the computer's domain. You can look up the sAMAccountName for a computer in Active Directory Users and Computers or by running the get_zone_computers command.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_zone_computer sales2$@acme.com
```

This example looks for the zone computer named sales2 in the current zone and, if found, selects it as the current zone computer.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and manage the zone computers:

- get_zone_computers returns a Tcl list of the Active Directory names of all zone computers in the current zone.
- list_zone_computers lists to stdout the zone computers in the current zone.
- new_zone_computer creates a new zone computer and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- delete_zone_computer deletes the zone computer from Active Directory and from memory.
- get_zone_computer_field reads a field value from the currently selected zone computer.
- save_zone_computer saves the zone computer with its current settings to Active Directory.
- set_zone_computer_field sets a field value in the currently selected zone computer.

select_zone_group

Use the select_zone_group command to retrieve a zone group in the currently selected zone from Active Directory. The command stores the zone group in memory and makes it the currently selected zone group for subsequent ADEdit commands. The zone group remains selected until you select another zone group, delete the zone group, or end the ADEdit session.

If you use ADEdit commands such as set_zone_group_field to change settings for the zone group, you must save the zone group using the save_zone_group command for your changes to take effect in Active Directory. If you select another zone group or end the ADEdit session before saving the currently selected zone group, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

```
select_zone_group AD_group_UPN
```

Abbreviation

```
slzg
```

Options

This command takes no options.

Arguments

This command takes the following argument:

AD_group_UPN	string	Required. Specifies the user principal name (UPN) of a zone group in the currently selected zone.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_zone_group poweradmins@acme.com
```

This example looks for the group named poweradmins in the current zone and, if found, selects it as the current zone group.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select zone groups:

- get_zone_groups returns a Tcl list of the Active Directory names of all zone groups in the current zone.

- list_zone_groups lists to stdout the zone groups in the current zone.
- new_zone_group creates a new zone group and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- delete_zone_group deletes the selected zone group from Active Directory and from memory.
- get_zone_group_field reads a field value from the currently selected zone group.
- save_zone_group saves the selected zone group with its current settings to Active Directory.
- set_zone_group_field sets a field value in the currently selected zone group.

select_zone_user

Use the select_zone_user command to retrieve a zone user in the currently selected zone from Active Directory. This command stores the zone user in memory, and makes it the currently selected zone user for subsequent ADEdit commands. The zone user remains selected until you select another zone user, delete the zone user, or end the ADEdit session.

If you use ADEdit commands such as set_zone_user_field to change settings for the zone user, you must save the zone user using the save_zone_user command for your changes to take effect in Active Directory. If you select another zone user or end the ADEdit session before saving the currently selected zone user, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

```
select_zone_user user
```

Abbreviation

slzu

Options

This command takes no options.

Arguments

This command takes the following argument:

user	string	Required. Specifies the sAMAccountName@domain or user principal name (UPN) of a zone user in the currently selected zone. ADEdit resolves the user with the sAMAcccountName first, then the UPN. If the zone user is an orphan user—that is, the corresponding Active Directory user no longer exists—you must specify the user's security identifier (SID) instead.

Return Value

This command returns nothing if it runs successfully.

Examples

```
select_zone_user adam.avery@acme.com
```

This example looks for the Active Directory user adam.avery in the current zone and, if found, selects that user as the current zone user.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone user:

- get_zone_users returns a Tcl list of the Active Directory names of all zone users in the current zone.
- list_zone_users lists to stdout the zone users and their NSS data in the current zone.
- new_zone_user creates a new zone user and stores it in memory.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- delete_zone_user deletes the selected zone user from Active Directory and from memory.
- get_zone_user_field reads a field value from the currently selected zone user.
- save_zone_user saves the selected zone user with its current settings to Active Directory.
- set_zone_user_field sets a field value in the currently selected zone user.

set_dzc_field

Use the set_dzc_field command to set the value for a specified field in the currently selected UNIX command stored in memory. The set_dzc_field command does *not* set a field value stored in Active Directory for the selected UNIX command.

If you change any fields, you must save the UNIX command using the save_dz_command command for your changes to take effect in Active Directory. If you select another UNIX command or end the ADEdit session before saving the currently selected UNIX command, your changes will be lost.

You can only use the set_dzc_field command to set UNIX command fields if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

When executing privileged commands on computers running Security-Enhanced Linux (SELinux), the security context contains additional information that is used to make access control decisions.

Zone Type

Classic and hierarchical

Syntax

set_dzc_field field value

Abbreviation

sdzcf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field you want to set. The possible values are: **description**: Text describing the UNIX command. **cmd**: The UNIX command string or strings. You can use wild cards or a regular expression. **path**: The path to the command's location. You can use wild cards or a regular expression. **form**: An integer that indicates whether the cmd and path strings use wild cards (0) or a regular expression (1). **dzdo_runas**: A list of users and groups that can run this command under dzdo (similar to sudo). Users can be listed by user name or UID. **dzsh_runas**: A list of users and groups that can run this command in a restricted shell environment (dzsh). Users can be listed by user name or UID. You cannot set this field value if the selected zone is a classic4 zone. **keep**: A comma-separated list of environment variables from the current user's environment to keep. **del**: A comma-separated list of environment variables from the current user's environment to delete. **add**: A comma-separated list of environment variables to add to the final set of environment variables. **pri**: An integer that specifies the command priority for the restricted shell command object.
		umask: An integer that defines who can execute the command. **flags**: An integer that specifies a combination of different properties for the command. **selinux_role**: Specifies the SELinux role to use when constructing a new security context for command

field (continued)	string	execution. **selinux_type**: Specifies the SELinux type to use when constructing a new security context for command execution. **digest**: Specifies the SHA-2 digest to verify the file checksum before command execution. Note that selinux_role and selinux_type are only supported on Red Hat Enterprise Linux systems and effective only on systems with SELinux enabled and joined to a hierarchical zone.
value		Required. Specifies the value to assign to the specified field. The data type depends on the field specified. In most cases, you can assign an empty string or null value (0) to unset a field value, depending on the data type of the field.

Setting the cmd and path field values

You can specify the cmd and path strings using wild cards (*, ?, and !), or as a regular expression. If you specify the cmd and path strings using wild cards, use an asterisk (*) to match zero or more characters, the question mark (?) to match exactly one character, or the exclamation mark (!) to negate matching of the specified string.

To set to the command path to the equivalent of the **Standard user path** option, you can set the value of the path field to USERPATH. To set to the path to the equivalent of the **Standard system path** option, set the value of the path field to SYSTEMPATH. To set to the path to the equivalent of the **System search path** option, set the value of the path field to SYSTEMSEARCHPATH.

For both the cmd and path fields, the form field controls whether the specified string is interpreted as a regular expression or as a string that includes wild cards.

Specifying the environment variables to use

You can use the keep, del, and add settings to control the environment variables used by the commands specified by the cmd string. The keep and del settings are mutually exclusive. The keep field only takes effect if the flag 16 is included in the setting for the flag field. The del field only takes effect if the flag 16 is not included in the setting for the flag field.

Any environment variables kept or deleted are in addition to the default set of the user's environment variables that are either retained or deleted. The default set of environment variables to keep is defined in the dzdo.env_keep configuration parameter in the centrifydc.conf file. The default set of environment variables to delete is defined in the dzdo.env_delete configuration parameter in the centrifydc.conf file. You can also add environment variables to the final set of environment variables resulting from the keep or del fields.

Specifying the command priority

You can use the pri field to specify the command priority when there are multiple matches for the UNIX commands specified by wild cards. If commands specified by this UNIX command object match commands specified by another UNIX command object, the UNIX command object with the higher command priority prevails. This field takes an integer value; the higher the number, the higher the priority.

Specifying the umask value

You can use the umask field to define who can execute the command. The umask field specifies a 3-digit octal value that defines read, write, or execute permission for owner, group, and other users. The left digit defines the owner execution rights, the middle digit defines the group execution rights, and the right digit defines other execution rights. Each digit is a combination of binary flags, one flag for each right as follows:

- 4 is read
- 2 is write
- 1 is execute

You add these values add together to define the rights available for each entity. For example, an umask value of 600 indicates read and write permission (4+2) for the owner, but no permissions for the group or other users. Similarly, an umask value of 740 indicates read, write, execute permissions (4+2+1) for the owner, read permissions for the group, but no permissions for other users.

Specifying command properties using the flags field

You can use the flags field to define a combination of binary flags, with one flag for each of the following properties:

1—Prevents nested command execution. If this flag value is not set, nested command execution is allowed.

2—Requires re-authentication using the login user's password.

4—Requires authentication using the run-as user's password.

8—Preserves group membership. If this flag value is not set, group membership is not preserved.

16—Resets environment variables for the command, deleting the variables specified in the dzdo.env_delete parameter and keeping the variables specified in the keep field. If this flag is not set, the command removes the unsafe environment variables specified in the dzdo.env_delete parameter along with any additional environment variables specified by the del field.

32—Requires multi-factor authentication to execute the command.

64—Prevents navigation up the path hierarchy when executing the command.

You add these values together to define the setting for the flags field. For example, a flags field value of 5 prevents nested command execution and requires authentication using the run-as user's password (1+4). You cannot set the 2 flag and the 4 flag or the 4 flag and the 32 flag simultaneously. If you don't set any of these flags, re-authentication is not required.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example sets the current UNIX command dzdo_runas field to root:

```
set_dzc_field dzdo_runas root
```

The following example sets the UNIX command properties so that nested command execution is not allowed and authentication is required with the user's password:

```
sdzcf flags 3
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a UNIX command to work with:

- get_dz_commands returns a Tcl list of UNIX commands in the current zone.
- list_dz_commands lists to stdout the UNIX commands in the current zone.
- new_dz_command creates a new UNIX command and stores it in memory.
- select_dz_command retrieves a UNIX command from Active Directory and stores it in memory.

After you have a UNIX command stored in memory, you can use the following commands to work with that command:

- delete_dz_command deletes the selected command from Active Directory and from memory.
- get_dzc_field reads a field value from the currently selected command.
- save_dz_command saves the selected command with its current settings to Active Directory.

set_ldap_timeout

Use the set_ldap_timeout command to set the time-out interval used by LDAP commands. LDAP commands are ADEdit commands such as select_zone that perform read/write operations on Active Directory through a binding. The time-out value controls how long these commands will wait for a response before declaring a time-out and ceasing operation.

The default value is five minutes.

Zone Type

Not applicable

Syntax

```
set_ldap_timeout timeout_in_seconds
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes the following argument:

timeout_in_seconds	integer	Required. Specifies the number of seconds to wait for a response from Active Directory before ending an operation. The default value is 300 seconds (5 minutes).

Return Value

This command returns nothing if it runs successfully.

Examples

```
set_ldap_timeout 120
```

This example sets the LDAP time-out interval to 120 seconds (2 minutes).

Related Commands

None.

set_local_group_profile_field

Use the set_local_group_profile_field command to set the value of the specified profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone. Before executing this command, you must create a new local group by executing the new_local_group_profile command, or select an existing local group by executing the select_local_group_profile command.

You can save a group object before the group profile is complete. However, the group profile is not added to /etc/group on each UNIX and Linux computer in the zone until the group profile is complete and the profileflag field is set to 1 (enabled). See new_local_group_profile for details about which fields (attributes) a group profile must have to be considered complete.

Zone Type

Hierarchical only.

Syntax

```
set_local_group_profile_field field_name value
```

Abbreviation

```
slgpf
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

field_name	string	Required. Specifies the local group profile field to set. The possible values are: **gid member profileflag** You can also specify AIX extended attributes as the field to set an extended attribute value for a group. Extended attribute fields start with the aix. prefix. For example, the admin extended attribute can be set by specifying aix.admin as the field.
value		Required. The data type depends on the field being set. The possible values for each field are: **Any field**: Clear any field by entering a hyphen character (-). **gid**: A numeric group identifier. **member**: The UNIX name of a local user to add to the group. **profileflag**: 1 or 3.If set to 1, the group profile is enabled. If the group profile is complete and the profile flag is set to 1, the profile will be installed or updated in /etc/group at the next local account refresh interval. If set to 3, the group profile is removed from /etc/group at the next local account refresh interval.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example sets the GID of the currently selected group to 20001.

```
set_local_group_profile_field gid 20001
```

The following example adds the UNIX user anton.splieth to the currently selected local group.

```
set_local_group_profile_field member anton.splieth
```

The following example sets the profile flag of the currently selected group to 1 (enabled), so that if the group profile is complete, the profile will be installed or updated in /etc/group at the next local account refresh interval.

```
set_local_group_profile_field profileflag 1
```

If the current group is on AIX, you can set group AIX extended attributes and values. For example, to identify the current group as an administrative group, you can set the admin extended attribute:

```
set_local_group_profile_field aix.admin true
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_user_profile_field sets the value of a field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.

set_local_user_profile_field

Use the set_local_user_profile_field command to set the value of the specified profile field for the currently selected local UNIX or Linux user that has a profile

defined in the current zone. Before executing this command, you must create a new local user by executing the new_local_user_profile command, or select an existing local user by executing the select_local_user_profile command.

You can save a user object before the user profile is complete. However, the user profile is not added to /etc/passwd on each UNIX and Linux computer in the zone until the user profile is complete, the profileflag field is set to 1 (enabled) or 2 (disabled), and the user is assigned a visible role such as local listed. See new_local_user_profile for details about which attributes a user profile must have to be considered complete.

Zone Type

Hierarchical only.

Syntax

```
set_local_user_profile_field field_name value
```

Abbreviation

slupf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field_name value	String	Required. Specifies the local user profile field to set. Fields and possible values are: **Any field**: Clear any field by entering a hyphen character (-). **uid**: The user's numeric identifier. **gid**: The user's primary group numeric identifier. **shell**: The local user's default shell on the local computer. Possible values are: /bin/bash, /bin/csh, /bin/ksh, /bin/sh, /bin/tcsh, %. **home**: The local user's default home directory on the local computer. **gecos**: General information about the local user account. **profileflag**: The value of the user's profile flag as set in the user object in the zone. For the user to be managed by the agent, the profile flag must be set to 1 , 2, or 3.If set to 1, the user profile is enabled. If the user profile is complete, the profile flag is set to 1, and the user is assigned a visible role, the profile will be installed or updated in /etc/passwd at the next local account refresh interval. If set to 2, the user profile is disabled. If the user profile is complete, the profile flag is set to 2, and the user is assigned a visible role, the profile will be installed or updated in /etc/passwd at the next local account refresh interval. However, the password field in /etc/passwd will be set to !!, and the user will not be able to log into the local computer. This state results in what is typically called a "locked account." If set to 3, the user profile is removed from /etc/passwd at the next local account refresh interval.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example sets the UID of the currently selected user to 10001.

```
set_local_user_profile_field uid 10001
```

The following example sets the primary group ID for the currently selected user to 20001.

```
set_local_user_profile_field gid 20001
```

The following example sets the default shell for the currently selected user to /bin/csh:

```
set_local_user_profile_field shell /bin/csh
```

The following example sets the home directory for the currently selected user to /home.

```
set_local_user_profile_field home /home
```

The following example sets the profile flag of the currently selected user to 1 (enabled), so that if the user profile is complete and the user is assigned a visible role, the profile will be installed or updated in /etc/passwd at the next local account refresh interval.

```
set_local_user_profile_field profileflag 1
```

Related Commands

The following related ADEdit commands let you view and administer local UNIX and Linux users and groups that have profiles defined in the current zone:

- delete_local_group_profile deletes a local UNIX or Linux group that has a profile defined in the current zone.
- delete_local_user_profile deletes a local UNIX or Linux user that has a profile defined in the current zone.
- get_local_group_profile_field displays the value of a profile field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.
- get_local_groups_profile displays a TCL list of profiles for local groups that are defined in the current zone.
- get_local_user_profile_field displays the value of a profile field for the currently selected local UNIX or Linux user that has a profile defined in the current zone.
- get_local_users_profile displays a TCL list of profiles for local users that are defined in the current zone.
- list_local_groups_profile displays a list of local UNIX and Linux groups that have a profile defined in the current zone.
- list_local_users_profile displays a list of local UNIX and Linux users that have a profile defined in the current zone.
- new_local_group_profile creates an object for a local UNIX or Linux group in the currently selected zone.
- new_local_user_profile creates an object for a local UNIX or Linux user in the currently selected zone.
- save_local_group_profile saves the currently selected local UNIX or Linux group object after you create the group object or edit profile field values in the group object.
- save_local_user_profile saves the currently selected local UNIX or Linux user object after you create the user object or edit profile field values in the user object.
- select_local_group_profile selects a local UNIX or Linux group object for viewing or editing.
- select_local_user_profile selects a local UNIX or Linux user object for viewing or editing.
- set_local_group_profile_field sets the value of a field for the currently selected local UNIX or Linux group that has a profile defined in the current zone.

set_object_field

Use the set_object_field command to set the value for a specified field in the currently selected Active Directory object stored in memory. The set_object_field command does *not* set a field value stored in Active Directory for this object.

If you change any fields, you must save the object using the save_object command for your changes to take effect in Active Directory. If you select another object or end the ADEdit session before saving the currently selected object, your changes will be lost.

The set_object_field command does not check to see if fields and values are valid. When you save an object, Active Directory will check fields and values at that time and report an error if they aren't valid.

Zone Type

Not applicable

Syntax

```
set_object_field field value
```

Abbreviation

sof

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field you want to set. The *field* argument can by any attribute that is valid for the type of Active Directory object currently selected in memory.
value		Required. Specifies the value to assign to the specified field. The data type depends on the specified field. The set_object_field command does not check whether the value is valid. Active Directory will check for valid values when ADEdit saves the object.

Return Value

This command returns nothing if it runs successfully.

Examples

```
set_object_field sd $sdvalue
```

This example sets the current object's security descriptor field to the string contained in the variable sdvalue (an SDDL string).

Related Commands

The following commands enable you to view and select Active Directory objects:

- get_objects performs an LDAP search of Active Directory and returns a Tcl list of the distinguished names of objects matching the specified search criteria.
- new_object creates a new Active Directory object and stores it in memory.
- select_object retrieves an object with its attributes from Active Directory and stores it in memory.

After you have an object stored in memory, you can use the following commands to work with that object:

- add_object_value adds a value to a multi-valued field attribute of the currently selected Active Directory object.
- delete_object deletes the selected Active Directory object from Active Directory and from memory.
- delete_sub_tree deletes an Active Directory object and all of its children from Active Directory.
- get_object_field reads a field value from the currently selected Active Directory object.
- remove_object_value removes a value from a multi-valued field attribute of the currently selected Active Directory object.
- save_object saves the selected Active Directory object with its current settings to Active Directory.

set_pam_field

Use the set_pam_field command to set the value for a specified field in the currently selected PAM application right stored in memory. The set_pam_field command does *not* set a field value stored in Active Directory for this PAM application right.

If you change any fields, you must save the PAM application right using the save_pam_app command for your changes to take effect in Active Directory. If you select another PAM application right or end the ADEdit session before saving the currently selected PAM application right, your changes will be lost.

You can only use the set_pam_field command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

```
set_pam_field field value
```

Abbreviation

spf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field that you want to set. The possible values are: **application**: The name of the PAM application that is allowed to use the adclient PAM authentication service. The name can be literal, or it can contain ? or * wildcard characters to specify multiple applications. **description**: Text describing the PAM application. Note that in a classic zone, setting the **application** field changes the name of the PAM application right. For example, assume you create a new PAM application right in a classic zone using a command like this: new_pam_app myftp If you then use this command to set the **application** field like this: set_pam_field application newftp The PAM application right itself will be renamed. If you were to use the list_pam_apps command after running the set_pam_field command, the right would be returned as newftp: list_pam_apps newftp : Renamed application right
value		Required. Specifies the value to assign to the specified field. In most cases, you can assign an empty string to unset a field value.

Return Value

This command returns nothing if it runs successfully.

Examples

set_pam_field application *

This example sets the application field for the current PAM application right to allow PAM access rights to all applications (* is the wildcard for all possible strings).

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select PAM application rights:

- get_pam_apps returns a Tcl list of PAM application rights in the current zone.
- list_pam_apps lists to stdout the PAM application rights in the currently selected zone.
- new_pam_app creates a new PAM application right and stores it in memory.
- select_pam_app retrieves a PAM application right from Active Directory and stores it in memory.

After you have a PAM application right stored in memory, you can use the following commands to work with that PAM application right:

- delete_pam_app deletes the selected PAM application right from Active Directory and from memory.
- get_pam_field reads a field value from the currently selected PAM application right.
- save_pam_app saves the selected PAM application right with its current settings to Active Directory.

set_role_assignment_field

Use the set_role_assignment_field command to sets the value for a specified field in the currently selected role assignment stored in memory. The set_role_assignment_field command does *not* set a field value stored in Active Directory for this role assignment.

If you change any fields, you must save the role assignment using the save_role_assignment command for your changes to take effect in Active Directory. If you select another role assignment or end the ADEdit session before saving the currently selected role assignment, your changes will be lost.

You can only use the set_role_assignment_field command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

set_role_assignment_field field value

Abbreviation

sraf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field that you want to set. The possible values are: **customAttr**: Sets custom text strings for the role assignment. This field is only applicable for hierarchical zones. **description**: Sets the description for the role assignment. **from**: Sets the starting date and time for the role assignment. The date and time is expressed in standard UNIX time. The Tcl clock command manipulates these time values. A value of 0 means no starting date and time for the role assignment. **role**: Sets the name of the role to assign and the zone in which the role was defined.The zone value is optional if the role is defined in the currently selected zone. The zone is required if the role is defined in another zone. **to**: Sets the ending date and time for the role assignment. The start and end dates and times are expressed in standard UNIX time. You can use the Tcl clock command to manipulate these values. A value of 0 indicates no date or time is set for the role assignment.
value	depends on field	Required. Specifies the value to assign to the specified field. In some cases, you can assign a dash (-) or an empty string to unset a field value. However, this is not supported for all fields or all zone types.

Return Value

This command returns nothing if it runs successfully.

Examples

set_role_assignment_field role su-root/global

This example assigns the role named su-root that is defined in the global zone.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a role assignment:

- get_role_assignments returns a Tcl list of role assignments in the current zone.
- list_role_assignments lists to stdout the role assignments in the current zone.
- new_role_assignment creates a new role assignment and stores it in memory.
- select_role_assignment retrieves a role assignment from Active Directory and stores it in memory.

After you have a role assignment stored in memory, you can use the following commands to work with that role assignment:

- delete_role_assignment deletes the selected role assignment from Active Directory and from memory.
- get_role_assignment_field reads a field value from the currently selected role assignment.
- save_role_assignment saves the selected role assignment with its current settings to Active Directory.
- write_role_assignment saves the selected role assignment to a file.

set_role_field

Use the set_role_field command to set the value for a specified field in the currently selected role stored in memory. The set_role_field does *not* set a field value stored in Active Directory for this role.

If you change any fields, you must save the role using the save_role command for your changes to take effect in Active Directory. If you select another role or end the ADEdit session before saving the currently selected role, your changes will be lost.

You can only use the set_role_field command if the currently selected zone is a classic4 or hierarchical zone. The command does not work in other types of zones.

Zone Type

Classic and hierarchical

Syntax

set_role_field field value

Abbreviation

srf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field that you want to set.
value		Required. Specifies the value to assign to the specified field. In most cases, you can assign an empty string or null value (0) to unset a field value, depending on the data type of the field.

The data type required depends on the field you are setting. The possible values are:

- **allowLocalUser**: Set the value to true to allow local users to be assigned to the role, or false if local users should not be assigned to the role. This field is not applicable in classic zones. The valid values are 1, y, yes, or true to enable or 0, n, no, or false to disable. All other values throw an exception.
- **AlwaysPermitLogin**: Set the value to true to enable "rescue rights" for users assigned to the role, or false if "rescue rights" should not be applied to the role. This field is not applicable in classic zones. The valid values are 1, y, yes, or true to enable or 0, n, no, or false to disable. All other values throw an exception.
- **auditLevel**: Set the value to one of the following to specify whether auditing is not requested, requested but not required, or required:
  - AuditIfPossible
  - AuditNotRequested
  - AuditRequired

  This field is not applicable in classic zones.
- **customAttr**: Sets custom text strings for the role. This field is only applicable for hierarchical zones.
- **description**: Set the value to a text string that describes the role.
- **sysrights**: Set the value to specify the system rights granted to the role. This value is an integer that represents a combination of binary flags, one for each right. This field is not applicable in classic zones.
- **timebox**: Set the value to indicate the hours in the week when the role is enabled. This value is a 42-digit hexadecimal number. When represented in binary, each bit represents an hour of the week as described in the appendix Timebox Value Format

- **visible**: Returns true or false depending on whether "User is visible" right is configured for the role. You cannot get this field value if the selected zone is a classic zone.

Setting the system rights field value for a role

You can specify the sysrights field to define the system rights that you want to grant to the currently selected role. This field value is an integer that represents a combination of binary flags, with one flag for each of the following system rights:

1—Password login and non password (SSO) login are allowed.

2—Non password (SSO) login is allowed.

4—Account disabled in Active Directory can be used by sudo, cron, etc.

8—Log in with non-restricted shell.

16—Audit not requested/required.

32—Audit required.

64—Always permit to login.

128—Remote login access is allowed for Windows computers.

256—Console login access is allowed for Windows computers.

512—Require multi-factor authentication through the Delinea Connector to log on.

1024—PowerShell remote access is allowed

These values are added together to define the sysrights field value. For example, a sysrights value of 6 indicates that the role is configured to allow single sign-on login and to ignore disabled accounts (2+4). A value of 11 indicates that most common UNIX system rights are enabled (1+2+8). A value of 384 indicates that most common Windows system rights are enabled (128+256).

Return Value

This command returns nothing if it runs successfully.

Examples

The following example sets the system rights for the current role to allow SSO login (2) and to provide a full shell (8):

```
set_role_field sysrights 10
```

The following example sets the current role to require auditing:

```
set_role_field auditLevel AuditRequired
```

Note that the sysrights field is a bit field, so you can add and remove bits for the field instead of setting the integer value directly. For example to add the system rights for single sign-on and full shell to existing system rights, you might use commands similar to this:

```
set sr [get_role_field sysrights]

set_role_field sysrights [expr { $sr | 10 }]
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select roles:

- get_roles returns a Tcl list of roles in the current zone.
- list_roles lists to stdout the roles in the current zone.
- new_role creates a new role and stores it in memory.
- select_role retrieves a role from Active Directory and stores it in memory.

After you have a role stored in memory, you can use the following commands to work with that role:

- add_command_to_roleadds a UNIX command to the current role.
- add_pamapp_to_role adds a PAM application right to the current role.
- delete_role deletes the selected role from Active Directory and from memory. *get_role_apps returns a Tcl list of the PAM applications associated with the currently selected role.
- get_role_commands returns a Tcl list of the UNIX commands associated with the current role.
- get_role_field reads a field value from the currently selected role.
- list_role_rights returns a list of all UNIX commands and PAM application rights associated with the current role. *remove_command_from_roleremoves a UNIX command from the current role.
- remove_pamapp_from_role removes a PAM application from the current role.
- save_role saves the selected role with its current settings to Active Directory.

set_rs_env_for_role

Use the set_rs_env_for_role command to assign a restricted shell environment to the currently selected role that is stored in memory. You should note that a role can only have one restricted shell environment assigned to it. If you assign a new restricted shell environment to a role, the current restricted shell environment—if one exists—will be removed. In addition, a role cannot be defined with both privileged commands and a restricted shell environment at the same time. If you assign a restricted shell environment to the currently selected role, all privileged commands previously defined for the role—if they exist—will be removed from the role.

The set_rs_env_for_role command does not modify the data stored in Active Directory for the restricted shell environment. If you run this command using ADEdit without saving the role to Active Directory, your changes do not take effect.

You can only use the set_rs_env_for_role command if the currently selected zone is a classic4 zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

set_rs_env_for_role environment

Abbreviation

srse

Options

This command takes no options.

Arguments

This command takes the following argument:

environment	string	Required. Specifies the name of the restricted shell environment to assign to the current role.

Return Value

This command returns nothing if it runs successfully.

Examples

set_rs_env_for_role rse1

This example sets the currently selected role's restricted shell environment to rse1, and removes any existing restricted shell environment or privileged commands if they exist in the role.

Related Commands

The following commands perform actions related to this command:

- clear_rs_env_from_role removes a restricted shell environment from the current role.
- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with that: restricted shell environment:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.

set_rsc_field

Use the set_rsc_field command to set the value for a specified field for the currently selected restricted shell command that is stored in memory. The set_rsc_field command does not set the field value stored in Active Directory for the selected restricted command field.

If you change any fields, you must save the restricted shell command using the save_rs_command command for your changes to take effect in Active Directory. If you select another restricted shell command or end the ADEdit session before saving the currently selected restricted shell command, your changes will be lost.

You can only use the set_rsc_field command if the currently selected zone is a classic4 zone is the selected zone. The command does not work in other types of zones.

Zone Type

Classic only

Syntax

set_rsc_field field value

Abbreviation

srscf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field whose value you want to set.
value		Required. Specifies the value you want to assign to the specified field. The data type depends on the field specified. In most cases, you can assign an empty string or null value (0) to unset a field value, depending on the data type of the field.

The possible field values are:

- **description**: Text describing the restricted shell command.
- **cmd**: The restricted shell command string or strings. You can use wild cards or a regular expression.
- **path**: The path to the command's location. You can use wild cards or a regular expression.
- **form**: An integer that indicates whether the cmd and path strings use wild cards (0) or a regular expression (1).
- **dzsh_runas**: A list of users and groups that can run this command in a restricted shell environment (dzsh). Users can be listed by user name or UID.

- **keep**: A comma-separated list of environment variables from the current user's environment to keep.
- **del**: A comma-separated list of environment variables from the current user's environment to delete.
- **add**: A comma-separated list of environment variables to add to the final set of environment variables.
- **pri**: An integer that specifies the command priority for the restricted shell command object.
- **umask**: An integer that defines who can execute the command.
- **flags**: An integer that specifies a combination of different properties for the command.
- **createTime**: The time and date this command was created, returned in generalized time format.
- **modifyTime**: The time and date this command was last modified, returned in generalized time format.
- **dn**: The command's distinguished name.

Setting the cmd and path field values for a restricted command

You can specify the cmd and path strings using wild cards (*, ?, and !), or as a regular expression. If you specify the cmd and path strings using wild cards, use an asterisk (*) to match zero or more characters, the question mark (?) to match exactly one character, or the exclamation mark (!) to negate matching of the specified string.

For both the cmd and path fields, the form field controls whether the specified string is interpreted as a regular expression or as a string that includes wild cards.

Specifying the environment variables for a restricted command

You can use the keep, del, and add settings to control the environment variables used by the commands specified by the cmd string. The keep and del settings are mutually exclusive. The keep field only takes effect if the flag 16 is included in the setting for the flag field. The del field only takes effect if the flag 16 is not included in the setting for the flag field.

Any environment variables kept or deleted are in addition to the default set of the user's environment variables that are either retained or deleted. The default set of environment variables to keep is defined in the dzdo.env_keep configuration parameter in the centrifydc.conf file. The default set of environment variables to delete is defined in the dzdo.env_delete configuration parameter in the centrifydc.conf file. You can also add environment variables to the final set of environment variables resulting from the keep or del fields.

Specifying the restricted command priority

You can use the pri field to specify the command priority when there are multiple matches for the restricted shell command object specified by wild cards. If there are multiple commands specified by this restricted shell command object, the restricted shell command with the higher command priority prevails.

Specifying the umask value for restricted commands

You can use the umask field to define who can execute the command. The umask field specifies a 3-digit octal value that defines read, write, or execute permission for owner, group, and other users. The left digit defines the owner execution rights, the middle digit defines the group execution rights, and the right digit defines other execution rights. Each digit is a combination of binary flags, one flag for each right as follows:

- 4 is read
- 2 is write
- 1 is execute

You add these values add together to define the rights available for each entity. For example, a umask value of 600 indicates read and write permission (4+2) for the owner, but no permissions for the group or other users. Similarly, a umask value of 740 indicates read, write, execute permissions (4+2+1) for the owner, read permissions for the group, but no permissions for other users.

Specifying restricted command properties using the flags field

You can use the **flags** field to define a combination of binary flags, with one flag for each of the following properties:

- 1 to prevent nested command execution. If this flag value is not set, nested command execution is allowed.
- 2 to require authentication with the user's password. You cannot set this flag and the 4 flag simultaneously. If neither 2 nor 4 is set, authentication is not required.
- 4 to require authentication with the run-as user's password

  If you do not set the 2 flag or the 4 flag, authentication is not required.

- 8 to preserve group membership. If this flag value is not set, group membership is not preserved.
- 16 to reset environment variables for the command, deleting the variables specified in the dzdo.env_delete parameter and keeping the variables specified in the keep field. If this flag is not set, the command removes the unsafe environment variables specified in the dzdo.env_delete parameter along with any additional environment variables specified by the del field

You add these values together to define the setting for the flags field. For example, a flags field value of 5 prevents nested command execution and requires authentication using the run-as user's password (1+4).

Return Value

This command returns nothing if it runs successfully.

Examples

```
set_rsc_field description {This is the restricted command description}
```

This example sets the current restricted shell command description field to the "This is the restricted command description" text string.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select the restricted shell command to work with:

- get_rs_commands returns a Tcl list of restricted shell commands in the current zone.
- list_rs_commands lists to stdout the restricted shell commands in the current zone.
- new_rs_command creates a new restricted shell command and stores it in memory.
- select_rs_command retrieves a restricted shell command from Active Directory and stores it in memory.

After you have a restricted shell command stored in memory, you can use the following commands to work with that restricted shell command:

- delete_rs_command deletes the selected command from Active Directory and from memory.
- get_rsc_field reads a field value from the currently selected command.
- save_rs_command saves the selected command with its current settings to Active Directory.

set_rse_field

Use the set_rse_field command to set the value for a specified field in the currently selected restricted shell environment that is stored in memory. The set_rse_field command does not set the field value stored in Active Directory for this restricted shell environment.

This command only sets the field value that is stored in memory. You must save the restricted shell environment using the save_rs_env command for your changes to take effect in Active Directory. If you select another restricted shell environment or end the ADEdit session before saving the currently selected restricted shell environment, your changes will be lost.

You can only use the set_rse_field command if the currently selected zone is a classic4 zone. The command does not work in other type of zones.

Zone Type

Classic only

Syntax

```
set_rse_field field value
```

Abbreviation

srsef

Options

This command takes no options.

Arguments

This command takes the following argument:

field	string	Required. Specifies the name of the field whose value you want to set. The only possible value is: **description**: Text describing the restricted shell environment.
value	depends on field	Required. Specifies the value to assign to the specified field. In most cases, you can assign an empty string to unset a field value.

Return Value

This command returns nothing if it runs successfully.

Examples

```
set_rse_field description {This string is the restricted shell description}
```

This example sets the description field for the current restricted shell environment to the "This string is the restricted shell description" text string.

Related Commands

Before you use this command, you must have a currently selected role stored in memory. The following commands enable you to view and select the role to work with restricted shell environments:

- get_rs_envs returns a Tcl list of restricted shell environments.
- list_rs_envs lists to stdout the restricted shell environments.
- new_rs_env creates a new restricted shell environment and stores it in memory.
- select_rs_env retrieves a restricted shell environment from Active Directory and stores it in memory.

After you have a restricted shell environment stored in memory, you can use the following commands to work with its fields:

- delete_rs_env deletes the current restricted shell environment from Active Directory and from memory.
- get_rse_field reads a field value from the current restricted shell environment.
- save_rs_env saves the restricted shell environment to Active Directory.

set_sd_owner

Use the set_sd_owner command to set the owner of a security descriptor (SD). This command requires you to specify the security descriptor in SDDL (security descriptor definition language) form and the security identifier (SID) of the owner. The command sets and returns the updated security descriptor in SDDL form with the new owner.

Zone Type

Not applicable

Syntax

```
set_sd_owner sddl_string owner_sid
```

Abbreviation

```
sso
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

sddl_string	string	Required. Specifies a security descriptor in SDDL format.
owner_sid	string	Required. Specifies the security identifier (SID) of the owner to set.

Return Value

This command returns an security descriptor in SDDL format if it runs successfully. The security descriptor contains the new owner set by the command.

Examples

This example sets a new owner for a security descriptor. The security descriptor is the first long string after the command. The SID of the new owner is the much shorter string at the end of the command (shown in **boldface**).

set_sd_owner O:DAG:DAD:AI (A;;RCWDWOCCDCLCSWRPWPLOCR;;;DA) (OA;;CCDC;bf967aba-0de6-11d0-a285-00aa003049e2;;AO) (OA;;CCDC;bf967a9c-0de6-11d0-a285-00aa003049e2;;AO) (OA;;CCDC;bf967aa8-0de6-11d0-a285-00aa003049e2;;PO) (A;;RCLCRPLO;;;AU)(OA;;CCDC;4828cc14-1437-45bc-9b07-ad6f015e5f28;;AO) (OA;CIIOID;RP;4c164200-20c0-11d0-a768-00aa006e0529;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;4c164200-20c0-11d0-a768-00aa006e0529;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;5f202010-79a5-11d0-9020-00c04fc2d4cf;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;5f202010-79a5-11d0-9020-00c04fc2d4cf;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;bc0ac240-79a9-11d0-9020-00c04fc2d4cf;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;bc0ac240-79a9-11d0-9020-00c04fc2d4cf;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;59ba2f42-79a2-11d0-9020-00c04fc2d3cf;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;59ba2f42-79a2-11d0-9020-00c04fc2d3cf;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;037088f8-0ae1-11d2-b422-00a0c968f939;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;037088f8-0ae1-11d2-b422-00a0c968f939;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;b7c69e6d-2cc7-11d2-854e-00a0c983f608;bf967a86-0de6-11d0-a285-00aa003049e2;ED) (OA;CIIOID;RP;b7c69e6d-2cc7-11d2-854e-00a0c983f608;bf967a9c-0de6-11d0-a285-00aa003049e2;ED) (OA;CIIOID;RP;b7c69e6d-2cc7-11d2-854e-00a0c983f608;bf967aba-0de6-11d0-a285-00aa003049e2;ED) (OA;CIIOID;RCLCRPLO;;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RCLCRPLO;;bf967a9c-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RCLCRPLO;;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIID;RPWPCR;91e647de-d96f-4b70-9557-d63ff4f3ccd8;;PS) (A;CIID;SDRCWDWOCCDCLCSWRPWPDTLOCR;;;EA) (A;CIID;LC;;;RU) (A;CIID;SDRCWDWOCCLCSWRPWPLOCR;;;BA) **S-1-5-21-1076040321-332654908-468068287-1109***

This example returns the updated security descriptor:

O:S-1-5-21-1076040321-332654908-468068287-1109G:DAD:AI (A;;RCWDWOCCDCLCSWRPWPLOCR;;;DA) (OA;;CCDC;bf967aba-0de6-11d0-a285-00aa003049e2;;AO) (OA;;CCDC;bf967a9c-0de6-11d0-a285-00aa003049e2;;AO) (OA;;CCDC;bf967aa8-0de6-11d0-a285-00aa003049e2;;PO) (A;;RCLCRPLO;;;AU) (OA;;CCDC;4828cc14-1437-45bc-9b07-ad6f015e5f28;;AO) (OA;CIIOID;RP;4c164200-20c0-11d0-a768-00aa006e0529;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;4c164200-20c0-11d0-a768-00aa006e0529;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;5f202010-79a5-11d0-9020-00c04fc2d4cf;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;5f202010-79a5-11d0-9020-00c04fc2d4cf;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;bc0ac240-79a9-11d0-9020-00c04fc2d4cf;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;bc0ac240-79a9-11d0-9020-00c04fc2d4cf;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;59ba2f42-79a2-11d0-9020-00c04fc2d3cf;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;59ba2f42-79a2-11d0-9020-00c04fc2d3cf;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;037088f8-0ae1-11d2-b422-00a0c968f939;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RP;037088f8-0ae1-11d2-b422-00a0c968f939;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RP;b7c69e6d-2cc7-11d2-854e-00a0c983f608;bf967a86-0de6-11d0-a285-00aa003049e2;ED) (OA;CIIOID;RP;b7c69e6d-2cc7-11d2-854e-00a0c983f608;bf967aba-0de6-11d0-a285-00aa003049e2;ED) (OA;CIIOID;RCLCRPLO;;4828cc14-1437-45bc-9b07-ad6f015e5f28;RU) (OA;CIIOID;RCLCRPLO;;bf967a9c-0de6-11d0-a285-00aa003049e2;RU) (OA;CIIOID;RCLCRPLO;;bf967aba-0de6-11d0-a285-00aa003049e2;RU) (OA;CIID;RPWPCR;91e647de-d96f-4b70-9557-d63ff4f3ccd8;;PS) (A;CIID;SDRCWDWOCCDCLCSWRPWPDTLOCR;;;EA) (A;CIID;LC;;;RU) (A;CIID;SDRCWDWOCCLCSWRPWPLOCR;;;BA)

Related Commands

The following commands perform actions related to this command:

- explain_sd converts an SD in SDDL format to a human-readable form.
- remove_sd_ace removes an access control entry (ACE) from an SD.
- add_sd_ace adds an access control entry to an SD.

set_user_password

Use the set_user_password command to set a new password for an Active Directory user or computer in Active Directory.

Zone Type

Not applicable

Syntax

set_user_password UPN password

Abbreviation

sup

Options

This command takes no options.

Arguments

This command takes the following arguments:

UPN	string	Required. Specifies the user principal name (UPN) of the user or computer whose password will be reset.
password	string	Required. Specifies the text string to set as the new password. If the string contains characters that might be misinterpreted by ADEdit's Tcl interpreter ($, for example), enclose the string in braces so that all characters are interpreted literally with no substitutions.

Return Value

This command returns nothing if it runs successfully.

Examples

```
set_user_password adam.avery@acme.com {B4uC$work}
```

This example sets the password for adam.avery@acme.com to B4uC$work.

Related Commands

None.

set_zone_computer_field

Use the set_zone_computer_field command to set the value for a specified field in the currently selected zone computer stored in memory. The set_zone_computer_field command does *not* set a field value stored in Active Directory for this zone computer.

If you change any fields, you must save the zone computer using the save_zone_computer command for your changes to take effect in Active Directory. If you select another zone computer or end the ADEdit session before saving the currently selected zone computer, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

```
set_zone_computer_field field value
```

Abbreviation

szcf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field whose value want set. The possible values are: **cpus**: Set to a positive integer for the number of CPUs in the computer. **enabled**: Set the value to 1, y, yes, or true if the computer is enabled in the zone or to 0, n, no, or false if the computer is not enabled in the zone. All other values throw an exception. **licensetype**: Specifies the type of license a computer uses. The valid values for this field are server or workstation.
value		Required. Specifies the value to assign to the specified field. In some cases, you can assign a dash (-) to a field to unset the field value. However, this is not supported for all fields or all zone types.

Return Value

This command returns nothing if it runs successfully.

Examples

```
set_zone_computer_field cpus 2
```

This example sets the current zone computer's number of CPUs to 2.

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and manage the zone computers:

- get_zone_computers returns a Tcl list of the Active Directory names of all zone computers in the current zone.
- list_zone_computers lists to stdout the zone computers in the current zone.
- new_zone_computer creates a new zone computer and stores it in memory.
- select_zone_computer retrieves a zone computer from Active Directory and stores it in memory.

After you have a zone computer stored in memory, you can use the following commands to work with that zone computer:

- delete_zone_computer deletes the zone computer from Active Directory and from memory.
- get_zone_computer_field reads a field value from the currently selected zone computer.
- save_zone_computer saves the zone computer with its current settings to Active Directory.
- set_zone_computer_field sets a field value in the currently selected zone computer.

set_zone_field

Use the set_zone_field command to set the value for a specified field in the currently selected zone stored in memory. The set_zone_field command does *not* set a field value stored in Active Directory for the selected zone.

If you change any fields, you must save the zone using the save_zone command for your changes to take effect in Active Directory. If you select another zone or end the ADEdit session before saving the currently selected zone, your changes will be lost.

This command is not applicable if the currently selected zone is a classic-computer zone. You cannot set zone field values for classic-computer zones.

Zone Type

Classic and hierarchical

Syntax

```
set_zone_field field value
```

Abbreviation

szf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field that you want to set.
value		Required. Specifies the value to assign to the specified field. In most cases, you can assign an empty string to unset the field value. For more information about the values set by the zone fields, see the Field value section.

The data type required depends on the field you are setting. The possible field values are:

- **availableshells**: Sets the list of shells available to choose from when adding new users to the zone.
- **block.parent.zgroup**: Sets the value of the block.parent.zgroup field in the zone object's description.
- **cloudurl**: Sets the URL of the cloud instance associated with the selected zone.
- **computers**: Sets the UPN of the computer group assigned to the selected computer role.
- **customAttr**: Sets custom text strings for the zone. This field is only applicable for hierarchical zones.
- **defaultgid**: Sets the default primary group to assign to new users.
- **defaultgecos**: Sets the default GECOS data to assign to new users.
- **defaulthome**: Sets the default home directory to assign to new users.
- **defaultshell**: Sets the default shell to assign to new users.
- **description**: Sets the text string that describes the zone.
- **gidnext**: Sets the next GID to use when auto-assigning GID numbers to new groups.
- **gidreserved**: Sets the GID number or range of numbers (1-100) that are reserved.
- **groupname**: Sets the default group name used for new groups in the zone.
- **nisdomain**: Sets the name of the NIS domain for NIS clients to use.
- **nssvar**: Sets the NSS substitution variable to add to the zone's list of substitution variables.
- **parent**: Sets the distinguished name of the zone's parent zone.
- **sfudomain**: Sets the Windows domain name for the SFU zone.
- **sid2iddomainmap**: Sets the domain ID map for the seleted zone. Specify the mapping with a comma-separated key value pairs string. See the examples section for a sample command with this field. Note that the range of domain IDs is 0 to 511. Duplicate mapping entries are not allowed (domain names are not case-sensitive). This field is not supported for auto zones nor classic zones.
- **tenantid**: Returns the Delinea Platform tenant ID for the zone. This field is only applicable for hierarchical zones.
- **uidnext**: Sets the next UID to use when auto-assigning UID numbers to new users.
- **uidreserved**: Sets the UID number or range of numbers (1-100, for example) that are reserved.
- **username**: Sets the default user name used for new users in the zone.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example sets the computer group associated with the currently selected computer role to linux_machines in the domain acme.com:

```
set_zone_field computers linux_machines@acme.com
```

The following example sets the parent zone of the current zone to global in the domain acme.com:

```
szf parent “CN=global,CN=zones,CN=Acme,CN=Program Data,DC=acme,DC=com”
```

The following example sets the domain ID mapping for the selected zone:

```
set_zone_field sid2iddomainmap domain0.test=0,domain1.test=1,domain2.test=2
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone to work with:

- create_zone creates a new zone in Active Directory.
- get_zones returns a Tcl list of all zones within a specified domain.
- select_zone retrieves a zone from Active Directory and stores it in memory.

After you have a zone stored in memory, you can use the following commands to work with that zone:

- delegate_zone_right delegates a zone use right to a specified user or computer.
- delete_zone deletes the selected zone from Active Directory and memory.
- get_child_zones returns a Tcl list of child zones, computer roles, or computer zones.
- get_zone_field reads a field value from the currently selected zone.
- get_zone_nss_vars returns the NSS substitution variable for the selected zone.
- save_zone saves the selected zone with its current settings to Active Directory.

set_zone_group_field

Use the set_zone_group_field command to set the value for a specified field in the currently selected zone group stored in memory. The set_zone_group_field command does *not* set a field value stored in Active Directory for the selected zone group.

If you change any fields, you must save the zone group using the save_zone_group command for your changes to take effect in Active Directory. If you select another zone group or end the ADEdit session before saving the currently selected zone group, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

set_zone_group_field field value

Abbreviation

szgf

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field that you want to set. The possible values are: **gid**: Sets the numeric identifier for the group (GID). **name**: Sets the text string for the group name. **required**: Specifies whether the zone group is required. Set the value to 1, y, yes, or true if the group is required in the zone or to 0, n, no, or false if the group in not required in the zone. All other values throw an exception.If a group is required, users cannot remove the group from their active set of groups. You can also specify AIX extended attributes as the field to set an extended attribute value for a group. Extended attribute fields start with the aix. prefix. For example, the admin extended attribute can be set by specifying aix.admin as the field.
value		Required. Specifies the value to assign to the specified field. The data type depends on the field specified. In some cases, you can assign a dash (-) to a field to unset the field value. However, this is not supported for all fields or all zone types.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example sets the current zone group's UNIX group name to managers.

```
set_zone_group_field name managers
```

If the current group is on AIX, you can set AIX group extended attributes and values. For example, to identify the current group as an administrative group, you can set the admin extended attribute:

```
set_zone_group_field aix.admin true
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select zone groups:

- get_zone_groups returns a Tcl list of the Active Directory names of all zone groups in the current zone.
- list_zone_groups lists to stdout the zone groups in the current zone.
- new_zone_group creates a new zone group and stores it in memory.
- select_zone_group retrieves a zone group from Active Directory and stores it in memory.

After you have a zone group stored in memory, you can use the following commands to work with that zone group:

- delete_zone_group deletes the selected zone group from Active Directory and from memory.
- get_zone_group_field reads a field value from the current zone group.
- save_zone_group saves the selected zone group with its current settings to Active Directory.

set_zone_user_field

Use the set_zone_user_field command to set the value for a specified field in the currently selected zone user stored in memory. The set_zone_user_field command does *not* set a field value stored in Active Directory for this zone user.

If you use ADEdit to change any field, you must save the zone user using the save_zone_user command for your changes to take effect in Active Directory. If you select another zone user or end the ADEdit session before saving the currently selected zone user, your changes will be lost.

Zone Type

Classic and hierarchical

Syntax

```
set_zone_user_field field value
```

Abbreviation

```
szuf
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

field	string	Required. Specifies the name of the field y want set. The possible values are: **uname**: Sets the text string to use for the UNIX user name. If you are setting this field in a Service for UNIX (SFU) zone, this name must be unique among all the SFU zones. If you duplicate a user name that exists in another SFU zone, that user will be moved to the currently selected SFU zone when you save the zone user. **uid**: Sets the numeric identifier for the user (UID). **gid**: Sets the numeric identifier for the user's primary group (GID).Set the value to 0x80000000 to indicate a private group (the user's UID is used as the GID). **gecos**: Sets the text string to use for the user's GECOS field. **home**: Sets the text string that specifies the user's home directory. **shell**: Sets the text string that specifies the user's default shell type. **enabled**: Specifies whether user is enabled or not. This field is only valid in classic zones. Set the value to 1, y, yes, or true if the user is enabled in the zone or to 0, n, no, or false if the user is disabled in the zone. All other values throw an exception. You can also specify AIX extended attributes as the field to set an extended attribute value for a zone user.

value		Required. Specifies the value to assign to the specified field. The data type depends on the field specified. In some cases, you can assign a dash (-) to a field to unset the field value. However, this is not supported for all fields or all zone types.

Return Value

This command returns nothing if it runs successfully.

Examples

The following example sets the current zone user's UNIX user name to buzz:

```
set_zone_user_field uname buzz
```

This following example sets the current zone user's primary GID to the same value as the user's UID:

```
set_zone_user_field gid 0x80000000
```

If the current zone user is on AIX, you can set extended attributes and values. For example:

```
select_zone_user aixu1@acme.com set_zone_user_field aix.ttys u1,u2,u3 set_zone_user_field aix.fsize 209715 set_zone_user_field aix.core 2097151 set_zone_user_field aix.cpu -1
save_zone_user
```

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select a zone user:

- get_zone_users returns a Tcl list of the Active Directory names of all zone users in the current zone.
- list_zone_users lists to stdout the zone users and their NSS data in the current zone.
- new_zone_user creates a new zone user and stores it in memory.
- select_zone_user retrieves a zone user from Active Directory and stores it in memory.

After you have a zone user stored in memory, you can use the following commands to work with that zone user:

- delete_zone_user deletes the selected zone user from Active Directory and from memory.
- get_zone_user_field reads a field value from the currently selected zone user.
- save_zone_user saves the selected zone user with its current settings to Active Directory.

show

Use the show command to display the current context of ADEdit. The command shows the domains ADEdit is bound to, the objects that are currently selected, and all available data for each selected object as it is stored in memory.

You should note that the command returns stored object data as it currently exists in memory. If you use ADEdit commands to change objects, but have not yet saved the data back to Active Directory, the information returned by the show command will not match the object data stored in Active Directory.

Zone Type

Not applicable

Syntax

```
show [all|bind|zone|user|computer|assignment|object|group| pamright|dzcommand|nismap|role|license|rse|rscommand localuser|localgroup]
```

Abbreviation

None.

Options

This command takes no options.

Arguments

This command takes the following argument of type string:

[all | user | bind | zone | user | computer | assignment | object | group | pamright | dzcommand | nismap | role | license | rse | rscommand | localuser | localgroup]

You can limit the information returned by specifying one of the following arguments. If no argument is supplied, the default is **all**.

- **all** returns the complete context of ADEdit—all of its current bindings and all currently selected objects in memory.
- **bind** returns ADEdit's currently bound domains and the server bound in each domain.
- **zone** returns the currently selected zone.
- **user** returns the currently selected user object.
- **computer** returns the currently selected zone computer.
- **assignment** returns the currently selected role assignment
- **object** returns the currently selected Active Directory object.
- **group** returns the currently selected zone group.
- **pamright** returns the currently selected PAM application right.
- **dzcommand** returns the currently selected UNIX command.
- **nismap** returns the currently selected NIS map.
- **role** returns the currently selected role.
- **license** returns the forest list where valid licenses have been found (it only reports the forests that have been queried).
- **rse** returns the currently selected restricted shell environment.
- **rscommand** returns the currently selected restricted shell command.
- **localuser** returns the currently selected local user.
- **localgroup** returns the currently selected local group.

Return Value

This command returns domain bindings and/or object data, depending on the supplied argument.

Examples

show

This example returns information all bound domains and selected objects similar to this:

Bindings: acme.com: calla.acme.com Current zone: CN=global,CN=Zones,CN=Acme,CN=Program Data,DC=acme,DC=com Current nss user: adam.avery@acme.com:adam:10001:10001:%{u:samaccountname}:%{home}/%{user}:%{shell}:

Related Commands

None.

sid_to_escaped_string

Use the sid_to_escaped_string command to specify a security identifier (SID) and have it converted to an escaped string format that works in an LDAP filter.

Zone Type

Not applicable

Syntax

sid_to_escaped_string sid

Abbreviation

stes

Options

This command takes no options.

Arguments

This command takes the following argument:

sid	string	Required. Specifies a security identifier (SID).

Return Value

This command returns an escaped string form of the supplied security identifier.

Examples

```
sid_to_escaped_string S-1-5-21-2076040321-3326545908-468068287-1157
```

This example returns an escaped string:

```
\01\05\00\00\00\00\00\05\15\00\00\00\81\dc\bd\7b\f4\0f\47\c6\bf\27\e6\1b\85\04\00\00
```

Related Commands

The following commands perform actions related to this command:

- sid_to_uid converts an Active Directory security identifier to a user ID (UID).
- principal_from_sid searches Active Directory for an security identifier and returns the security principal associated with the security identifier.

sid_to_uid

Use the sid_to_uid command to specify a security identifier (SID) of an Active Directory user to look up the Active Directory user in Active Directory. This command converts the user's security identifier to a numeric identifier for the user ID (the UID value). This conversion process is the same process used to generate UIDs for Delinea Express users or when you use Auto Zone to automatically generate UIDs for users.

Zone Type

Not applicable

Syntax

```
sid_to_uid [-domainidmap] sid
```

Abbreviation

```
stu
```

Options

This command takes the following options:

-domainidmap	Optional. Specifies a domain ID mapping for the selected zone. Before using this field, you must have a selected zone stored in memory. This field is not supported for auto zones nor classic zones. If the selected zone does not already have a domain ID mapping, the UID is generated normally. If the selected zone has a domain ID mapping already and the domain to which this SID belongs exists in the specified domain ID mapping, the UID is generated with the algorithm based on the domain ID mapping. If the selected zone has a domain ID mapping already but the domain to which this SID belongs does not exist in the specified domain ID mapping, the UID is generated normally. For example: sid_to_uid -domainidmap S-1-5-21-2076040321-3326545908-468068287-1157

Arguments

This command takes the following argument:

sid	string	Required. Specifies a security identifier (SID).

Return Value

This command returns a numeric user ID.

Examples

This example returns a unique UID for the user: **1874853888**

Related Commands

The following commands perform actions related to this command:

- principal_from_sid searches Active Directory for an SID and returns the security principal associated with the SID.

validate_license

Use the validate_license command to specify a path to the Delinea license container and determine if there is a valid license. If there is a valid license, the command stores an indicator in the ADEdit current context. If the command does not find a valid license, it reports an error and exits.

ADEdit requires a valid license before a zone is created. The create_zone and create_computer_role commands do an implicit search for a valid license. For example, you can call create_zone and let it attempt to find the container and validate the license. If that command fails to find a valid license, use validate_license to validate the license container from an explicit path.

You can call the validate_license command multiple times. Successive indicators take precedence. The command writes separate indicators for each forest—that is, each license is valid for a forest. You can use the show license command to see the list of forests that have been found to have a valid license.

Do not call validate_license before you bind to the domain.

The validate_license context is deleted when ADEdit exits.

Zone Type

Not applicable

Syntax

validate_license path

Abbreviation

vl

Options

This command takes no options.

Arguments

This command takes the following argument:

path	string	Required. Specifies the path is the license container's distinguished name (DN).

Return Value

This command returns nothing.

Examples

validate_license “CN=Licenses,OU=Acme,DC=acme,DC=com”

This example looks in the acme.com/Acme/Licenses container for a valid license.

Related Commands

The following commands perform actions related to this command:

- bind defines the current domain.
- create_zone does in implicit validate license during execution.
- show with the license option lists all forests that have a valid license.

write_role_assignment

Use the write_role_assignment command to write the selected role assignment with its current settings to a file in JSON format. You can use this command to save the currently selected role assignment that is stored in memory to a file with the permissions of 0600. If the file already exists, the command truncates the file. If the command cannot open or write to the specified file, the command fails with an error message.

Zone Type

Hierarchical only

Syntax

write_role_assignment file

Abbreviation

wra

Options

This command takes no options.

Arguments

This command takes the following argument:

file	string	Required. Specifies the file to which the command writes the role assignment.

Return Value

This command returns nothing.

Examples

write_role_assignment roleassignment.txt

Related Commands

Before you use this command, you must have a currently selected zone stored in memory. The following commands enable you to view and select role assignment to work with:

- get_role_assignments returns a Tcl list of role assignments in the current zone.
- list_role_assignments lists to stdout the role assignments in the current zone.
- new_role_assignment creates a new role assignment and stores it in memory.
- select_role_assignment retrieves a role assignment from Active Directory and stores it in memory.
- save_role_assignment saves a role assignment to Active Directory.

After you have a role assignment stored in memory, you can use the following commands to work with that role assignment's attributes, delete the role assignment, or save information for the role assignment:

- delete_role_assignment deletes the selected role assignment from Active Directory and from memory.
- get_role_assignment_field reads a field value from the current role assignment.
- save_role_assignment saves the selected role assignment with its current settings to Active Directory.
- set_role_assignment_field sets a field value in the current role assignment.
- write_role_assignment saves the selected role assignment to a file.

ADEdit Tcl Procedure Library Reference

This chapter describes the commands in the ade_lib Tcl library. The command descriptions are in alphabetical order. The syntax of each command shows optional elements in [square brackets] and variables in *italics*.

add_user_to_group

Use the add_user_to_group command to add an Active Directory user to an Active Directory group.

Syntax

add_user_to_group *user group*

Options

This command takes no options.

Arguments

This command takes the following arguments:

user	string	Required. Specifies the user principal name (UPN) of the Active Directory user to add.
group	string	Required. Specifies the UPN of the Active Directory group to which to add the user.

Return value

This command returns nothing if it runs successfully.

Examples

```
add_user_to_group adam.avery@acme.com pubs@acme.com
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_aduser creates a new Active Directory user account and sets its password.
- create_adgroup creates a new Active Directory group account and specifies its scope.
- create_user creates a new zone user based on an existing Active Directory user, assigns field values to the new user, and saves the new user to Active Directory.
- create_group creates a new zone group based on an existing Active Directory group, assigns it a UNIX name and group ID, and saves the new group to Active Directory.
- remove_user_from_group removes an Active Directory user from an Active Directory group.

convert_msdate

Use the convert_msdate command to specify a Microsoft date value from an Active Directory object field such as pwdLastSet and convert it into a human-readable form.

Syntax

convert_msdate *msdate*

Options

This command takes no options.

Arguments

This command takes the following argument:

msdate	string	Required. Specifies the Microsoft date value for conversion.

Return value

This command returns the day of the week, the day of the month, the time of day using a 24-hour clock, the time zone, and the year.

Examples

```
convert_msdate [get_object_field pwdLastSet]
```

This example returns converted into a format similar to this:

Thu Mar 24 14:40:26 PDT 2010

The unseen value returned by `get_object_field pwdLastSet` in this example was 129140268240625000, which was converted to a human-readable time and date.

Related Tcl library commands

None.

create_adgroup

Use the `create_adgroup` command to create a new Active Directory group account with a specified distinguished name (DN), sAMAccountName, and group scope.

Syntax

```
create_adgroup dn sam gscope`
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

dn	string	Required. Specifies the distinguished name of the new group.
sam	string	Required. Specifies the sAMAccountName of the new group.
gscope	string	Required. Specifies the scope for the new group. The possible values are: global universal local (for Domain local)

Return value

This command returns nothing if it runs successfully.

Examples

```
create_adgroup {CN=pubs,CN=Users,DC=acme,DC=com} pubs global
```

This example creates the group pubs with a global scope in the Active Directory Users container.

```
create_adgroup {CN=ApacheAdmins,OU=Unix Groups,OU=ACME,DC=acme,DC=com} pubs global
```

This example creates the group ApacheAdmins in the organizational unit Unix Groups, which is in the organizational unit ACME.

Related Tcl library commands

The following commands perform actions related to this command:

- `create_aduser` creates a new Active Directory user account and sets its password.
- `create_user` creates a new zone user based on an existing Active Directory user, assigns field values to the new user, and saves the new user to Active Directory.
- `create_group` creates a new zone group based on an existing Active Directory group, assigns it a UNIX name and group ID, and saves the new group to Active Directory.
- `add_user_to_group` adds an Active Directory user to an Active Directory group.
- `remove_user_from_group` removes an Active Directory user from an Active Directory group.

create_aduser

Use the `create_aduser` command to create a new Active Directory user account with a specified distinguished name (DN), user principal name (UPN), sAMAccountName, and password.

Syntax

```
create_aduser dn upn sam pw ?dname? ?gname? ?spn? ?gecos?
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

dn	string	Required. Specifies the distinguished name of the new user.
upn	string	Required. Specifies the user principal name of the new user.
sam	string	Required. Specifies the sAMAccountName of the new user.
pw	string	Required. Specifies the password for the new user.
dname	string	Optional. Specifies the displayName for the new user.
gname	string	Optional. Specifies the givenName for the new user.
spn	string	Optional. Specifies the servicePrincipalName for the new user.
gecos	string	Optional. Specifies the gecos for the new user.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_aduser {CN=ulysses urkham,CN=Users,DC=acme,DC=com} ulysses.urkham@acme.com ulysses.urkham {5$6fEr2B}
```

This example creates a new Active Directory user account ulysses.urkham@acme.com.

Related Tcl library commands

- create_adgroup creates a new Active Directory group account and specifies its scope.
- create_user creates a new zone user based on an existing Active Directory user, assigns field values to the new user, and saves the new user to Active Directory.
- create_group creates a new zone group based on an existing Active Directory group, assigns it a UNIX name and group ID, and saves the new group to Active Directory.
- add_user_to_group adds an Active Directory user to an Active Directory group.
- remove_user_from_group removes an Active Directory user from an Active Directory group.

create_assignment

Use the create_assignment command to create a new role assignment for a user or group and save it to Active Directory.

Syntax

```
create_assignment upn role[/zonename] [from] [to] [description]
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

upn	string	Required. Specifies the user principal name of the Active Directory user or group to whom to assign the role.
role*/[zonename]*	string	Required. Specifies the name of the role to assign and (optional) the name of the zone in which the role is assigned. If the zone name is present, a slash(/) separates the role name and the zone name. If the zone name isn't present, the role assignment occurs in the currently selected zone.
from	string	Optional. Specifies the start date and time for the role assignment. The start date and time can be expressed using the format: yr-mon-day hour:min
to	string	Optional. Specifies the expiration date and time for the role is assignment. The expiration date and time can be expressed using the format: yr-mon-day hour:min
description	string	Optional. Specifies a description of the role assignment.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_assignment ulysses.urkham@acme.com admin/support {} {} "Test assignment"
```

This example creates a role assignment for the rights defined in the role "admin" from the "support" zone to the user Ulysses Urkham. The role assignment is set to start immediately (by specifying) and never expire (by specifying the second) and has an optional description.

```
create_assignment amy@example.demo mgr {2021-03-31 10:51} {2021-03-31 12:51}
```

This example creates a role assignment for the rights defined in the role "mgr" from the current zone to the user amy@example.com. This role assignment is set to start at a specific time and expire two hours later and has no description.

Related Tcl library commands

None.

create_dz_command

Use the create_dz_command command to create a new UNIX privileged command in the currently selected zone.

Syntax

```
create_dz_command dzc cmd ?desc? ?form? ?dzdo_runas? ?dzsh_runas? ?flags? ?pri? ?umask? ?path? ?selinux_role? ?selinux_type?
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

name	string	Required. Specifies the name to assign to the new UNIX command.
command	string	Required. Specifies the UNIX command string or strings. You can use wild cards or a regular expression.
description	string	Optional. Specifies text describing the UNIX command.
form	integer	Optional. Specifies whether the command and path strings use wild cards (0) or a regular expression (1).
dzdo_runas	string	Optional. Specifies the list of users and groups that can run this command under dzdo (similar to sudo). Users can be listed by user name or UID.
selinux_role	string	Optional. Specifies the SELinux role to use when constructing a new security context for command execution. Note that selinux_role is only supported on Red Hat Enterprise Linux systems and effective only on systems with SELinux enabled and joined to a hierarchical zone.
selinux_type	string	Optional. Specifies the SELinux type to use when constructing a new security context for command execution. Note that selinux_type is only supported on Red Hat Enterprise Linux systems and effective only on systems with SELinux enabled and joined to a hierarchical zone.
dzsh_runas	string	Optional. Specifies the list of users and groups that can run this command in the restricted shell environment (dzsh). Users can be listed by user name or UID.
flags	integer	Optional. Specifies an integer that defines a combination of different properties for the command. For more information about setting this field, see set_dzc_field.
pri	integer	Optional. Specifies the command priority for the restricted shell command object. For more information about setting this field, see set_dzc_field.
umask	integer	Optional. Specifies an integer that defines who can execute the command. For more information about setting this field, see set_dzc_field.
path	string	Optional. Specifies the path to the command's location. You can use wild cards, a regular expression, or one of the following keywords: USERPATH to set to the command path to the equivalent of the Standard user path option. SYSTEMPATH to set to the path to the equivalent of the Standard system path option. SYSTEMSEARCHPATH to set to the path to the equivalent of the System search path option. If you don't specify this argument, the default is USERPATH.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_dz_command testvi vi {Test UNIX command vi} {} {sfapps:perez,cody} {} {16}
```

Related Tcl library commands

None.

create_group

Use the create_group command to create a new zone group for the currently selected zone. This command creates the new group based on an existing Active Directory group. It also assigns the new group a new UNIX profile that includes the UNIX group name and the UNIX group numeric identifier (GID).

Syntax

```
create_group upn name gid ?req?
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

upn	string	Required. Specifies the user principal name of the Active Directory group to use as the basis for the new zone group.
name	string	Required. Specifies the UNIX group name of the new zone group. For hierarchical zones only, specifying "-" unsets the name value.
gid	string	Required. Specifies the UNIX group ID to assign to the new zone group. For hierarchical zones only, specifying "-" unsets the gid value.
req	string	Optional. Specifies whether the zone group is required. Set the value to 1, y, yes, or true if the group is required in the zone or to 0, n, no, or false if the group in not required in the zone. All other values throw an exception. If a group is required, users cannot remove the group from their active set of groups.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_group pubs@acme.com pubs 1094
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_aduser creates a new Active Directory user account and sets its password.
- create_adgroup creates a new Active Directory group account and specifies its scope.
- create_user creates a new zone user based on an existing Active Directory user, assigns field values to the new user, and saves the new user to Active Directory.
- add_user_to_group adds an Active Directory user to an Active Directory group.
- remove_user_from_group removes an Active Directory user from an Active Directory group.

create_nismap

Use the create_nismap command to create a new NIS map in the currently selected zone.

Syntax

```
create_nismap map key:value comment
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

map	string	Required. Specifies the name of the new NIS map
key	string	Required. Specifies the key of the NIS map entry.
value	string	Required. Specifies the value of the NIS map entry.
comment	string	Required. Specifies the comment for the NIS map entry.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_nismap animals {{cat:1 {The cat says "Mew\!".}} {cow:1 {The cow says "Moo\!".}}}
```

Related Tcl library commands

None.

create_pam_app

Use the create_pam_app command to create a new PAM application access right in the currently selected zone.

Syntax

```
create_pam_app name application description
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

name	string	Required. Specifies the name to assign to the new PAM application access right.
		Required. Specifies the name of the PAM application that is allowed to use the adclient PAM authentication service. The name can be literal, or it can contain ? or * wild card characters to specify multiple applications. Note that in a classic zone, setting the **application**

application	string	field changes the name of the PAM application right. For example, assume you create a new PAM application right in a classic zone using a command like this: create_pam_app myftp newftp "Sample PAM FTP application". The PAM application right itself will be renamed as newftp: list_pam_apps newftp: Sample PAM FTP application. Therefore, in a classic zone, you should always specify the same string for the name and application arguments. In a hierarchical zone, you can specify different strings for the arguments.
description	string	Optional. Specifies the text describing the PAM application.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_pam_app testvi vi {Test UNIX command vi}
```

Related Tcl library commands

None.

create_role

Use the create_role command to create a new role definition in the currently selected zone.

Syntax

```
create_role name description sysrights pamrights cmdrights allowlocal rsenv visible
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

name	string	Required. Specifies the name to assign to the new role.
description	string	Specifies the text string that describes the role.
sysrights	integer	Specifies the system rights granted to the role. This value is an integer that represents a combination of binary flags, one for each system right. This field is not applicable in classic zones.
pamrights[/zonename]	string	Specifies the PAM application rights to add to the currently selected role. If the PAM application right that you want to add is defined in the current zone, the *zonename* argument is optional. If the PAM application right is defined in a zone other than the currently selected zone, the *zonename* argument is required to identify the specific PAM application right to add.
cmdrights[/zonename]	string	Specifies the UNIX command rights to add to the currently selected role. If the UNIX command right that you want to add is defined in the current zone, the *zonename* argument is optional. If the UNIX command right is defined in a zone other than the currently selected zone, the *zonename* argument is required to identify the specific UNIX command right to add.
allowlocal	Boolean	Specifies whether local users can be assigned to the role. If this argument is specified, local users can be assigned to the role. This argument is only applicable if the zone is a hierarchical zone.

rsenv	string	Specifies a restricted shell environment for the role you are creating. This argument is only applicable if the zone is a classic zone.
visible	Boolean	Specifies whether the account profiles for Active Directory users in the role are visible on computers in the zone. This argument is only applicable if the zone is a hierarchical zone.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_role dba {Database admins - US} 11 {{oracle} {ftp}} {{testvi} {ora-stp}}
```

Related Tcl library commands

None.

create_rs_command

Use the create_rs_command command to create a new restricted shell command for the currently selected restricted shell environment.

Syntax

```
create_rs_command rsc_name cmd description form dzsh_runas flags pri umask path
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

rsc_name	string	Required. Specifies the name of the restricted shell command.
cmd	string	Required. Specifies the restricted shell command string or strings. You can use wild cards or a regular expression.
description	string	Optional. Specifies the text describing the restricted shell command.
form	integer	Optional. Indicates whether the cmd and path strings use wild cards (0) or a regular expression (1).
dzsh_runas	string	Optional. Specifies the list of users and groups that can run this command in a restricted shell environment (dzsh). Users can be listed by user name or UID.
flags	string	Optional. Specifies an integer that specifies a combination of different properties for the command. For more information about setting this field, see set_rsc_field.
pri	integer	Optional. Specifies the command priority for the restricted shell command object. For more information about setting this field, see set_rsc_field.
umask	integer	Optional. Specifies an integer that defines who can execute the command. For more information about setting this field, see set_rsc_field.
		Optional. Specifies the path to the restricted command. You can use wild cards, a regular expression, or one of the following

path	string	keywords: USERPATH to set to the command path to the equivalent of the Standard user path option. SYSTEMPATH to set to the path to the equivalent of the Standard system path option. SYSTEMSEARCHPATH to set to the path to the equivalent of the System search path option. If you don't specify this argument, the default is USERPATH.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_rs_command test_id id {Sample restricted command description}
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_rs_env creates a new restricted shell environment.

create_rs_env

Use the create_rs_env command to create a new restricted shell environment for the currently selected zone.

Syntax

```
create_rs_env rse_name rse_description
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

rse_name	string	Required. Specifies the name of the new restricted shell environment.
rse_description	string	Optional. Specifies the description for the new restricted shell environment.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_rs_env restrictedenv “This is a restricted shell environment”
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_rs_command creates a new restricted shell command.

create_user

Use the create_user command to create a new zone user for the currently selected zone. This command creates the new user based on an existing Active Directory user. It also assigns the new user a new UNIX profile that includes the user name, user ID, primary group ID, GECOS data, home directory, shell type,

and role (or in classic zones whether the user is enabled or disabled).

You can assign the new user a role in a non-classic zone or you can enable or disable the new user in a classic zone. In a non-classic zone, create_user uses whatever role you specify to create a new role assignment object that links the new zone user to the specified role.

Syntax

```
create_user UPN uname uid gid gecos home shell role
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

UPN	string	Required. Specifies the user principal name of the Active Directory user to use as the basis for the new zone user.
uname	string	Required. Specifies the user name of the new zone user. For hierarchical zones, you can specify a dash (-) for this argument if you don't want to set the user name.
uid	string	Required. Specifies the user ID for the new zone user. For hierarchical zones, you can specify a dash (-) for this argument if you don't want to set the user ID.
gid	string	Required. Specifies the group ID for the new zone user. For hierarchical zones, you can specify a dash (-) for this argument if you don't want to set the group ID.
gecos	string	Required. Specifies the GECOS value (new user account information) for the new zone user. For hierarchical zones, you can specify a dash (-) for this argument if you don't want to set the GECOS value. You can't set the GECOS value if the currently selected zone is a classic zone.
home	string	Required. Specifies the home directory for the new zone user. For hierarchical zones, you can specify a dash (-) for this argument if you don't want to set the home directory.
shell	string	Required. Specifies the shell type for the new zone user. For hierarchical zones, you can specify a dash (-) for this argument if you don't want to set the shell type.
role	string or Boolean value	Required. For classic zones, this argument determines whether to enable or disable the new zone user. A value of 1, Y, or y enables the user. Any other value disables the user. For hierarchical zones, this argument identifies the role to assign to the new zone user. You can specify a dash (-) for this argument if you don't want to set the role. However, a role must be assigned before the new zone user has access to computers in hierarchical zones.

Return value

This command returns nothing if it runs successfully.

Examples

```
create_user ulysses.urkham@acme.com ulysses 1005 - - %{home}/%{user} %{shell} -
```

This example creates a zone user "ulysses" based on the Active Directory user ulysses.urkham@acme.com. It sets a UID, does not set a GID or GECOS value by using dashes, sets home and shell values, and does not set a role value (specified by using a dash).

Related Tcl library commands

- create_aduser creates a new Active Directory user account and sets its password.

- create_adgroup creates a new Active Directory group account and specifies its scope.
- create_group creates a new zone group based on an existing Active Directory group, assigns it a UNIX name and group ID, and saves the new group to Active Directory.
- add_user_to_group adds an Active Directory user to an Active Directory group.
- remove_user_from_group removes an Active Directory user from an Active Directory group.

decode_timebox

Use the decode_timebox command to convert an internal timebox value that defines when a role is enabled or disabled into a format that can be evaluated. The command converts the internal hexadecimal value for a role timebox to a hexadecimal timebox value format as described in **Timebox Value Format**.

The command returns a 168-bit value in hexadecimal format that delineates the hours of the week from midnight Sunday to 11 PM Saturday in order from most-significant bit to least-significant bit. If a bit is set to 1, its corresponding hour is enabled for the role. If set to 0, its corresponding hour is disabled.

This command is useful for deciphering the value returned by the get_role_field for the timebox field.

Syntax

```
decode_timebox strTimeBox
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

strTimeBox	hex	A 42-digit hexadecimal timebox value. A value of zero disables all hours of the week. A value of FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF enables all hours of the week.

Return value

This command returns a decoded hexadecimal value that is the timebox value for a role.

Examples

```
>select_role test1
>get_role_field timebox
FFF7FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF
>package require ade_lib
1.0
>decode_timebox [grf timebox]
```

This example returns the decoded 42 hexadecimal that indicates the role is disabled from midnight to one on Sunday:

7FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF

Related Tcl library commands

The following commands perform actions related to this command:

- encode_timebox converts a readable timebox value to an internal timebox format.
- modify_timebox defines an hour of the week and enables or disables that hour in the timebox value.

encode_timebox

Use the encode_timebox command to convert a human-readable timebox value that defines the when a role is enabled or disabled to an internal timebox value format.

The command converts the hexadecimal timebox value format described in **Timebox Value Format** to the internal hexadecimal value for a role. The command accepts a 168-bit value in hexadecimal format that delineates the hours of the week from midnight Sunday to 11 PM Saturday from most-significant bit to leastsignificant bit. If a bit is set to 1, its corresponding hour is enabled for the role. If set to 0, its corresponding hour is disabled.

This command is useful for setting the timebox field with the set_role_field command.

Syntax

```
encode_timebox strTimeBox
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

strTimeBox	hex	A 42-digit hexadecimal timebox value. A value of zero disables all hours of the week. A value of FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF enables all hours of the week.

Return value

This command returns a decoded hexadecimal value that is the timebox value for a role.

Examples

```
>package require ade_lib
>set tb 7FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF
>encode_timebox \$tb
```

This example returns the encoded 42 hexadecimal that indicates the role is disabled from midnight to one on Sunday:

```
FFF7FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF
```

Related ade_lib Tcl library commands

The following commands perform actions related to this command:

- decode_timebox converts an internal timebox value to a decipherable format.
- modify_timebox defines an hour of the week and enables or disables that hour in the timebox value.

explain_groupType

Use the explain_groupType command to convert a groupType value from an Active Directory object field into human-readable form.

Syntax

```
explain_groupType gt
```

Options

This command takes no options.

Arguments

This command takes the following argument:

gt	string	Required. A groupType value for conversion.

Return value

This command returns a hexadecimal version of the supplied value followed by the names of any flags that are set in the value.

Examples

```
explain_groupType [get_object_field groupType]
```

This example returns:

```
80000004 DOMAIN_LOCALSECURITY
```

The unseen value returned by get_object_field groupType in this example was -2147483644, which was converted to the hexadecimal value 80000004 and the name of the set flag DOMAIN_LOCALSECURITY.

Related Tcl library commands

The following commands perform actions related to this command:

- explain_trustAttributes converts a trustAttributes value from an Active Directory object into human-readable form.
- explain_trustDirection converts a trustDirection value from an Active Directory object into human-readable form.
- explain_userAccountControl converts a userAccountControl value from an Active Directory object into human-readable form.

explain_ptype

Use the explain_ptype command to translate the account type for a role assignment into a descriptive text string.

Syntax

```
explain_ptype pt
```

Options

This command takes no options.

Arguments

This command takes the following argument:

pt	string	Required. Specifies the ptype value returned for a role assignment that you want to convert to a text string.

Return value

This command returns a text string that describes the type of account associated with a role assignment.

Examples

```
select_role_assignment "lulu@acme.test/UNIX Login"
get_role_assignment_field ptype
a
explain_ptype a
```

This example returns:

```
All AD users
```

The following table summarizes the descriptive names for different account types that can be associated with a role assignment:

Local UNIX user	#
Local UNIX group	%
Local Windows User	$
Local Windows Group	:
All AD users	a
All Unix users	x
All Windows users	w

explain_trustAttributes

Use the explain_trustAttributes command to convert a trustAttributes value from an Active Directory object field into human-readable form.

Syntax

```
explain_trustAttributes ta
```

Options

This command takes no options.

Arguments

This command takes the following argument:

ta	string	Required. A trustAttributes value for conversion.

Return value

This command returns a hexadecimal version of the supplied value followed by the names of any flags that are set in the value.

Examples

```
explain_trustAttributes [get_object_field trustAttributes]
```

This example returns:

```
8 FOREST_TRANSITIVE
```

The unseen value returned by get_object_field trustAttributes in this example was 8, which was converted to the hexadecimal value 8 and the name of the set flag DOMAIN_LOCALSECURITY.

Related Tcl library commands

The following commands perform actions related to this command:

- explain_groupType converts a groupType value from an Active Directory object into human-readable form.
- explain_trustDirection converts a trustDirection value from an Active Directory object into human-readable form.
- explain_userAccountControl converts a userAccountControl value from an Active Directory object into human-readable form.

explain_trustDirection

Use the explain_trustDirection command to convert a trustDirection value from an Active Directory object field into human-readable form.

Syntax

```
explain_trustDirection td
```

Options

This command takes no options.

Arguments

This command takes the following argument:

td	string	Required. A trustDirection value for conversion.

Return value

This command returns the English version of the trust direction specified by the trustDirection value.

Examples

```
explain_trustDirection [get_object_field trustDirection]
```

This example returns:

two-way

Related Tcl library commands

The following commands perform actions related to this command:

- explain_groupType converts a groupType value from an Active Directory object into human-readable form.
- explain_trustAttributes converts a trustAttributes value from an Active Directory object into human-readable form.
- explain_userAccountControl converts a userAccountControl value from an Active Directory object into human-readable form.

explain_userAccountControl

Use the explain_userAccountControl command to convert a userAccountControl value from an Active Directory object field into a human-readable form.

Syntax

```
explain_userAccountControl uac
```

Options

This command takes no options.

Arguments

This command takes the following argument:

uac	string	Required. A userAccountControl value for conversion.

Return value

This command returns a hexadecimal version of the supplied value followed by the names of any flags that are set in the value.

Examples

```
explain_userAccountControl [get_object_field userAccountControl]
```

returns:

```
10200 ADS_UF_NORMAL_ACCOUNT ADS_UF_DONT_EXPIRE_PASSWD
```

The unseen value returned by get_object_field userAccountControl in this example was 66048, which was converted to the hexadecimal value 10200 and the name of the set flags ADS_UF_NORMAL_ACCOUNT and ADS_UF_DONT_EXPIRE_PASSWD.

Related Tcl library commands

The following commands perform actions related to this command:

- explain_groupType converts a groupType value from an Active Directory object into human-readable form.
- explain_trustAttributes converts a trustAttributes value from an Active Directory object into human-readable form.
- explain_trustDirection converts a trustDirection value from an Active Directory object into human-readable form.

get_all_zone_users

Use the get_all_zone_users command to check Active Directory and return a list of zone users defined within the specified zone and all of its parent zones. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed.

Note that this command does *not* use the currently selected zone to find its list of users. It uses instead the zone specified as an argument for the command. It ignores the currently selected zone. The selected zone remains the selected zone after the command executes.

Syntax

```
get_all_zone_users [-upn] zone_DN
```

Abbreviation

None.

Options

This command takes the following option:

-upn	string	Return user names in the Tcl list as universal principal names (UPNs).

Arguments

This command takes the following argument:

zone_DN	string	Required. The distinguished name (DN) of the zone for which to return users.

Return value

This command returns a Tcl list of zone users defined in the currently selected zone and all of its parent zones. Each entry in the list is in the format sAMAccountName@domain. If a zone user is an orphan user (its corresponding Active Directory user no longer exists), the user is listed by its security identifier (SID) instead of the sAMAccountName.

If the -upn option is present, each entry in the returned Tcl list is a universal principal name (UPN).

Examples

```
get_all_zone_users engineering
```

The example returns the list of zone users:

```
adam.avery@acme.com
brenda.butler@acme.com
chris.carter@acme.com
dave.douglas@acme.com
elliot.evans@acme.com
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_user creates a new zone user and user profile based on a specified Active Directory user.
- create_group creates a new zone group and group profile based on a specified Active Directory group.
- get_effective_groups returns a Tcl list of groups to which a specified user belongs.

get_effective_groups

Use the get_effective_groups command to return the list of effective groups from current zone up the zone hierarchy. Only groups who have a complete profile—whether defined in the current zone or inherited from a parent zone—are included.

The command supports hierarchical zone and classic zones. For classic zones, the command starts from current zone. For hierarchical zones, you can start the search for effective groups at the computer level by specifying the -hostname option.

You can use the adinfo command to return the computer name.

Syntax

```
get_effective_groups [-hostname computer_name]
```

Options

This command takes the following option:

-hostname	string	Specifies the name of the computer to start the search at the computer or computer role level if you run the command in a hierarchical zone with computer-level overrides or computer roles. If you don't specify this option, the search starts in the current zone and computer roles are ignored.

Return value

This command returns a Tcl list of groups with complete profiles in the currently selected zone and all of its parent zones.

Example

```
get_effective_groups -hostname centos7.ajax.com
```

The example returns the list of effective groups starting at the computer level for the computer named centos7.ajax.com.

get_effective_users

Use the get_effective_users command to return the list of effective users from current zone up the zone hierarchy. Only users who have a complete profile—whether defined in the current zone or inherited from a parent zone—are included. Similarly, only users who have a role assignment in the current zone or inherited from a parent zone are included.

The command supports hierarchical zone and classic zones. For classic zones, the command starts from current zone. For hierarchical zones, you can start

the search for effective users at the computer level by specifying the -hostname option.

Syntax

```
get_effective_users [-hostname computer_name]
```

Options

This command takes the following option:

-hostname	string	Specifies the name of the computer to start the search at the computer or computer role level if you run the command in a hierarchical zone with computer-level overrides or computer roles. If you don't specify this option, the search starts in the current zone and computer roles are ignored.

Return value

This command returns a Tcl list of users with complete profiles and at least one role assignment in the currently selected zone and all of its parent zones.

Example

```
get_effective_users -hostname centos7.ajax.com
```

The example returns the list of effective users starting at the computer level for the computer named centos7.ajax.com.

get_user_groups

Use the get_user_groups command to check Active Directory for a specified user and return a list of the groups to which the user belongs. If executed in a script, this command does not output its list to stdout, and no output appears in the shell where the script is executed.

Syntax

```
get_user_groups [-dn] [-z] user_DN|user_UPN
```

Abbreviation

None.

Options

This command takes the following options:

-dn	Return groups in the Tcl list as distinguished names (DNs) instead of user principal names (UPNs).
-z	Restricts the Tcl list of groups to groups that belong to the current zone.

Arguments

This command takes the following argument:

user_DN|user_UPN	string	Required. The user whose groups to return. This argument may specify the user with a distinguished name (DN) or a user principal name (UPN).

Return value

This command used without options returns a Tcl list of all groups listed in Active Directory to which the specified user belongs. Each entry in the list is the user principal name (UPN) of a group that you can use to look up that group.

If the -dn option is set, the Tcl list uses distinguished names (DNs) for groups.

If the -z option is set, the Tcl list is restricted to groups that belong to the currently selected zone.

Note that the command will not return groups for domains that aren't currently bound to ADEdit. If the command finds one or more groups outside of the currently bound domains, it will return a "no binding" message for each unbound domain in which it finds a user's group.

Examples

```
get_user_groups fred.forth@acme.com
```

This example returns a list of groups:

```
poweradmins@acme.com auditors@acme.com
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_group creates a new zone group and group profile based on a specified Active Directory group.
- create_user creates a new zone user and user profile based on a specified Active Directory user.
- get_all_zone_users returns a Tcl list of zone users for the specified zone and all of its parent zones.

get_user_role_assignments

Use the get_user_role_assignments command to retrieve all of the role assignments in the current zone for a specified user. This command returns all of the role assignments from the groups to which the user belongs and the role assignments assigned directly to the user account.

The command checks Active Directory for the user you specify, identifies the groups that the user is a member of, then returns all the role assignments for the list of groups the user is a member and that have been specifically assigned to the user account, including any user role assignments made in computer roles for the currently selected zone.

Syntax

```
get_user_role_assignments [-visible] [-hostname hostname] user_DN
```

Abbreviation

None.

Options

This command takes the following option:

-visible	Specifies that you want to return only visible role assignments in the zone. Use this option to return role assignments for the roles that are identified as visible. This option is only applicable in hierarchical zones.
-hostname	Specifies the computer name to search for role assignments to the user in computer roles. If you set this option, the command checks for computer role assignments in the currently selected zone.

Arguments

This command takes the following argument:

user_DN	string	Required. Specifies the user whose role assignments you want to return. You can use this argument to specify the distinguished name (DN) for a user or a group.

Return value

This command returns a list of all role assignments for the specified Active Directory user in the currently selected zone.

Note that the command does not return role assignments for all zones where the user might be assigned a role.

Examples

```
select_zone
“cn=northamerica,cn=zones,ou=acme,dc=pistolas,dc=org”

get_user_role_assignments
“cn=amy.adams,cn=users,dc=pistolas,dc=org”
```

This example returns a list of groups:

```
{amy.adams@pistolas.org/UNIX Login/northamerica}
{admsf@pistolas.org/Root/sanfrancisco}
{apps@pistolas.org/demos/seattle}
```

Related Tcl library commands

The following commands perform actions related to this command:

- get_all_zone_users returns a Tcl list of zone users for the specified zone and all of its parent zones.
- get_effective_groups returns a list of the groups to which the user belongs.

list_zones

Use the list_zones command to list the zones within a specified domain along with information about each zone. If executed in a script, this command outputs its list to stdout so that the output appears in the shell where the script is executed. The command does not return a Tcl list back to the executing script. Use the ADEdit command get_zones to return a Tcl list.

Syntax

```
list_zones domain
```

Options

This command takes no options.

Arguments

This command takes the following argument:

domain	string	Required. The name of the domain in which to list zones.

Return value

This command returns a list to stdout of the zones within the specified domain. Each entry in the list contains:

- `The zone's distinguished name (DN)
- `The zone type: tree (supported in Server Suite 2012 or later), classic3 or classic4
- `The schema used in the zone

Each entry component is separated from the next by a colon (:).

Examples

list_zones

This example returns a list of zones similar to this:

```
{CN=default,CN=Zones,CN=Acme,DC=acme,DC=com} : classic4 : std
{CN=cz1,CN=Zones,CN=Acme,DC=acme,DC=com} : tree : std
{CN=cz2,CN=Zones,CN=Acme,DC=acme,DC=com} : tree : std
{CN=global,CN=Zones,CN=Acme,DC=acme,DC=com} : tree : rfc
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_assignment creates a new role assignment and saves it to Active Directory.
- precreate_computer creates a zone profile and, if necessary, a new Active Directory computer account.

lmerge

Use the lmerge command to merge and sort the specified lists. You specify the lists to merge as arguments. You must enclose the list commands you want to merge in square brackets.

Syntax

lmerge [list1] [list2] [list[...]]

Options

This command takes no options.

Arguments

This command takes the following arguments:

[list1]	string	Specifies the list command that return the information you want to include first in the merged results.
[list2)	string	Specifies the list command that return the information you want to include second in the merged results.
[list[...]]	string	Specifies any additional list commands that return information you want to include in the merged results.

Return value

This command returns nothing if it runs successfully.

Examples

lmerge [list_zone_users] [list_zone_computers] [list_roles]

This example returns a merged list of zone users, zone computers, and zone roles similar to this:

```
fred@pistolas.org:fred:580398:648:%{u:displayName}:%{home}/%{user}:%{shell}:
lane@pistolas.org:lane:580397:648:%{u:displayName}:%{home}/%{user}:%{shell}:
maya@pistolas.org:maya:580320:648:%{u:displayName}:%{home}/%{user}:%{shell}:
ubu1$@pistolas.org: cpus(1) agentVersion(CentrifyDC 5.2.0): ubu1.pistolas.org
nic3$@pistolas.org: cpus(2) agentVersion(CentrifyDC 5.2.0): nic3.pistolas.org
Rescue - always permit login
listed
UNIX Login
UnixAdminRights
Windows Login
```

You can specify the list arguments using full command names or abbreviations. For example:

```
lmerge [lszc] [lspa]
ubu1$@pistolas.org: cpus(1) agentVersion(CentrifyDC 5.2.0): ubu1.pistolas.org
nic3$@pistolas.org: cpus(2) agentVersion(CentrifyDC 5.2.0): nic3.pistolas.org
dzssh-all/Headquarters : dzssh-* : All of ssh services
login-all/Headquarters : * : Predefined global PAM permission. Do not delete.
```

Related Tcl library commands

None.

modify_timebox

Use the modify_timebox command to modify a timebox value that defines the hours of a week when a role is enabled or disabled. The command defines an hour of the week and then enables or disables that hour in the timebox value. This command is very useful in the set_role_field ADEdit command when setting the timebox field.

Execute this command multiple times on a timebox value to set more than one hour in the value.

For more information about the timebox value format, read the **Timebox Value Format**.

Syntax

```
modify_timebox strTimeBox day hour avail
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

strTimeBox	hex	A 42-digit hexadecimal timebox value. A value of zero disables all hours of the week. A value of FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF enables all hours of the week.
day	integer	Required. The day of the week when the hour occurs. 0=Sunday, 1=Monday, and so on to 6=Saturday.
hour	integer	Required. The hour of the day to enable or disable. Takes a value from 0 to 23. 0 is from midnight to 1 AM, 1 is from 1 AM to 2 AM, and so on to 23, which is from 11 PM to midnight.
avail	integer	Required. Whether to enable or disable the specified hour. 0=disable; all other values=enable.

Return value

This command returns a hexadecimal value that is the timebox value after enabling or disabling the specified hour of the week.

Examples

```
set tb 000000000000000000000000000000000000000000
set tb [modify_timebox $tb 6 23 1]
```

This example returns the modified timebox value:

```
800000000000000000000000000000000000000000
```

Related Tcl library commands

The following commands perform actions related to this command:

- decode_timebox converts an internal timebox value to a decipherable format.

- encode_timebox converts a readable timebox value to an internal timebox format.

precreate_computer

Use the precreate_computer command to create a zone profile for a computer in Active Directory before using the adjoin command to join the domain. The zone profile—a serviceConnectionPoint (scp) object—is usually created by the adjoin command when a computer joins the domain. In some cases, however, creating the zone profile before joining is useful. For example, preparing the computer object before joining enables you to check that you have user profiles and role assignments correctly defined before you join UNIX computers to zones. Verifying this information before the join operation helps to ensure a smooth migration without disrupting users' access to files or applications.

The zone profile is part of an Active Directory computer object. If an Active Directory computer object doesn't exist, precreate_computer can create one and then add the zone profile to the new Active Directory computer object. The zone profile is created in ADEdit's currently selected zone. You can also use the precreate_computer command to specify a container where Active Directory will store the new Active Directory computer object.

You can use the precreate_computer command to create a service connection point for a new or existing Active Directory computer object. You can also use the command to create a computer-specific zone for machine-level zone overrides (in essence a one-computer zone) for the precreated computer. You should note that performing these tasks requires access to the global catalog by default. You can intentionally skip the global catalog search if you know the service connection point you are creating is unique in the forest. However, skipping the global catalog search might prevent you from joining the computer to the domain if there is a conflict.

The precreate_computer command also sets the Active Directory computer object's password and permissions when creating a zone profile. The password is the computer's host name in lower case. The permissions the computer object has are:

- Read and Write permissions to the operatingSystemServicePack, operatingSystem, and operatingVersion attributes of the computer object.
- Read permission for the userAccountControl attribute of the computer object.
- Validate write to the servicePrincipalName and dNSHostName attributes.

You can use precreate_computer to specify a DNS name for the precreated computer and one or more trustees for the precreated computer. Each trustee can be either a user or a group, and has the rights needed to join the computer to the precreated computer account using adjoin.

Use the precreate_computer command option, enctype, to specify encryption types.

The precreate_computer command is similar to using adjoin -precreate, but provides more options and flexibility. You can also precreate computer accounts using Access Manager. For more information about precreating computer accounts, See the **Administrator's Guide for Linux and UNIX**.

Syntax

```
precreate_computer *samaccount@domain*[-ad] [-scp] [-czone] [-all] [-container *rdn*]
[-dnsname *dnsname*] [licensetype *type*] [-trustee *upn*[-trustee *upn*] ...] [nogc]
[stype *spn* [-stype *spn*] ...] [-enctype type [-enctype type] ...]
[-notdelegateanyright]
```

Options

This command takes the following options:

-ad	Creates an Active Directory computer object. precreate_computer won't create an Active Directory computer object if it already exists for the computer specified by the argument upn. Note that if no options specify Active Directory computer object creation and no Active Directory computer object already exists, precreate_computer will fail.
-all	Creates an Active Directory computer object (if one doesn't exist already), a service connection point for the computer object, and a computer zone for the computer object: in essence all of the previous three options combined.
-container	Stores the new Active Directory computer object (if created) in the Active Directory container specified by rdn, which is the relative distinguished name (RDN) of the container. The root of the specified Active Directory container is the distinguished name (DN) of the current domain. precreate_computer appends the RDN to the root DN to come up with the container DN.
-czone	Creates a computer zone for the computer object.
	Sets the DNS name for the computer account to the provided DNS name. If this option isn't present, the precreate_computer

-dnsname	command automatically sets the DNS name for the computer account. It derives the DNS name from the computer's sAMAccount name and the domain name.
-enctype	Set the msDS encryption types permitted in precreate _computer command. Default is 31. Options are: aes256-cts-hmac-sha1-96, aes256-cts aes128-cts-hmac-sha1-96, aes128-cts arcfour-hmac, rc4-hmac, arcfour-hmac-md5 des-cbc-md5, des des-cbc-crc
-licensetype	Specifies the type of license a computer uses. The valid values are server workstation
-nogc	Allows you to create the computer account without binding to a global catalog domain controller. You should only use this option if you know the computer scp object does not exist in the domain.
-notdelegateanyright	Allows you to create the computer account without delegating any rights. If you specify this option, note that the -trustee option has no effect.
-scp	Creates a service connection point for the Active Directory computer object.
-stype	Specifies the service principal types to create for a precreated computer account. You can specify multiple -stype options, with each specifying a different service principal type. If you don't specify this option, the precreate_computer command automatically creates the several default service principal names for the following service principal types: ipp afpserver nfs cifs ftp http host For each type of service, the precreate_computer command specifies two service principal names in the form of *serviceNamel computerName* and *serviceName/computerName.domain.com*. For example: ftp/rhel6 ftp/rhel6.acme.com If you specify one or more -stype options, only the service principal names for those service types are created for the precreated computer account.
-trustee	Gives the user or group specified by the *upn* argument permission to join a computer to the precreated computer account. You can specify multiple -trustee options, with each specifying a different user or group, to give multiple users and groups permission to join a precreated computer to a zone.

Arguments

This command takes the following argument:

samaccount@domain	string	Required. Specifies the name of the computer account and the domain to join. The computer name is the sAMAccountName for the account in the form of *computer$*. For example: engserv$@acme.com

Return value

This command returns nothing if it runs successfully.

Examples

```
precreate_computer redhat\$@acme.com -trustee adam.avery@acme.com
\-trustee martin.moore@acme.com -enctype arcfour-hmac
```

This example precreates a zone profile in the currently selected zone for the computer "redhat$@acme.com", and specifies as trustees the Active Directory users Adam Avery and Martin Moore.

Because the example does not include the -stype option, this example also automatically creates the following default service principal names for services on the computer:

- ipp/redhat and ipp/redhat.acme.com
- afpserver/redhat and afpserver/redhat.acme.com
- nfs/redhat and nfs/redhat.acme.com
- cifs/redhat and cifs/redhat.acme.com
- ftp/redhat and ftp/redhat.acme.com

- http/redhat and http/redhat.acme.com
- host/redhat and host/redhat.acme.com

Related Tcl library commands

The following commands perform actions related to this command:

- list_zones returns a list of zones in a specified domain to stdout.
- create_assignment creates a new role assignment and saves it to Active Directory.

remove_user_from_group

Use the remove_user_from_group command to remove an Active Directory user from an Active Directory group.

Syntax

```
remove_user_from_group user group
```

Options

This command takes no options.

Arguments

This command takes the following arguments:

user	string	Required. The user principal name (UPN) of the Active Directory user to remove.
group	string	Required. The UPN of the Active Directory group from which to remove the user.

Return value

This command returns nothing if it runs successfully.

Examples

```
remove_user_from_group adam.avery@acme.com pubs@acme.com
```

Related Tcl library commands

The following commands perform actions related to this command:

- create_aduser creates a new Active Directory user account and sets its password.
- create_adgroup creates a new Active Directory group account and specifies its scope.
- create_user creates a new zone user and user profile based on an existing Active Directory user.
- create_group creates a new zone group and group profile based on an existing Active Directory group.
- add_user_to_group adds an Active Directory user to an Active Directory group.

set_change_pwd_allowed

Use the set_change_pwd_allowed command to modify the ADS_UF_PASSWD_CANT_CHANGE flag in the UserAccountControl attribute. This flag controls whether an Active Directory user can change his or her domain password. You must specify the distinguished name of a valid Active Directory user account that should be allowed to change his or her password.

Syntax

```
set_change_pwd_allowed userdn
```

Options

This command takes no options.

Arguments

This command takes the following argument:

userdn	string	Required. Specifies the distinguished name of the Active Directory user who is allowed to change his or her password.

Return value

This command returns nothing if it runs successfully.

Examples

```
set_change_pwd_allowed
CN=frank.smith,CN=Users,DC=ajax,DC=test

get_object_field sd

(OA;;CR;ab721a53-1e2f-11d0-9819-00aa0040529b;;WD)
(OA;;CR;ab721a53-1e2f-11d0-9819-00aa0040529b;;PS)
```

This example deselects the "User cannot change password" account property for the Active Directory user frank.smith.

Related Tcl library commands

The following commands perform actions related to this command:

- create_aduser creates a new Active Directory user account and sets the password for the account.
- set_change_pwd_denied prevents an Active Directory user from changing the domain password for his or her account.

set_change_pwd_denied

Use the set_change_pwd_denied command to modify the ADS_UF_PASSWD_CANT_CHANGE flag in the UserAccountControl attribute. This flag controls whether an Active Directory user can change his or her domain password. You must specify the distinguished name of a valid Active Directory user account that should not be allowed to change his or her password.

Syntax

```
set_change_pwd_denied userdn
```

Options

This command takes no options.

Arguments

This command takes the following argument:

userdn	string	Required. Specifies the distinguished name of the Active Directory user who is not allowed to change his or her password.

Return value

This command returns nothing if it runs successfully.

Examples

```
set_change_pwd_denied CN=adam.avery,CN=Users,DC=ajax,DC=test

get_object_field sd

(OD;;CR;ab721a53-1e2f-11d0-9819-00aa0040529b;;WD)
(OD;;CR;ab721a53-1e2f-11d0-9819-00aa0040529b;;PS)
```

This example selects the “User cannot change password” account property for the Active Directory user adam.avery.

Related Tcl library commands

The following commands perform actions related to this command:

- create_aduser creates a new Active Directory user account and sets the password for the account.
- set_change_pwd_allowed allows an Active Directory user to change the domain password for his or her account.

Timebox Value Format

A Delinearole specifies a collection of rights. A role object contains a field, timebox, that defines what hours in a week a role is either enabled or disabled. Setting the timebox field in a role object defines when a role's rights are in effect.

You can read a role's timebox field using the ADEdit command get_role_field and set the timebox value using set_role_field. You can modify an existing timebox value one hour at a time using the ADEdit library command modify_timebox.

To interpret a timebox value, or to set it directly, you must know the timebox value format which is, unfortunately, not simple as defined by Active Directory. This appendix explains the format.

Hex string

The timebox value is a 42-character (21-byte) hexadecimal value stored as a string. When the hex value is converted to a binary value, its 168 bits each map to a single hour within the week. If a bit is set to 1, its corresponding hour is enabled for the role. If set to 0, its corresponding hour is disabled.

After you define the 168 bits using a hexadecimal value, you can usee the encode_timebox function to convert the value into an internal format that specifies when a role is available to use.

Hour mapping

Each day of the week takes three bytes (24 bits) to specify how its hours are enabled or disabled. The following tables show how the hours of a day are mapped to the bits within each of a day's three bytes.

Byte 0

12-1 AM	0 (least-significant bit)
1-2 AM	1
2-3 AM	2
3-4 AM	3
4-5 AM	4
5-6 AM	5
6-7 AM	6
7-8 AM	7 (most-significant bit)

Byte 1

8-9 AM	0 (least-significant bit)
9-10 AM	1
10-11 AM	2
11-12 AM	3
12-1 PM	4

1-2 PM	5
2-3 PM	6
3-4 PM	7 (most-significant bit)

Byte 2

4-5 PM	0 (least-significant bit)
5-6 PM	1
6-7 PM	2
7-8 PM	3
8-9 PM	4
9-10 PM	5
10-11 PM	6
11-12 PM	7 (most-significant bit)

Day mapping

Each of the seven days in a week have three bytes within the 21-byte timebox value. These bytes are in chronological order from most-significant byte to least-significant byte. (Note that this is the opposite of chronological bit order within each byte, which is LSB to MSB.) The starting point of a week is 4 PM on Saturday afternoon.

The table below shows how each day's three bytes (0-2) map to the timebox value's bytes, listed here in order from most-significant byte to least-significant byte.

Saturday, byte 2	20 (most-significant byte)
Sunday, byte 0	19
Sunday, byte 1	18
Sunday, byte 2	17
Monday, byte 0	16
Monday, byte 1	15
Monday, byte 2	14
Tuesday, byte 0	13
Tuesday, byte 1	12

Tuesday, byte 2	11
Wednesday, byte 0	10
Wednesday, byte 1	9
Wednesday, byte 2	8
Thursday, byte 0	7
Thursday, byte 1	6
Thursday, byte 2	5
Friday, byte 0	4
Friday, byte 1	3
Friday, byte 2	2
Saturday, byte 0	1
Saturday, byte 1	0 (least-significant byte)

Using ADEdit with Classic Zones

Delineasupports both classic and hierarchical zones. If you have upgraded agents to a version of Delineasoftware that supports hierarchical zones (version 5.x or later), you can choose to either migrate your classic zones into a hierarchical zone structure or maintain them as classic zones.

If you choose to maintain any zones as classic zones, however, you should be aware that the authorization model in classic zones differs from the authorization model used in hierarchical zones. For example, in classic zones, authorization is an optional feature that can be enabled or disabled. If authorization is not enabled in a classic zone, any user with a valid profile in a zone is automatically granted login access to all computers joined to that zone.

Because authorization is handled differently in classic zones, there are specialized ADEdit commands and command options for creating and managing rights and roles in classic zones. The commands in this appendix are only applicable when you are working with classic zones.

Enabling Authorization in Classic Zones

The following ADEdit commands are used to enable or disable authorization in a classic zone and to check whether authorization is currently enabled or disabled.

is_dz_enabled	Checks whether authorization is enabled in a currently selected classic zone.
manage_dz	Enables or disables authorization in classic zones.

Working with privileged Commands and PAM Applications

With some limitations, you can use most of the ADEdit commands for working with rights, role definitions, and role assignments in classic zones in the same way you work with them in hierarchical zones. In a classic zone, however, you must explicitly enable authorization for the zone. Thereafter, defining rights and roles or making role assignments work the same in classic zones and hierarchical zones.

In most cases, any differences or limitations for classic zones involve options or arguments that are not supported or not applicable in classic zones. For example, fields such as allowLocalUser, alwaysPermitLogin, and auditLevel are not applicable in classic zones. You can use the set_role_field command to set other field values in a classic zone. Individual commands specify these types of limitations.

Working with Restricted Shell Environments and Commands

Before you can use the restricted shell (dzsh) to run commands in a classic zone, you must create the restricted shell environment. After you have created the restricted shell environment in your working context, you can run restricted shell commands in that dzsh context.

Restricted commands cannot be assigned to a role directly. A restricted shell environment has to be created first. The restricted shell commands can then be created under the currently selected restricted shell environment. Only one restricted shell environment can be assigned to a role. The restricted shell environment and privileged UNIX commands cannot be assigned to a role simultaneously. Assigning a new restricted shell environment to a role removes all of the previously defined privileged UNIX commands from the restricted shell. Assigning new privileged commands to a role that previously had a restricted shell environment removes the restricted shell environment and any restricted shell commands defined for the restricted shell environment.

Setting up the restricted shell environment

The following ADEdit commands are used to set up and manage the restricted shell environment prior to working with any restricted shell commands.

clear_rs_env_from_role	Removes the restricted shell environment from the currently selected role that is stored in memory.
delete_rs_env	Deletes the currently selected restricted environment from Active Directory and also from memory.
get_role_rs_env	Gets the restricted shell environment from the currently selected role that is stored in memory.
get_rs_envs	Gets the list of restricted environments that are defined within the currently selected zone.

get_rse_cmds	Gets a Tcl list of restricted shell commands associated with the currently selected restricted shell environment.
get_rse_field	Gets the value for a specified field from the restricted shell environment stored that is stored in memory.
list_rs_envs	Prints a list of restricted shell environments defined for the currently selected zone to stdout.
new_rs_env	Creates a new restricted shell environment for the current zone, stores it in memory, and sets it to be the currently selected restricted shell environment.
save_rs_env	Saves the currently selected restricted environment that is stored in memory to Active Directory.
select_rs_env	Retrieves a restricted shell environment for the currently selected zone from Active Directory, stores it in memory, and sets it to be the currently selected restricted shell environment for other ADEdit commands.
set_rs_env_for_role	Assigns a restricted shell environment to the currently selected role that is stored in memory.
set_rse_field	Sets the value for a specified field in the currently selected restricted shell environment stored in memory.

Using restricted commands

The following ADEdit commands are used to set up and manage the restricted shell restricted shell commands.

delete_rs_command	Deletes the currently selected restricted shell command from Active Directory and from memory.
get_role_rs_commands	Returns a Tcl list of restricted shell commands associated with the currently selected role.
get_rs_commands	Checks Active Directory and returns a Tcl list of restricted shell commands defined for the currently selected zone.
get_rsc_field	Gets the value for a specified field from the currently selected restricted shell command that is stored in memory.
list_rs_commands	Prints a list of restricted shell commands defined for the currently selected zone to stdout.
new_rs_command	Creates a new restricted shell command under the currently selected restricted shell environment, stores it in memory, and sets it to be the currently selected restricted shell command.
save_rs_command	Saves the currently selected restricted shell command that is stored in memory to Active Directory.
select_rs_command	Retrieves a restricted shell command in the currently selected zone from Active Directory, stores it in memory, and sets it to be the currently selected restricted shell command for other ADEdit commands.
set_rsc_field	Sets the value for a specified field for the currently selected restricted shell command that is stored in memory.

Creating computer-level role assignments in classic zones

Classic zones support computer-level role assignments. If you want to configure computerlevel role assignments, keep the following in mind:

- The classic zone that the computer is a member of must have authorization enabled before you can create role definitions and role assignments.
- The role assignment is only valid on the computer where you have made the assignment.
- The role definition you use must be defined in the classic zone that the computer is a member of.

A computer-level role assignment in a classic zone is similar to computer-level overrides in hierarchical zones, except that you cannot save user or group profile information for individual computers. User and group information is stored in the classic zone. To enable computer-specific role assignments in classic zones, you must use a specialized zone type, the classic-computer zone type.

To create a computer-level role assignment in a classic zone:

1. Precreate the computer in a classic4 zone, if it doesn't already exist.
2. Create a zone that uses the specialized zone type of classic-computer.
3. Select the classic-computer zone within the classic zone.
4. Create the role assignment.

The following code snippet illustrates the commands to execute in ADEdit to make computer-specific role assignments in classic zones:

```
bind ajuba.net
package require ade_lib
    1.0
select_zone cn=cls,cn=zones,dc=ajuba,dc=net
get_zone_field type
    classic4
precreate_computer rhelqa$@ajuba.net
get_zone_computers
    {comp5$@ajuba.net} {rhelqa$@ajuba.net}
create_zone classic-computer rhelqa.ajuba.net@cn=cls,cn=zones,dc=ajuba,dc=net
select_zone rhelqa.ajuba.net@cn=cls,cn=zones,dc=ajuba,dc=net
new_role_assignment user5@ajuba.net
set_role_assignment_field role role1/cls
save_role_assignment
```

You can then get the classic-computer zones by running the get_child_zones command when the classic zone is selected. For example:

```
select_zone cn=cls,cn=zones,dc=ajuba,dc=net
get_child_zones
helqa.ajuba.net@CN=c122,CN=Zones,DC=ajuba,DC=net
comp5.ajuba.net@CN=c122,CN=Zones,DC=ajuba,DC=net
```

Quick reference for commands and library procedures

The following table lists the ADEdit and ade_lib commands in alphabetical order. The table summarizes the command syntax for each command with optional elements in [square brackets] and variables in italics. For more detailed information about any command, see the previous sections **ADEdit command reference** or **ADEdit Tcl Procedure Library Reference**.

This section contains topics on scripting operations using Microsoft PowerShell for use with the Server Suite Authentication and Privilege Elevation services.

- Scripting Access Control and Privilege Management with PowerShell
- Auditing and Analysis Scripting Guide

Scripting Access Control and Privilege Management with PowerShell

Note: Subject matter (not formatting) last updated December 2021 (release 2021.1).

Introduction

Overview

This topic discusses access control and privilege management using PowerShell-based command-line programs. This information is intended to help you develop scripts for creating and populating zones and performing other administrative tasks on Windows computers. With scripts, you can automate the administrative tasks you might otherwise perform using the Access Manager console.

Specifically, the topic describes the Delinea authentication and privilege PowerShell-based command set. These PowerShell cmdlets run on Windows computers and can be used to automate access control and privilege management tasks, such as the creation of Delinea zones, rights, and roles. You can also use the cmdlets to perform other administrative tasks. For example, you can write scripts to add UNIX profiles for Active Directory users and groups to Delinea zones, assign UNIX and Windows users and groups to roles, and manage network information through NIS maps.

Intended audience

This topic provides information for Active Directory administrators who want to use PowerShell scripts to install or maintain Delinea software. This document supplements the help provided within the PowerShell environment using the get-help function. Whereas the get-help function describes each cmdlet in detail, this document introduces the access module for Windows PowerShell objects and how you can use PowerShell cmdlets and scripts to perform access control and privilege management tasks.

This topic assumes general knowledge of Microsoft Active Directory, PowerShell scripts and syntax, and the Windows PowerShell modules used to write scripts for Active Directory. You should also understand the structure of Active Directory, including the Active Directory schema your organization is using.

In addition to scripting skills, you should be familiar with Delinea architecture, terms, and concepts, and understand how to perform administrative tasks for authentication and privilege elevation and for the UNIX platforms you support.

Subtopics

This topic is divided into these subtopics:

- **Developing Scripts for Administrative Tasks:** An introduction to access control and privilege management using Windows PowerShell.
- **Installing the PowerShell Access Module:** How to download and install the module as a separate package.
- **Managing Delinea Objects using Windows PowerShell Scripts:** How to use cmdlets to connect to Active Directory and perform access control and privilege management tasks.
- **Objects and Properties:** Lists the objects defined by the authentication and privilege-elevation PowerShell module and the properties of each object.
- **Adding Users in a One-way Trust Environment:** How to add a user in a one-way trust environment using the authentication and privilege-elevation PowerShell module.
- **Using Predefined Scripts to Generate Reports:** Describes predefined report scripts that are included with the authentication and privilege-elevation PowerShell module and how to configure report output files to generate HTML- and PDF-formatted report files.

Compatibility and Limitations

The information in this topic is intended for use with Server Suite, version 5.1.x or later and Server Suite 2017.2 or later. Although intended to be accurate and up to date, interfaces are subject to change without notice and can become incompatible or obsolete when a newer version of the software is released.

In general, APIs attempt to be backward-compatible but are not guaranteed to work with older versions of the software. Because the authentication and privilege elevation cmdlets are subject to change, enhancement, or replacement, the information in this topic can also become incomplete, obsolete, or unsupported in future versions. If you are unsure whether this topic is appropriate for your software version, consult the Delinea Web site or Delinea Support to find out if another, more appropriate, topic is available.

Developing Scripts for Administrative Tasks

This section introduces access control and privilege management using Windows PowerShell. It consists of the following:

- APIs in the form of PowerShell command-line programs, called cmdlets, that are packaged in Dynamic Link Libraries (DLLs).
- A PowerShell help file that includes complete cmdlet reference information and this scripting guide.
- Sample scripts to illustrate administrative tasks.
- Predefined scripts to generate reports.
- Individual help files for each predefined report script.

On Windows computers, you can use the authentication and privilege elevation module for Windows PowerShell to develop your own custom scripts that access, create, or modify Delinea-specific data in Active Directory.

Getting Started with cmdlets for PowerShell

The access module for PowerShell consists of cmdlets that you can use to manage Delinea-specific information in Active Directory. A *cmdlet* is a lightweight command-line program that runs in the Windows PowerShell environment. In most cases, cmdlets perform a basic operation and return a Microsoft .NET Framework object to the next command in the pipeline.

The cmdlets in the Delinea module enable you to access, create, modify, and remove information about Delinea zones, including details for each zone about the defined user, group, and computer profiles; all aspects of the rights, roles, and role assignments; and the available NIS maps and NIS map entries. You can combine cmdlets and use them in scripts to automate administrative tasks, such as user or group profile provisioning or creating rights, roles, and role assignments.

In most cases, you can use cmdlets to manipulate Delinea objects in any type of zone. However, because the implementation of authorization differs greatly in hierarchical zones from authorization in classic zones, the access module for Window PowerShell cmdlets that enable you to create and work with rights, roles, or role assignments are only applicable in hierarchical zones. You should not use the cmdlets for rights, roles, and role assignments in classic zones.

Managing UNIX information from a Windows Computer

You can use the cmdlets to work with information for any Delinea-managed computer and to manage UNIX profiles and access rights. However, you can only run the cmdlets on Windows-based computers that have the Windows PowerShell command-line shell available. If you want to develop scripts that run on UNIX computers, you can use the ADEdit program (adedit). The ADEdit application provides functionality similar to the cmdlets. For detailed information about using ADEdit, see the ADEdit Command Reference and Scripting topic.

Writing Programs in Other Languages

If you want to develop programs or scripts that run on Windows but outside of the Windows PowerShell environment, you can use any language that supports the Component Object Model (COM) interface. The Delinea COM-based interface is available as part of the Delinea Windows Software Development Kit (SDK). The SDK package is a completely separate API that provides reusable objects that you can call in programs written in .NET or COM-enabled languages. You can, therefore, create or modify your own applications to use these objects in VBScript and JScript or in .NET-compliant (such as C#) languages. For more information about using the COM-based API, see the Windows API Programmer's Guide.

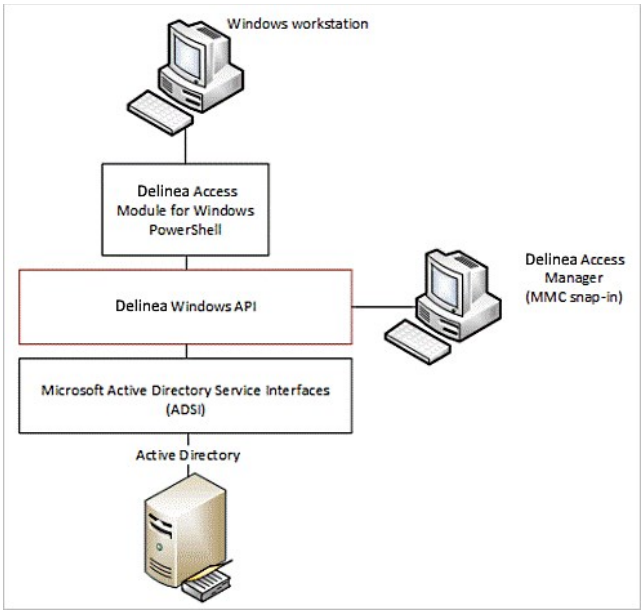
Accessing information stored in Active Directory

The Delinea access module for PowerShell cmdlets connect to Active Directory to access all of the Delinea-specific information stored there. You can, therefore, write PowerShell scripts to automate procedures that you would otherwise have to perform using access manager.

The cmdlets rely on the underlying interfaces provided by Microsoft Active Directory Service Interfaces (ADSI) and the Delinea Windows API. The ADSI layer provides low-level functions that permit applications to read and write data in Active Directory. The cmdlets provide a task and object-based level of abstraction for retrieving and manipulating Delinea-specific information so that you do not need to know the details of how the data is stored or how to use any of the underlying ADSI functions directly.

The following figure illustrates how the Delinea access module for PowerShell provides an abstraction layer between the data stored in Active Directory and your scripting environment.

Figure: PowerShell Abstraction Layer



The Active Directory schema defines how all of the objects and attributes in the database are stored. When you add Delinea objects to the Active Directory database, how that data is stored depends on the Active Directory schema you have installed. The Delinea access module for PowerShell, however, provides a logical view of the data, eliminating the need to know the details of how data is stored in different schemas when performing common administrative tasks. The cmdlets also provide a simple and Delinea-focused method for accessing subject UNIX objects.

Using the cmdlets, you can write scripts that automatically create and manage zones or update user, group, or computer properties. In most cases, the cmdlets enable you to perform exactly the same tasks from the command line that you would otherwise perform interactively using access manager.

Installing the PowerShell Access Module

This section explains how to download and install the module as a separate package. You can install the authentication and privilege elevation module for PowerShell from the Server Suite setup program or as a separate package. This section includes the access control and privilege management cmdlets for Windows PowerShell, sample scripts, and documentation for performing common administrative tasks using PowerShell scripts. This section describes how to install the software if you download it as a separate package or run the package-specific setup program on a Windows computer.

Selecting and Downloading a Standalone Package

The cmdlets that run in Windows PowerShell are defined in DLLs that can be installed on any computer where you install other Windows-based components, such as the Access Manager console. You can also download these libraries separately, along with sample scripts and documentation, onto computers where access manager is not installed.

> **Note:** You can download the access module for PowerShell as a separate package from the Delinea Download Center under Software Development Kits. However, you must obtain an unlocking code or license key from your Delinea sales representative to access the module.

Running the Setup program

After you have downloaded the compressed file to your computer, you can extract the files and run the setup program to install the access module for PowerShell files.

To use the authentication and privilege elevation module for Windows PowerShell on a Windows Server server-core computer, you must have Windows PowerShell, version 2.0 or later, installed first. Also, install the authentication and privilege elevation module for Windows PowerShell on a Windows Server Core environment in silent mode, due to a user interface limitation. Please check the process exit code to see whether the installation succeeded or failed.

> **Note:** Server core is a minimal installation option that is available when you are deploying Windows Server. Server core includes most but not all server roles. Server Core has a smaller attack surface due to a smaller code base.

To run the standalone setup program:

1. Download the file.
2. Right-click downloaded file and select **Extract All** to extract the compressed files to a folder.
3. Double-click the standalone executable to start the setup program. For example, for the 64-bit version of the file, double click the CentrifyDC_PowerShell-5.2.0-win64.exe file.

   Note: Alternatively, you can install from the Microsoft Installer (.msi) file. For example, you might run the following command: msiexec.exe /i "CentrifyDC_PowerShell-5.2.0-win64.msi" /norestart.

   The Welcome page appears.
4. Click the **Next** button. The License Agreement page appears.
5. Click to select the **I accept the terms in the License Agreement** check box.
6. Click the **Next** button. The Location page appears.
7. Accept the default location or click **Change** to choose a different one. If you accept the default location, the authentication and privilege elevation cmdlets are in a separate authentication and privilege elevation for Windows PowerShell console. If you want the authentication and privilege elevation cmdlets to be available in the default Windows PowerShell console with other PowerShell modules, select the following location:

   C:\Windows\System32\WindowsPowerShell\v1.0\Modules\Centrify.DirectControl.PowerShell
8. Click the **Next** button.
9. Click the **Install** button.
10. Click the **Finish** button to complete the installation.

Importing cmdlets into the Windows PowerShell Console

If you install the authentication and privilege elevation module for Windows PowerShell in the default location, it is a self-contained Windows PowerShell console. If you install the files in the location for system modules so that cmdlets from other modules are available in the same console, you should import the authentication and privilege elevation module into your default Windows PowerShell console.

To import the authentication and privilege elevation module:

1. On the **Start** menu, select **Windows PowerShell** to display a menu extension with a list of tasks.
2. On the tasks menu, select **Import System Modules** to import the authentication and privilege elevation module and open the Windows PowerShell console.
3. Verify the installation and import completed successfully by typing the following command at the PowerShell prompt:

   get-command -Cdm

   You should see a listing of the authentication and privilege elevation cmdlets, similar to the following partial list:

```
CommandType   Name                  Definition
-----------   ----                  ----------
 Cmdlet       Add-CdmApplicationRight   Add-CdmApplicationRight -Right ...
 Cmdlet       Add-CdmCommandRight       Add-CdmCommandRight -Right <Cdm...
 Cmdlet       Add-CdmDesktopRight       Add-CdmDesktopRight -Right <Cdm...
 Cmdlet       Add-CdmNetworkAccessRight Add-CdmNetworkAccessRight -Righ...
 Cmdlet       Add-CdmPamRight           Add-CdmPamRight -Right <CdmPamR...
 Cmdlet       Add-CdmSshRight           Add-CdmSshRight -Right <CdmSshR...
 Cmdlet       Get-CdmApplicationRight   Get-CdmApplicationRight [-Zone ...
 Cmdlet       Get-CdmCommandRight       Get-CdmCommandRight [-Zone <Cdm...
 Cmdlet       Get-CdmComputerRole       Get-CdmComputerRole -Zone <CdmZ...
 Cmdlet       Get-CdmDesktopRight       Get-CdmDesktopRight [-Zone <Cdm...
 Cmdlet       Get-CdmGroupProfile       Get-CdmGroupProfile [-Zone <Cdm...
 ...
```

Managing Delinea Objects Using Windows PowerShell Scripts

This section provides an overview of how to use cmdlets to access and manage authentication and privilege elevation information stored in Active Directory using Windows PowerShell scripts. It provides a summary of the operations you can perform using cmdlets and how to establish a connection to Active Directory. For more examples of how to perform common administrative tasks using the cmdlets, see the samples included with the software.

Using cmdlets to Manage Access

The Delinea access module for PowerShell provides cmdlets that perform operations on objects that correspond to the core elements of Delinea data. Those core elements are:

- Computer role definitions
- Computers
- Groups and group profiles
- NIS network maps and map entries
- Role assignments
- UNIX and Windows rights
- User role definitions
- Users and user profiles
- Zones and zone properties

In most cases, cmdlets can manipulate Delinea information in any type of zone. However, because authorization differs greatly between hierarchical and classic zones, the cmdlets that enable you to work with rights, roles, or role assignments are only applicable in hierarchical zones. You should not use the cmdlets for rights, roles, and role assignments in classic zones. Other than this limitation, you can use the cmdlets to create, access, modify, and remove information associated with any of the core elements of Delinea data for access control and privilege management.

Most of the cmdlets perform one of the following basic operations:

- Add-CdmXxx cmdlets add a right to a specified role.
- Get-CdmXxx cmdlets get the properties of a specified object.
- New-CdmXxx cmdlets create new Delinea objects, such as a new zone or a new role definition.
- Remove-CdmXxx cmdlets delete a specified object or remove a right from a specified role.
- Set-CdmXxx cmdlets set or change the properties of a specified object.

In addition to these basic operations, there are cmdlets for exporting and importing rights and roles from one zone to another and for establishing connections with Active Directory.

For descriptions of the use and parameters for each cmdlet, use the get-help command within the PowerShell console. For example, if you want to see a description and syntax summary for the New-CdmZone cmdlet, type the following command in the PowerShell console:

```
get-help New-CdmZone
```

To see detailed information about a cmdlet's parameters and code examples, you can use the -detailed or -full option. For example, type the following command in the PowerShell console:

```
get-help New-CdmZone -detailed
```

Creating and Using a Connection

Because the Delinea access module for PowerShell cmdlets manipulate objects in Active Directory, you must establish a connection with Active Directory before using cmdlets to perform other tasks. To do that, you must specify a target domain or domain controller and the credentials to use when connecting to that domain or domain controller.

Once the credentials are set, all subsequent calls share that information—you do not have to provide the credential or the domain controller for any subsequent calls.

The following example illustrates how to use the administrator account to connect to the finance.acme domain, then add the user joe.doe to the Engineering zone:

```
PS C:\> Set-CdmCredential "finance.acme" "administrator"
PS C:\> Get-CdmCredential
Target          Type   User
------          ----   ----
finance.acme    Forest administrator@finance.acme
PS C:\> $zone = Get-CdmZone -Name "Engineering"
PS C:\> New-CdmUserProfile -Zone $zone -User "joe.doe@finance.acme" -Login "jdoe"
```

In this example, the cmdlets that get the zone and create the user profile use the credential that is cached by the Set-CdmCredential command. The Get-CdmCredential cmdlet shows what credentials are currently cached.

Managing Connections

You can use the following cmdlets to manage connections to Active Directory by adding, modifying, or using cached credentials or specifying domain-controller-to-domain mappings:

- Set-CdmCredential to add or modify a credential in the cache.
- Get-CdmCredential to list the credentials currently cached.
- Set-CdmPreferredServer to specify a domain controller to use for a domain.
- Get-CdmPreferredServer to list all previously defined domain mappings.

Specifying Credentials

You can use the Set-CdmCredential cmdlet to specify a credential that you want to cache as a PSCredential object. Create the PSCredential object using the Get-Credential cmdlet. The Get-Credential cmdlet prompts users to specify a username and password. You can also pass the username as a parameter to the Get-Credential cmdlet to have the cmdlet prompt the user for the password.

Organizing cmdlet Operations in a Sequence

There is no fixed sequence for calling cmdlets. There is, however, a logical sequence to follow to pass data from one cmdlet to another. For example, to get all of the user UNIX profiles in a zone, you must first identify the zone object before you call the Get-CdmUserProfile cmdlet, To accomplish this, you could organize the calls in the following sequence:

```
$zone = Get-CdmZone -Name "myZone"
Get-CdmUserProfile -Zone $zone
```

Similarly, to get all of the UNIX user profiles for a computer, you must first identify the computer object:

```
$computer = Get-CdmManagedComputer -Name "myComputer"
Get-CdmUserProfile -Computer $computer
```

In most cases, you can determine from the parameters of a cmdlet whether you need to call another cmdlet first. For example, if you want to add a right to a role, you must have created the role first so it can be specified as a parameter to the Add-CdmXxx cmdlet.

For most Set-CdmXxx or Remove-CdmXxx cmdlets, you must call the corresponding Get-CdmXxx or Add-CdmXxx cmdlet to obtain the object first. For example, to delete role1 from zone1, you might call the cmdlets as follows:

```
Get-CdmRole -Zone "cn=zone1,cn=Zones,dc=acme,dc=com" -Name "role1" | Remove-CdmRole
```

In this example, the Get-CdmRole cmdlet retrieves “role1” from the specified zone and passes it to the Remove-CdmRole cmdlet via a PowerShell pipe.

Confirming Licenses

All of the authentication and privilege elevation cmdlets check for a valid license before performing the requested action. The license check succeeds only if there is at least one evaluation, workstation, or server license that has not expired.

If the license check fails, the cmdlet displays an error and stops running. Otherwise, the result is cached. The next time a cmdlet tries to access the same forest, it uses the cached result rather than performing the license check again.

> **Note:** The cache is only effective in one PowerShell console. If another PowerShell console runs a cmdlet accessing the same forest, the cmdlet in that console must perform a separate license check.

Working with Sample Scripts

Introduction

There are several sample scripts included with the software to demonstrate a few common administrative tasks. You can copy and modify these samples to use them in your environment or study them as examples for writing your own custom scripts. The sample scripts include detailed comments about the operations performed to accomplish the following tasks.

Table: Sample Scripts for Administrative Tasks

backup.ps1	How to create a backup copy of a self-contained Delinea zone. This script creates an XML file that contains all computer, user, and group profiles, authorization information, and child zone information for a parent Delinea zone. You cannot use this script to backup SFU zones or child zones.
CreateZoneAndDelegate.ps1	How to create a new zone and delegate all zone administrative tasks to a specific trustee.
RemoveAllOrphans.ps1	How to find and delete all user, group, and computer profiles that no longer have a corresponding Active Directory account on all managed computers in each zone.
RemoveEmptyCompRoles.ps1	How to find and remove computer roles that have no members. This script is only applicable for hierarchical zones.
RemoveEmptyZones.ps1	How to find and remove zones that have no computers, users, or authorization information. This script only removes a zone if it contains no user or group profiles, joined computers, role assignments, computer roles, or child zones. If any of these objects exist for a zone, the zone is not removed. This script is only applicable for hierarchical zones.
ResetOrphanChildZones.ps1	How to find child zones that no longer have a parent zone and reset them as independent zones.
restore.ps1	How to restore a self-contained Delinea zone from a backup created using the backup.ps1 sample script.

Running a Sample Script

To run a sample script:

1. Open the Delinea access module for PowerShell.
2. Verify you have permission to execute scripts by running Get-ExecutionPolicy. In most cases, the permission to execute scripts is restricted.
3. If necessary, use Set-ExecutionPolicy to allow execution. For example:

   ```
   Set-ExecutionPolicy Unrestricted
   ```

   Note: For more about execution policies and the options available, run the get-help command.
4. Verify you are in the directory where the scripts are located.
5. Execute the sample script. For example:

   ```
   .\RemoveAllOrphans
   ```

Modifying the Backup and Restore Scripts for Your Needs

If you want to use the sample backup and restore scripts to backup self-contained Delinea zones, you must modify the content of the scripts before executing them. To run a modified sample backup script:

1. Open the backup.ps1 file in a text editor.
2. Modify the path to the zone you want to back up and the path to the backup file at the start of the sample script. For example:

   ```
   $zoneDn = "CN=Headquarters,CN=Zones,OU=Acme Sales,DC=pistolas,DC=org"
   $xmlPath = "C:\Program Files\Centrify\HQ-test.xml"
   ```
3. Modify the confirmation message at the end of the script to display the path to the backup file. For example:

   ```
   Write-Host "Backup to C:\Program Files\Centrify\HQ-test.xml is done."
   ```
4. Save your changes with a new file name, for example, HQbackup.ps1, to keep the sample backup.ps1 script unchanged.
5. Open the Delinea access module for PowerShell.

Using the Default Windows PowerShell Console

Alternatively, you can use the default Windows PowerShell console. If you choose to use that console, run import-module with the path to the access module for PowerShell libraries before performing the above procedure. For example, if you installed the module in the default location, run the following command to import the Delinea access module for PowerShell:

```
import-module "C:\Program Files\Centrify\PowerShell\Centrify.DirectControl.PowerShell.dll"
```

Creating New Zones with the Sample CreateZoneAndDelegate Script

You can use the CreateZoneAndDelegate.ps1 sample script to automate creating new zones and assigning an Active Directory user or group as the zone administrator. By default, the script delegates all administrative tasks to the user or group you specify. To use the script without modification, simply specify the Active Directory container where you want to create the zone, the zone name, and the user or group designated as the zone administrator.

To create new zone using the sample script:

1. Open the Delinea access module for PowerShell.
2. Verify you are in the directory where the scripts are located.
3. Execute the sample script with the required command line arguments. For example:

   ```
   .\CreateZoneAndDelegate -Container "cn=Zones,ou=Acme Sales,dc=pistolas,dc=org" -ZoneName seattle -trustee  frank.smith@pistolas.org
   ```

4. Open Access Manager.
5. Right click **Zones** and select **Open Zone** to search for and select the new zone.
6. If you want to delegate specific administrative tasks, copy the sample script and modify the Set-CdmDelegation call to specify a list of tasks. For example:

   ```
   Set-CdmDelegation -Zone $zone -Task "AddUsers","AddGroups" -Trustee $trustee;
   Write-Host "$trustee is delegated the rights to add users and groups.";
   ```

Generating Reports from Predefined Scripts

Most of the predefined reports in access manager report center have a corresponding PowerShell script that you can use to generate reports from the PowerShell console. See Using Predefined Scripts to Generate Reports for details.

Writing Custom Scripts

Most cmdlets and scripts return information efficiently without any special handling or any noticeable effect on performance. If you plan to write custom scripts that may return large data sets, you should consider ways to improve performance. For example, if you are writing a script that exports a large number of zones or reports on a large number of users, you might want to use the following recommendations as guidelines:

- When testing the performance of the script, use the standard Measure-Command cmdlet to accurately measure cmdlet and script performance.

  Note: The Measure-Command cmdlet ignores the time it takes to print all of the results returned to the PowerShell console. In many cases, the execution of a script is efficient, but rendering the results in the PowerShell console might make the cmdlet or script performance seem unacceptable.

- Consider how you want to balance memory usage and performance when using the PowerShell pipeline if your cmdlet or script returns large data collections.

  For example, you might use foreach in a script instead of using the pipeline to improve performance. Use syntax similar to this:

  ```
  foreach ($cmd in Get-CdmUserProfile -Zone $z) { action_on_each_cmd }
  ```

  Instead of:

  ```
  Get-CdmUserProfile -Zone $z | action_on_each_cmd
  ```

  However, if you choose not to use the pipeline, all of the returned objects stay in memory and might cause an out-of-memory error. Therefore, you should try to maintain balance between the scripts memory usage and performance.

- Cache the data, if possible, by writing the results to a file.

  For example, to add 1000 users to a zone use syntax similar to this to get a zone once:

```
$zone = Get-CdmZone -Dn "cn=QA,cn=Zones,dc=ajax,dc=org" $profile1 = New-CdmUserProfile -Zone $zone -User user1@ajax.org -Uid 10001 ... $profile1000 = New-CdmUserProfile -Zone $zone -User user1000@ajax.org -Uid 11000
```

Instead of using syntax like this, which gets the zone from its distinguished name (DN) for every user:

```
$profile1 = New-CdmUserProfile -Zone "cn=QA,cn=Zones,dc=ajax,dc=org" -User user1@domain.com -Uid 10001 ... $profile1000 = New-CdmUserProfile -Zone "cn=QA,cn=Zones,dc=ajax,dc=org" -User user1000@domain.com -Uid 11000
```

- Use Export-Csv instead of Out-File if possible. The Export-Csv cmdlet writes results to a file faster than the Out-File cmdlet.
- If you are writing a script that generates a very large data set—for example, reporting information for a global zone—you might want to use the native .NET FileStream function. The FileStream function is the fastest way to write content to a file.

  For example, you might use a code snipper like this:

```
$fs = New-Object IO.FileStream <file>, 'Append','Write','Read'
   $fw = New-Object System.IO.StreamWriter $fs
     $zone = Get-CdmZone -Dn "cn=global,cn=Zones,dc=ajax,dc=org"
    foreach ($cz in $zone) {$fw.WriteLine("{0} {1}", $cz.Name, $cz.Type)}
  $fw.Close()
 $fs.Dispose()
```

Enabling Logging for cmdlets

For performance, logging for cmdlets is disabled by default. To enable logging, you must modify the registry on the computer where you are running the access module for Windows PowerShell.

To enable logging:

1. Run regedit to open the Registry Editor
2. Select the HKEY_CURRENT_USER > Software > Delinea registry key.
3. Right-click, then select New > Key and type CIMS.
4. Select the new CIMS key, right-click, then select New > String Value with the name of LogPath.
5. Specify the path to the log file as the value. For example, set the value to C:\Temp\Log.
6. Select the new CIMS key, right-click, then select New > DWORD (32-bit) Value with the name of TraceLevel.
7. Specify the level of detail to write to the log file as the value. The valid settings are:

   0 to disable logging. 1 to only log error messages. 2 to log errors and warning messages. 3 to log errors, warnings, and informational messages. 4 to log all debugging and tracing messages.

   For example, set the value to 4 to enable detailed logging of all messages.

Viewing a Summary of cmdlet Commands

You can use the get-help command with different options to get summary about the cmdlets available in the Delinea access module for PowerShell or detailed information about the specific cmdlets you want to use. For example, you can use get-help with the -full command-line option to see complete reference information for a specified cmdlet or get-help -example to display only the examples for a specified cmdlet.

To see the current list of cmdlets available open the Delinea access module for PowerShell, run the get-help cdm command. This command displays a summary of the access module for PowerShell cmdlets similar to the following table (rendered as ASCII characters):

Table: Summary of cmdlet Commands Output by the get-help cdm Command

Objects and Properties

This section lists the objects defined by the authentication and privilege-elevation PowerShell module and the properties of each object.

This chapter provides an alphabetical listing of the objects and the properties of each object defined in the Access module for PowerShell. Note that not all properties are available as parameters in the PowerShell cmdlets.

CdmAdObject Object

Represents an Active Directory object. The following properties are defined for this object.

Table: CdmAdObject Properties

Class	string	Class of the Active Directory object.
DistinguishedName	string	Distinguished name of the Active Directory object.
Guid	Guid	Globally unique identifier (GUID) of the Active Directory object.
Name	string	Name of the Active Directory object.

CdmAdPrincipal Object

Represents an Active Directory account principal. The following properties are defined for this object.

Table: CdmAdPrincipal Properties

Class	string	Class of the Active Directory object.
DistinguishedName	string	Distinguished name of the Active Directory object.
Guid	Guid	Globally unique identifier (GUID) of the Active Directory object.
Name	string	Name of the Active Directory object.
SamAccountName	string	SAM account name of the Active Directory principal.
Sid	SecurityIdentifier	Security identifier (SID) of the Active Directory principal.

CdmApplicationRight Object

Represents a Windows application access right. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmApplicationRight Properties

Description	string	Description of the application right.
IsRequireMfa	Boolean	Indicates whether the application right requires multi-factor authentication.
MatchCriteria	MatchCriteria[]	Filter criteria defined by an array of MatchCriteria objects that identifies the application associated with the application right.
Name	string	Name of the application right.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Priority	int	Priority of the application right; highest priority prevails.
RequirePassword	Boolean	Indicates whether the application right requires authentication.
RunasSelfGroups	group	The group privileges to add to the user's account when running the application associated with the application right.
RunasUser	user	The user to run the application as.
Zone	zone	Zone where the application right is defined.

CdmCommandRight Object

Represents a UNIX command right. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmCommandRight Properties

AddVar	string	Comma separated list of environment variable name-value pairs to add to the final list resulting from KeepVar or DeleteVar property (for instance, "var1=a,var2=b,var3=c").
Authentication	string	The authentication type of the command right: none, user, or runastarget.
DeleteVar	string	Comma separated list of environment variables to remove from default set when command is run.
Description	string	Description of the command right.
Digests	string	Specifies SHA-2 digests so that sudo can verify the binary's checksum (SHA-2) before sudo executes the binary. The supported hash types are sha224, sha256, sha384, and sha512.
DzdoRunAsGroup	string	Comma-separated string of groups allowed to run this command using dzdo (for example, "group1,group2,group3"). The asterisk wild card (*) means any group enabled for the zone can run the command. An empty string ("") means the command cannot run as any group.
DzdoRunAsUser	string	Comma-separated list of users allowed to run this command using dzdo (for example, "user1,user2,user3"). - The asterisk wild card (*) means any user enabled for the zone can run the command. An empty string ("") means the command cannot run as any user.
DzshRunas	string	The user this command will run as under dzsh, '$' means current user.
IsAllowNested	Boolean	True if the command is allowed to start another program or open a new shell.
IsDisablePathTraverse	Boolean	True if the command does not allow navigation up the path hierarchy as an argument.
IsPreserveGroup	Boolean	True to retain the user's group membership while executing a command.
IsRequireMfa	Boolean	Indicates whether the command right requires multi-factor authentication.
KeepVar	string	Comma separated list of environment variables to keep in addition to those in dzdo.env_keep when command is run.
MatchPath	string	The path for matching the command.
Name	string	Name of the command right.
Pattern	string	Command pattern for matching the command.
PatternType	string	The type of pattern—glob or regexp—used to match the command.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Priority	int	Priority for this command; highest priority prevails.
SELinuxRole	string	Sets the SELinux security context to use the specified role when executing a command using dzdo or dzsh. Applies to command rights on Red Hat Enterprise Linux systems that have SELinux enabled and are joined to a hierarchical zone.
SELinuxType	string	Sets the SELinux security context to use the specified type when executing a command using dzdo or dzsh. Applies to command rights on Red Hat Enterprise Linux systems that have SELinux enabled and are joined to a hierarchical zone.
UMask	string	User file-creation mode mask (umask) value that defines who can execute the command.
Zone	CdmZone	Zone of the command right.

CdmComputer Object

Represents an Active Directory computer object. The following properties are defined for this object.

Table: CdmComputer Properties

Class	string	Class of the Active Directory object.
DistinguishedName	string	Distinguished name of the Active Directory object.
DNSHostName	string	DNS host name of the Active Directory computer.
Enabled	Boolean	True if the Active Directory computer is enabled.
Guid	Guid	GUID of the Active Directory object.
Name	string	Name of the Active Directory object.
SamAccountName	string	SAM account name of the Active Directory principal.
Sid	SecurityIdentifier	SID of the Active Directory principal.
UserPrincipalName	string	User principal name of the Active Directory computer.

CdmComputerRole Object

Represents a Delinea computer role. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmComputerRole Properties

CustomAttributes	string	Custom text strings for the computer role.
Description	string	Description of the computer role.
Group	CdmGroup	Computer group associated with this computer role.
Name	string	Name of the computer role.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Zone	CdmZone	Zone that contains the computer role.

CdmDesktopRight Object

Represents a Windows desktop access right. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmDesktopRight Properties

Description	string	Description of the desktop right.
IsRequireMfa	Boolean	Indicates whether the desktop right requires multi-factor authentication.
Name	string	Name of the desktop right.

PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Priority	int	Priority of the desktop right; highest priority prevails.
RequirePassword	Boolean	True if the desktop right requires a password.
RunasSelfGroups	CdmGroup[]	Groups whose privileges are added to the user account running the desktop.
RunasUser	CdmUser	User to run the desktop as.
Zone	CdmZone	Zone of the desktop right.

CdmEffectiveUnixRights Object

Represents the UNIX rights assigned to a user that are in effect on a Linux or UNIX computer in a zone. The following properties are defined for this object.

Table: CdmEffectiveUnixRights Properties

AuditLevel	string	Effective auditing level.
CommandRights	CdmEffectiveCommandRight []	The array of effective command rights assigned to the user.
Computer	CdmManagedComputer	The computer in which the roles and rights are effective.
HasRescueRight	Boolean	True if the user has the rescue right.
PamRights	CdmEffectivePamRight[]	The array of effective PAM rights assigned to the user.
Profiles	CdmEffectiveUserProfile[]	Effective UNIX profiles for the Active Directory user in the computer.
Roles	CdmEffectiveRole[]	The array of effective roles assigned to the user.
SshRights	CdmEffectiveSshRight[]	The array of effective SSH rights assigned to the user.
UnixSystemRights	string[]	Effective UNIX system rights.
User	CdmUser	Active Directory user assigned to the role.

CdmEffectiveWindowsRights Object

Represents the Windows rights assigned to a user that are in effect on a Windows computer in a zone. The following properties are defined for this object.

Table: CdmEffectiveWindowsRights Properties

AuditLevel	string	Effective auditing level.
ApplicantionRights	CdmEffectiveApplicationRight	The array of effective application rights assigned to the user.
Computer	CdmManagedComputer	The computer in which the roles and rights are effective.

DesktopRights	CdmEffectiveDesktopRight	The array of effective desktop rights assigned to the user.
HasRescueRight	Boolean	True if the user has the rescue right.
NetworkRights	CdmEffectiveNetworkRigh	The array of effective network access rights assigned to the user.
Roles	CdmEffectiveRole	The array of effective roles assigned to the user.
WindowsSystemRights	string[]	Effective Windows system rights.
User	CdmUser	Active Directory user assigned to the role.

CdmGroup Object

Represents an Active Directory group. The following properties are defined for this object.

Table: CdmGroup Properties

Class	string	Class of the Active Directory object.
DistinguishedName	string	Distinguished name of the Active Directory object.
GroupCategory	ADGroupCategory	Category of the Active Directory group.
GroupScope	ADGroupScope	Scope of the Active Directory group.
Guid	Guid	GUID of the Active Directory object.
Name	string	Name of the Active Directory object.
SamAccountName	string	SAM account name of the Active Directory principal.
Sid	SecurityIdentifier	SID of the Active Directory principal.

CdmGroupProfile Object

Represents a UNIX group profile. The following properties are defined for this object.

Table: CdmGroupProfile Properties

Computer	CdmManagedComputer	Computer that contains the profile.
Gid	long	GID of the group profile.
Group	CdmGroup	Active Directory group of the group profile.
IsHierarchical	Boolean	True if the group profile is in a hierarchical zone.
IsMembershipRequired	Boolean	True if users are required to be a member of this group.
IsOrphan	Boolean	True if the group profile is an orphan profile, that is, it has no corresponding Active Directory group.

IsSfu	Boolean	True if the group profile is a SFU profile.
Name	string	Name of the group profile.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Zone	CdmZone	Zone that contains the profile.

CdmLocalGroupProfile Object

Represents a local UNIX group profile. The following properties are defined for this object.

Table: CdmLocalGroupProfile Properties

CanonicalName	string	Canonical name of the local group profile.
Computer	CdmManagedComputer	Computer where the local group profile is defined.
Domain	string	Domain of the local group profile.
Gid	long	GID of the group profile.
Members	string[]	Members of the local group profile.
Name	string	Name of the group profile.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
State	enum	State of the local group profile. The valid values are: Enable, Remove. and Inherit The default state is Inherit.
Zone	CdmZone	Zone that contains the profile.

CdmLocalUserProfile Object

Represents a local UNIX user profile. The following properties are defined for this object.

Table: CdmLocalUserProfile Properties

CanonicalName	string	Canonical name of the local user profile.
Computer	CdmManagedComputer	Computer where the local user profile is defined.
Domain	string	Domain of the local user profile.
Gecos	string	GECOS field of the local user profile.
HomeDir	string	Home directory of the user associated with the local profile.
Name	string	Name of the user associated with the local profile.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.

PrimaryGroupId	long	Primary group ID of the user associated with the local profile.
Shell	string	Default shell of the user associated with the local profile.
State	enum	State of the local user profile. The valid values are: Enable, Remove, and Inherit The default state is Inherit.
Uid	long	Numeric user identifier (UID) of the user associated with the local profile.
Zone	CdmZone	Zone where the local user profile is defined.

CdmLocalWindowsGroup Object

Represents a local Windows group account. The following properties are defined for this object.

Table: CdmLocalWindowsGroup Properties

CanonicalName	string	Canonical name of the local group in Active Directory.
Computer	CdmManagedComputer	Computer where the local group is defined.
Description	string	Description for the local group.
Domain	string	Domain of the local group in Active Directory.
Members	string[]	Members of the local group .
Name	string	Name of the local group .
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
State	LocalWindowsGroupState enum	State of the local group . The valid values are: Enable, Remove, and Inherit The default state is Inherit.
Zone	CdmZone	The zone where the local group is defined.

CdmLocalWindowsUser Object

Represents a local Windows user account. The following properties are defined for this object.

Table: CdmLocalWindowsUser Properties

CanonicalName	string	Canonical name of the local user account in Active Directory.
Computer	CdmManagedComputer	Computer where the local user is defined.
Description	string	Description for the local user.
Domain	string	Domain of the local user account in Active Directory.
FullName	string	Full name of the local user.

Name	string	Name of the local user.
PasswordOptions	LocalWindowsUserPasswordOption enum	Password options of the local user. Possible values are: None, Inherit, UserMustChangePasswordAtNextLogon, UserCannotChangePassword, PasswordNeverExpires. It can be a combination of UserMustChangePasswordAtNextLogon and PasswordNeverExpires, UserCannotChangePassword and PasswordNeveExpires.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
State	LocalWindowsUserState enum	State of the local user. he valid values are: Enable, Remove, and Inherit The default state is Inherit.
Zone	CdmZone	The zone where the local user is defined.

CdmManagedComputer Object

Represents a computer managed by authentication and privilege elevation. The following properties are defined for this object.

Table: CdmManagedComputer Properties

AgentVersion	string	Version number of the Delinea Agent installed on the managed computer.
Computer	CdmComputer	Corresponding Active Directory computer account.
ComputerZonePath	string	Path to the computer zone.
IsComputerZoneOnly	Boolean	True if the managed computer has a computer zone only (that is, the computer is not joined to a zone).
IsExpressMode	Boolean	True if the managed computer is in Express (unlicensed) mode.
IsHierarchical	Boolean	True if the managed computer is joined to a hierarchical zone.
IsOrphan	Boolean	True if the managed computer is an orphan profile, that is, it has no corresponding Active Directory computer object.
IsWindows	Boolean	True if the managed computer is a Windows computer.
IsWorkstationMode	Boolean	True if the managed computer is joined to Auto Zone in Workstation mode.
IsJoinedToZone	Boolean	True if the managed computer is joined to a zone.
LicenseType	string	Type of license being used. This property is Server if the managed computer is a Windows or UNIX server or Workstation if the managed computer is not used as a server.
Name	string	Name of the managed computer.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
ScpPath	string	Path to the service connection point for the managed computer.
Zone	CdmZone	Zone of the managed computer.

CdmMatchCriteria Object

Represents an application right match criteria object defined using the application rights match criteria filters. The following properties are defined for this object.

Table: CdmMatchCriteria Properties

Argument	string	The argument for the application.
CompanyName	string	All or part of the company name associated with the application.
CompanyNameMatchOption	string	Specifies whether the company name string should be an exact match (is) or a partial match (contains).
Description	string	The description for the application criteria.
FileDescription	string	All or part of the file description for the application.
FileDescriptionMatchOption	string	Specifies whether the file description string should be an exact match (is) or a partial match (contains).
FileHash	string	The file hash for an application.
FileName	string	The file name for an application.
FileType	string	The file type for an application.
FileVersion	string	All or part of the file version information for an application.
FileVersionMatchOption	string	Specifies whether the file version string should be an exact match (equal), an earlier or equal version (earlier or equal), or a later or equal version (later or equal).
IsArgumentCaseSensitive	Boolean	True if the argument specified is case sensitive.
IsArgumentExactMatch	Boolean	True if the argument must be matched exactly as specified.
IsRequireAdministrator	Boolean	True if the application requires administrator privileges to execute.
LocalOwner	string	The local owner for the application.
LocalOwnerType	string	The local owner type for the application.
OwnerSid	string	The owner security identifier (SID) for the application.
Path	string	The path to an application.
ProductName	string	All or part of the product name associated with the application.
ProductNameMatchOption	string	Specifies whether the product name string should be an exact match (is) or a partial match (contains).
ProductVersion	string	All or part of the product version information for an application.
ProductVersionMatchOption	string	Specifies whether the product version string should be an exact match (equal), an earlier or equal version (earlier or equal), or a later or equal version (later or equal).
Publisher	string	The publisher for an application.
PublisherMatchOption	string	Specifies whether the publisher string should be an exact match (is), a partial match (contains), start with, or end with the specified string.

SerialNumber	string	The serial number for an application.
SerialNumberMatchOption	string	Specifies whether the serial number string should be an exact match (is), a partial match (contains), start with, or end with the specified string.

CdmNetworkRight Object

Represents a Windows network access right. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmNetworkRight Properties

Description	string	Description of the network right.
IsRequireMfa	Boolean	Indicates whether the network access right requires multi-factor authentication.
Name	string	Name of the network right.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Priority	int	Priority of the network right; highest priority prevails.
RequirePassword	Boolean	True if the network right requires a password.
RunasSelfGroups	CdmGroup[]	Groups whose privileges are added to the user account accessing the network.
RunasUser	CdmUser	Run-as user of the network right.
Zone	CdmZone	Zone of the network right.

CdmPamRight Object

Represents a PAM application access right. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmPamRight Properties

Application	string	PAM application for this right.
Description	string	Description of the PAM access right.
Name	string	Name of the PAM access right.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Zone	CdmZone	Zone of the PAM access right.

CdmRole Object

Represents a authentication and privilege elevation role. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmRole Properties

AllowLocalUser	Boolean	True if the role can be assigned to a local user.
AuditLevel	string	Audit setting for this role.
CustomAttributes	string	Custom text strings for the role.
Description	string	Description of the role.
HasRescueRight	Boolean	True if this role can operate without being audited in case of audit system failure.
Name	string	Name of the role.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
RequireMfa	Boolean	True if the role requires multi-factor authentication.
TimeBox	Hashtable	Active time of the role.
UnixSystemRights	string[]	UNIX system rights granted to the role.
WindowsSystemRights	string[]	Windows system rights granted to the role.
Zone	CdmZone	Containing zone.

CdmRoleAssignment Object

Represents a authentication and privilege elevation role assignment. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmRoleAssignment Properties

AdTrustee	CdmAdPrincipal	The trustee, if it is an Active Directory account.
Computer	CdmManagedComputer	Containing computer.
ComputerRole	CdmComputerRole	Containing computer role.
CustomAttributes	string	Custom text strings for the role assignment.
Description	string	The role assignment description.
EndTime	DateTime	The ending date and time for the role assignment.
IsNeverExpire	Boolean	True if the role assignment never expires.
IsRoleOrphaned	Boolean	True if the role is missing or invalid.
IsStartImmediately	Boolean	True if the role assignment starts immediately.
IsTrusteeOrphaned	Boolean	True if the trustee is missing or invalid.
LocalTrustee	string	The trustee, if it is a local account.

PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Role	CdmRole	Assigned role.
StartTime	DateTime	The starting date and time for the role assignment.
TrusteeType	string	Type of trustee.
Zone	CdmZone	Containing zone.

CdmSshRight Object

Represents an SSH application access right. This object is only applicable in hierarchical zones. The following properties are defined for this object.

Table: CdmSshRight Properties

Application	string	Secure shell application for this right.
Description	string	Description of the SSH right.
Name	string	Name of the SSH right.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
Zone	CdmZone	Zone of the SSH right.

CdmUser Object

Represents an Active Directory user. The following properties are defined for this object.

Table: CdmUser Properties

Class	string	Class of the Active Directory object.
DistinguishedName	string	Distinguished name of the Active Directory object.
Enabled	Boolean	True if the Active Directory user is enabled.
GivenName	string	Given name of the Active Directory user.
Guid	Guid	GUID of the Active Directory object.
IsAllADUser	Boolean	True if the user is an Active Directory domain user account.
Name	string	Name of the Active Directory object.
SamAccountName	string	SAM account name of the Active Directory principal.
Sid	SecurityIdentifier	SID of the Active Directory principal
Surname	string	Surname of the Active Directory user.

UserPrincipalName	string	User principal name of the Active Directory user.

CdmUserProfile Object

Represents a UNIX user profile. The following properties are defined for this object.

Table: CdmUserProfile Properties

Computer	CdmManagedComputer	Containing computer.
Gecos	string	GECOS field of the user profile.
HomeDirectory	string	Home directory of the user associated with the profile.
IsHierarchical	Boolean	True if the user profile is in a hierarchical zone.
IsOrphan	Boolean	True if the user profile is an orphan profile, that is, it has no corresponding Active Directory user.
IsSecondary	Boolean	True if the user profile is a secondary profile.
IsSfu	Boolean	True if the user profile is an SFU profile.
IsUseAutoPrivateGroup	Boolean	True if the user private group is to be used as the primary group.
Name	string	Name of the user associated with the profile.
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
PrimaryGroupId	long	Primary group ID of the user associated with the profile.
Shell	string	Default shell of the user associated with the profile.
Uid	long	UID of the user associated with the profile.
UnixEnabled	Boolean	True if the user profile is enabled for a classic zone. This property is not applicable in hierarchical zones.
User	CdmUser	Active Directory user for whom this is the user profile.
Zone	CdmZone	Containing zone.

CdmZone Object

Represents a Delinea zone. The following properties are defined for this object.

Table: CdmZone Properties

AgentlessPasswordAttribute	string	Attribute in which to store the password hash for agentless client.
AvailableShells	string[]	Array of available shells that can be used as the default shell for zone users.
CanonicalName	string	Canonical name of the zone.

CloudInstance	String	Cloud instance URL to which the zone connects.
DefaultGecos	string	Default GECOS field for zone users.
DefaultGid	long	Default GID value to use for zone groups.
DefaultGroupName	string	Default group name to use for zone groups.
DefaultHomeDirectory	string	Default home directory for zone users.
DefaultPrimaryGroup	string	Default primary group to use for zone users.
DefaultShell	string	Default shell for zone users.
DefaultUid	long	Default UID value to use for zone users.
DefaultUserName	string	Default user name to use for zone users.
DefaultValueZone	CdmZone	Zone to use as the source for default values in a selected zone.
Description	string	Description of the zone.
DistinguishedName	string	Distinguished name of the zone.
Domain	string	Active Directory domain associated with the zone.
IsBlockGroupInheritance	Boolean	True if groups defined in a parent zone are not inherited, and therefore not visible, in a child zone. This property is only applicable for hierarchical zones.
IsHierarchical	Boolean	True if it is a hierarchical zone.
IsOrphanChildZone	Boolean	True if the zone is a child zone with no parent zone (Hierarchical zone only).
IsSfu	Boolean	True if it is a SFU zone.
Name	string	Name of the zone.
NextGid	long	Next GID value available for assignment to a zone group.
NextUid	long	Next UID value available for assignment to a zone user.
NisDomain	string	NIS domain for SFU zone or agentless mode.
Parent	CdmZone	Parent zone (Hierarchical zone only).
PreferredServer	string	Preferred server to use for committing changes to Active Directory.
ReservedGid	long	Reserved GID values that cannot be assigned to a zone group.
ReservedUid	long	Reserved UID values that cannot be assigned to a zone user.
Schema	string	Schema of the zone.
SfuDomain	string	SFU domain of the zone (SFU zone only).

TenantId	String	The TenantId of the zone
TruncateUserName	Boolean	True if user names longer than 8 characters are automatically truncated for the zone.
Type	string	Type of the zone.
Variables	string[]	Array of runtime variables.

Adding Users in a One-Way Trust Environment

This section explains how to add a user in a one-way trust environment using the authentication and privilege-elevation PowerShell module.

Some operations, such as adding a user to a zone, may require more than one credential. For example, if you want to add a user from one forest to a zone in another forest when there is a one-way trust between the forest, you might need to specify credentials for each forest. This section explains how to add a user in a one-way trust environment when using PowerShell cmdlets.

Using One Account Credential

If you want to add the user targetuser, who has a domain user account in forest2.net to the zone1 in forest1.net, where forest1.net trusts forest2.net (a one-way trust), you must use an account that has the following permissions:

- Permission to add a user to zone1 in forest1.net.
- Permission to read accounts in forest2.net.

If you have a single account with the appropriate permissions—for example, superuser in forest2.net—you can add the targetuser from forest2.net to the zone1 in forest1.net as follows:

```
Set-CdmCredential "forest1.net" "forest2\superuser"
New-CdmUserProfile -Zone "cn=zone1,cn=Zones,dc=forest1,dc=net" -User "cn=targetuser,cn=Users,dc=forest2,dc=net" -login "UNIXname" -uid nnnnn
```

where UNIXname is the UNIX login name of targetuser and nnnn is the UID of the targetuser.

Using Two Account Credentials

If you do not have a single account with the appropriate permissions in the two forests, adding the targetuser to a zone in another forest will require two account credentials. For example, you must identify accounts with the following permissions:

- An account in forest1.netthat has permission to add a user to zone1 (user1).
- An account in forest2.net that has read permission on forest2.net (user2).

After you identify the accounts with the appropriate permissions—for example, user1 in forest1.net and user2 in forest2.net—you can add the targetuser from forest2.net to the zone1 in forest1.net as follows:

```
Set-CdmCredential "forest1.net" "forest1\user1"
Set-CdmCredential "forest2.net" "forest2\user2"
New-CdmUserProfile -Zone "cn=zone1,cn=Zones,dc=forest1,dc=net" -User "targetUser@forest2.net" -login "UNIXname" -uid nnnnn
```

where UNIXname is the UNIX login name of targetuser and nnnn is the user's UID.

Using Predefined Scripts to Generate Reports

This section describes the predefined report scripts that are included with the authentication and privilege-elevation PowerShell module and how to configure report output files to generate HTML- and PDF-formatted report files.

Most of the predefined reports in Access Manager Report Center have a corresponding PowerShell script to generate reports from the PowerShell console. When you use a PowerShell script to generate a report, the report content displays as text in the PowerShell console window. You can optionally format the report content as an HTML or PDF file using third-party tools.

Provided Report Scripts

The following report scripts are included with authentication and privilege elevation PowerShell. The scripts are typically installed in the following folder:

C:\Program Files\Centrify\PowerShell\Centrify.DirectControl.PowerShell\Reports

For details about script syntax, parameters, and examples, see the script help files. Execute the PowerShell Get-Help command to display the help for a script. For example, to display help details for the ZonesReport.ps1 script, execute the following command from the PowerShell command line:

PS> Get-Help .\ZonesReport.ps1 -Detailed

AuthorizationReportForComputers.ps1	Lists each computer in the zone and indicates which users are allowed to access each computer. This report applies to classic zones only. This report includes details from the user's UNIX profile for each user listed, including the user's Active Directory user name, UNIX user name, zone, UID, shell, home directory, and primary group.	Classic Zone – Authorization Report for Computers
AuthorizationReportForUsers.ps1	Lists each user account in the zone and indicates which computers each user can access. This report applies to classic zones only. This report includes details from the user's UNIX profile for each user listed, including the user's UNIX user name, zone, UID, shell, home directory, and primary group.	Classic Zone – Authorization Report for Users
ComputerEffectiveAuditLevelReport.ps1	Lists the audit level in effect for all authorized users on computers in each zone. This report applies to hierarchical zones only.	Hierarchical Zone – Computer Effective Audit Level
ComputerEffectiveRightsReport.ps1	Lists the privileges granted on each computer. This report applies to hierarchical zones only.	Hierarchical Zone – Computer Effective Rights
ComputerEffectiveRolesReport.ps1	Lists the roles assigned on each computer. This report applies to hierarchical zones only.	Hierarchical Zone – Computer Effective Roles
ComputerRoleAssignmentsReport.ps1	Lists the computer roles that are defined for each zone. The report includes the users and groups and their associated roles. This report applies to hierarchical zones only.	Hierarchical Zone – Computer Role Assignments
ComputerRoleMembershipReport.ps1	Lists the computer roles that are defined for each computer and the zone to which they belong. This report applies to hierarchical zones only.	Hierarchical Zone – Computer Role Membership Report
ComputersReport.ps1	Lists computer account information for each computer in each zone. The information displayed includes the computer account name in Active Directory, the computer's DNS name, the computer's operating system, and the version of the Delinea Agent for *NIX installed on the computer, if available.	Computers Report

GroupsReport.ps1	Lists group information for each group in each zone. The information that is displayed includes the Active Directory group name, the UNIX group name, the UNIX group identifier (GID), and whether the group is an orphan.	Groups Report
StaleComputersReport.ps1	Lists information about all authentication service-enabled computers that have not changed their password in a specified number of days (90 days by default).	Stale Computers Report
UnixUserEffectiveRightsReport.ps1	Lists the effective rights for each UNIX user on each computer. The report shows the name of the right, its type, and where it is defined. This report applies to hierarchical zones only.	Hierarchical Zone – UNIX User Effective Rights
UserAccountReport.ps1	Lists Active Directory account details for the users that have UNIX profiles in each zone. The report includes the Active Directory display name, logon name, and domain for the account. It also includes the account status, such as the date and time of the account's last logon and whether the account is configured to expire, locked out, or disabled.	User Account Report
UsersReport.ps1	Lists information from the UNIX profile for each user in each zone. The report includes the user's Active Directory user name, UNIX user name, UID, shell, home directory, and primary group.	Users Report
WindowsUserEffectiveRightsReport.ps1	Lists the effective rights for each Windows user on each computer. The report shows the name of the right, its type, and where it is defined. This report applies to hierarchical zones only.	Hierarchical Zone – Windows User Effective Rights
ZoneDelegationReport.ps1	Lists the administrative tasks for each zone and the users or groups (trustees) that have been delegated to perform each task. When you grant administrative rights to designated users and groups, you make them "trustees" with permission to perform specific operations. This report indicates which users or groups have permission to perform specific tasks, such as add groups, join computers to a zone, or change zone properties.	Zone Delegation Report
ZoneRolePrivilegesReport.ps1	Lists the roles that are defined for each hierarchical zone and the rights granted by each of these roles, including where each right is defined.	Hierarchical Zone – Zone Role Privileges Report
ZonesReport.ps1	Lists the zone UNIX properties for each zone. This report includes the zone name, list of available shells, the default shell, the default home directory path, the default primary group, the next available UID, reserved UIDs, the next available GID, and reserved GIDs.	Zones Report

Running Report Scripts

When you perform the steps described in this section, the report content displays as text in the PowerShell console window. To generate formatted reports, see Formatting Reports.

To run a report script:

1. Open the Delinea access module for PowerShell reports.

2. Verify you have permission to execute scripts by running Get-ExecutionPolicy. In most cases, the permission to execute scripts is restricted. You can use the Set-ExecutionPolicy to allow execution. For example:

   ```
   Set-ExecutionPolicy Unrestricted
   ```

   Note: For more information about execution policies and the options available, use the get-help function.

3. Verify that you are in the directory where the report scripts are located. For example:

   ```
   C:\Program Files\Centrify\PowerShell\Centrify.DirectControl.PowerShell\Reports
   ```

4. Execute the report script. For example:

   ```
   .\ZonesReport.ps1
   ```

Formatting Reports

You can use the following cmdlets to format report output so it can be displayed or processed by third-party tools:

- Export-Csv
- Out-GridView
- Format-Table
- ConvertTo-Html

The following sections describe these cmdlets in detail.

Export-Csv cmdlet

Use this cmdlet to format report output as a CSV file. For example, execute the following command to format the output from the UsersReport.ps1 script as a CSV file:

```
PS> ./UsersReport.ps1 | Export-Csv C:\Report\UsersReport.csv -NoTypeInformation
```

In this example, the output file C:\Report\UsersReport.csv is created, and no type information for the input object is provided. After the CSV file is created, you can open it with third-party applications such as Microsoft Excel.

Out-GridView cmdlet

Use this cmdlet to format report output as an interactive table in a grid view window. For example, execute the following command to format the output from the UsersReport.ps1 script:

```
PS> ./UsersReport.ps1 | Out-GridView
```

Format-Table cmdlet

Use this cmdlet to format report output as a table that is displayed in the PowerShell console window with the selected properties of the object in each column. The object type determines the default layout and properties that are displayed in each column, but you can use the property parameter to select the properties that you want to display. You can specify any of the following parameters on the command line:

- AD User
- Home Directory
- Is Enabled
- Is Orphan
- Primary Group
- Shell
- UID
- UNIX User Name
- Zone

For example, the following command displays the output of UsersReport.ps1 in a table. The -GroupBy option shown here specifies that separate tables are displayed for each zone. Each zone table contains columns for AD User, UNIX User Name, UID, Shell, Home Directory, Is Enabled, Primary Group, and Is

Orphan.

```
. PS> ./UsersReport.ps1 | Format-Table "AD User", "UNIX User Name", "UID", "Shell", "Home Directory", "Is Enabled", "Primary Group", "Is Orphan" -GroupBy Zone
```

Depending on your site's zone configuration, this command would result in output similar to the following:

> **Note:** If the results are too wide to display in the PowerShell console default window size, you can change the PowerShell screen size, and enable some arguments (such as wrap or autosize) provided by this cmdlet.

ConvertTo-Html cmdlet

Use this cmdlet to format report output as an HTML file. This cmdlet returns the result to the PowerShell console window. You can then redirect the result to an HTML file by using the cmdlet Out-File, so that you can read the output using a Web browser. The HTML file created by this cmdlet uses the style sheet defined in the report.css file that is included with authentication and privilege elevation PowerShell.

For example, the following command converts the results of the UsersReport.ps1 script into HTML using the style defined in report.css, and writes the resulting HTML to the output file C:\Report\UsersReport.html.

```
PS> .\UsersReport.ps1 | ConvertTo-Html -CssUri report.css | Out-File C:\Report\UsersReport.html
```

Generating a PDF report

Overview

This section describes how to use the PDFCreator third-party tool to generate PDF output from a report script. The general steps are as follows:

1. Install the PDFCreator third-party tool.
2. Generate HTML output from a report script using the ConvertTo-Html cmdlet.
3. Configure the PDFCreator printer that will convert the HTML output file into a PDF file.
4. Direct the HTML output file to the PDFCreator printer to generate the PDF file.

Procedure Details

The following steps describe how to generate PDF output from the ZonesReport.ps1 script.

1. Note the following
   - You must have administrator privileges to perform these steps.
   - Unless otherwise noted, you perform the steps described here in the PowerShell console window.
   - In this example, the PDF printer that converts HTML to PDF is named "PDFCreator." If the printer has a different name in your environment, use your printer's name.
2. Install PDFCreator from pdfforge.
3. Generate HTML output from the ZonesReport.ps1 script by executing the following command in the PowerShell console:

   ```
   .\ZonesReport.ps1 | ConvertTo-Html -Head "<Style>$(Get-Content .\Report.css)</Style>" | Out-File c:\Reports\ZonesReport.html
   ```

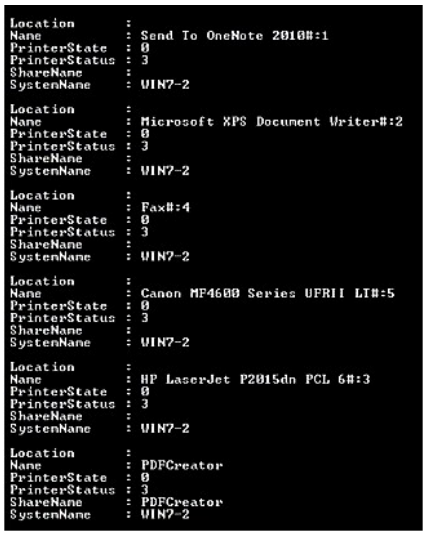
   When you execute this command, the file c:\Reports\ZonesReport.html is created using the styles in Report.css.
4. Specify PDFCreator as the default printer:
   1. Execute the following command to get all installed printers:

      ```
      $printers = gwmi win32_printer
      ```

   2. Run the following variable to list the printers:

      ```
      $printers
      ```

   3. In the list of printers, note the position of the PDFCreator printer in the list. For example, in the following list of printers, PDFCreator is the sixth printer listed:



4. Make PDFCreator the default printer. In this example, because PDFCreator is the sixth printer on the list, you would execute the following command:

   ```
   $printers[5].SetDefaultPrinter()
   ```

5. Ensure PDFCreator is the default printer by clicking **Devices and Printers** on the Windows Start Menu. If PDFCreator is not the default printer, you can make it the default printer there.

5. Configure the auto-save printer settings as follows:

   1. Change the auto-save directory to C:\Reports.
   2. Change the auto-save file name to ZonesReport.
   3. Enable the auto-save feature so that there will be no dialog prompts asking for which file name to save.

6. Perform the following steps to configure the registry to implement these changes. These steps assume that the default registry path is HKCU:\Software\PDFCreator\Program. If your registry path is different, change these commands as appropriate for your environment.

   1. Execute the following command to change the auto-save directory to C:\Reports:

      ```
      Set-ItemProperty -Path "HKCU:\Software\PDFCreator\Program"  -Name "AutoSaveDirectory" -Value "C:\Reports"
      ```

   2. Execute the following command to change the auto-save file name to ZonesReport:

      ```
      Set-ItemProperty -Path "HKCU:\Software\PDFCreator\Program" -Name "AutoSaveFileName" -Value "ZonesReport"
      ```

   3. Execute the following command to enable the auto-save feature:

      ```
      Set-ItemProperty -Path "HKCU:\Software\PDFCreator\Program" -Name "UseAutoSave" -Value "1"
      ```

7. Use Windows Internet Explorer to print the HTML file that you created with the default (PDFCreator) printer. This creates the PDF file.

8. Create and run the following script in the PowerShell console window. The script performs the following tasks:

   1. Creates an IE object and stores it into the $ie variable.
   2. Sets IE output to not display on the screen. This part is optional—if you want IE output to display, you can omit this in the script.
   3. Instructs the $ie object to read the HTML content from the location C:\Reports\ZonesReport.html (the HTML file that you created earlier).
   4. Prints the content of $ie using default printer (PDFCreator), resulting in the generation of the PDF file.

9. The recommended script is as follows:

   ```
   $ie = New-Object -com "InternetExplorer.Application"
   $ie.Visible = $false`
   $ie.Navigate("C:\Reports\ZonesReport.html")
   while ( $ie.busy ) { Start-Sleep -second 1 }
   ```

```
  $ie.ExecWB(6,2)
while ( $ie.busy ) { Start-Sleep -second 1 }
  $ie.quit()
```

Note: This script is specific to the example used in this procedure. If you changed any of the steps in this procedure because of differences in your environment, you might have to make corresponding changes in the script shown.

Auditing and Analysis Scripting Guide

This guide describes the Audit Module for PowerShell command set. These PowerShell cmdlets run on Windows computers and can be used to automate auditing-related management tasks, such as the creation of new audit store databases. You can also use the cmdlets to get or set properties for an installation and perform other administrative tasks. For example, you can write scripts to find and remove sessions matching specific criteria, export audit trail events, or manage audit roles and auditor assignments.

Intended Audience

This guide provides information for auditing infrastructure administrators who want to use PowerShell scripts to manage auditing-related features and components of Server Suite software. This document supplements the help provided within the PowerShell environment using the get-help function. Whereas the get-help function describes each cmdlet in detail, this document provides an introduction to the Auditing Module for Windows PowerShell objects and how you can use PowerShell cmdlets and scripts to perform auditing-related tasks.

This guide assumes general knowledge of PowerShell scripts and syntax, and of the Windows PowerShell modules used to write scripts for Active Directory. You should also be familiar with basic Active Directory operations, such as connecting to a domain controller and managing objects and attributes.

In addition to scripting skills, you should be familiar with Server Suite architecture, terms, and concepts, and know how to perform administrative tasks for the Audit & Monitoring Service and for the platforms you support.

Using this Guide

This guide discusses audit-related administrative tasks using PowerShell-based command-line programs. This information is intended to help you develop scripts for managing the auditing infrastructure, including collectors, audited computers, the audit management database, and the active and attached audit store databases and performing other administrative tasks on Windows computers. With scripts, you can automate the administrative or analytical tasks you might otherwise perform using Audit Manager or Audit Analyzer.

The guide provides the following information:

- Developing Scripts for Administrative Tasks provides an introduction to using Windows PowerShell to perform auditing-related administrative activity.
- Installing the Audit Module for PowerShell describes how to download and install the module as a separate package.
- Managing Audit-Related Objects with Windows Powershell Scripts describes how to use the cmdlets to connect to Active Directory and perform access control and privilege management tasks.
- Auditing-Related Objects and Properties lists the objects defined by the Audit Module for PowerShell, and the properties of each object.

Compatibility and Limitations of This Guide

The information in this guide is intended for use with Server Suite 2015, or later. Although intended to be accurate and up-to-date, interfaces are subject to change without notice and can become incompatible or obsolete when a newer version of the software is released.

In general, application programming interfaces are also intended to be backward-compatible, but are not guaranteed to work with older versions of the software. Because the authentication and privilege elevation cmdlets are subject to change, enhancement, or replacement, the information in this guide can also become incomplete, obsolete, or unsupported in future versions. If you are unsure whether this guide is appropriate for the version of the software you have installed, you can consult the Delinea website or Delinea Support to find out if another version of this guide is available.

Developing Scripts for Administrative Tasks

The Audit Module for PowerShell consists of the following:

- Application programming interfaces in the form of PowerShell command-line programs, or cmdlets, that are packaged in dynamic link libraries (.DLLs).
- A PowerShell help file that includes complete cmdlet reference information and this scripting guide.
- Sample scripts to illustrate administrative tasks.

On Windows computers, you can use the Audit Module for PowerShell to develop your own custom scripts that access, create, or modify auditing components or auditing-related information, such as session activity and audit trail events.

Getting Started with cmdlets For Powershell

The Audit Module for PowerShell consists of "cmdlets" that you can use to manage Server Suite-specific information. A "cmdlet" is a lightweight command-line program that runs in the Windows PowerShell environment. In most cases, cmdlets perform a basic operation and return a Microsoft .NET Framework object to the next command in the pipeline.

The cmdlets in the Audit Module for PowerShell module enable you to access, create, modify, and remove information about Server Suite auditing components and auditing-related information. Using the cmdlets you can manage the entire auditing infrastructure, including installation properties, collectors, audited computers, the audit management database, and the active and attached audit store databases. You can also use cmdlets to manage permissions, audit roles, and role assignments and to work with captured session activity and audit trail events. By combining cmdlets into scripts, you can also automate common administrative tasks, such as the creation of new audit store databases.

Managing Unix Information from a Windows Computer

You can use the cmdlets to work with information for any Server Suite-managed computer where you have enabled the auditing service. However, you can only run the cmdlets on Windows-based computers that have the Windows PowerShell command-line shell available. If you want to develop scripts that run directly on UNIX computers, you can use the ADEdit program (adedit). However, the ADEdit application only provides functionality similar to the cmdlets for access control and privilege management. You cannot use ADEdit to develop scripts for auditing-specific tasks. For detailed information about using ADEdit, see the *ADEdit Command Reference and Scripting Guide*.

Writing Programs in Other Languages

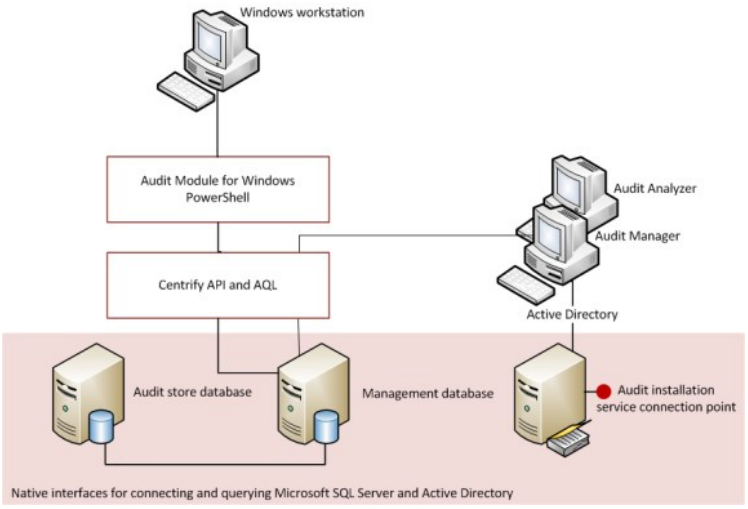
If you want to develop programs or scripts that run on Windows but outside of the Windows PowerShell environment, you can use the Component Object Model (COM) interface that is available as part of the auditing software development kit (SDK). For information about auditing-specific objects you can use the COM-based applications, see the *Database Management Guide*.

Accessing Audit Information Using Native Interfaces

The Audit Module for PowerShell cmdlets connect to Active Directory or to Microsoft SQL Server databases to access audit information. You can, therefore, write PowerShell scripts to automate procedures that you would otherwise perform interactively using Audit Manager or Audit Analyzer.

The cmdlets rely on the underlying interfaces provided by Microsoft Active Directory Service Interfaces (ADSI), Microsoft SQL Server AQL query language, and Server Suite Windows API objects. The ADSI and AQL layers provide low-level functions that permit applications to read and write data. The cmdlets provide a task and object-based level of abstraction for retrieving and manipulating Server Suite audit information so that you do not need to know the details of how the data is stored or how to use any of the underlying ADSI or AQL functions directly.

The following figure illustrates how the Audit Module for PowerShell provides a layer of abstraction between the data stored in Active Directory, the management database, the audit store databases, and your scripting environment.



The Audit Module for PowerShell provides a logical view of the auditing infrastructure and captured information, eliminating the need to know the details of how data is stored in the management database or the audit store databases when performing common administrative tasks. The cmdlets also provide a simple method for accessing audit-related objects without needing to write complex AQL queries.

Using the cmdlets, you can write scripts that automatically create and make active new audit store databases or delete sessions that are no longer of interest. In most cases, the cmdlets enable you to perform exactly the same tasks from the command line that you would otherwise perform interactively using Audit Manager or Audit Analyzer.

Installing the Audit Module for PowerShell

You can install the Audit Module for PowerShell from the Server Suite setup program or as a separate package. It includes the auditing-related cmdlets for Windows PowerShell, sample scripts, and documentation for performing common administrative tasks using PowerShell scripts. This chapter describes how to install the software on a Windows computer.

The following topics are covered:

- About the standalone package
- Running the setup program
- Importing the cmdlets into the Windows PowerShell console

About the Standalone Package

The cmdlets that run in Windows PowerShell are defined in dynamic link libraries that can be installed on any computer where you install other Windows-based components, such as Audit Manager or Audit Analyzer. You can also install these libraries separately, along with sample scripts and documentation, onto computers where no Server Suite software is installed.

If you did not install the Audit Module for PowerShell as a component of a Server Suite installation, you can install it separately. The Audit Module for PowerShell files are available in the same disk image from which you installed Server Suite.

Running the Setup Program

You run the setup program to install the Audit Module for PowerShell files.

To run the standalone setup program

1. Select the downloaded file, right-click, then select **Extract All** to extract the compressed files to a folder.
2. In the Windows disk image for Server Suite, navigate to the /DirectAudit/Powershell folder and double-click the standalone executable to start the setup program.

   For example, double click the Delinea DirectAudit PowerShell64.exe file.
3. At the Welcome page, click **Next**.
4. Select **I accept the terms in the License Agreement**, then click **Next**.
5. Accept the default location or click **Change** to choose a different location, then click **OK**.

   If you accept the default location, the cmdlets are available in a separate Audit Module for PowerShell console.

   If you want the cmdlets to be available in the default Windows PowerShell console with other PowerShell modules, select the following location:

   C:\Windows\System32\WindowsPowerShell\v1.0\Modules\Centrify.DirectAudit.PowerShell
6. Verify the path to the Centrify.DirectAudit.PowerShell folder, then click **Next**.
7. Click **Install**.
8. Click **Finish** to complete the installation.

Importing the cmdlets into the Windows PowerShell Console

If you install the Audit Module for PowerShell in the default location, it is a self-contained Windows PowerShell console. If you install the files in the location for system modules so that cmdlets from other modules are available in the same console, you should import the Audit Module for PowerShell into your default Windows PowerShell console.

> **Note**: According to Microsoft, the Import System Modules task is available only Windows 7 and Windows Server 2008 R2 when Windows PowerShell 3.0 is not installed on the computer. Beginning in Windows PowerShell 3.0, modules are imported automatically the first time that you use a cmdlet in the module.

To import the auditing module

1. On the Start menu, select Windows PowerShell to display a menu extension with a list of Tasks.
2. On the Tasks menu, select **Import System Modules** to import the auditing module and open the Windows PowerShell console.
3. Verify the installation and import completed successfully by typing the following command:

   ```
   get-command *-Cda*
   ```

You should see a listing of the audit cmdlets, similar to the following:

CommandType	Name	Version	Source
Cmdlet	Attach-CdaDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Detach-CdaDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Export-CdaAuditSessionRecording	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaActiveDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAgent	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditEvent	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditRole	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditRoleAssignment	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditRoleRight	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditSession	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditSessionDataIntegrityStatus	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditSessionReviewer	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditStore	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaAuditStoreRight	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaCollector	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaDetailedExecution	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaInstallation	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaInstallationRight	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaManagementDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaManagementDatabaseRight	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaMonitoredExecution	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaMonitoredFile	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaQuery	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaQueryRight	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaUnixCommand	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaUnixCommandTranscript	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaUserEvent	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Get-CdaWindowsEvent	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	New-CdaAuditRole	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	New-CdaAuditRoleAssignment	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	New-CdaAuditStore	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	New-CdaDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	New-CdaSearchCriteria	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Publish-CdaInstallation	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Remove-CdaAgent	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Remove-CdaAuditRole	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Remove-CdaAuditRoleAssignment	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Remove-CdaAuditSession	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Remove-CdaCollector	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Remove-CdaDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaActiveDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaAuditRole	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaAuditSession	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaAuditSessionReviewer	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaAuditStore	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaConfiguration	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaInstallation	3.5.2.570	Centrify.DirectAudit.PowerShell
Cmdlet	Set-CdaManagementDatabase	3.5.2.570	Centrify.DirectAudit.PowerShell

Managing Audit-Related Objects with Windows PowerShell Scripts

This chapter provides an overview of how you can use the cmdlets to access and manage audit information stored in Microsoft SQL Server databases and Active Directory using Windows PowerShell scripts. For more examples of how to perform common administrative and auditing analysis tasks using the cmdlets in PowerShell scripts, see the samples included with the software.

Using cmdlets to Manage Auditing

The Audit Module for PowerShell provides cmdlets that perform operations on objects that correspond to the core elements of Server Suite data. The core elements of Server Suite data for auditing are the following:

- Audited computers with the Server Suite auditing services
- Collectors that transfer audited activity from audited computers to the active audit store database
- Active and attached audit store databases
- Management database
- Audit installation
- User sessions
- Audit trail events
- Audit roles
- Audit role assignments

You can use the cmdlets to create, access, modify, and remove information associated with these core elements of Server Suite data for auditing. Most of the cmdlets perform one of the following basic operations:

- New-Cda*Xxx* cmdlets create new Server Suite objects, such as a new audit role or a new audit store database.
- Get-Cda*Xxx* cmdlets get the properties of a specified object.
- Set-Cda*Xxx* cmdlets set or change the properties of a specified object.
- Remove-Cda*Xxx* cmdlets delete a specified object.

In addition to these basic operations, there are cmdlets for attaching or detaching an audit store database, exporting session activity to a file, and for publishing installation information to Active Directory.

For reference information describing the use and parameters for each cmdlet, you can use the get-help function within the PowerShell console. For example, if you want to see a description and syntax summary for the New-CdaAuditStore cmdlet, type the following command in the PowerShell console:

```
get-help New-CdaAuditStore
```

If you want to see more detailed information about a cmdlet's parameters and code examples, you can use the -detailed or -full option. For example, type the following command in the PowerShell console:

```
get-help New-CdaAuditStore -detailed
```

Preparing the Environment to Run cmdlets

Because the Audit Module for PowerShell cmdlets run in the context of a domain account, you don't need to make an explicit connection to an Active Directory domain.

Setting the Preferred Domain Controller

If there is more than one domain controller in the current domain, you can use the SetCdaConfiguration cmdlet to specify the preferred domain controller server to which you want to connect. The following example illustrates how to connect to the preferred domain controller for the finance.acme domain:

```
PS C:\> Set-CdaConfiguration -DomainController "win-2012r2dc.finance.acme"
```

You can also use the SetCdaConfiguration cmdlet to connect to an auditing installation in another trusted forest. In this case, specify the domain controller that is in the other trusted forest.

Setting the Logging Level

You can use the SetCdaConfiguration cmdlet to specify a logging level for running cmdlets. The following example illustrates how to use the Set-CdaConfiguration cmdlet to enable verbose logging:

```
PS C:\> Set-CdaConfiguration -LogLevel "Verbose"
```

The default path to the log file is C:\Program Files\Common Files\Centrify Shared\Logs\DirectAudit_*date-time*.log.

Running cmdlets under Another Account

Some Audit Module for PowerShell cmdlets require permission to connect and update Microsoft SQL Server. If your login credentials do not have the required permissions, you can run cmdlets under another account. To run cmdlets as another user, you can use the standard PowerShell Start-Process -Credential to specify a different user name, then type the user's password when prompted, or you can right-click the Audit Module for PowerShell menu item, then select **Run As Administrator** to run the cmdlets as the local administrator.

Organizing cmdlet Operations in a Sequence

There is no fixed sequence in which cmdlets must be called. There is, however, a logical sequence to follow to make information available from one to another. For example, to get all of the audit roles in an installation, you might first want to identify the installation object you want to work with before you call the Get-CdaAuditRole cmdlet, To accomplish this, you could organize the calls in the following sequence:

```
$site = Get-CdaInstallation -Name "production"
Get-CdaAuditRole $site
```

Similarly, before converting an active database into an attached database, you might organize the calls to create a new audit store database, then set the new database to be the active audit store database:

```
$install = Get-CdaInstallation -Name "site1"

$auditStore = Get-CdaAuditStore -Installation $install -Name "auditstore1"

// Use New-CdaDatabase to create and attach the new database
$newDB = New-CdaDatabase -AuditStore $auditStore -Name "audit-us-Oct2014" -Server "sql_server1.domain.com\da" -Database "audit-us-Oct2014"

// Set the newly created database as the active database for this audit store
Set-CdaActiveDatabase -AuditStore $auditStore -Database $newDB

// Create another new database
$newDB2 = New-CdaDatabase -AuditStore $auditStore -Name "audit-us-Nov2014" -Server "sql_server1.domain.com\da" -Database "audit-us-Nov2014"

// Set the second database as active database
Set-CdaActiveDatabase -AuditStore $auditStore -Database $newDB2

// Detach the first database if it is no longer needed
Detach-CdaDatabase -Database $newDB
```

In most cases, you can determine from the parameters of a cmdlet whether you need to call another cmdlet first. For example, most Set-Cda*Xxx* or Remove-Cda*Xxx* cmdlets, you must call the corresponding GetCda*Xxx* cmdlet to obtain the object first. For example, to delete the "forensics" audit role from the "production" audit installation, you could call the cmdlets as follows:

```
Get-CdaAuditRole -Installation "production" -Name "forensics" | RemoveCdaAuditRole
```

In this example, the Get-CdaAuditRole cmdlet retrieves "forensics" from the specified installation and passes it to the Remove-CdaAuditRole cmdlet.

Checking for Valid Licenses

All of the cmdlets check for a valid license before performing the requested action. The license check succeeds only if one of the following conditions is true:

- There is at least one evaluation license that has not expired.
- There is at least one workstation license.
- There is at least one server license.

If the license check fails, the cmdlet displays an error and stops running. If the license check succeeds, the result is cached. The next time a cmdlet tries to access the same forest, it uses the cached result rather than performing the license check again. Note that the cache is only effective in one PowerShell console. If another PowerShell console runs a cmdlet accessing the same forest, the cmdlet in that console performs a separate license check.

Specifying Parameters using Different Formats

For certain types of parameters, you can specify a value using any one of several different supported formats. For example, you can specify a user principal for a CdaAdPrincipal object type by providing the information that identifies the user in any of the following formats:

- distinguished name (DN) for the user.

- security identifier for the user (SID).
- sAMAccountName attribute for the user in either the *sAMAccountName*@*domain* format or *domain**sAMAccountName* format.
- in a stored user object.

The following formats are all valid for specifying an Active Directory user principal:

```
New-CdaRoleAssignment -AuditRole $role -Assignee "cn=ben,cn=Users,dc=acme,dc=com"

New-CdaRoleAssignment -AuditRole $role -Assignee "S-1-5-21-12345678-98765432-500"

New-CdaRoleAssignment -AuditRole $role -Assignee  "ben@acme.com"

New-CdaRoleAssignment -AuditRole $role -Assignee "acme\ben"

New-CdaRoleAssignment -AuditRole $role -Assignee $userObject
```

The following table lists the supported formats for each type of parameter.

CdaInstallation	You can specify an installation name as string, for example, "DefaultInstallation," or using a CdaInstallation object.
CdaAdPrincipal	You can specify Active Directory users, groups, or computers using any of the following formats: - Distinguished name string - SID string - *sAMAccountName@domain* - *domain**sAMAccountName* You can specify Active Directory users, groups, or computers using a CdaAdPrincipal object.
CdaAccessAccount	You can specify a Windows account name or a SQL Server login account name and password, for example. For a Windows user account, all of the same formats listed for a CdaAdPrincipal object are supported. For SQL Server login accounts, the format is "sql:*sql_name*:*sql_password*". The password can be empty.
CdaAuditScope	You can specify the audit scope using the Active Directory site name as a string, for example, "default-first-site" or by specifying a network subnet definition as a string, for example, "192.168.100.0/24".

If a parameter is not listed in the table, you must specify the object instance returned by a previously cmdlet. For example, you can use the Get-CdaAuditStore cmdlet to return an object instance of the audit store then use that object instance for parameters in other cmdlets that require it.

```
# Get the audit store object instance and store it in $cdaAuditStoreObject

$cdaAduitStoreObject = Get-CdaAuditStore -Installation "DefaultInstallation" -Name "Default-First-Site"

# Use the audit store object instance to specify a parameter value

Attach-CdaDatabase -AuditStore $cdaAduitStoreObject -Name "audit-store-db" -Server "win2012\instance1" -Database "audit-store-database"
```

Working with Sample Scripts

The Audit Module for PowerShell includes some sample scripts that you can use to do database rotation; rotating a database involves creating a new audit store database and making the new database the active database for the installation. You can copy and modify the sample scripts to use the code directly in your environment or study the syntax used in the script to serve as an example for writing your own custom scripts.

- db_rotation.ps1

  This PowerShell script demonstrates how to use the following cmdlets to do database rotation:

  - New-CdaDatabase
  - Set-CdaDatabase
  - Detach-CdaDatabase

- db_rotation_sql_script.ps1

  This PowerShell script demonstrates how to do database rotation using the SQL scripts and PowerShell cmdlets.

- SetupDatabase.sql, SetupServer.sql

  You can modify the file path settings in these SQL scripts to create a new audit store database using the New-CdaDatabase cmdlet with the DatabaseScriptFile and ServerScriptFile parameters. This case is useful if you want to create a new audit store database with a customized database file folder path, database log file folder path, or database full-text catalog root path.

  If you want to use these SQL scripts and you also want to customize the StoredProcedureAccount, IsAwsRds, and IntegrityCheckEnabled settings, you also need to customize the settings in the SQL scripts instead of using the StoredProcedureAccount, IsAwsRds, and IntegrityCheckEnabled parameters. These three parameters can't be used along with the DatabaseScriptFile and ServerScriptFile parameters.

To run the sample script:

1. Open the Audit Module for PowerShell.
2. Verify you have permission to execute scripts.

   ```
   Get-ExecutionPolicy
   ```

   In most cases, the permission to execute scripts is restricted. You can use the SetExecutionPolicy to allow execution. For example:

   ```
   Set-ExecutionPolicy Unrestricted
   ```

   For more information about execution policies and the options available, use the gethelp function.
3. Verify you are in the directory where the db_rotation.ps1 script is located.
4. Execute the sample script.

Writing Your Own Scripts

You can combine Audit Module for PowerShell cmdlets with native Windows PowerShell cmdlets to perform many common administrative tasks. The following examples illustrate how you can combine the Audit Module for PowerShell cmdlets and native cmdlets to accomplish a simple but specific goal.

- Exporting Specific Session Fields for a Report
- Checking the Status of Agents and Collectors

Exporting Specific Session Fields For A Report

By default, the cmdlet for getting session information might return more information than you want for a simple report. If you want to narrow down the fields returned, you can use a native cmdlet, such as Select-Object, to specify the fields of interest, then another native cmdlet, such as Out-File, to export the results to a text file. For example, to limit the results to a few key fields, you might specify a command similar to this:

```
Get-CdaAuditSession -Installation "installation-name"
| Select-Object -Property User, Machine, StartTime, EndTime,
State, | Out-File c:\samplesession.txt
```

This example pipes the results from the Audit Module for PowerShell GetCdaAuditSession cmdlet to the Select-Object cmdlet, then uses another pipe to send the resulting output to a file.

Checking the status of agents and collectors

You can use Server Suite cmdlets to get status information for agents and collectors and combine those cmdlets with native or custom cmdlets to schedule checking for connectivity to run on a regular basis and to trigger an email notification if the status returned for the agent or collector in any interval is Disconnected. For example, to check for disconnected agents, you might specify a command similar to this:

```
Get-CdaAgent -i "*installation-name*" | Where { $_.Status -eq "Disconnected" }
```

To check for agents that haven't connected to the collector since a specific time, you might specify a command similar to this:

```
Get-CdaAgent -i "*installation-name*" | where { $_.LastUpdateTime -lt ([DateTime]"12:00:00 AM, 12/29/2014") }
```

Similarly, you can use the Get-CdaCollector cmdlet to check for connectivity between a collector and the Microsoft SQL Server database you are using as the active audit store database.

```
Get-CdaCollector -i "*installation_name*" | where { $_.LastUpdateTime –lt "10:00:00 AM, 12/17/2014"}
```

You can include these cmdlets in scripts that run automatically using a task scheduler to check for connectivity issues at the interval you specify, such as once a day or once a week, and to send the results to specified channels, such as an email message or SNMP trap, using a cmdlet such as Send-MailMessage.

Recommendations for Writing Custom Scripts

Most cmdlets and scripts return information efficiently without any special handling or any noticeable effect on performance. If you plan to write custom scripts that could potentially return large data sets, however, you should consider ways to improve performance. For example, if you are writing a script that exports a large number of sessions or reports on activity for a large audit installation, you might want to use the following recommendations as guidelines.

- When testing the performance of the script, use the standard Measure-Command cmdlet to accurately measure cmdlet and script performance.

  The Measure-Command cmdlet ignores the time it takes to print all of the results returned to the PowerShell console. In many cases, the execution of a query or script is efficient, but rendering the results in the PowerShell console might make the cmdlet or script performance seem unacceptable.

- Avoid using the PowerShell pipeline if your cmdlet or script returns large data collections.

  For example, you might use foreach in a script instead of using the pipeline to improve performance.

  Use syntax similar to this:

  ```
  foreach ($cmd in Get-CdaUnixCommand -Session $s) { *action_on_each_cmd* }
  ```

  Instead of:

  ```
  Get-CdaUnixCommand -Session $s | *action_on_each_cmd*
  ```

- Cache the data, if possible, by writing the results to a file.

  For example, use syntax similar to this:

  ```
  $cmds = Get-CdaUnixCommand -Session $s
  Out-File -InputObject $cmds -FilePath file
  ```

  Instead of:

  ```
  Get-CdaUnixCommand -Session $s | Out-File -FilePath file
  ```

- Use Export-Csv instead of Out-File if possible. The Export-Csv cmdlet writes results to a file faster than the Out-File cmdlet.

- If you are writing a script that generates a very large data set—for example, reporting information for a global audit installation—you might want to use the native .NET FileStream function. The FileStream function is the fastest way to write content to a file.

  For example, you might use a code snipper like this:

  ```
  $fs = New-Object IO.FileStream &lt;file&gt;, 'Append','Write','Read'
    $fw = New-Object System.IO.StreamWriter $fs
          $cmds = Get-CdaUnixCommand -Session $s
          foreach ($cmd in $cmds) {$fw.WriteLine("{0} {1} {2}",
                $cmd.Sequence, $cmd.Time, $cmd.Command)}
    $fw.Close()
  ```

$fs.Dispose() ```

Executing Custom Scripts

In most cases, the permission to execute scripts is restricted. You can use the native PowerShell cmdlet Get-ExecutionPolicy to check whether you have permission to execute scripts using your current account credentials and the native Set-ExecutionPolicy cmdlet to specify an execution policy.

To check and update the execution policy for scripts

1. Open the Audit Module for PowerShell.
2. Verify you have permission to execute scripts.

```
Get-ExecutionPolicy
```

3. Run the SetExecutionPolicy cmdlet to change the execution policy. For example:

   ```
   Set-ExecutionPolicy Unrestricted
   ```

   For more information about execution policies and the options available, use the gethelp function.

4. Verify you are in the directory where your scripts are located.

5. Execute the sample script.

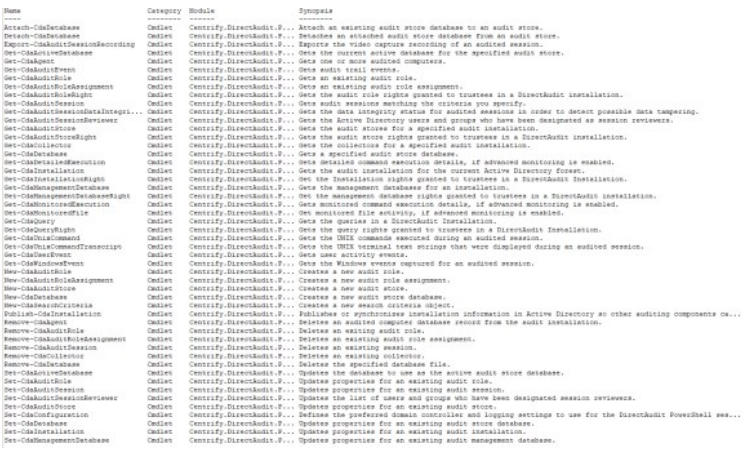
Getting Information about the cmdlet Available

You can use the get-help command with different options to get summary or detailed information about the cmdlets available in the Audit Module for PowerShell or about the specific cmdlets you want to use. For example, you can use get-help with the full command-line option to see complete reference information for a specified cmdlet or get-help -example to display only the examples for a specified cmdlet.

To see the current list of cmdlets available open the Audit Module for PowerShell, then run the following command:

```
get-help *-cda*
```

This command displays a summary of the Audit Module for PowerShell cmdlets similar to the following partial list of commands:



```
Name                                Category  Module                    Synopsis
----                                --------  ------                    --------
Attach-CdaDatabase                  Cmdlet    Centrify.DirectAudit.P... Attach an existing audit store database to an audit store.
Detach-CdaDatabase                  Cmdlet    Centrify.DirectAudit.P... Detaches an attached audit store database from an audit store.
Export-CdaAuditSessionRecording     Cmdlet    Centrify.DirectAudit.P... Exports the video capture recording of an audited session.
Get-CdaActiveDatabase               Cmdlet    Centrify.DirectAudit.P... Gets the current active database for the specified audit store.
Get-CdaAgent                        Cmdlet    Centrify.DirectAudit.P... Gets one or more audited computers.
Get-CdaAuditEvent                   Cmdlet    Centrify.DirectAudit.P... Gets audit trail events.
Get-CdaAuditRole                    Cmdlet    Centrify.DirectAudit.P... Gets an existing audit role.
Get-CdaAuditRoleAssignment          Cmdlet    Centrify.DirectAudit.P... Gets an existing audit role assignment.
Get-CdaAuditRoleRight               Cmdlet    Centrify.DirectAudit.P... Gets the audit role rights granted to trustees in a DirectAudit installation.
Get-CdaAuditSession                 Cmdlet    Centrify.DirectAudit.P... Gets audit sessions matching the criteria you specify.
Get-CdaAuditSessionDataIntegri...   Cmdlet    Centrify.DirectAudit.P... Gets the data integrity status for audited sessions in order to detect possible data tampering.
Get-CdaAuditSessionReviewer         Cmdlet    Centrify.DirectAudit.P... Gets the Active Directory users and groups who have been designated as session reviewers.
Get-CdaAuditStore                   Cmdlet    Centrify.DirectAudit.P... Gets the audit stores for a specified audit installation.
Get-CdaAuditStoreRight              Cmdlet    Centrify.DirectAudit.P... Gets the audit store rights granted to trustees in a DirectAudit installation.
Get-CdaCollector                    Cmdlet    Centrify.DirectAudit.P... Gets the collectors for a specified audit installation.
Get-CdaDatabase                     Cmdlet    Centrify.DirectAudit.P... Gets a specified audit store database.
Get-CdaDetailedExecution            Cmdlet    Centrify.DirectAudit.P... Gets detailed command execution details, if advanced monitoring is enabled.
Get-CdaInstallation                 Cmdlet    Centrify.DirectAudit.P... Gets the audit installation for the current Active Directory forest.
Get-CdaInstallationRight            Cmdlet    Centrify.DirectAudit.P... Get the Installation rights granted to trustees in a DirectAudit Installation.
Get-CdaManagementDatabase           Cmdlet    Centrify.DirectAudit.P... Gets the management databases for an installation.
Get-CdaManagementDatabaseRight      Cmdlet    Centrify.DirectAudit.P... Get the management database rights granted to trustees in a DirectAudit installation.
Get-CdaMonitoredExecution           Cmdlet    Centrify.DirectAudit.P... Gets monitored command execution details, if advanced monitoring is enabled.
Get-CdaMonitoredFile                Cmdlet    Centrify.DirectAudit.P... Get monitored file activity, if advanced monitoring is enabled.
Get-CdaQuery                        Cmdlet    Centrify.DirectAudit.P... Gets the queries in a DirectAudit Installation.
Get-CdaQueryRight                   Cmdlet    Centrify.DirectAudit.P... Gets the query rights granted to trustees in a DirectAudit Installation.
Get-CdaUnixCommand                  Cmdlet    Centrify.DirectAudit.P... Gets the UNIX commands executed during an audited session.
Get-CdaUnixCommandTranscript        Cmdlet    Centrify.DirectAudit.P... Gets the UNIX terminal text strings that were displayed during an audited session.
Get-CdaUserEvent                    Cmdlet    Centrify.DirectAudit.P... Gets user activity events.
Get-CdaWindowsEvent                 Cmdlet    Centrify.DirectAudit.P... Gets the Windows events captured for an audited session.
New-CdaAuditRole                    Cmdlet    Centrify.DirectAudit.P... Creates a new audit role.
New-CdaAuditRoleAssignment          Cmdlet    Centrify.DirectAudit.P... Creates a new audit role assignment.
New-CdaAuditStore                   Cmdlet    Centrify.DirectAudit.P... Creates a new audit store.
New-CdaDatabase                     Cmdlet    Centrify.DirectAudit.P... Creates a new audit store database.
New-CdaSearchCriteria               Cmdlet    Centrify.DirectAudit.P... Creates a new search criteria object.
Publish-CdaInstallation             Cmdlet    Centrify.DirectAudit.P... Publishes or synchronizes installation information in Active Directory so other auditing components ca...
Remove-CdaAgent                     Cmdlet    Centrify.DirectAudit.P... Deletes an audited computer database record from the audit installation.
Remove-CdaAuditRole                 Cmdlet    Centrify.DirectAudit.P... Deletes an existing audit role.
Remove-CdaAuditRoleAssignment       Cmdlet    Centrify.DirectAudit.P... Deletes an existing audit role assignment.
Remove-CdaAuditSession              Cmdlet    Centrify.DirectAudit.P... Deletes an existing session.
Remove-CdaCollector                 Cmdlet    Centrify.DirectAudit.P... Deletes an existing collector.
Remove-CdaDatabase                  Cmdlet    Centrify.DirectAudit.P... Deletes the specified database file.
Set-CdaActiveDatabase               Cmdlet    Centrify.DirectAudit.P... Updates the database to use as the active audit store database.
Set-CdaAuditRole                    Cmdlet    Centrify.DirectAudit.P... Updates properties for an existing audit role.
Set-CdaAuditSession                 Cmdlet    Centrify.DirectAudit.P... Updates properties for an existing audit session.
Set-CdaAuditSessionReviewer         Cmdlet    Centrify.DirectAudit.P... Updates the list of users and groups who have been designated session reviewers.
Set-CdaAuditStore                   Cmdlet    Centrify.DirectAudit.P... Updates properties for an existing audit store.
Set-CdaConfiguration                Cmdlet    Centrify.DirectAudit.P... Defines the preferred domain controller and logging settings to use for the DirectAudit PowerShell ses...
Set-CdaDatabase                     Cmdlet    Centrify.DirectAudit.P... Updates properties for an existing audit store database.
Set-CdaInstallation                 Cmdlet    Centrify.DirectAudit.P... Updates properties for an existing audit installation.
Set-CdaManagementDatabase           Cmdlet    Centrify.DirectAudit.P... Updates properties for an existing audit management database.
```

Auditing-Related Objects and Properties

Most Audit Module for PowerShell cmdlets return object instances either directly or as properties of other objects. This section provides an alphabetical listing of the objects and the properties of each object defined in the Audit Module for PowerShell. Note that not all properties are available as parameters in the PowerShell cmdlets.

CdaAccessAccount CdaAdPrincipal CdaAgent CdaAuditEvent CdaAuditRole CdaAuditRoleAssignment CdaAuditRoleRight CdaAuditScope CdaAuditSession CdaAuditSessionTag CdaAuditSessionDataIntegrityStatus CdaAuditStore CdaAuditStoreRight CdaCollector CdaDatabase CdaDetailedExecution CdaInstallation CdaInstallationRight CdaManagementDatabase CdaManagementDatabaseRight CdaMonitoredExecution CdaMonitoredFile CdaQuery CdaQueryRight CdaSearchCriteria CdaUnixCommand CdaUnixCommandTranscript CdaUserEvent CdaWindowsEvent

CdaAccessAccount

Represents a Windows user or SQL Server login account with access to auditing components. The following properties are defined for this object.

AccountName	String	Name of the Windows user or SQL Server login account.
Type	Enum	Account type. The valid values are: 1 if the account is a Windows account that uses Windows authentication. 2 if the account is a Microsoft SQL Server login account that uses SQL Server authentication.

CdaAdPrincipal

Represents an Active Directory principal. The principal can be an Active Directory user, group, or computer account. You can use the Class property to identify the type of principal. Only the account name for the principal is stored in the database. The following properties are defined for this object.

Class	String	Principal type of the Active Directory object.
DistinguishedName	String	Distinguished name of the Active Directory object.
Domain	String	Domain name for the Active Directory principal.
GUID	Guid	Globally unique identifier (GUID) for the Active Directory object.
Name	String	Name of the Active Directory object.
SamAccountName	String	The sAMAccountName attribute for the Active Directory principal.
SID	Security identifier	The security identifier (SID) for the Active Directory principal.

CdaAgent

Represents an audited computer where the auditing service is enabled. The following properties are defined for this object.

AuditedSystemType	Enum	Specifies whether the audited systems are system-based ("SystemBased") or vault-based ("VaultBased"). This parameter is optional. If you do not specify this parameter, the results include a list of both types of audited systems. System-based describes a Windows or UNIX computer that is running an agent. You can access these systems either directly or from the Privileged Access Service Admin Portal. Vault-based describes a Windows or UNIX computer or a network device that is not running an agent (agentless). You can access these systems from the Privileged Access Service Admin Portal. Note: Some properties display different values for vault-based systems: * Version: this property is empty because vault-based systems are agentless * Status: this property displays as none * StartupTime: this property displays as a default date-time value of "1/1/0001 12:00:00 AM" * UpTime: this property displays as 00:00:00

LastUpdateTime	DateTime	Time at which the auditing service agent was last updated.
MachineAddress	String	IP address of the computer hosting the auditing service.
MachineName	String	Name of the computer hosting the auditing service.
MachineSid	String	Security identifier string for the computer hosting the auditing service.
StartupTime	DateTime	Time at which the auditing service agent first started.
Status	Enum	Status of the auditing service. The valid values are: Connected Disconnected
Type	Enum	Type of operating system running on the computer hosting the auditing service. The valid values are: 0 — Unknown 1 — UNIX 2 — Windows
UpTime	TimeSpan	Total time the auditing service agent was connected time from the startup time to the last update time.
Version	String	Auditing service agent version number.

CdaAuditEvent

Represents an audit trail event. The following properties are defined for this object.

Description	String	Description of the audit trail event.
EventId	Integer	Event identifier for the audit trail event. Event instances that share the same event type will also have the same EventId.
EventName	String	Name of the audit trail event.
Machine	String	Computer name associated with the audit trail event.
Parameters	String Array	List of parameters for this audit trail event.
Result	String	Result returned by the audit trail event.
SessionId	String	Identifying string for the session associated with the audit trail event, if there is one.
SessionUri	String	The uniform resource identifier (URI) for the session associated with the audit trail event, if there is one.
Time	DateTime	Date and time the audit trail event occurred.
UniqueId	Long	Unique identifier for the event instance.
User	String	User name associated with the audit trail event.

CdaAuditRole

Represents an audit role. The following properties are defined for this object.

Definition	String	String that defines the criteria used in the audit role to specify the sessions to include.
Description	String	Description of the audit role.
Name	String	Name of the audit role.
Privilege	Enum array	User privileges for the audited sessions that match the criteria specified for this audit role.

CdaAuditRoleAssignment

Represents an audit role assignment. The following properties are defined for this object.

Assignee	CdaAdPrincipal	User, group, or computer account assigned to the audit role.
AuditRole	CdaAuditRole	Name of the audit role being assigned.

CdaAuditRoleRight

This object represents the rights granted to a trustee on the audit role. The following properties are defined for this object.

AuditRole	CdaAuditRole	The audit role
Trustee	String	Trustee name in format <DOMAIN>\<User account name> Note: The consistent name format is shown in the Audit Manager console. For an orphan trustee, it shows SID in SDDL format.
TrusteeType	String	Indicate the type of the trustee,for example Active Directory User or Group
Rights	string[]	The collection of rights granted to the trustee on the audit role. Possible rights: Full Control Change Permissions Change Role Membership Change Role Definition

CdaAuditScope

Represents the audit scope for an audit store. The following properties are defined for this object.

Definition	String	String that defines the audit scope. If the audit scope is an Active Directory site, this property is the site name. If the scope is a subnet, this property is the IP address and subnet mask.
Type	Enum	The type of audit scope. The valid values are: 1 if the audit scope is an Active Directory site. 2 if the audit scope is a network subnet segment.

CdaAuditSession

Represents an audited user session. The following properties are defined for this object.

AuditStore	String	Name of the audit store.

ClientAddress	String	Client IP address.
ClientName	String	Client name.
Comment	String array	Comments that have been added by reviewers to the session.
EndTime	DateTime	Session end time.
IsADUser	Boolean	Indicates whether the user is an Active Directory user.
Machine	String	Host name of the computer where the session ran.
MachineAddress	String	Computer IP address of the computer where the session ran.
MachinePrincipal	String	Computer principal name of the computer where the session ran.
ReviewedBy	ADUser	Name of the user who last updated the review status for the session.
ReviewStatus	Enum	Session review status. The valid values are: 0 for None 1 for ToBeReviewed 2 for Reviewed 3 for PendingForAction 4 for KeepForever 5 for ToBeDeleted
ReviewTime	DateTime	Date and time of the last review status update for the session.
SessionID	String	Globally unique identifier (GUID) for the object.
Size	Integer	Total size of the session in KB.
StartTime	DateTime	Session start time.
State	Enum	Status of the session. The valid values are: -1 for Unknown 0 for InProgress 1 for Terminated 2 for Disconnected 3 for Completed
Tags	String	The tags associated with the audit session
Type	Enum	Session type. The valid values are: 1 if the session is a Windows session 2 if the session is a UNIX session
Uri	String	The uniform resource identifier (URI) for replaying the session in the session player.
User	String	User name associated with the session.
UserDisplayName	String	User display name associated with the session.
Zone	String	Server Suite zone name.

CdaAuditSessionTag

Represents the keyword tag that is associated with an audited session. The following properties are defined for this object.

AuditStoreDatabaseId	int	The ID of the audit store database
Id	long	The ID of the tag

Mode	string	The mode of the tag, which indicates if the session was tagged by an automatic process or manually tagged. The possible values are: Manual Automatic
ReplayTimestamp	DateTime	The session replay time of the tag in the audit session
Session	CdaAuditSession	The audit session(s) that the tag is associated with
Tag	string	The tag
Tagger	string	The user name of the auditor who tagged the audit session
TagTimestamp	DateTime	The timestamp when the audit session was tagged

CdaAuditSessionDataIntegrityStatus

If you've enabled the audit store database for data integrity checking, this object refers to the session's data integrity status. Data integrity checking provides the ability to detect if auditing data has been tampered. The following properties are defined for this object.

Session	CdaAuditSession	The audited user session
Status	Integer	Unknown = -1 Passed = 0 Not Enabled = 1 Session Not Found = 2 Missing Final Thumbprint = 3 Invalid Final Thumbprint = 4 Missing Thumbprint = 5 Invalid Thumbprint = 6 Failed = 7
StatusMessage	String	The friendly display message of the status
Source	String	The source name of the audit session data (which contains the database table name and record Id)

CdaAuditStore

Represents an audit store. The following properties are defined for this object.

Affinity	AffinityType enum	The type agents that the audit store serves, either Windows, UNIX, or both. The possible values are: WindowsAndUnix - 0 Windows - 1 Unix - 2
Name	String	Name of the audit store.
Scopes	CdaAuditScope[]	Audit store scopes.
TrustedAgentEnabled	Boolean	Whether the trusted agent filter is enabled or not.
TrustedAgents	CdaComputer[]	Trusted agent computers.
TrustedCollectorEnabled	Boolean	Whether the trusted collector filter is enabled or not.
TrustedCollectors	CdaComputer[]	Trusted collector service computers.

CdaAuditStoreRight

This object represents the rights granted to a trustee on the audit store. The following properties are defined for this object.

AuditStore	CdaAuditStore	The audit store
Trustee	String	Trustee name in format <DOMAIN>\<User account name> Note: The consistent name format is shown in the Audit Manager console. For an orphan trustee, it shows SID in SDDL format.
TrusteeType	String	Indicate the type of the trustee,for example Active Directory User or Group
Rights	string[]	The collection of rights granted to the trustee on the auditstore. Possible rights: Full Control Change Permissions Modify Name Manage Scopes Manage SQL Logins Manage Collectors Manage Audited Systems Manage Databases Manage Database Trace

CdaCollector

Represents a collector service computer. The following properties are defined for this object.

AuditStoreDatabase	String	The audit store database the collector connects to.
LastUpdateTime	DateTime	The date and time at which the collector received the last update.
MachineAddress	String	IP address of the computer hosting the collector service.
MachineName	String	Name of the computer hosting the collector service.
PortNumber	Integer	Collector connection port number.
Sid	String	Security identifier string for the computer hosting the collector service.
StartupTime	DateTime	The date and time at which the collector first connected to the audit store database.
Status	Enum	Status of the collector service. The valid values are: Connected Disconnected
UpTime	TimeSpan	Total time the collector was connected time from startup to the last update time.
Version	String	Collector service version number.

CdaDatabase

Represents an audit store database. The following properties are defined for this object.

ActiveEndTime	DateTime	The date and time at which the database stopped being the active database.
ActiveStartTime	DateTime	The date and time this database became the active database.
AllowedCollectors	CdaAccessAccount[]	Allowed collector accounts.
AllowedManagementServers	CdaAccessAccount[]	Allowed management database accounts.
AuditStore	CdaAuditStore	The audit store object instance for the database.
CollectorCount	Integer	Number of collectors connected to the database.

Database	String	Microsoft SQL Server database name for the audit store database.
DiskUsage	Integer	Database file size, in 8KB pages.
IsActive	Boolean	Specifies whether this is the active database for the audit store.
Name	String	Display name of the audit store database.
RecordCount	Integer	Number of session records in the database.
Server	String	Microsoft SQL Server host name and instance.
Status	Enum	Database status. The valid values are: Connected Disconnected
Version	String	Database version number.

CdaDetailedExecution

Represents detailed command execution details, if advanced monitoring is enabled. The following properties are defined for this object.

User	String	The user name associated with the event
Machine	String	The computer name associated with the event
Time	DateTime	The date and time when the command was executed
EnteredCommand	String	The name of the entered command
ExecutedCommand	String	The name of the executed command
CommandArguments	String	The command arguments
RunAsUser	String	The run as user name
AccessStatus	String	The access status: Succeeded or Failed
AccessStatusDetails	String	The detailed message about the status
CurrentDirectory	String	The current directory of the command execution
ProcessId	String	The process ID of the command execution
ParentProcessId	String	The process ID of the parent process of the command execution

CdaInstallation

Represents an audit installation. The installation defines the scope of the auditing infrastructure and audit data available for review and play back. The following properties are defined for this object.

		Indicates whether users can delete their own sessions. This installation-wide option takes

DisableSelfDelete	Boolean	precedence over the permissions granted to a user account. If you set this option to be True, users cannot delete their own sessions regardless of the rights granted to their audit roles.
DisableSelfReview	Boolean	Indicates whether users can update the review status or the comments on their own sessions. This installation-wide option takes precedence over the permissions granted to a user account. If you set this option to be True, users cannot update the review status or add comments for their own sessions regardless of the rights granted to their audit roles.
EnableVideoCapture	Boolean	Indicates whether the video capture auditing of user activity is enabled or not.
ManagementDatabase	CdaManagementDatabase	The default connected management database for the installation.
Name	String	Name of the installation.
NotificationImage	String	Name of the notification banner image file in base64 string format.
NotificationMessage	String	Name of the file containing the notification message text.
PublishLocations	String Array	One or more Active Directory locations where the installation service connection point is published.

CdaInstallationRight

This object represents the rights granted to a trustee on the DA Installation. The following properties are defined for this object.

Trustee	String	Trustee name in format <DOMAIN>\<User account name> Note: The consistent name format is shown in the Audit Manager console. For an orphan trustee, it shows SID in SDDL format.
TrusteeType	String	Indicate the type of the trustee,for example Active Directory User or Group
Rights	string[]	The collection of rights granted to the trustee on the DA Installation. Possible rights: Full Control Change Permissions Modify Name Manage Management Database List Manage Audit Store List Manage Collectors Manage Audited Systems Manage Audit Role Manage Queries Manage Publications Manage Licenses Manage Notification Manage Audit Option View

CdaManagementDatabase

Represents an audit management database. The following properties are defined for this object.

AllowedIncomingUsers	CdaUser[]	Allowed incoming users of the management database.
Database	String	Microsoft SQL Server database name for the management database.
Name	String	Display name of the management database.
OutgoingAccount	CdaAccessAccount	Outgoing account of the management database.
Scope	CdaAuditScope[]	Audit store scopes defined for the management database.
Server	String	Microsoft SQL Server host name and instance name.
Status	Enum	Status of the management database. The valid values are: Connected Disconnected

CdaManagementDatabaseRight

This object represents the rights granted to a trustee on the management database. The following properties are defined for this object.

ManagementDatabase	CdaManagementDatabase	The management database
Trustee	String	Trustee name in format <DOMAIN>\<User account name> Note: The consistent name format is shown in the Audit Manager console. For an orphan trustee, it shows SID in SDDL format.
TrusteeType	String	Indicate the type of the trustee,for example Active Directory User or Group
Rights	string[]	The collection of rights granted to the trustee on the management database. Possible rights: Full Control Change Permissions Modify Name Manage Scopes Remove Database Manage SQL Logins Manage Database Trace

CdaMonitoredExecution

Represents monitored command execution details, if advanced monitoring is enabled. The following properties are defined for this object.

User	String	The user name associated with the event
Machine	String	The computer name associated with the event
Time	DateTime	The date and time when the command was executed
Command	String	The name of the executed command
CommandArguments	String	The command arguments
RunAsUser	String	The run as user name
AccessStatus	String	The access status: Succeeded or Failed
AccessStatusDetails	String	The detailed message about the status
CurrentDirectory	String	The current directory of the command execution
ProcessId	String	The process ID of the command execution
ParentProcessId	String	The process ID of the parent process of the command execution

CdaMonitoredFile

Represents monitored file details, if advanced monitoring is enabled. The following properties are defined for this object.

User	String	The user name associated with the event
Machine	String	The computer name associated with the event
Time	DateTime	The date and time when the command was executed

FileName	String	The filename of the file being accessed
Command	String	The name of the executed command
RunAsUser	String	The run as user name
SystemCallName	String	The name of the system call
AccessType	String	The type of the file access: Write or ChangeAttribute
AccessStatus	String	The access status: Succeeded or Failed
AccessStatusDetails	String	The detailed message about the status
CurrentDirectory	String	The current directory of the command execution
ProcessId	String	The process ID of the command execution
ParentProcessId	String	The process ID of the parent process of the command execution

CdaQuery

This object represents a query. The following properties are defined for this object.

Name	String	The query name
Description	String	The query description
IsPredefined	boolean	Whether this query is predefined or not

CdaQueryRight

This object represents the rights granted to a trustee on the query. The following properties are defined for this object.

Query	CdaQuery	The query
Trustee	String	Trustee name in format <DOMAIN>\<User account name> Note: The consistent name format is shown in the Audit Manager console. For an orphan trustee, it shows SID in SDDL format.
TrusteeType	String	Indicate the type of the trustee,for example Active Directory User or Group
Rights	string[]	The collection of rights granted to the trustee on the query. Here are the possible rights: Full Control Change Permissions Read Delete Modify

CdaSearchCriteria

Represents a search criteria object that defines the filters to use to find sessions that can be passed to other cmdlets. For example, you can create a search criteria object to define the sessions that are applicable for a given audit role. The following properties are defined for this object.

Application	String array	Filter sessions by using the Windows application name used.
AuditStore	String	Filter sessions by using the name of the audit store.
ClientName	String	Filter sessions by using the client name of the session.
Comment	String array	Filter sessions by using the comments that have been added by reviewers to the session.
Group	String array	Filter sessions by using the session owner's Active Directory security group.
Installation	String	Filter sessions by using the name of the audit installation.
Machine	String	Filter sessions by using the host name of the computer where the session ran.
ReviewStatus	Enum	Filter sessions by using the session review status. The valid values are: 0 for None 1 for ToBeReviewed 2 for Reviewed 3 for PendingForAction 4 for KeepForever 5 for ToBeDeleted
State	Enum	Filter sessions by using the status of the session. The valid values are: 0 for InProgress 1 for Terminated 2 for Disconnected 3 for Completed
TimeAfter	DateTime	Filter sessions that ran after a specific date and time.
TimeBefore	DateTime	Filter sessions that ran before a specific date and time.
TimeBetween	DateTime	Filter sessions that ran between a start time and an end time.
Type	Enum	Filter sessions by using the session type. The valid values are: 1 if the session is a Windows session 2 if the session is a UNIX session
UnixCommand	String array	Filter sessions by using the UNIX command line input and output.
UnixCommandName	String array	Filter sessions by the UNIX command name only.
UnixCommandTimeAfter	DateTime	Filter sessions that ran after a specific date and time based on the UNIX command input time.
UnixCommandTimeBefore	DateTime	Filter sessions that ran before a specific date and time based on the UNIX command input time.
UnixCommandTimeBetween	DateTime	Filter sessions that ran between a start and end time based on the UNIX command input time.
UnixOutput	Text	Filter sessions by using the UNIX terminal output text captured in the session.
User	String	Filter sessions by using the user name associated with the session.

CdaUnixCommand

Represents an indexed UNIX command captured in an audited session. The following properties are defined for this object.

Command	String	Text of the UNIX command line that was executed.

Sequence	Integer	Sequence number that identifies where in the indexed list of events this event occurs.
Session	CdaAuditSession	The session object.
Time	DateTime	Date and time when the command was executed.

CdaUnixCommandTranscript

Represents the UNIX command input and output captured in an audited session. The following properties are defined for this object.

EndTime	DateTime	The time at which the capture of this command ended.
LineNumber	Integer	The line number at which the text displayed in the terminal.
Role	String	The DirectAuthorize role assigned to this command.
Session	CdaAuditSession	The session object.
StartTime	DateTime	The time at which the capture of this command started.
Text	String	The text displayed in the terminal.
Ticket	String	The trouble ticket assigned to this command.
Type	Enum	Indicates whether the captured text was input or output.

CdaUserEvent

Represents a user event. The following properties are defined for this object.

User	String	User name associated with the user event.
Machine	String	Computer name associated with the audit trail event.
Time	DateTime	The date and time when the command was executed.
Activity	String	A brief description of the user event.

CdaWindowsEvent

Represents an indexed Windows event captured in an audited session. The following properties are defined for this object.

Application	String	Application name associated with the event.
Desktop	String	Desktop name associated with the event if the event occurred when using a desktop access right.
IsAudited	Boolean	Indicates whether this event occurred when using an audited role with a desktop right.

Sequence	Integer	Sequence number that identifies where in the indexed list of events this event occurs.
Time	DateTime	Date and time when the event occurred.
Title	String	Windows title bar text for the application when the event occurred.
Type	Enum	Type of event. The most common event types indicate when a new window or a new application starts or when the title of an existing windows changes.

This chapter explains how to add a user in a one-way trust environment by using the Delinea Windows API.

To add a user in a one-way trust environment, follow these steps:

1. Select an account in a domain that is in a one-way trust relationship with the remote forest so that the account has access to resources in both domains.

   For example, suppose the corporate domain company.corp.com is trusted by the remote domain companyDMZ.com, which is where you intend to add a user. Select an account in the company.corp.com domain that can access resources in the companyDMZ.com domain.

2. Verify that the selected account has permission to modify a zone.

   You can use the zone delegation wizard to add this permission to the selected account. By default, if the user account is a member of the Domain Administrators group in companyDMZ.com, you have the necessary permissions.

3. Use Cims.Connect() to connect to the companyDMZ.com domain to get the Cims object.

4. Obtain an IADsUser object for the remote forest user that you will add to the zone.

   To obtain an IADsUser for company.corp.com using VBScript, for example, use the following code:

   u = GetObject(LDAPCOMPANY.CORP.NETCN=UserName,CN=Users,DC=wonder,DC=land)

   If you log in as a domain user from company.corp.com, you should have sufficient permission.

5. Get the User object by passing the IADsUser object you obtained in the previous step to cims.GetUser(x).

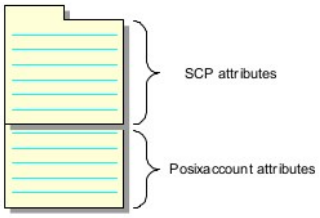
6. With the User object, you can use User.AddUnixProfile() to add the zone profile.

Data Storage for Delinea Zones

This chapter provides a detailed description of how Delinea-specific information is stored in Active Directory. Understanding how this information is stored will enable you to manipulate data for UNIX users and groups using standard LDAP tools, such as ldapadd, directly from UNIX computers, or using Active Directory LDAP utilities, such as adinfo, on Windows computers without using Access Manager, COM objects, or .NET programs.

Classic RFC 2307 Zones (3.x, 4.x)

The classic RFC 2307-compatible zone is similar to the classic Delinea zone, except that the data in the serviceConnectionPoint objects is associated with Active Directory user and group objects stored in RFC 2307-compliant attributes. For RFC 2307-compatible zones, Delinea makes use of a Windows Server feature, called Dynamic Auxiliary Classes, to dynamically bind posixAccount or posixGroup instances to the serviceConnectionPoint objects.



Binding the posixAccount or posixGroup to the user or group serviceConnectionPoint results in an Active Directory object with:

- Two object classes: the serviceConnectionPoint objectClass and the posixAccount or posixGroup objectClass.
- Two sets of attributes: those contributed by the serviceConnectionPoint object and those contributed by posixAccount or posixGroup object.

The structure of the zone and its sub-containers is the same as the classic Delinea zone layout, with each zone stored as a separate tree in the directory and sub-containers for the **Users**, **Groups**, and **Computers** in each zone, but you can use attributes from the posixAccount or posixGroup objectClass to store data in the RFC 2307-compliant format. Storing the data in RFC 2307-compliant attributes enables the information to be used by applications that conform to the RFC 2307 standard.

Zone Attributes in Classic RFC 2307 Zones

The zone object class and its attributes in the classic RFC 2307compliant zone are the same as the classic Delinea zone. The zone object is stored as a container object, and the common name (cn) of the object must be set to the zone name. Most of the other attributes for a zone are stored as pseudo-attributes using the Active Directory description attribute.

The following table summarizes how zone attributes are stored in Active Directory for classic RFC 2307-compliant zones. For more information about any attribute setting, see Zone attributes in classic Delinea zones.

ZoneName	cn:ZoneName For example: cn:default
ZoneVersion	displayName:ZoneVersion The valid values are: ZoneVersion \$CimsZoneVersion3 for RFC 2307 zones, compatible with Delinea, version 3.x \$CimsZoneVersion4 for standard classic zones. \$CimsZoneVersion5 for classic RFC 2307 zones, compatible with Delinea, version 4.x For example: displayName:\$CimsZoneVersion5
Description	description:value For example: description:description:Pilot EMEA
NextUid	description:uidnext:value For example: description:uidnext:12098
NextGid	description:gidnext:value For example: description:gidnext:12098
ReservedUids	description:uidreserved:value For example: description:uidreserved:0-99:501
ReservedGids	description:gidreserved:value For example: description:gidreserved:1000-2500
Availableshells	description:availableshells:value For example: description:availableshells:/bin/sh
DefaultHomeDirectory	description:defaulthome:value For example: description:defaulthome:/nfs/\${user}
DefaultShell	description:defaultshell:value For example: description:defaultshell:/bin/bash
DefaultGroup	description:defaultgid:value For example: description:defaultgid:12098
ZoneType	schema:Dynamic_Schema_Version The valid values for classic RFC 2307compliant zones are: CDC_RFC_2307 (3.x compatible). CDC_RFC_2307_2 (4.x compatible). For example: description: schema:CDC_RFC_2307

User Attributes in Classic RFC 2307 Zones

There are two object classes for the user extension object created in the Users subcontainer of the zone: the serviceConnectionPoint object class and the posixAccount object class.

UnixName	cn:userlogin and uid:userlogin For example: uid:cain
UserVersion	displayName:UserVersion This attribute determines compatibility between a user profile object and the Access Manager console. The only valid value for this attribute is \$CimsUserVersion3. For example: displayName:\$CimsUserVersion3
Uid	uidNumber:value For example: uidNumber:458
Gid	gidNumber:value For example: gidNumber:458
Home	unixHomeDirectory:value For example: unixHomeDirectory:/home/shea
Shell	loginShell:value For example: loginShell:/bin/bash
ParentLink	managedBy:DN_ActiveDirectoryUser If the zone is a 2.x and 3.x compatible zone, you should set this attribute to the DN of the parent Active Directory user object. For example: managedBy:cn=ben'lau,cn=users,dc=ice,dc=net If the zone does not need to be compatible with older versions of Delinea software, you can use the keywords attribute and parentLink pseudo-attribute to specify the security identifier (SID) of the parent Active Directory user object. For example: keywords:parentLink:S-n-n-nn-nnn..
UnixEnabled	keywords:unix_enabled:value For example: keywords:unix_enabled:True
ForeignForest	keywords:foreign:value This attribute indicates whether a user in a zone is from an external forest. For example: keywords:foreign:False

Note: The attribute name unixHomeDirectory is not RFC 2307compliant. Microsoft used this name because the attribute homeDirectory was already used in Active Directory.

Group Attributes in Classic RFC 2307 Zones

There are two object classes for the group extension object created in the Groups sub-container of the zone: the serviceConnectionPoint object class and the posixAccount object class.

UnixName	cn:GroupName For example: cn:performx
GroupVersion	displayName:GroupVersion This attribute determines compatibility between a group profile object and the Access manager console. The only valid value for this attribute is \$CimsGroupVersion3. For example: displayName:\$CimsGroupVersion3
Gid	gidNumber:value For example: gidNumber:458
ParentLink	managedBy:DN_ActiveDirectoryGroup If the zone is a 2.x and 3.x compatible zone, you should set this attribute to the DN of the parent Active Directory group object. For example: managedBy:cn=interns,cn=users,dc=ice,dc=net If the zone does not need to be compatible with older versions of Delinea software, you can use the keywords attribute and parentLink pseudo-attribute to specify the security identifier (SID) of the parent Active Directory group object. For example: keywords:parentLink:S-n-n-nn-nnn..
UnixEnabled	keywords:unix_enabled:value For example: keywords:unix_enabled:True
ForeignForest	keywords:foreign:value This attribute indicates whether a group in a zone is from an external forest. For example: keywords:foreign:False

Note: The posixGroup group membership attributes are not set. Delinea uses the normal Active Directory mechanism for determining group membership.

Computer Attributes in Classic RFC 2307 Zones

A computer extension object is a serviceConnectionPoint object that is created in the Computers sub-container of the zone. The pseudoattributes for this object are stored in the keywords attribute.

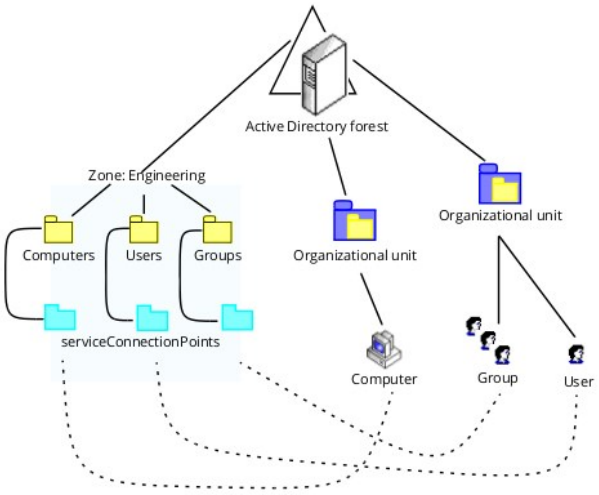
UnixName	name:ComputerName Normally, computer attribute values are set by the adjoin process and do not need to be modified. For example: name:magnolia.ajax.org
ComputerVersion	displayName:ComputerVersion This attribute determines compatibility between a computer profile object and the Access Manager console. The only valid value for this attribute is $CimsComputerVersion3. For example: displayName:$CimsComputerVersion3
ParentLink	managedBy:DN_ActiveDirectoryGroup If the zone is a 2.x and 3.x compatible zone, you should set this attribute to the DN of the parent Active Directory computer object. For example: managedBy:cn=hr,cn=computers,dc=ajax,dc=org If the zone does not need to be compatible with older versions of Delinea software, you can use the keywords attribute and parentLink pseudo-attribute to specify the security identifier (SID) of the parent Active Directory computer object. For example: keywords:parentLink:S-n-n-nn-nnn..
AgentVersion	keywords:agentVersion:value For example: keywords:agentVersion:CentrifyDC 4.1 >**Note:** This attribute is set as a keywords attribute if you are using Delinea, versions 3.0.x through 4.1.x. With the Delinea Agent, version 4.2 or later, the AgentVersion is stored using the operatingSystemServicePack attribute of the computer object.
CpuCount	keywords:cpus:value For example: keywords:cpus:2 >**Note:** This attribute is only set if you are using Delinea, versions 3.0.x through 4.1.x. The attribute is not set or updated for computers with the Delinea Agent, version 4.2 or later.
JbossEnabled	keywords:jboss_enabled:value This attribute indicates whether the computer hosts JBoss applications. For example: keywords:jboss_enabled:False
TomcatEnabled	keywords:tomcat_enabled:value This attribute indicates whether the computer hosts Tomcat applications. For example: keywords:tomcat_enabled:False
UnixEnabled	keywords:unix_enabled:value For example: keywords:unix_enabled:True
WebLogicEnabled	keywords:weblogic_enabled:value This attribute indicates whether the computer hosts WebLogic applications. For example: keywords:WEBLOGIC_enabled:True
WebSphereEnabled	keywords:websphere_enabled:value This attribute indicates whether the computer hosts WebSphere applications. For example: keywords:websphere_enabled:True

) [tags]: # (windows api) [priority]: # (1)

Classic Delinea Zones (2.x, 3.x, 4.x)

In classic Delinea zones, each zone is a separate tree stored in the directory. The root of the zone tree is an Active Directory container with the same name as the zone. The zone attributes described in the logical data model are stored in the attributes of this container object. Within the zone container, there are sub-containers for the **Users**, **Groups**, and **Computers** in the zone.

The following figure illustrates the basic structure used for classic zones.



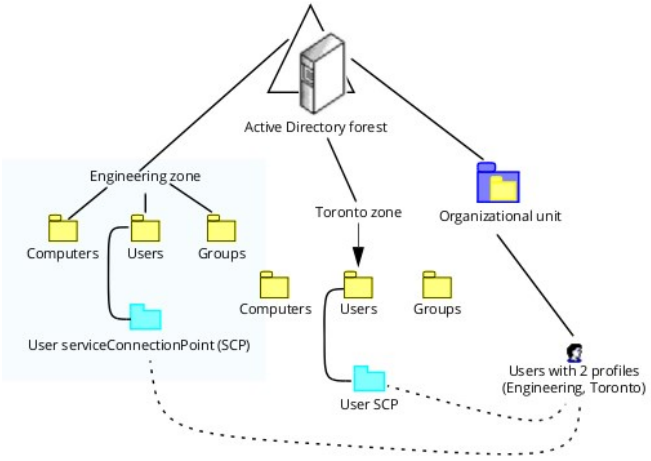
Within each of the sub-containers, there are serviceConnectionPoint (SCP) objects. The serviceConnectionPoint (SCP) objects contain the Delinea attributes for each user, group, or computer defined for the zone. Each of user, group, or computer serviceConnectionPoint objects also has a link back to its parent object (shown as dotted lines in the figure above).

> **Note:** Although Figure 1 illustrates the basic layout for a classic zone using a simple scenario, more complex configurations are possible. For example, in the illustrated scenario, the parent user and group objects are in the same organizational unit (OU), but this is not a requirement. Similarly, the zone tree does not need to be in the same domain as the user or computers objects.

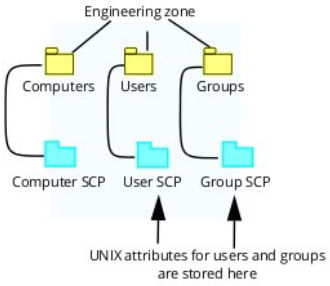
The zone tree structure separates Delinea and UNIX-specific attributes for each zone from every other zone and from the base Active Directory objects for the users and groups. This structure has the following important benefits:

- It enables a single Active Directory user to have many different UNIX profiles.
- It enables you to delegate administrative tasks to users and groups on a zone-by-zone basis.

The following figure illustrates how the zone tree structure enables a single Active Directory user to have many different UNIX profiles.



In a classic zone, the Delinea and UNIX-specific attributes are separate from all of the other zones and from the base Active Directory objects for the users and groups. This enables delegated management of UNIX-related tasks, such as adding or removing UNIX profiles, within each zone.



Parent link Attributes

For each serviceConnectionPoint object in the zone, there is a link back to the corresponding Active Directory object that owns the serviceConnectionPoint object. This link is stored in one of two ways:

- Using the ParentLink pseudo-attribute. This attribute contains the string security identifier (SID) of the parent Active Directory object. This attribute is used in Delinea, version 3.x and later.
- Using the managedBy Active Directory attribute. This attribute is set to the distinguished name (DN) of the parent object. This attribute was used in Delinea, version 2.x, but discontinued because there are cases when it is not possible to set the managedBy attribute.

Zone Attributes in Classic Delinea Zones

The zone object class is stored as a container object. The common name (cn) of the object must be set to the zone name. Most of the other attributes for a zone are stored as pseudoattributes using the Active Directory description attribute. The following table summarizes how zone attributes are stored in Active Directory for Delinea zones.

ZoneName	cn:ZoneName For example: cn:default
ZoneVersion	displayName:ZoneVersion This attribute determines compatibility between a zone object and the Access Manager console. The valid values are: \$CimsZoneVersion2 for zones compatible with Delinea versions 2.x and 3.x \$CimsZoneVersion3 for RFC 2307 classic zones compatible with Delinea versions 2.x and 3.x \$CimsZoneVersion4 for classic zones compatible with Delinea, version 4.x \$CimsZoneVersion5 for hierarchical zones For example: displayName: \$CimsZoneVersion5
Description	description:description:value For example: description:description:Pilot EMEA
NextUid	description:uidnext:value For example: description:uidnext:12098
NextGid	description:gidnext:value For example: description:gidnext:12098
ReservedUids	description:uidreserved:value This attribute can be a multi-valued list, using a colon as the separator. Values can be individual numbers or a range of numbers separated with a dash character (). For example: description:uidreserved:0-99:501
ReservedGids	description:gidreserved:value This attribute has the same format as the reserveduids attribute. For example: description:gidreserved:1000-2500
Availableshells	description:availableshells:value This attribute can be a multi-valued list of shell names, using a colon as the separator. For example: description:availableshells:/bin/sh
DefaultHomeDirectory	description:defaulthome:value For example: description:defaulthome:/nfs/\${user}
DefaultShell	description:defaultshell:value For example: description:defaultshell:/bin/bash
DefaultGroup	description:defaultgid:value For example: description:defaultgid:12098
ZoneType	schema:Dynamic_Schema_Version This attribute identifies the schema layout a zone object uses. The valid values are: Dynamic_Schema_1_0 for Delinea, version 1.0, zones. This schema type is obsolete for version 2.x and later. Dynamic_Schema_2_0 for classic Delinea zones, 2.x and 3.x compatible. Dynamic_Schema_3_0 for classic Delinea zones, 3.x and 4.x compatible. Dynamic_Schema_5_0 for hierarchical Delinea zones, 5.x compatible. SFU_3_0 for SFU zones with the Microsoft Services for UNIX (SFU), version 3.x, schema extension. SFU_4_0 for SFU zones with the Microsoft Services for UNIX (SFU), version 4.x, schema extension. CDC_RFC_2307 for classic RFC 2307compliant zones, Delinea 2.x and 3.x compatible. CDC_RFC_2307_2 for classic RFC 2307compliant zones, Delinea 4.x compatible. CDC_RFC_2307_3 for hierarchical RFC 2307compliant zones, Delinea 5.x compatible. For example: description:schema:Dynamic_Schema_5_0

User Attributes in Classic Delinea Zones

A user extension object is a serviceConnectionPoint object that is created in the Users sub-container of the zone. The pseudoattributes for this object are stored in the keywords attribute.

UnixName	cn:userlogin For SCP objects, the Name attribute is a logical pointer that is the same as the CN attribute. You can use either attribute to store the user's UNIX login name. For example: cn:cain
UserVersion	displayName:UserVersion This attribute determines compatibility between a user profile object and the Access Manager console. The only valid value for this attribute is \$CimsUserVersion2. For example: displayName:\$CimsUserVersion2
ParentLink	managedBy:DN_ActiveDirectoryUser You can use the managedBy or keywords attribute to store the parentLink. If the zone is a 2.x and 3.x compatible zone, you should set this attribute to the DN of the parent Active Directory user object. For example: managedBy:cn=ben.lau,cn=users,dc=ice,dc=net If the zone does not need to be compatible with older versions of Delinea software, you can use the keywords attribute and parentLink pseudo-attribute to specify the security identifier (SID) of the parent Active Directory user object. For example: keywords:parentLink:S-n-n-nn-nnn..
Uid	keywords:uid:value For example: keywords:uid:458
Gid	keywords:gid:value For example: keywords:gid:458
Home	keywords:home:value For example: keywords:home:/home/shea
Shell	keywords:shell:value For example: keywords:shell:/bin/bash
UnixEnabled	keywords:unix_enabled:value For example: keywords:unix_enabled:False
ForeignForest	keywords:foreign:value This attribute indicates whether a user in a zone is from an external forest. For example: keywords:foreign:False
AppEnabled	This attribute is no longer used.

Group Attributes in Classic Delinea Zones

A group extension object is a serviceConnectionPoint object that is created in the Groups sub-container of the zone. The pseudoattributes for this object are stored in the keywords attribute.

UnixName	name:GroupName For SCP objects, the Name attribute is the same as the CN attribute. Either attribute can be set, but attribute use should be consistent with other objects. For example: name:performx
GroupVersion	displayName:GroupVersion This attribute determines compatibility between a group profile object and the Access manager console. The only valid value for this attribute is \$CimsGroupVersion3. For example: displayName:\$CimsGroupVersion3
ParentLink	managedBy:DN_ActiveDirectoryGroup If the zone is a 2.x and 3.x compatible zone, you should set this attribute to the DN of the parent Active Directory group object. For example: managedBy: cn=interns,cn=users,dc=ice,dc=net If the zone does not need to be compatible with older versions of Delinea software, you can use the keywords attribute and parentLink pseudoattribute to specify the security identifier (SID) of the parent Active Directory group object. For example: keywords:parentLink:S-n-n-nn-nnn..
Gid	gid:value For example: keywords:gid:458
UnixEnabled	This attribute is only applicable in classic 4.x zones.
ForeignForest	Not supported in 3.x or 4.x.

Computer Attributes in Classic Delinea Zones

A computer extension object is a serviceConnectionPoint object that is created in the Computers sub-container of the zone. The pseudoattributes for this object are stored in the keywords attribute.

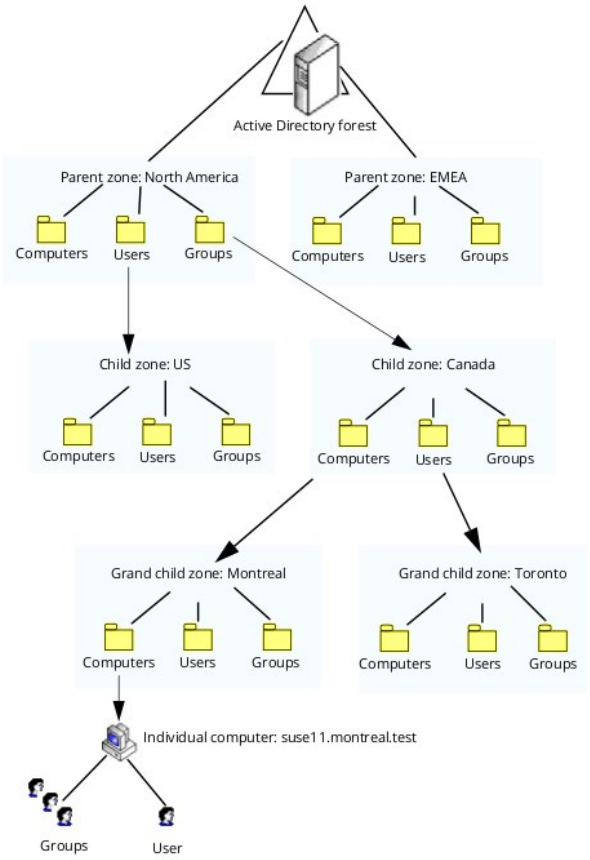
UnixName	name:ComputerName For SCP objects, the Name attribute is the same as the CN attribute. Either attribute can be set, but attribute use should be consistent with other objects. Normally, computer attribute values are set by the adjoin process and do not need to be modified. For example: name:magnolia.ajax.org
ComputerVersion	displayName:ComputerVersion This attribute determines compatibility between a computer profile object and the Access Manager console. The only valid value for this attribute is \$CimsComputerVersion3. For example: displayName:\$CimsComputerVersion3
ParentLink	managedBy:DN_ActiveDirectoryGroup If the zone is a 2.x and 3.x compatible zone, you should set this attribute to the DN of the parent Active Directory computer object. For example: managedBy:cn=hr,cn=computers,dc=ajax,dc=org If the zone does not need to be compatible with older versions of Delinea software, you can use the keywords attribute and parentLink pseudo-attribute to specify the security identifier (SID) of the parent Active Directory computer object. For example: keywords:parentLink:S-n-n-nn-nnn
AgentVersion	keywords:agentVersion:value For example: keywords:agentVersion:CentrifyDC 4.1 **Note** This attribute is set as a keywords attribute if you are using Delinea, versions 3.0.x through 4.1.x. With the Delinea Agent, version 4.2 or later, the agentVersion is stored using the operatingSystemServicePack attribute of the computer object.
CpuCount	keywords:cpus:value For example: keywords:cpus:2 **Note** This attribute is only set if you are using Delinea, versions 3.0.x through 4.1.x. The attribute is not set or updated for computers with the Delinea Agent, version 4.2 or later.
JbossEnabled	keywords:jboss_enabled:value This attribute indicates whether the computer hosts JBoss applications. For example: keywords:jboss_enabled:False
TomcatEnabled	keywords:tomcat_enabled:value This attribute indicates whether the computer hosts Tomcat applications. For example: keywords:tomcat_enabled:False
UnixEnabled	keywords:unix_enabled:value For example: keywords:unix_enabled:True
WebLogicEnabled	keywords:weblogic_enabled:value This attribute indicates whether the computer hosts WebLogic applications. For example: keywords:jboss_enabled:True
WebSphereEnabled	keywords:websphere_enabled:value This attribute indicates whether the computer hosts WebSphere applications. For example: `keywords:websphere_enabled:True

) [tags]: # (windows api) [priority]: # (1)

Hierarchical Delinea Zones (5.x)

In hierarchical Delinea zones, each zone is part of a tree of zones and Active Directory containers for users, groups, and computers. The effective profile for each user, group, or computer in a hierarchical zone is determined by attributes defined in the current zone, in parent zones, and in zone default values, with values lower in the hierarchy taking priority. In addition, individual computers can have computer-level overrides of users, groups, and role assignments. When you assign computer-level overrides for a specific computer, internally Delinea creates a *computer-specific zone* that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed as zones in Access Manager, but are treated as end nodes in the zone hierarchy.

The following figure illustrates the basic structure used for hierarchical Delinea zones. Attributes are inherited from higher-level to lower-level zones as indicated by the arrows in the figure.



In hierarchical zones, because User and Zone objects inherit from their parent zones, it is not necessary for every hierarchical level to have a full set of attributes. If a user profile is incomplete after inheriting all the ancestor's attributes, missing mandatory attributes are filled from defaults. Missing UIDs are generated from an RID-based algorithm.

See Classic Delinea zones (2.x, 3.x, 4.x) for a general description of the way Delinea attributes are stored in Active Directory.

Zone Attributes in Standard Hierarchical Zones

The zone object class is stored as a container object. The common name (cn) of the object must be set to the zone name. Most of the other attributes for a zone are stored as pseudoattributes using the Active Directory description attribute. The following table summarizes how zone attributes are stored in Active Directory for hierarchical Delinea zones.

ZoneName	cn:ZoneName For example: cn:global	No
Description	description:description:value For example: description:description:Pilot-NA	No
AvailableShells	description:availableshells:shell1:shell2 For example: description:availableshells:/bin/sh	Yes
DefaultShell	description:defaultshell:value or description:defaultshell:%{shell} For example: description:defaultshell:/bin/bash	Yes
DefaultHomeDirectory	description:defaulthome:value or description:defaulthome:%{home}/%{user} For example: description:defaulthome:/nfs/jsmith	Yes
UserDefaultGecos	description:defaultgecos:\${u:cn} For example: description:defaulttgecos:\${u:upn}	Yes
customVariable	description:%variablename:value One for each variable. For example: description:%admin:sAMAccountName	Yes
ReservedUids	description:uidreserved:value This attribute can be a multi-valued list, using a colon as the separator. Values can be individual numbers or a range of numbers separated with a dash character (). For example: description:uidreserved:0-99:501	Yes
ReservedGids	description:gidreserved:value This attribute has the same format as the reserveduids attribute. For example: description:gidreserved:1000-2500	Yes
UserDefaultUid	description:defaultuid:value Set value to \${uidnext} to use the zone's cram attribute uidnext. The cram attribute is where the key-value pairs ("name:value") are stored. Set value to \${autosid} to generate the UID from the domain SID and user RID. For example: description:defaultuid:\${autosid}	Yes
DefaultGroup	description:defaultgid:value Set value to -1 to use private groups. For example: description:defaultgid:12098	Yes
UserDefaultName	description:username:\${u:sAMAccountName}	Yes
UserDefaultRole	description:defaultrole:role-name	Yes
GroupDefaultGid	description:defaultgroupgid:value Set value to \${gidnext} to use the zone's cram attribute gidnext in classic zones. Set value to \${autosid} to generate the GID from the domain SID and group RID in hierarchical zones. For example: description:defaultgid:\${autosid}	Yes
GroupDefaultName	description:groupname:\${g:CN}	Yes
NISDomain	description:nisdomain:name	Yes
Schema	description:schema:name Possible values are: CDC_RFC_2307 (for a classic RFC 2307 zone) CDC_GENERIC (for a classic Delinea zone) SFU_3_0 (For a classic SFU-compliant R2 schema zone) SFU_3_0V1 (For a classic SFU-compliant zone) For example: description:Cchema:DC_GENERIC	No
AgentlessAttribute	description:pwsync:attributeName For example: description:pwsync:msSFU30Password	Yes
Licenses	description:license:guid	Yes
SFUDomain	description:alternateDomain:domain.name This is a multi-value attribute. Multi-value attributes are possible because the keyword and value are combined, making each line of the description-keyword string unique.	Yes
Parent	description:parentLink:MS-GUID@DOMAIN.NAME For example: samAccountName@domain.name[:N]: "joe@ajax.com"	No

objectType	displayName=\$CimsZoneVersionnumber where the zone version number can be: \$CimsUserVersion4 for a Delinea zone \$CimsUserVersion5 for a RFC 2307 zone	No

User Attributes in Hierarchical Zones

A user extension object is a serviceConnectionPoint object that is created in the Users sub-container of the zone. The pseudoattributes for this object are stored in the keywords attribute.

cn	sAMAccountName@domain.name[:*N*]	No
objectType	displayName=\$CimsUserVersion4	No
Name	keywords:login:name For example: keywords:login:cain	Yes
Uid	keywords:uid:value For example: keywords:uid:458	Yes
Gid	keywords:gid:value For example: keywords:gid:458	Yes
Home	keywords:home:value For example: keywords:home:/home/shea	Yes
Shell	keywords:shell:value For example: keywords:shell:/bin/bash	Yes
Gecos	gecos:value For example: gecos:%{u:displayName}	Yes

User and group extended attributes are specific to a particular computer and can be set on a per-user or per-group basis. The format for extended attributes depend on the format required for a particular operating system. Currently, only AIX extended attributes are supported.

Each attribute name starts with a prefix that indicates the operating system to which it applies (for example, aix.) and is followed by the attribute name. The valid values for each attribute depend on the attribute type, and can be a string, number or Boolean value. Attributes that support multiple values are specified with separate namevalue pairs.

The specific user and group extended attributes that are available for you to set depend on the version of the operating system running on the computer where the attributes are used. For detailed information about the extended attributes available and valid values on a specific version of the AIX operating system, see your AIX documentation.

The following table lists some of the most commonly-used **user extended attributes** for illustration purposes. It does not represent the complete list of user and group extended attributes that might be available on any given version of the operating system.

aix.admin	Specifies the administrative status of the user as true or false.
aix.admgroups	Lists the groups that the user administrates as a comma-separated list of group names.
aix.daemon	Specifies whether the user can execute programs using the the cron daemon or the system resource controller (src).
aix.rlogin	Specifies whether the user account can be logged into remotely using telnet or rlogin.
aix.su	Indicates whether other users can switch to the user account with the su command.
aix.sugroups	Lists the groups can switch to the user account as a comma-separated list of group names.
aix.tpath	Indicates the user's trusted path status.
aix.ttys	Lists the terminals that can access the account as a comma-separated list of full path names, or using ALL to indicate all terminals.
aix.fsize	Sets the soft limit for the largest file a user's process can create or extend or a value of -1 to specify unlimited for this attribute.

aix.core	Sets the soft limit for the largest core file a user's process can create or a value of -1 to specify unlimited for this attribute.
aix.cpu	Sets the soft limit for the maximum number of seconds of system time that a user's process can use or a value of -1 to specify unlimited for this attribute.
aix.data	Sets the soft limit for the size of a user's data segment or a value of -1 to specify unlimited for this attribute
aix.rss	Sets the soft limit for the largest amount of physical memory a user's process can allocate or a value of 1 to specify unlimited for this attribute.
aix.stack	Sets the soft limit for the largest process stack segment for a user's process or a value of 1 to specify unlimited for this attribute.
aix.nofiles	Sets the soft limit for the number of file descriptors a user process can have open at one time or a value of 1 to specify unlimited for this attribute.
aix.umask	Determines file permissions for the user using a three-digit octal value such as 022.

Group Attributes in Hierarchical Zones

A group extension object is a serviceConnectionPoint object that is created in the Groups sub-container of the zone. The pseudoattributes for this object are stored in the keywords attribute.

version	displayName=\$CimsZoneVersion4 or, for RFC 2307 objects, use version 5: displayName=\$CimsZoneVersion5	No
name	keywords:login:Name For example: keywords:login:ibmdba	Yes
gid	keywords:gid:value For example: keywords:gid:458 If the group is in a standard zone, the GID is stored as gid:xxx in the keywords attribute. If the group is in an RFC 2307 zone, the GID is stored in the schema's gid attribute.	Yes
parentLink	keywords:parentLink:MS-SID For example: keywords:parentLink:S-1-5-21-387451290	No
IsMembershipRequired	keywords:required:value For example: keywords:required:true	Yes
InheritFromParent	keywords:inherit:value For example: keywords:inherit:true	No

Computer Attributes in Hierarchical Zones

A computer extension object is a serviceConnectionPoint object that is created in the Computers sub-container of the zone. The pseudoattributes for this object are stored in the keywords attribute.

unixName	cn:name:ComputerName Normally, the computer attribute values are set by the adjoin process and do not need to be modified.
schemaVersion	displayName:ComputerVersion This attribute determines compatibility between a computer profile object and the Access Manager console. The only valid value for this attribute is \$CimsComputerVersion3. For example: displayName:\$CimsComputerVersion3
agentVersion	keywords:agentVersion:Version For example: keywords:agentVersion:CentrifyDC 5.4.0-197
parentLink	keywords:parentLink:MS-SID For example: keywords:parentLink:S-1-5-21-387451290-2189

Computer-Specific Zone Attributes in Standard Hierarchical Zones

A computer zone object is a zone object that contains computerspecific users and groups. This object is a special type of hierarchical Zone container with computerName:zone and version displayName=\$CimsComputerZoneVersion1.

User Attributes in RFC 2307-Compliant Zones

If you create a hierarchical zone when using the RFC 2307-compliant schema, user attributes are stored in much the same way as in a classic zone with user object attributes stored in corresponding Active Directory attributes.

cn	sAMAccountName@domain.name[:N]	No
Version	displayName=\$CimsUserVersion5	No
Name	uid	Yes
Uid	uidNumber	Yes
Gid	gidNumber	Yes
Home	unixHomeDirectory	Yes
Shell	loginShell	Yes
Gecos	gecos	Yes

For more information, see User attributes in classic RFC 2307 zones.

Group Attributes in RFC 2307-Compliant Zones

If you create a hierarchical zone when using the RFC 2307-compliant schema, group attributes are stored in much the same way as in a classic zone with group object attributes stored in corresponding Active Directory attributes.

Version	displayName=\$CimsUserVersion5	No
Name	keywords=login:Name	Yes
Gid	gidNumber	Yes
Gecos	gecos	Yes

For more information, see Group attributes in classic RFC 2307 zones.

User Attributes in Hierarchical SFU Zones

If you create a hierarchical zone when using the Microsoft Services for UNIX (SFU) schema, user attributes are stored in the same way as in a classic SFU zone with the following exceptions:

- If the SFU schema is version 3.x, the Gecos field is stored in the msSFU30Gecos Active Directory attribute.
- If the SFU schema is version 4.x, the Gecos field is stored in the gecos Active Directory attribute.

For more information, see User attributes in classic SFU-compliant zones.

Group Attributes in Hierarchical SFU Zones

If you create a hierarchical zone when using the Microsoft Services for UNIX (SFU) schema, group attributes are stored in the same way as in a classic SFU zone. For more information, see Group attributes in classic SFU-compliant zones.

The Logical Data Model for Objects

This section describes the logical data model associated with each type of Delinea object. The data types used in the discussion of the logical data model, however, may not reflect the actual implementation of the data for a given zone type. For example, a user's UID value might be stored as an integer in SFU zones or as a string in Delinea zones, but represented as an integer (int) in the logical data model.

Similarly, the names used in the logical data model may not reflect the actual Active Directory attribute names for a given zone type. For example, in Delinea zones, there are UNIX-specific attributes, such as the UID value, that are stored in an Active Directory object where the schema does not have a corresponding attribute, whereas the schema for SFU zones provides this attribute.

Use of Existing Attributes

Delinea uses existing Active Directory attributes to store data. For example, most Delinea zones use Active Directory serviceConnectionPoint objects to store UNIX-specific data. The serviceConnectionPoint class is intended to hold information about services. The keywords attribute of the serviceConnectionPoint object holds name-value pairs that an Active Directory service can use to store its own attributes.

For example, if you were to use ldapsearch to filter the keywords attribute for a user's serviceConnectionPoint class in a Delinea zone, you would see results similar to the following:

```
keywords: foreign:False
keywords: gid:800 keywords: home:/home/jae
keywords: parentLink:S-1-5-21-3619765212-102450798-26543
keywords: shell:/bin/bash
keywords: uid:810
keywords: unixEnabled:True
```

Once you are familiar with the logical data model for Delinea objects, refer to the appropriate zone-specific section for more detailed information about which Active Directory attributes are used to store data in a particular type of zone.

Logical Data Attributes for Zones

The following table describes the logical attributes for Delinea zone objects.

NextUid	int	The value of the next UID that will be allocated automatically.
NextGid	int	The value of the next GID that will be allocated automatically.
ReservedUids	string	UIDs that should not be used in the automatic allocation sequence.
ReservedGids	string	GIDs that should not be used in the automatic allocation sequence.
AvailableShells	string	Which shells are available in the zone. This attribute is used to populate the list of available shells that can be assigned in the user's UNIX profile.
DefaultHomeDirectory	string	The default value for the user's home directory. Typically, this attribute contains the string \${user} which is replaced with the user's login name in the home directory path. For example, if this attribute is /home/\${user}, and the user's login name is shea, the user's home directory path is defined as /home/shea.
DefaultShell	string	The default shell to use for the zone.
ZoneName	string	The name of the zone.
DefaultGid	int	The value of the GID for the group profile associated with the Active Directory group used as the default group for new users.
Description	string	The text string to use as a description for the zone. This attribute is used to display additional information about a zone in Access Manager. For example, if the value for Description attribute is Business development zone, the console displays this string after the zone name:

Logical Data Attributes for Users

The following table describes the logical attributes for the UNIX user object. Most of these attributes represent elements of the user's entry in the /etc/passwd file. The last two are specific to Delinea.

Uid	int	The value of the user's UID in the UNIX profile.
UnixName	string	The user's login name in the UNIX profile.
Gid	int	The value of the user's primary group identifier (GID).
Home	string	The path to use for the user's home directory in the user's UNIX profile.
Shell	string	The path to use for the user's shell in the user's UNIX profile.
UnixEnabled	bool	Whether the user is allowed to log on to computers in classic zones. This attribute allows a user profile to exist in a classic zone but not allowed to log on to any computers. Disabling user access is particularly useful for recording who used to own a retired UID. This attribute is not used in hierarchical zones.
AppEnabled	bool	Not used. **Note** You might see this attribute if you have a legacy version of Delinea software installed in your environment.

Logical Data Attributes for Groups

The following table describes the logical attributes for the UNIX group object. Note that there is no attribute for group membership. Group membership for groups with a UNIX profile is always derived from the Active Directory group membership.

Gid	int	The value of the group identifier (GID) for the group's UNIX profile.
UnixName	string	The group name for the group's UNIX profile.

Logical Data Attributes for Computers

The following table describes the logical attributes for the UNIX computer object. The computer attributes are used to are used to provide specific details about computers joined to a zone. In most cases, you should not change these attributes. They are created automatically by the adjoin process.

cpuCount	int	The number of CPUs detected on a computer joined to the domain. This attribute was used for licensing calculations in earlier versions of Delinea software (versions 3.0.x through 4.1.x).
agentVersion	string	The version of the Delinea Agent installed on a computer joined to the domain.

Logical Data Attributes for NIS Maps

The NIS maps for a zone are stored in a NisMaps container object. The NisMaps container object is similar to the Users, Groups, or Computers container objects that contains a zone's UNIX data. Each individual NIS map object is also a container object. The name of the object and its GUID are its only attributes. Because the NIS map objects don't require any special mapping between a logical attribute name and an Active Directory attribute name, the standard Active Directory attribute names are used. The following table describes the Active Directory attributes for NIS map objects.

Common Name (cn)	string	The name of the NIS map.
Description	string	The GUID of the map type. This attribute is used by the Access Manager console. If the attribute value is not specified, the console attempts to resolve to the most appropriate map type.

Under each NIS map object, each map entry is stored as a key/value pair of classStore objects. The following table describes the Active Directory attributes for the entry objects.

Common Name (cn)	string	The unique key of the key/value pair.
Description	string	The key for the map entry.
adminDescription	string	The value for the map entry.
wwwHomePage	string	The text comment for the map entry. This attribute is only used to display the comment in Access Manager. The comment cannot be served to NIS clients.

) [tags]: # (windows api) [priority]: # (1)

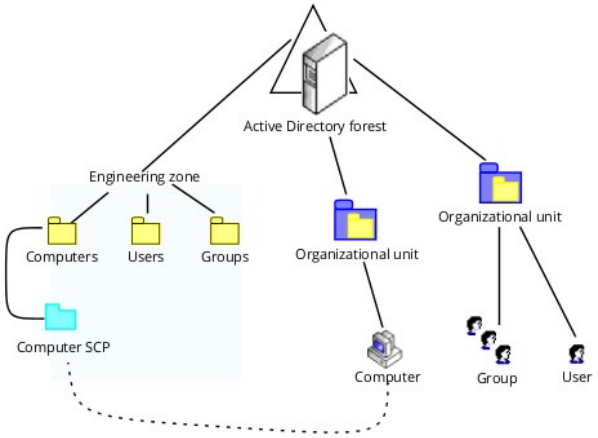
Classic SFU-Compliant Zones (version 3.5)

If you have the Microsoft Services for UNIX (SFU) schema extension installed, you have the option of using SFU-compliant zones for storing data. With SFU-compliant zones, UNIX-specific attributes for users and groups are stored in the actual Active Directory user and Active Directory group objects, using attributes in Microsoft Services For UNIX (SFU) schema extension.

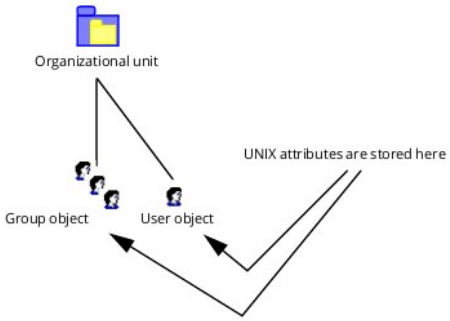
> **Note:** The schema extension must be already be installed in the forest. You cannot create SFU-compliant zones if the schema extension is not installed.

Unlike standard Delinea zones, where a single Active Directory user can have multiple UNIX profiles, a single Active Directory user can only exist in one SFU zone because there is only one set of attributes in the Active Directory user object. A single user can, however, be in any number of Delinea zones and zero or one SFU zone.

The structure of the zone and its sub-containers is the same as the classic Delinea zone layout, with each zone stored as a separate tree in the directory and sub-containers for the **Users**, **Groups**, and **Computers** in each zone, but only the Computers sub-container is used.



Unlike classic Delinea zones, in which UNIX attributes are stored in the serviceConnectionPoint objects, the SFU zones store UNIX attributes in the User and Group objects and use attributes provided by the SFU schema extension.



Zone Attributes in Classic SFU-Compliant Zones

The zone object class and its attributes in the classic SFU zone are similar to the classic Delinea zone, except that the zone must also include the NIS domain name and domain attributes. Like the classic Delinea zones, the zone object is stored as a container object, and the common name (cn) of the object must be set to the zone name. Most of the other attributes for a zone are stored as pseudo-attributes using the Active Directory description attribute.

The following table summarizes how zone attributes are stored in Active Directory for SFU-compliant zones. For more information about any attribute setting, see Zone attributes in classic Delinea zones.

ZoneName	cn:ZoneName For example: cn:default
ZoneVersion	displayName:ZoneVersion The only valid value is \$CimsZoneVersion2. For example: displayName:\$CimsZoneVersion2
Description	description:description:value For example: description:description:Pilot EMEA
NextUid	description:uidnext:value For example: description:uidnext:12098
NextGid	description:gidnext:value For example: description:gidnext:12098
ReservedUids	description:uidreserved:value For example: description:uidreserved:0-99:501
ReservedGids	description:gidreserved:value For example: description: gidreserved:1000-2500
Availableshells	description:availableshells:value For example: description:availableshells:/bin/sh
DefaultHomeDirectory	description:defaulthome:value For example: description:defaulthome:/nfs/$
DefaultShell	description:defaultshell:value For example: description:defaultshell:/bin/bash
DefaultGroup	description:defaultgid:value For example: description:defaultgid:12098
ZoneType	description:schema:Dynamic_Schema_Version The only valid value for SFU zones is: SFU_3_0 for the Microsoft Services for UNIX (SFU) versions 3.x or 4.x schema extension. For example: description:schema:SFU_3_0
NisDomain	description:Nisdomain:value This attribute describes the NIS domain for that defines the scope of the zone. For more information about this setting, see the User object attributes. For example: description: Nisdomain:XXX
SFUDomain	description:Sfudomain:value The SFU domain contains the users and groups. The members of an SFU domain can only come from one domain. For example: description:Sfudomain:mfg.ajax.org

User Attributes in Classic SFU-Compliant Zones

In classic SFU zones, UNIX-specific user attributes are stored as part of the Active Directory user object.

UnixName	MSSFU30Name:userlogin For example: MSSFU30Name:cain
Uid	MSSFU30UidNumber:value For example: MSSFU30UidNumber:458
Gid	MSSFU30GidNumber:value For example: MSSFU30GidNumber:458
Home	MSSFU30HomeDirectory:value For example: MSSFU30HomeDirectory:/home/shea
Shell	MSSFU30Shell:value For example: MSSFU30Shell:/bin/bash
NisDomain	MSSFU30NisDomain:value This attribute must be defined. Delinea uses this setting to determine if the user is a member of the zone. When you create SFU-compliant zones, you must specify the NIS domain name that should be included. For example, you can configure zone_bejing to include all users and groups whose NIS domain attribute is set to nisbejing. For example: MSSFU30NisDomain:nisbejing.local
UnixEnabled	Not supported.

Group Attributes in Classic SFU-Compliant Zones

In classic SFU-compliant zones, UNIX-specific group attributes are stored as part of the Active Directory group object.

UnixName	MSSFU30Name:GroupName For example: MSSFU30Name:performx
Gid	MSSFU30GidNumber:value For example: MSSFU30GidNumber:458
NisDomain	MSSFU30NisDomain:value This attribute must be defined. Delinea uses this setting to determine if the group is a member of the zone. When you create SFU-compliant zones, you must specify the NIS domain name that should be included. For example, you can configure zone_bejing to include all users and groups whose NIS domain attribute is set to nisbejing. For example: MSSFU30NisDomain:nisbejing.local
UnixEnabled	Not supported.

Note: The Microsoft Services for UNIX schema extension supports group membership as an attribute of the group object in the same way the RFC 2307-compliant schema does. Delinea does not use this attribute, however. Delinea uses Active Directory group membership to identify group members.

) [tags]: # (windows api) [priority]: # (1)

Classic SFU-Compliant Zones (version 4.0)

if you have the Microsoft Services for UNIX (SFU), version 4.0, schema extension installed, you have the option of using SFU-compliant zones for storing data. Delinea SFU-compliant zones for the Microsoft Services for UNIX (SFU), version 4.0, schema extension are similar to SFU-compliant zones for version 3.5, except that Microsoft Services for UNIX (SFU), version 4.0, uses the R2 schema. The UNIX-specific attributes for users and groups are still stored in the actual Active Directory user and Active Directory group objects, but use the R2 schema attributes instead of the msSFU* attributes used in Microsoft Services For UNIX (SFU), version 3.5.

> **Note:** You can only create this type of zone if the R2 schema is installed. If the R2 schema attributes are not available, you cannot create this type of zone.

Zone Attributes in Classic SFU 4.0 Zones

The zone object class and its attributes in the classic SFU-compliant zones for the Microsoft Services for UNIX (SFU), version 4.0, schema extension are the same as described in Zone attributes in classic SFU-compliant zones. For more information about any attribute setting, see Zone attributes in classic Delinea zones.

User Attributes in Classic SFU 4.0 Zones

In classic SFU-compliant zones, UNIX-specific attributes are stored as part of the Active Directory user object. With Microsoft Services for UNIX, version 4.0, however, the R2 schema attributes are used.

UnixName	uid:userlogin For example: uid:cain
Uid	uidNumber:value For example: uidNumber:458
Gid	gidNumber:value For example: gidNumber:458
Home	unixHomeDirectory:value For example: unixHomeDirectory:/home/shea
Shell	loginShell:value For example: loginShell:/bin/bash
NisDomain	MSSFU30NisDomain:value This attribute must be defined. Delinea uses this setting to determine if the user is a member of the zone. When you create SFU-compliant zones, you must specify the NIS domain name that should be included. For example, you can configure zone_bejing to include all users and groups whose NIS domain attribute is set to nisbejing. For example: MSSFU30NisDomain:nisbejing.local
UnixEnabled	Not supported.

Group Attributes in Classic SFU 4.0 Zones

In classic SFU-compliant zones, UNIX-specific attributes are stored as part of the Active Directory group object. With Microsoft Services for UNIX, version 4.0, however, the R2 schema attributes are used.

UnixName	cn:GroupName For example: cn:performx
Gid	gidNumber:value For example: gidNumber:458
NisDomain	MSSFU30NisDomain:value This attribute must be defined. Delinea uses this setting to determine if the group is a member of the zone. When you create SFU-compliant zones, you must specify the NIS domain name that should be included. For example, you can configure zone_bejing to include all users and groups whose NIS domain attribute is set to nisbejing. For example: MSSFU30NisDomain:nisbejing.local
UnixEnabled	Not supported.

Using Commands and Scripts to Perform Tasks

With an understanding of how the data is stored in Active Directory for different zones types, you can use ADEdit or LDAP commands to perform a wide range of tasks from the UNIX command line or in scripts and custom programs. The following examples illustrate how you can use the OpenLDAP command line interface (CLI) that is installed with the Delinea Agent to perform administrative tasks. The OpenLDAP CLI is Kerberos-enabled, so it is not necessary to supply credentials. All operations run with the permissions of the Active Directory user currently logged in. For information about using ADEdit to perform administrative tasks, see the *ADEdit Command Reference and Scripting Guide*.

Getting Started

The OpenLDAP commands provided with the Delinea Agent package support all of the standard command line options, plus some additional options to make it easier to use them to work with Active Directory. For example, the LDAP commands packaged with the Delinea Agent accept a URL of the form:

```
LDAP://domain_name
```

to specify the nearest domain controller in the specified domain, or a URL of:

```
`LDAP://`
```

In addition to the LDAP commands, Delinea includes several other command line programs and environment variables you may find useful in creating scripts to perform administrative tasks. For example, your scripts can take advantage of the environment variables that are set for an Active Directory user upon authentication. You can also use commands such as `adinfo` and `adfinddomain` to return information or supply input for administrative scripts.

On Linux and UNIX computers with a Delinea Agent, version 5.0 or later, you can use the ADEdit command line utility and library of commands to perform administrative tasks instead of using LDAP commands or single-purpose commands. For information about using ADEdit, see the *ADEdit Command Reference and Scripting Guide*.

Creating a Classic Zone

The following example shows the commands and data needed to create a classic Delinea zone named "zone1". Zone creation is almost identical for all zone types. Only the value of displayName and the schema pseudo-attribute differ from zone type to zone type.

Before you can create the zone itself, however, you must create an Active Directory container with the appropriate properties. The zone container must also contain four other sub-containers to accommodate the UNIX attributes for Computers, Users, Groups, and NISMaps for the zone. You can create your zone anywhere within the directory tree.

To create a zone container and zone properties using the ldapadd command:

```
ldapadd -H ldap://mydc.acme.com \<\< END_DATA

# Add the zone container
dn: cn=zone1,cn=myzones,dc=acme,dc=com
objectClass: container
cn: zone1
description: uidnext:10005
description: gidnext:10007
description: gidreserved:0-99
description: uidreserved:0-99
description: availableshells:/bin/bash:/bin/csh:/bin/sh:/bin/tcsh
description: defaulthome:/home/\${user}
description: privategroupcreation:True
description: defaultshell:/bin/bash
description: schema:Dynamic_Schema_3_0
displayName: \\\$CimsZoneVersion2
showInAdvancedViewOnly: TRUE
name: default

# Add the Computers sub-container

Add a User to a Classic Zone

Adding a UNIX user or group profile to an Active Directory user or group object requires you to know the security identifier (SID) for the Active Directory user or Active Directory group. This information is necessary to link the UNIX attributes in the UNIX profile to its corresponding Active Directory account. One way to get this information is to use the Windows Server directory service command-line tool dsquery to return the SID for a specific user:

```
dsquery user -samid user \| dsget user -sid -samid
```

For example, to list the samAccount name and SID for the user with the samaccountname jane:

```
dsquery user -samid jane \| dsget user -sid -samid
```

> **Note:** For more information on using dsquery, search for the command on the Microsoft website.

Once you have identified the SID for a user or group, you can use the ldapadd command to add a profile for the user or group to the zone.

The following example illustrates how to add user "joe" to "zone1" where "zone1" is a classic RFC 2307-compliant zone:

```
ldapadd -H ldap://mydc.acme.com \<\< END_DATA
dn: CN=joe,CN=Users,cn=zone1,cn=myzones,dc=acme,dc=com
objectClass: posixAccount
objectClass: serviceConnectionPoint
cn: joe
displayName: \\\$CimsUserVersion3
showInAdvancedViewOnly: TRUE
name: joe
keywords: unix_enabled:True
keywords: parentLink:S-1-5-21-397955417-626881126-188441444-512
uid: joe
uidNumber: 123
gidNumber: 234
unixHomeDirectory: /home/joe
loginShell: /bin/bash
END_DATA
```

The following example illustrates how to add the user profile "joe" to "zone1" where "zone1" is a Standard zone:

```
ldapadd -H ldap://mydc.acme.com \<\< END_DATA
dn: CN=joe,CN=Users,cn=zone1,cn=myzones,dc=acme,dc=com
objectClass: serviceConnectionPoint
cn: joe
displayName: \\\$CimsUserVersion2
showInAdvancedViewOnly: TRUE
name: joe
keywords: unix_enabled:True
keywords: parentLink:S-1-5-21-397955417-626881126-188441444-512
keywords: uid:123
keywords: gid:234
keywords: home:/home/joe
keywords: shell:/bin/bash
END_DATA
```

Basic requirements

Delinea stores UNIX-specific properties for users, groups, and computers, as well as zones and zone properties, within Active Directory by adhering to Microsoft standards for data storage. Because of this adherence to Microsoft standards, Delinea stores the UNIX-specific information differently depending on the Active Directory schema you are using and the type of Delinea zones you create.

The Delinea Windows API provides a logical abstraction of the data model so that you can manipulate Delinea-specific information without understanding the differences between zone types. If you want to manipulate the data directly without the logical abstraction, however, you need to understand the details of how UNIX-specific properties and zone information are stored for each type of zone and schema. Once you have a more detailed understanding of the physical and logical data model for each zone type, you may be able to perform tasks that are not possible with the Access Manager console.

Differences between Types of Zones

The user and group attributes described in the logical data model are stored differently in Delinea zones than they are in SFU zones.

- When you have the Microsoft Services for UNIX (SFU) schema extension, version 3.5 or version 4.0, and use SFU-compatible zones, user and group UNIX attributes are stored in the Active Directory user and Active Directory group objects.
- In classic and hierarchical Delinea and RFC 2307-compatible zones, user and group UNIX attributes are stored in one serviceConnectionPoint object per zone for each user and group.

Schemas and zones

Delinea stores UNIX identity data and Delinea zone data in Active Directory, without modifying or extending the standard Active Directory schema. Delinea stores UNIX account profiles in standard text properties in an existing Active Directory object. This data model can be used with the default Active Directory schema or with any standard schema extension provided by Microsoft. Zones and their properties are stored in the same manner, using standard text properties in an existing Active Directory object.

The default data storage model and Delinea zones enable a single Active Directory user account to be associated with any number of unique UNIX profiles that a user may have across your environment. These UNIX profiles can have unique UIDs, GIDs, home directories, and preferred shells on one or more different UNIX systems.

How the zone type can affect features

Because the details of the data model depend on the Active Directory schema and the zone type, the zone type can also impact the features a particular zone can support. For example, classic and hierarchical Delinea zones support multiple profiles for each user but SFU zones do not. The following table summarizes key differences between zone types.

Classic Delinea zones (2.x, 3.x, 4.x)	Yes	Yes	No
Classic RFC 2307compatible	Yes	Yes	No
Hierarchical Delinea zones (5.x)	Yes	Yes	Yes
Hierarchical RFC 2307-compatible zones	Yes	Yes	Yes
Hierarchical Services for UNIX (SFU) zones	No	No	Yes*
Services for UNIX (SFU), version 3.5, zones	No	No	No
Services for UNIX (SFU), version 4.0, zones	No	No	No
* A hierarchical SFU zone can only be the root parent zone. You cannot create any Service for UNIX zone as a child zone.			

For more information about differences in how data is stored in a specific zone type, see Differences between types of zones.

Supported zone types

Standard Delinea zones use the default data storage model. However, Delinea can also support the RFC 2307 data model if you are using the Microsoft RFC 2307 schema extension, or the Microsoft Services for UNIX (SFU) data model if you are using that schema extension. To support these schema extensions, you can choose the zone type you want to use for each zone.

The following table lists the supported zone types and the relationship between the zone type and the Active Directory schema.

Classic Delinea zones, versions 2.x, 3.x, and 4.x	Any schema
Hierarchical standard zones, version 5.x or later	Any schema
Classic RFC 2307-compatible zones, versions 2.x, 3.x, and 4.x	RFC 2307-compliant schema
Hierarchical RFC 2307compatible zones, version 5.x or later	RFC 2307-compliant schema
SFU-compatible zones, version 3.5	Microsoft Services for UNIX (SFU), version 3.5
SFU-compatible zones, version 4.0	Windows Services for UNIX (SFU), version 4.00

Note: Classic RFC 2307-compatible zones require Active Directory Dynamic Auxiliary Classes. The forest functional level must be at least Windows Server 2003 to use Dynamic Auxiliary Classes. All hierarchical zones require the domain functional level to be at least Windows Server 2003.

Delinea

Delinea SDK

The Delinea Software Development Kit (SDK) consists of the following:

- Application programming interfaces that packaged in a dynamic link library (.DLL).
- A compiled help file that includes complete object reference information.
- Sample scripts in multiple languages.
- Supporting documentation and reference information for UNIX developers.

On Windows computers, you can use the API to develop your own custom applications that access or modify Delinea-specific data in Active Directory.

As part of the Delinea SDK, this guide also provides detailed information about the underlying Delinea data storage model and how attributes managed by Delinea are stored in Active Directory. This information is critical for developing programs that access or modify Delinea data but are run on UNIX computers.

Development Platform

You can use the Windows API to develop programs that manage UNIX user, group, and computer profiles; zones and zone properties; and NIS maps and NIS map entries. The methods and properties that make up the API enable you to access, create, modify, and remove information stored in Active Directory. Although you can use the Windows API to manage all of the UNIX information stored in Active Directory, including UNIX profile attributes and computer accounts, the API does not run on UNIX computers.

If you want to develop programs that run on UNIX computers to access data that's stored in Active Directory, you can use the ADEdit program (adedit) or the command line programs included with the Delinea Agent for *NIX to perform queries and updates. For example, you can use ADEdit commands in custom scripts to create zones and add, update, or remove users and groups. For detailed information about using ADEdit, see the *ADEdit Command Reference and Scripting Guide*.

You can also use OpenLDAP commands to manipulate data in Active Directory directly. The key to writing programs that use OpenLDAP or other commands is understanding how the data is stored in Active Directory and the command line options supported for each of the commands you want to use. For information about using command line programs, see the man page for the corresponding program.

Depending on the task you want to perform and the development platform you want to use, you can write scripts that manage Delinea data using either the Windows API or UNIX command line programs. For example, you can perform most provisioning-related tasks using calls to the objects, methods, and properties in the Windows API, or using common LDAP commands on UNIX.

Windows SDK

If you plan to develop programs that run on Windows computers, the Delinea SDK includes the following:

- A library of commands for access control and privilege management that run in Windows PowerShell.
- Sample scripts that use the Delinea PowerShell cmdlets to illustrate common administrative tasks.
- Dynamic link libraries that expose interfaces for working with Delinea objects and attributes stored in Active Directory.
- Sample scripts that illustrate adding and removing users, groups, and zones in VBScript, PowerShell, and .NET (C#) languages.
- An overview of the programming interface architecture, its relationship to the Access Manager console, and the object properties and methods available.
- Reference information for all object properties and methods.

For more information about using Windows PowerShell cmdlets, see the *Access Control and Privilege Management Scripting Guide*.

For more information about developing COM- or .NET-based applications, see Overview of the Delinea Windows API object model and Delinea object reference

For a more detailed understanding of how Delinea-specific data is stored by zone type, see Data storage for Delinea zones

UNIX SDK

If you plan to develop programs that run on UNIX computers, the Delinea SDK includes the following:

- The ADEdit command line application and library of procedures for scripting access control and privilege management tasks.
- Sample scripts written in ADEdit that illustrate common administrative tasks.
- Detailed information about how data is stored in Active Directory and how data storage differs by zone type.
- Examples that illustrate how to use OpenLDAP commands and other command line tools to perform common administrative tasks.

For detailed information about using ADEdit, see the *ADEdit Command Reference and Scripting Guide*. For more information about developing scripts that use LDAP commands, see Data storage for Delinea zones

Overview of the Delinea Windows API Object Model

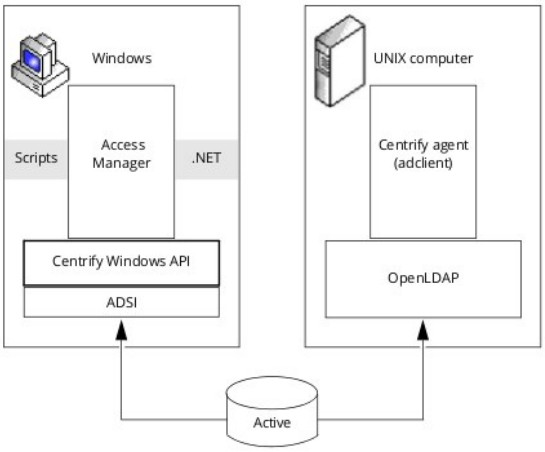
This chapter provides an overview of the architecture and capabilities of the object library exposed in the Delinea Windows API included in the SDK and how you can use the objects in applications to access and manage Delinea data on Windows computers. It includes a discussion of the Delinea framework classes, the order in which objects are created, and examples of how to use the programming interfaces in scripts written in VBScript, PowerShell, and .NET languages.

How the Delinea Windows API Relies on COM Interfaces

On Windows computers, the Delinea API supports the Component Object Model (COM) interface. The Component Object Model (COM) interface enables you to create objects that can interact with Active Directory or be used in other applications. These are re-usable objects that can provide access to all of the Delinea data stored in Active Directory. The objects can be used in any program written in .NET or COM-enabled languages. You can, therefore, create or modify applications to use these objects in COM-aware languages such as VBScript and PowerShell or .NET-compliant languages such as C#. The object model used to access the data is the same, but the specific syntax required depends on the programming language you choose to use.

The objects that make up the Delinea Windows API rely on the underlying interfaces provided by Microsoft's Active Directory Service Interfaces (ADSI). ADSI provides the base-level functions that permit applications to read and write data in Active Directory. The purpose of the Delinea Windows API is to provide a higher level of abstraction for performing Delinea-specific tasks than would be available if you were to call ADSI functions directly.

The following figure illustrates how the Delinea Windows API provides a layer of abstraction between the raw ADSI functions and the Access Manager console and other applications.



The Active Directory schema defines how all of the objects and attributes in the database are stored. When you add Delinea data to the Active Directory database, how that data is stored depends on the Active Directory schema you have installed. The Delinea Windows API, however, provides a logical view of the data, eliminating the need to know the details of how data is stored in different schemas when performing common administrative tasks. The Delinea Windows API also provides a simpler interface for accessing the well-defined set of UNIX objects that must be operated on than that offered by the general purpose ADSI. In fact, when you perform administrative tasks with the Access Manager console MMC snap-in, the console uses the same Delinea Windows API objects documented in this guide to manipulate the data.

Therefore, with the Delinea Windows API and any commonly-used Windows programming language, you can write scripts or programs that perform a wide range of tasks using Delinea data, including programs that automatically create and manage Delinea zones or update user, group, or computer properties.

> **Note**: You can use ADSI directly instead of using the Delinea Windows API, if you prefer. For more detailed information about the objects and attributes used in Active Directory when different schemas are used, see Data Storage for Delinea Zones.

Administrative Tasks You Can Perform

Using the Delinea Windows API, you can perform a wide range of common administrative tasks, including the following:

- Add, modify, and delete zones, including hierarchical zones.
- Add, modify, and delete users within zones.
- Add, modify, and delete groups in zones.
- Add, modify, and delete computers in zones.
- Create, modify, and delete rights, roles, and role assignments.
- Check on licenses and keys.
- Create, modify, and delete NIS maps and NIS map entries.

For examples of performing common activities such as these using Delinea objects, see the sample scripts and help included with the software package.

Although you can use the Delinea Windows API to perform many common administrative tasks programmatically, you cannot create new Active Directory users or groups directly. To create new Active Directory user or group objects, you must use the underlying Active Directory Service Interfaces (ADSI) rather than the abstracted interface provided by the Delinea Windows API. To learn how to create user or group objects programmatically or perform other tasks that are not provided by the Delinea Windows API, such as changing access rights, refer to Microsoft's ADSI documentation.

Delinea-specific Objects Classes

The Delinea Windows API consists of several common, interdependent classes that correspond with the core elements of Delinea-managed data, such as computers, users, groups, and zones. These basic classes provide properties, methods, and attributes that you can manipulate in programs and scripts to set or retrieve data.

The following table lists the classes that compose the Delinea Windows API.

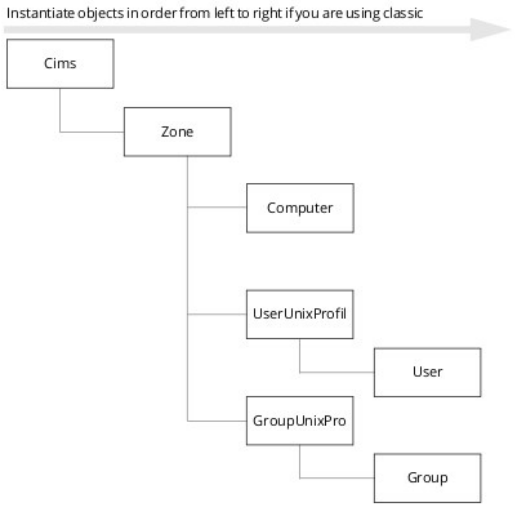
AzRoleAssignment	Represents a computer-role assignment.
Cims	Initiates interaction with Active Directory. This top-level class connects to Active Directory and prepares the Active Directory domain and forest for working with Delinea objects.
Command : Right	Represents the right to run a command, including which users and groups have that right.
Commands	Represents a collection of command rights.
Computer	Manages an individual computer account object.
ComputerGroupUnixProfiles : GroupUnixProfiles	Represents the groups in a computer zone.
ComputerRole	Manages a computer role.
ComputerRoles	Represents a collection of computer roles.
Computers	Represents a collection of computers in a zone.
ComputerUserUnixProfiles: UserUnixProfiles	Represents the users in a computer zone.
Group	Manages an individual group account object.
GroupUnixProfile	Manages the properties in the UNIX profile of a group.
GroupUnixProfiles	Represents a collection of UNIX groups in a zone.
HierarchicalGroup : GroupUnixProfile	Manages the properties in the UNIX profile of a group in a hierarchical zone.
HierarchicalUser : UserUnixProfile	Manages the properties in the UNIX profile of a user in a hierarchical zone.
HierarchicalZone : Zone	Represents a hierarchical zone.
HierarchicalZoneComputer: Computer	Manages the properties in the profile of a computer object joined to a hierarchical zone.
HzRoleAssignment : RoleAssignment	Manages a zone-level role assignment in a hierarchical zone.
InheritedRoleAsg	Represents an inherited role assignment.
Key	Represents a license key.
Keys	Represents a collection of Delinea license keys.

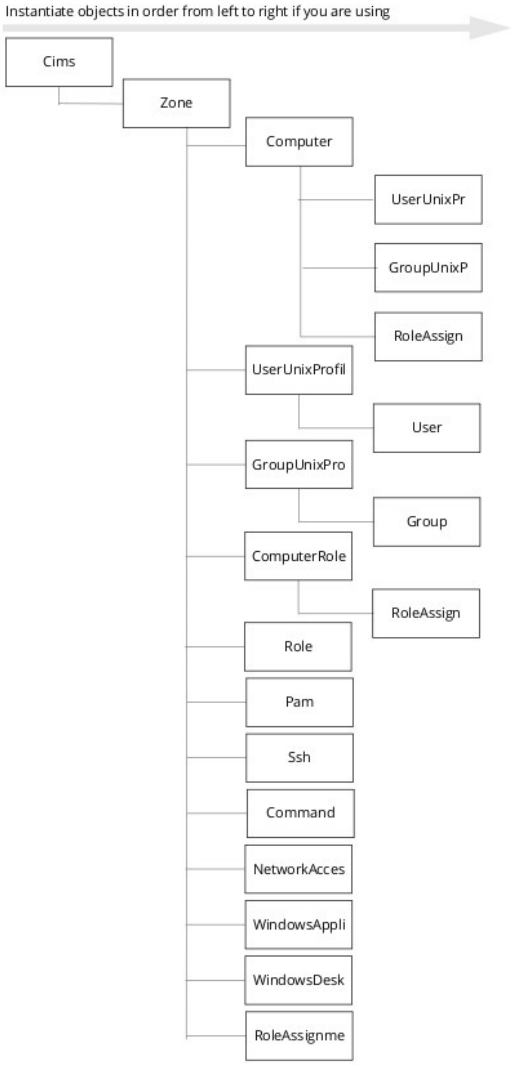
License	Represents a Delinea license.
Licenses	Represents a collection of Delinea licenses in a license container object.
LicensesCollection	Manages all the Delinea licenses in all of the Licenses parent containers defined for a forest.
MzRoleAssignment : RoleAssignment	Represents a computer-level role assignment.
NetworkAccesses	Represents a collection of network access rights.
Pam : Right	Represents a PAM (Pluggable Authentication Module) application right.
Pams	Represents a collection of PAM application rights.
Right	The base class for all rights.
Right : NetworkAccess	Represents a Windows network access right.
Right : WindowsApplication	Represents a Windows application right.
Right : WindowsDesktop	Represents a Windows desktop right.
Role	Manages a Delinea role.
RoleAssignment	Represents a role assignment.
RoleAssignments	Represents a collection of role assignments.
Roles	Represents a collection of roles.
User	Represents an individual user account object.
UserUnixProfile	Manages the properties in the profile associated with an individual UNIX user.
UserUnixProfiles	Represents a collection of users in a zone.
WindowsApplications	Represents a collection of Windows application rights.
WindowsDesktops	Represents a collection of Windows desktop rights.
WindowsUser	Represents a Windows user.
WindowsUsers	Represents a collection of Windows users.
Zone	Represents a Delinea zone, including the users, groups, and computers that have been added to the zone.

In addition to these objects, there are optional objects for managing and manipulating NIS maps and NIS map entries in Active Directory. For an overview of those objects, see Working With NIS Maps. For more information about all of the objects that enable you to manipulate Delinea-specific data in Active Directory, see Delinea Object Reference.

Creating Objects in the Proper Order

Delinea objects must be created in a particular order because some objects rely on the existence of others. For example, your application must create the Cims object first to establish communication with the Active Directory domain controller. After you create an instance of the Cims object, you must create the Zone object before you can create User, Group, or Computer objects because these objects exist in Active Directory in the context of the zone. The following figures illustrate the order for creating Delinea-related objects:





Getting and setting object properties

You can read or write most object properties; however a few are read-only. The syntax line in the object reference indicates whether an object property's value can be read ({get;}) or both read and written ({get; set;}). For example, the nextAvailableUID property can be both read and written:

int nextAvailableUID {get; set;}

To retrieve the existing value for this property, you could include a line similar to this:

read_uid_value = zone.nextAvailableUID

To set a new value for this property, you could include a line similar to this:

zone.nextAvailableUID = set_uid_value

Interface naming conventions

The Delinea Windows API objects are stored in Active Directory using the IADs interface. The IADs interface is a Microsoft standard that defines basic object features—such as properties and methods—of any Active Directory Service Interface (ADSI) object. The most common ADSI objects include users, computers, services, file systems, and file service operations. The IADs interface ensures that all ADSI objects provide a simple and consistent representation of underlying directory services.

In addition to the basic ADSI objects, Delinea-specific objects are implemented as IADs interfaces. Using interfaces for the Delinea objects enables them to change internally without requiring any changes to the API. By convention, when objects are implemented as interfaces rather than class objects, they are identified by a capital "I" as a prefix. The Delinea-specific objects that are implemented as interface objects have the same names as the classes in Delinea-specific objects classes, with the addition of the "I" prefix; for example, the IZone interface object corresponds to the Zone class.

For more information about the IADs interface and working with interface objects, see the Microsoft Developer Network Library.

Creating the Top-level Cims Object

The Cims object is the top-level object in the Delinea Windows API. This object is used to establish the connection with Active Directory and set up the environment so that other operations can be performed. Before you can retrieve any information from Active Directory, such as a zone object or user profile, you must create a Cims object. If you are writing COM-based for Delinea software, version 5.0 or later, the top-level Cims object is named Cims3. For example:

```
set cdc = CreateObject("Centrify.DirectControl.Cims3")
```

If you have scripts created for a previous version of Delinea software, you should modify the object created to be a Cims3 object.

If you are writing programs using a .NET language, the namespace for the top-level Cims object is Centrify.DirectControl.API.Cims, regardless of the version of Delinea software you are using. For example, to create the top-level Cims object in a .NET program, you would type:

```
Centrify.DirectControl.API.Cims cdc = new Centrify.DirectControl.API.Cims();
```

After creating the top-level Cims object, you can use the other Delinea objects to access and manage zones, computers, user UNIX profiles, and group UNIX profiles (see Creating Objects in the Proper Order). By writing scripts that retrieve or set object properties, you can provision users programmatically without using the Access Manager console or other MMC snap-ins.

Working With NIS Maps

In addition to the zone, computer, user, and group objects, you can use the Delinea Windows API to manage Network Information Service (NIS) maps in Active Directory. NIS maps store network information that can be used to respond to client requests on computers where the Delinea Agent cannot be installed. You can create or import NIS maps using the Access Manager console or programmatically using the API. The NIS maps you create or import are zone-specific information in Active Directory. Once the information is stored in Active Directory, NIS clients can send requests to the Delinea Network Information Service (adnisd) to receive the data.

For more detailed information about working with NIS maps and the Delinea Network Information Service, see the *Planning and Deployment Guide* and the *NIS Administrator's Guide*.

The Delinea Windows API for working with NIS maps includes the following classes:

Store	Attaches to a zone and creates NIS maps in the zone.
Map	Works with an individual map and its records.
Entry	Manages the fields in an individual record.

Writing Scripts that Use Delinea Windows API Calls

To handle Delinea tasks programmatically, you can write programs that call Delinea Windows API functions using any of the tools commonly used to write programs for Windows-based operating environments. Some of the most common of these tools include VBScript, PowerShell, and Visual Studio (C#).

To illustrate using these tools, the following sections describe how to create and run a program that uses the Delinea objects to open a zone and lists all the users in it using VBScript and PowerShell. For more detailed examples of performing common tasks using these scripting languages, see the sample scripts included in the SDK package.

- Using VBScript
- Using PowerShell
- Using Visual Studio C#

Using VBScript

In most cases, you can use VBScript to write scripts that call the Delinea Windows API.

The following steps illustrate how to create and run a VBScript script that uses the Delinea Windows API. This sample script opens a zone and lists all the users in it.

1. Verify that the computer you are using has Access Manager console or the Delinea Windows API Runtime environment from the Delinea SDK installed.
2. Verify that the computer you are using is a member of the Active Directory domain you want to work with.
3. Log in as a domain user with permission to read the zone data for the zone you will be listing.

   If you can list the users in the zone using the Access Manager console with the credentials provided, you have the correct permissions. For information about configuring a user's rights to read zone data, see the *Planning and Deployment Guide*.
4. Use a text editor to create a file called zone-list.vbs.
5. Add the following text to zone-list.vbs, replacing the domain_name and the path to the zone with a domain name and zone location appropriate for your environment.

   ```
   set cims = CreateObject("Centrify.DirectControl.Cims3")
   set zone = cims.GetZone("domain_name/zone_path/zone_name")
   set users = zone.GetUserUnixProfiles()

   for each user in users
   if (user.IsNameDefined) then
   name = user.Name
   else
   name = "<Empty>"
   end if

   if (user.IsUidDefined) then
   uid = user.Uid
   else
   uid = "<Empty>"
   end if

   wscript.echo name & " | " & uid
   next
   ```

   For example if you are using the domain test.acme.com and want to list users in the "default" zone in its default container location:

   ```
   set zone = cims.getzone("test.acme.com/program data/centrify/zones/default")
   for each user in users
   wscript.echo user.name, user.Uid
   next
   ```

6. Click **Start > Run**, then type cmd to open a command window.
7. Change directory to the location of the VBScript file and type:

   cscript zone-list.vbs

   You should see output similar to the following:

   ```
   C:\>cscript zone-list.vbs
   Microsoft (R) Windows Script Host Version 5.6
   Copyright (C) Microsoft Corporation 1996-2001. All rights reserved.

   jane 10000
   jim.smit 10002
   jimsmith 10003
   joe 10004
   paul 10006
   rachel 10016
   ```

Using PowerShell

Delinea provides a separate Access Module for PowerShell that includes predefined "cmdlets" for performing a broad range of administrative tasks without requiring any knowledge of the underlying API calls. If you prefer, however, you can write PowerShell scripts that call the Delinea Windows API directly. The following steps illustrate how to create and run a sample script that opens a zone and lists all the users in it.

1. Verify that the computer you are using has Access Manager or the Delinea Windows API Runtime environment from the Delinea SDK installed.
2. Verify that the computer you are using is a member of the Active Directory domain you want to work with.
3. Log in as a domain user with permission to read the zone data for the zone you will be listing.

   If you can list the users in the zone using Access Manager with the credentials provided, you have the correct permissions. For information about configuring a user's rights to read zone data, see the *Planning and Deployment Guide*.
4. Use a text editor to open the sample script file util.ps1.
5. Modify the util.ps1 script to specify a user name and password with administrative access to the Active Directory domain.

   For example, replace the "******" string with an administrator user name and password:

   ```
   $usrname = "administrator";
   $passwd = "1234abcepassword";
   ```
6. Use a text editor to create a file called zone-list.ps1.
7. Add the following text to zone-list.ps1, replacing the domain_name and the path to the zone with a domain controller and zone location appropriate for your environment.

   ```
   $api = "Centrify.DirectControl.API.{0}";
   $cims = New-Object($api -f "Cims");
   $objZone = $cims.GetZone("domain_name/zone_path/zone_name");
   $users = $objZone.GetUserUnixProfiles();

   foreach ($user in $users)
   {
   if ($objZone.IsHierarchical)
   {
   if ($user.IsNameDefined)
   {
   $name = $user.Name;
   }
   else
   {
   ```

```
$name = "<Empty>";
}
if ($user.IsUidDefined)
{
$uid = $user.UID;
}
else
{
$uid = "<Empty>";
}
}
else
{
$name = $user.Name;
$uid = $user.UID;
}

write-Host ("{0} I {1}" -f $name, $uid);
}
```

For example if you are using the domain test.acme.com and want to list users in the "global" zone in its default container location:

```
var zone = cims.getzone("test.acme.com/program data/centrify/zones/global");
```

8. Click **Start > Run**, then type cmd to open a command window.
9. Change directory to the location of the script file and type the following to run the script using Windows Script Host:

   ```
   cscript zone-list.ps1
   ```

   You should see output similar to the output for the VBScript sample script. For information about using the Access Module for PowerShell instead of writing scripts that call the Delinea Windows API, see the *Access Control and Privilege Management Scripting Guide*.

Using Visual Studio C#

The following steps describe how to call the Delinea Windows API when using Visual Studio 2010. Alternatively you can use the command line compilers that come in Microsoft .Net Framework SDK or the Visual Studio Express Edition. The example below is created using C#, however using **vb.net** is very similar.

Note that the .NET assemblies are not installed in the Global Assembly Cache, but they do have version numbers on them. This means that the calling applications are tied to using the same assembly versions they were compiled with. To avoid problems using the assemblies, you should install the assemblies and the applications that use the assemblies in the same directory.

1. Verify that the computer you are using has Access Manager or the Delinea Windows API Runtime environment from the Delinea SDK installed.
2. Verify that the computer you are using is a member of the Active Directory domain you want to work with.
3. Log in as a domain user with permission to read the zone data for the zone you will be listing.

   If you can list the users in the zone using Access Manager with the credentials provided, you have the correct permissions. For information about configuring a user's rights to read zone data, see the *Planning and Deployment Guide*.
4. Start **vs2010** and start a new project of type **C# console application**.
5. Click **Project > Add reference**.
6. Click the **.NET** tab, then click **Browse**.
7. Navigate to the directory where Access Manager or the SDK is installed. For example, browse to the default location C:\Program Files\Centrify\.
8. Select the following dynamic link libraries to add:

   ```
   centrifydc.api.dll
   interface.dll
   nismap.api.dll
   ```

PropSheetHost.dll
util.dll

9. Add a reference to **system.directory** services. From the **Project** menu, select **Add references**. In the **.NET** tab scroll down to system.directoryservices.dll.

10. Open the class file that contains the application's Main function. By default, Visual Studio creates this file as class1.cs.

11. Add the following code in the **Main** function, replacing the domain_name and the path to the zone with a domain controller and zone location appropriate for your environment:

```
Centrify.DirectControl.API.Cims cims = new
Centrify.DirectControl.API.Cims();
Centrify.DirectControl.API.IZone zone =
cims.GetZone("domain_name/zone_path/zone_name");
foreach (Centrify.DirectControl.API.IUserUnixProfile user in zone.GetUserUnixProfiles())
{
string name, uid;
if (zone.IsHierarchical &&
!
((Centrify.DirectControl.API.CDC50.UserUnixProfile)user).IsNameDefined)
{
name = "<Empty>";
}
else

if (zone.IsHierarchical &&
!
((Centrify.DirectControl.API.CDC50.UserUnixProfile)user).IsUidDefined)
{
uid = "<Empty>";
}
else

Console.WriteLine(name + " I " + uid);
}
```

For example if you are using the domain dc2k.seattle.test and want to list users in the "default" zone in its default container location:

```
Centrify.DirectControl.API.IZone zone =
cims.GetZone("dc2k.seattle.test/program data/centrify/zones/default");
```

12. Press **F5** to compile and run the application.

Delinea Object Reference

This chapter describes the classes, methods, and properties available for working with objects for access control and privilege management. The primary classes for working with data objects are defined in the Centrify.DirectControl.API namespace and consist of:

- AzRoleAssignment
- Cims
- Command
- Commands
- Computer
- ComputerGroupUnixProfiles
- ComputerRole
- ComputerRoles
- Computers
- ComputerUserUnixProfiles
- CustomAttributeContainer
- CustomAttributes
- CustomAttribute
- Group
- GroupUnixProfile
- GroupUnixProfiles
- HierarchicalGroup
- HierarchicalUser
- HierarchicalZone
- HierarchicalZoneComputer
- HzRoleAssignment
- InheritedRoleAsg
- Key
- Keys
- License
- Licenses
- LicensesCollection
- MzRoleAssignment
- NetworkAccess
- NetworkAccesses
- Pam

- Pams
- Right
- Role
- RoleAssignment
- RoleAssignments
- Roles
- Ssh
- Sshs
- User
- UserUnixProfile
- UserUnixProfiles
- WindowsApplication
- WindowsApplicationCriteria
- WindowsApplications
- WindowsDesktop
- WindowsDesktops
- WindowsUser
- WindowsUsers
- Zone

In addition to the basic classes, the following classes are defined in the Centrify.DirectControl.NISMap.API namespace for working with NIS maps:

- Entry
- Map
- Store

There are also separate classes for pending import groups and users. The following classes are defined in the Centrify.DirectControl.API.Import namespace for working with groups and users imported from UNIX with the “Import from UNIX” wizard:

- GroupInfo
- GroupInfos
- GroupMember
- GroupMembers
- UserInfo
- UserInfos

Delinea

AzRoleAssignment

The AzRoleAssignment class represents a computer role assignment, where a role assignment object contains information about an Active Directory object (trustee—that is, user or group) that has been added to a computer role.

Syntax

```
public interface IAzRoleAssignment : IRoleAssignment
```

Methods

The AzRoleAssignment class provides the following methods:

Commit	Commits changes in the role to Active Directory. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
ClearCustomAttributes	VBScript interface to clear the custom attributes for this class. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
Delete	Deletes the role. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
GetComputerRole	Returns the computer role that logically contains this role assignment. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
GetTrustee	Returns the trustee being assigned. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
ICustomAttributeContainer GetCustomAttributeContainer	.NET interface that returns the directory entry for the parent container object for the custom attributes for this class. (Inherited from RoleAssignment.)
SetCustomAttribute	VBScript interface to set the custom attributes for this class. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
Validate	Validates this role assignment. (Inherited from [RoleAssignment] (../roleassignment/index.md).)

Properties

The AzRoleAssignment class provides the following properties:

CustomAttributes	VBScript only: Gets or sets custom attributes for this class. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
EndTime	Determines the time at which this role becomes inactive. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
Id	Gets the GUID of the role assignment. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
IsRoleOrphaned	Indicates whether the role assignment is orphaned due to missing or invalid data. (Inherited from RoleAssignment
IsTrusteeOrphaned	Indicates whether the role assignment is orphaned due to a missing trustee. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
LocalTrustee	Gets the local trustee being assigned. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
Role	Gets the role the trustee is assigned to. (Inherited from [RoleAssignment] (../roleassignment/index.md).)

StartTime	Specifies the time from which this role becomes effective. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
TrusteeDn	Gets the distinguished name of the trustee assigned the role. (Inherited from [RoleAssignment] (../roleassignment/index.md).)
TrusteeType	Gets the trustee type of the role assignment. (Inherited from RoleAssignment.)

Discussion

A computer role describes the intended use of a group of computers; for example, the set of computers dedicated as database servers. See ComputerRoles for a discussion of computer roles.

GetComputerRole

Gets the computer role that logically contains this role assignment.

Syntax

```
IComputerRole GetComputerRole()
```

Return value

The ComputerRole instance containing this role assignment.

Discussion

The role assignment contains information about an Active Directory object that has been assigned to a computer role.

Exceptions

GetComputerRole throws an ApplicationException if no computer role is found, multiple computer roles are found, or an error occurs when accessing Active Directory.

Example

The following code sample illustrates using this method in a script:

```
...
IComputerRole compRole = objZone.GetComputerRole(strName);
if (compRole != null)
{
    Console.WriteLine("Computer role " + strName + " already exists.");
}
...
```

Cims

The Cims class is the top-level class in the Delinea Windows API.

Syntax

```
public interface ICims
```

Discussion

This class is used to establish the connection with Active Directory and set up the environment so that other operations can be performed. Before you can retrieve any information from Active Directory, you must create a Cims object. For example:

```
'Create a CIMS object to interact with Active Directory

set cims = CreateObject("Centrify.DirectControl.Cims")
```

If you are writing programs using Delinea, version 5.0 or later, the top-level Cims object is named Cims3. For example:

```
set cdc = CreateObject("Centrify.DirectControl.Cims3")
```

If you have scripts created for a previous version of Delinea software, you should modify the object created to be a Cims3 object to work with version 5.0 or later.

If you are writing programs using a .NET language, the namespace for the top-level Cims object is Centrify.DirectControl.API.Cims, regardless of the version of Delinea you are using. For example, to create the top-level Cims object in a .NET program, type:

```
Centrify.DirectControl.API.Cims cdc = new Centrify.DirectControl.API.Cims();
```

Methods

The Cims class provides the following methods:

AddComputer	Adds a computer object to a specific zone.
AddComputerZone	Adds a computer zone to a computer object.
AddWindowsComputer	Adds a Windows computer object to a hierarchical zone.
ConfigureForest	Configures the Active Directory forest to work with Delinea software.
Connect	Connects to an Active Directory domain controller.
CreateZone	Creates an individual zone object in a parent container object.
CreateZoneWithSchema	Creates an individual zone object with a specified schema type in a parent container object.
GetComputer	Returns a computer object with its related data by its directory object.
GetComputerByComputerZone	Returns a computer object given the LDAP path to the computer zone.
GetComputerByPath	Returns a computer object given the LDAP path to the computer.
GetGroup	Returns a group object with its related data by its directory object.
GetGroupByPath	Returns a group object with its related data by its LDAP path.
GetUser	Returns a user object with its related data by its directory object.

[GetUserByPath](dev/windows-api/object-reference/cims/	Returns a user object with its related data by its LDAP path.
GetWindowsUser	Returns a Windows user object.
GetWindowsUserByPath	Returns a Windows user object given the path to the object.
GetZone	Returns a zone object with its related data by object name.
GetZoneByPath	Returns a zone object with its related data by its LDAP path.
IsForestConfigured	Checks whether the forest is properly configured with valid Delinea licenses.
LoadLicenses	Returns all of the Delinea licenses for the connected domain.

Properties

The Cims class provides the following properties:

Password	Gets the password used to establish the connection to the Active Directory domain.
Server	Gets the domain controller computer name used to establish the connection to the Active Directory domain.
UserName	Gets the user name used to establish the connection to the Active Directory domain.

AddComputer

Adds a computer object to a specific zone.

Syntax

```
IComputer AddComputer(IADs computer, IZone zone)
IComputer AddComputer(string computerDn, IZone zone)
```

Parameters

Specify one of the following parameters when using this method.

computer	The Active Directory computer object that you wish to add to the zone.
computerDn	The distinguished name of the computer object.

Specify the following parameter when using this method.

zone	The zone to which you wish to add the computer object.

Return value

The newly-added computer object.

Exceptions

`AddComputer` throws an `ArgumentNullException` if any parameter value is `null` or empty.

AddComputerZone

Adds a computer zone to a computer object.

Syntax

```
IHierarchicalZoneComputer AddComputerZone(string dnsname, IZone zone)
```

Parameters

Specify the following parameters when using this method.

dnsname	The DNS host name of the Active Directory computer object to which you wish to add a computer zone.
zone	The hierarchical zone to which the computer object belongs.

Return value

The hierarchical computer object that contains the computer zone.

Discussion

Computer-level overrides for user, group, or computer role assignments are contained in a *computer zone*, a Delinea zone in Active Directory that contains properties that are specific to only one computer. Computer zones are not exposed in Access Manager.

This method adds a computer zone to a computer object in a hierarchical zone. If the Active Directory computer object exists, the method adds the computer zone to that computer. If the computer object does not exist, the method creates an orphan computer zone. When you create an Active Directory computer with the same DNS host name and call the AddComputer method to add it to the zone, this computer zone is linked to that computer object.

Exceptions

`AddComputerZone` may throw one of the following exceptions:

- `ArgumentNullException` if the DNS name parameter value is `null`.
- `ArgumentException` if the DNS name is not valid or the zone is not recognized.

AddWindowsComputer

Adds a Windows computer object to a hierarchical zone.

Syntax

```
IComputer AddWindowsComputer(IADs computer, IHierarchicalZone zone)
IComputer AddWindowsComputer(string computerDn, IHierarchicalZone zone)
```

Parameters

Specify one of the following parameters when using this method.

computer	The Active Directory computer object that you wish to add to the zone.
computerDn	The distinguished name of the computer object.

Specify the following parameter when using this method.

zone	The zone to which you wish to add the computer object.

Return value

The newly-added computer object.

Exceptions

AddWindowsComputer throws an ArgumentNullException if any parameter value is null or empty.

ConfigureForest

Configures the Active Directory forest to work with Delinea software.

Syntax

void ConfigureForest(string licenseContainerPath)

Parameters

Specify the following parameter when using this method.

licenseContainerPath	The LDAP path to the license container holding your Delinea licenses.

Discussion

Your Delinea license container must be set up before calling this function. See the Licenses class for more information about license containers.

Exceptions

ConfigureForest throws an ArgumentException if the parameter value is null or empty or if the method cannot find the license container object.

Connect

Establishes a connection to an Active Directory domain controller.

Syntax

void Connect(string server, string username, string password)

Parameters

Specify the following parameters when using this method.

server	The name of the Active Directory domain controller to which you are establishing a connection.
username	The Active Directory user account for connecting to the domain controller. The rights associated with this account used to establish the connection to Active Directory can control the operations you are allowed to perform in a script.
password	The password for the Active Directory user account connecting to the domain controller.

Discussion

This method enables you to connect to a specific domain controller using a specific user name and password, if the Active Directory server name, user name, and user password are all valid. This method is not required when you connect to Active Directory using the credentials you used to log on to the computer.

Call Cims.Connect("domaincontroller", NULL, NULL) to use the default user account

Example

The following code sample illustrates using this method in a script:

```
...
'Specify credentials to use for connecting to Active Directory
cims.Connect("ginger.ajax.org", "dane", "Niles9!");
```

CreateZone

Creates a zone in the specified parent container and returns the zone object created.

Syntax

```
IZone CreateZone(IADs container, string name)
```

Parameters

Specify the following parameters when using this method.

container	The IADs interface of the parent container object to be used to store the new zone. You can use the standard ADSI GetObject function to retrieve this interface.
name	The name of the new zone.

Return value

The zone object and its related data as Centrify.DirectControl.API.IZone.

Discussion

The CreateZone function requires you to specify the Active Directory container object or organizational unit where the zone should be created. You can use the Active Directory GetObject function to retrieve the ADSI pointer to the specified container.

Exceptions

CreateZone may throw one of the following exceptions:

- ArgumentNullException if the container object is a null reference.
- ArgumentException if the zone name is invalid.
- ApplicationException if a global catalog server error occurs.
- UnauthorizedAccessException if the container object cannot be read because of insufficient permissions.
- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using this method in a script to create a new hierarchical zone named Sample_Zone in the parent container Program Data/Centrify/Zones:

```
...
string strParent = "CN=zones,CN=Centrify,CN=Program Data";
string strZone = "sample_zone";
// Create a CIMS object to interact with AD.
Cims cims = new Cims();
// Note: There is no cims.connect function.
// By default, this script will use the connection to the domain controller
// and existing credentials from the computer already logged in.
// Obtain an active directory container object.
DirectoryEntry objRootDSE = new DirectoryEntry("LDAP://rootDSE");
DirectoryEntry objContainer = new DirectoryEntry("LDAP://" + strParent + "," +
objRootDSE.Properties["defaultNamingContext"].Value.ToString());
IHierarchicalZone objZone = cims.CreateZone(objContainer, strZone) as
IHierarchicalZone;
...
```

CreateZoneWithSchema

Creates a zone with a specified schema type in the specified parent container and returns the zone object created.

Syntax

```
IZone CreateZoneWithSchema(IADs container, string name, int schema, int objectType)
```

Parameters

Specify the following parameters when using this method.

container	The IADs interface of the parent container object to be used to store the new zone.
name	The name of the new zone.
schema	The schema type to use for the new zone. This parameter determines how the zone data is stored in Active Directory. For more information about the valid schema types you can specify, see Schema.
objectType	The Active Directory object type to use for the zone. The valid values are: 0 defines the zone object as a Container object. 1 defines the zone object as an Organization Unit.

Return value

The zone object as Centrify.DirectControl.API.IZone.

Discussion

The CreateZoneWithSchema function requires you to specify the Active Directory container object or organizational unit where the zone should be created. You can use the standard Active Directory GetObject function to retrieve the ADSI pointer to the specified container.

Exceptions

CreateZoneWithSchema may throw one of the following exceptions:

- ArgumentNullException if the container object is a null reference.
- ArgumentException if the zone name is invalid.
- ApplicationException if a global catalog server error occurs.
- UnauthorizedAccessException if the container object cannot be read because of insufficient permissions.
- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using this method in a script to create a new classic zone named ConsumerDiv as an organization unit in the parent container ajax.org/Corporate/Zones:

```
...
'Specify the parent container location for the zone
set objContainer = GetObject("LDAP://cn=Zones,cn=Corporate, dc=ajax,dc=org")
'Create a new zone named “ConsumerDiv”
set objZone = cims.CreateZoneWithSchema(objContainer, “ConsumerDiv”, 3, 1)
...
```

The GetObject call retrieves the ADSI pointer to the specified container.

GetComputer

Returns a computer object with all of its related Delinea-specific data, including all of the Computer object's properties and methods.

Syntax

IComputer GetComputer(IADs computer)

Parameter

Specify the following parameter when using this method:

computer	The IADs interface to the computer object you want to retrieve. You can use the standard ADSI GetObject function to retrieve this interface.

Return value

The computer object as:

Centrify.DirectControl.API.IComputer

Discussion

This method returns the computer object using the IADs interface to locate the object. The IADs interface is the directory object that represents the computer in Active Directory. The IADs object is useful for retrieving Active Directory-specific information, such as the site, for a computer object.

The method returns the computer object as Centrify.DirectControl.API.IComputer. You can then use the IComputer object to retrieve Delinea-specific information, such as the version of the Delinea Agent installed on the computer.

Exceptions

GetComputer throws an ArgumentException if the computer path is null or empty.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/east_div")
'Identify the computer you want to work with
set objIADsComputer = GetObject("LDAP://CN=magnolia,
CN=Computers,DC=ajax,DC=org")
'Get the directory object for the computer
set objComputer = cims.GetComputer(objIADsComputer)
...
```

GetComputerByComputerZone

Returns a computer object with all of its related Delinea-specific data, given the path to the computer zone associated with the computer.

Syntax

```
IHierarchicalZoneComputer GetComputerByComputerZone(string zonepath)
```

Parameter

Specify the following parameter when using this method:

zonepath	The LDAP path or distinguished name of the computer zone of the computer object you want to retrieve.

Return value

The computer object as:

```
Centrify.DirectControl.API.IHierarchicalZoneComputer
```

Discussion

When you assign computer-level overrides for user, group, or computer role assignments, the Delinea Windows API creates a *computer zone*, a Delinea zone in Active Directory that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed in Access Manager.

This method returns the computer object using the LDAP path or distinguished name of the computer zone. The LDAP path to a computer zone uses the following format:

```
LDAP://[domain/]attr=name,[...],dc=domain_part,[...]
```

For example, if you use the default parent location for computer accounts in the domain `arcade.com`, the LDAP path for the computer account `magnolia` is:

```
LDAP://cn=magnolia,cn=Computers,dc=arcade,dc=com
```

Exceptions

`GetComputerByComputerZone` throws an `ApplicationException` if the method cannot find the specified computer.

GetComputerByPath

Returns a computer object with all of its related Delinea-specific data, including all of the Computer object's properties and methods.

Syntax

```
IComputer GetComputerByPath(string path)
```

Parameter

Specify the following parameter when using this method:

path	The LDAP path or distinguished name of the computer object you want to retrieve.

Return value

The computer object as:

```
Centrify.DirectControl.API.IComputer
```

Discussion

This method returns the computer object using the LDAP path or distinguished name of the object. The LDAP path to a computer account uses the following format:

```
LDAP://[domain/]attr=name,[...],dc=domain_part,[...]
```

For example, if you use the default parent location for computer accounts in the domain `arcade.com`, the LDAP path for the computer account `magnolia` is:

```
LDAP://cn=magnolia,cn=Computers,dc=arcade,dc=com
```

The method returns the computer object as `Centrify.DirectControl.API.IComputer`.

Exceptions

`GetComputerByPath` throws an `ArgumentException` if the computer path is `null` or empty.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/east_div")
'Identify the computer you want to work with
Set objComputer = cims.GetComputerByPath("LDAP://cn=magnolia,
cn=computers,dc=ajax,dc=org")
...
```

GetGroup

Returns an Active Directory group object with all of its related Delinea-specific data.

Syntax

IGroup GetGroup(IADs group)

Parameter

Specify the following parameter when using this method:

group	The IADs interface to the group object you want to retrieve. You can use the standard ADSI GetObject function to retrieve this interface.

Return value

The group object as:

Centrify.DirectControl.API.IGroup

Discussion

This method uses the IADs interface to locate the group object. The IADs interface is the directory object that represents the group in Active Directory. The IADs object is useful for retrieving Active Directory-specific information, such as the site, for a group.

The method returns the group object as Centrify.DirectControl.API.IGroup. You can then use the IGroup object to retrieve Delinea-specific information. For example, you can use IGroup.UnixProfiles to retrieve the UNIX group profiles associated with an Active Directory group or IGroup.AddUnixProfile to add a UNIX group profile for an Active Directory group to the zone.

Exceptions

GetGroup throws an ArgumentException if the parameter is null or empty.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/east_div")
'Identify the Active Directory group you want to work with
set objIADsGroup = GetObject("LDAP://CN=IT Interns,CN=Users, DC=ajax,DC=org")
'Get the directory object for the group
set objGroup = cims.GetGroup(objIADsGroup)
...
```

GetGroupByPath

Returns an Active Directory group object with all of its related Delinea-specific data given the path to the object.

Syntax

```
IGroup GetGroupByPath(string path)
```

Parameter

Specify the following parameter when using this method:

path	The LDAP path or distinguished name of the group object you want to retrieve.

Return value

The group object as:

```
Centrify.DirectControl.API.IGroup
```

Discussion

This method returns the group object using the LDAP path or distinguished name of the object. The LDAP path to a group uses the following format:

```
LDAP://[domain/]attr=name,[...],dc=domain_part,[...]
```

For example, if you use the default parent location for groups in the domain `arcade.com`, the LDAP path for the IT Interns group is:

```
LDAP://cn=IT Interns,cn=Users,dc=arcade,dc=com
```

The method returns the group object as `Centrify.DirectControl.API.Group.ObjectName`.

Exceptions

`GetGroupByPath` throws an `ArgumentException` if the group path is `null` or empty.

Example

The following code sample illustrates using this method in a script:

```
...
string strParent = "CN=zones,CN=Centrify,CN=Program Data";
if (args.Length != 2)
{
    Console.WriteLine("Usage:");
    Console.WriteLine(" test_remove_group.exe
    \"cn=sample_group,ou=groups,dc=domain,dc=tld\\" \\"default\\"");
    return;
}
string strGroup = args[0];
string strZone = args[1];
// Need to obtain an active directory container object
DirectoryEntry objRootDSE = new DirectoryEntry("LDAP://rootDSE");
DirectoryEntry objContainer = new DirectoryEntry("LDAP://" + strParent + "," +
    objRootDSE.Properties["defaultNamingContext"].Value.ToString());
string strContainerDN = objContainer.Properties["DistinguishedName"].Value as string;
// Create a CIMS object to interact with AD
ICims cims = new Cims();
// Note the lack of the cims.connect function.
// By default, this application will use the connection to the domain controller
// and existing credentials from the computer already logged in.
// Get the group object
IGroup objGroup = cims.GetGroupByPath(strGroup);
// Get the zone object
IZone objZone = cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN);
...
```

GetUser

Returns an Active Directory user object with all of its related Delinea-specific data.

Syntax

```
IUser GetUser(IADs user)
```

Parameter

Specify the following parameter when using this method:

user	The IADs interface to the user object you want to retrieve.

Return value

The user object as:

`Centrify.DirectControl.API.IUser`

Discussion

This method uses the IADs interface to locate the user object. The IADs interface is the directory object that represents the user in Active Directory. The IADs object is useful for retrieving Active Directory-specific information, such as the site, for a user.

The method returns the user object as `Centrify.DirectControl.API.IUser`. You can then use the IUser object to retrieve Delinea-specific information.

Exceptions

`GetUser` throws an `ArgumentException` if the parameter is `null` or empty.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/east_div")
'Identify the Active Directory user you want to work with
Set objUser = cims.GetUser("ajax.org/Users/Jae Smith")
...
```

GetUserByPath

Returns an Active Directory user object with all of its related Delinea-specific data given the path to the object.

Syntax

```
IUser GetUserByPath(string path)
```

Parameter

Specify the following parameter when using this method:

path	The LDAP path or distinguished name of the user object you want to retrieve.

Return value

The user object as:

```
Centrify.DirectControl.API.IUser
```

Exceptions

`GetUserByPath` throws an `ArgumentException` if the computer path is `null` or empty.

Discussion

This method returns the user object using the LDAP path or distinguished name of the object. The LDAP path to a user object uses the following format:

```
LDAP://[domain/]attr=name,[...],dc=domain_part,[...]
```

The method returns the user object as `Centrify.DirectControl.API.User.ObjectName`. For example, if the Active Directory user account is Jae Smith and the LDAP path to the account is `CN=Jae Smith, CN=Users, DC=ajax, DC=org`, the method returns the user object as:

```
Centrify.DirectControl.API.User.Jae Smith
```

Example

The following code sample illustrates using this method in a script:

```
...
string strUser = args[0];
if (string.IsNullOrEmpty(strUser))
{
    Console.WriteLine("User DN cannot be empty.");
    return;
}
// Obtain an active directory container object
// Configure the test container
DirectoryEntry objRootDSE = new DirectoryEntry("LDAP://rootDSE")
DirectoryEntry objContainer = new DirectoryEntry("LDAP://" + strParent + "," +
    objRootDSE.Properties["defaultNamingContext"].Value.ToString());
string strContainerDN = objContainer.Properties["DistinguishedName"].Value as string;

// Create a CIMS object to interact with AD
ICims cims = new Cims();

// Note the lack of the cims.connect function.'
// By default, this application will use the connection to domain controller
// and existing credentials from the computer already logged in.

IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

IUser objUser = cims.GetUserByPath(strUser);
if (objUser == null)
{
    Console.WriteLine("User " + strUser + " does not exist.");
```

```
    return;
}
...
```

GetWindowsUser

Returns a Windows user object.

Syntax

```
IWindowsUser GetWindowsUser(IADs user)
```

Parameter

Specify the following parameter when using this method:

user	The IADs interface to the user object you want to retrieve.

Return value

The user object as:

```
Centrify.DirectControl.API.IUser
```

Exceptions

`GetWindowsUser` throws an `ArgumentException` if the parameter is `null` or empty.

Discussion

This method uses the IADs interface to locate the user object. The IADs interface is the directory object that represents the user in Active Directory. The IADs object is useful for retrieving Active Directory-specific information, such as the site, for a user.

The method returns the user object as `Centrify.DirectControl.API.IUser`. You can then use the IUser object to retrieve Delinea-specific information.

GetWindowsUserByPath

Returns a Windows user object given the path to the object.

Syntax

```
IUser GetWindowsUserByPath(string path)
```

Parameter

Specify the following parameter when using this method:

path	The LDAP path or distinguished name of the user object you want to retrieve.

Return value

The user object as:

```
Centrify.DirectControl.API.IUser
```

Exceptions

`GetWindowsUserByPath` throws an `ArgumentException` if the path is `null` or empty.

Discussion

This method returns the user object using the LDAP path or distinguished name of the object. The LDAP path to a user object uses the following format:

```
LDAP://[domain/]attr=name,[...],dc=domain_part,[...]
```

The method returns the user object as `Centrify.DirectControl.API.User.ObjectName`. For example, if the Active Directory user account is `Jae Smith` and the LDAP path to the account is `CN=Jae Smith, CN=Users, DC=ajax, DC=org`, the method returns the user object as:

```
Centrify.DirectControl.API.User.Jae Smith
```

GetZone

Returns a zone object with all of its related Delinea-specific data given the zone name.

Syntax

```
IZone GetZone(string zoneName)
```

Parameter

Specify the following parameter when using this method:

zoneName	The name of the individual zone object to retrieve.

Return value

If the operation is successful, GetZone returns the named zone object and its related data as:

```
Centrify.DirectControl.API.IZone
```

Discussion

This method requires the full path to the individual zone object you want to retrieve.

This method uses the Active Directory canonical name for the zone. The canonical name for the zone uses the following naming structure:

```
domain_name/container_name/[container_name...]/zone_name
```

For example, if you use the default parent location for zones, the canonical name for the “default” zone is:

```
domain_name/Program Data/Centrify/Zones/default
```

Exceptions

GetZone may throw one of the following exceptions:

- ArgumentNullException if no zoneName parameter is passed.
- ApplicationException if the specified zone name is not valid.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/east_div")
...
```

GetZoneByPath

Returns a zone object with all of its related Delinea-specific data given its LDAP path.

Syntax

```
IZone GetZoneByPath(string path)
```

Parameter

Specify the following parameter when using this method:

path	The full LDAP path to the individual zone object you want to retrieve.

Return value

If the operation is successful, GetZoneByPath returns the zone object and its related data as Centrify.DirectControl.API.IZone.

Discussion

The LDAP path to a zone uses the following format:

```
LDAP://[domain/]attr=name,[...],dc=domain_part,[...]
```

For example, if you use the default parent location for zones in the domain arcade.com, the LDAP path for the "default" zone is:

```
LDAP://cn=default,cn=zones,cn=Centrify,cn=program data, dc=arcade,dc=com
```

> **Note**: The LDAP portion of the path is case sensitive. If you are unsure of the LDAP path for a zone, you can use the adinfo command on any computer in the zone to display the path.

Exceptions

GetZoneByPath may throw one of the following exceptions:

- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- ApplicationException if the object cannot be located by the specified path.

Example

The following code sample illustrates using this method in a script:

```
...
string strUser = args[0];
if (string.IsNullOrEmpty(strUser))
{
    Console.WriteLine("User DN cannot be empty.");
    return;
}
// Obtain an active directory container object
// Configure the test container
DirectoryEntry objRootDSE = new DirectoryEntry("LDAP://rootDSE");
DirectoryEntry objContainer = new DirectoryEntry("LDAP://" + strParent + "," +
    objRootDSE.Properties["defaultNamingContext"].Value.ToString());
string strContainerDN = objContainer.Properties["DistinguishedName"].Value as string;
// Create a CIMS object to interact with AD
ICims cims = new Cims();
// Note the lack of the cims.connect function.
// By default, this application will use the connection to the domain controller
// and existing credentials from the computer already logged in.
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;
```

```
IUser objUser = cims.GetUserByPath(strUser);
if (objUser == null)
{
    Console.WriteLine("User " + strUser + " does not exist.");
    return;
}
…
```

IsForestConfigured

Indicates whether the Active Directory forest is configured with valid Delinea licenses.

Syntax

```
bool IsForestConfigured()
```

Return value

Returns `true` if the Active Directory forest is properly configured with at least one readable license, or `false` if no valid licenses are found.

Exceptions

`IsForestConfigured` may throw one of the following exceptions:

- `COMException` if there is an LDAP error. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- `ApplicationException` if there is a global catalog server error. This exception may be thrown if the global catalog is not found or if LDAP errors occur during the discovery of the global catalog.

Example

The following code sample illustrates using this method in a script:

```
…
'Check the Active Directory forest for licenses
If not cims.IsForestConfigured then
    wScript.Echo “Forest is not configured”
End if
…
```

LoadLicenses

Returns all of the Delinea licenses installed on the connected domain.

Syntax

```
ILicensesCollection LoadLicenses()
```

Return value

The Centrify.DirectControl.API.Licenses object containing the collection of Delinea licenses installed on the connected domain.

Discussion

This method returns the collection of all licenses in all of the license parent containers found in the forest and represented in the LicensesCollection object.

Exceptions

LoadLicenses throws an ApplicationException if no license container is found or if any error occurs while accessing Active Directory.

Example

The following code sample illustrates using this method in a script:

```
...
'Get the collection of licenses
If cims.IsForestConfigured = true then
    set objLicense = LoadLicenses()
end if
...
```

Password

Gets the logged-in user's password for connecting to the domain.

Syntax

```
string Password {get;}
```

Property value

The password used to connect to the domain.

Example

The following code sample illustrates using this property in a script:

```
…
'Connect to the domain controller Active Directory
cims.Connect("paris.ajax.org","pierre","lesbleUs")
‘Display the password used to log on
wScript.Echo “Current Password:” & cims.Password
…
```

Server

Gets the Active Directory domain controller name being used to establish the connection to the Active Directory domain.

Syntax

```
string Server {get;}
```

Property value

The domain controller name used to connect to the domain.

Example

The following code sample illustrates using this property in a script:

```
…
'Connect to the domain controller Active Directory
cims.Connect("paris.ajax.org","pierre","lesbleUs")
‘Display the domain controller name
wScript.Echo “Connected to: “ & cims.Server
…
```

UserName

Gets the Active Directory user name used to establish the connection to the Active Directory domain.

Syntax

```
string UserName {get;}
```

Property value

The Active Directory user name used to connect to the domain.

Example

The following code sample illustrates using this property in a script:

```
…
'Connect to the domain controller Active Directory
cims.Connect("paris.ajax.org","pierre","lesbleUs")
‘Display the user name
wScript.Echo “Current User Credentials:” cims.UserName
…
```

Command

The Command class represents a command right.

Syntax

```
public interface ICommand : IRight
```

Methods

The Command class provides the following methods:

Commit	Commits changes in the right to Active Directory. (Inherited from Right.)
Delete	Removes the right. (Inherited from Right.)

Properties

The Command class provides the following properties:

AllowNestedExecution	If true, allows the command to start another program or open a new shell.
AuthenticationType	Specifies the type of authentication required to run a command.
CommandPattern	Gets or sets the command string that is matched to identify the command.
CommandPatternType	Gets or sets the type of pattern used to match the command.
Description	Gets or sets the description of the right. (Inherited from Right.)
DzdoRunAsGroupList	Gets or sets the list of groups allowed to run this command using dzdo.
DzdoRunAsUserList	Gets or sets the list of users and groups allowed to run this command using dzdo.
DzshRunAsUser	Gets or sets the user this command runs as when executed with dzsh.
Guid	Gets the GUID of the right.
IsReadable	Indicates whether the right is readable. (Inherited from Right.)
IsResetVariables	Resets or removes a default set of environment variables when running the command.
IsWritable	Indicates whether the right is writable. (Inherited from Right.)
MatchPath	Gets or sets the path for matching the specified command name.
Name	Gets or sets the name of the right. (Inherited from Right.)
PreserveGroupMembership	Determines whether to retain the user's group membership while executing a command.
UMask	Gets or sets the UMask value to use for the command.
VariablesToAdd	Gets or sets the list of environment name-value pairs to add, such as var1=a,var2=b,var3=c.

VariablesToKeepOrDelete	Gets or sets the list of environment variables to keep or delete.
Weight	Gets or sets the weight for this command.
Zone	Gets the zone to which this right belongs. (Inherited from Right.)

Discussion

A command right controls who has permission to run a specific command in a zone.

AllowNestedExecution

Determines whether the command is allowed to start another program or open a new shell.

Syntax

```
bool AllowNestedExecution {get; set;}
```

Property value

Set to `true` if the command is allowed to start another program or open a new shell. The default is `true`.

AuthenticationType

Determines the type of authentication required to run a command.

Syntax

```
AuthenticationType AuthenticationType {get; set;}
```

Property value

The default value is to have no authentication required. If authentication is required, this property specifies the account used to authenticate before allowing use of the command right.

Possible values:

```
public enum AuthenticationType
{
    // No authentication required
    None = 0,
    // Authenticate using logged-on user password
    LoggedOnUserPassword,
    // Authenticate using target run-as user password
    RunasUserPassword
}
```

CommandPattern

Gets or sets the command string that is matched to identify the command.

Syntax

```
string CommandPattern {get; set;}
```

Property value

The path to the command string.

Discussion

Use the CommandPatternType property to get or set the type of command-pattern string matching to use.

Exceptions

CommandPattern may throw the following exception:

- ArgumentException if the command pattern value is empty or null.

Example

Glob expression: "rm ./*"

Regular expression: "!finger sjohan \l epage"

CommandPatternType

Gets or sets the type of pattern used to match the command.

Syntax

```
PatternType CommandPatternType {get; set;}
```

Property value

The type of pattern-matching to use to identify the command.

Possible values:

```
public enum PatternType
{
    // Match using glob pattern
    Glob = 0,
    // Match using regular expression
    RegularExpression = 1
}
```

DzdoRunAsGroupList

Gets or sets the list of groups allowed to run this command using dzdo.

Syntax

```
string DzdoRunAsUserList {get; set}
```

Property value

A comma-separated string of group names (for example, "group1,group2,group3"). If a value of "*" is set, any group enabled for the zone can run the command.

DzdoRunAsUserList

Gets or sets the list of users and groups allowed to run this command using dzdo.

Syntax

```
string DzdoRunAsUserList {get; set}
```

Property value

A comma-separated string of user and group names (for example, "user1,user2,group1"). If a value of "*" is set, any user enabled for the zone can run the command.

Discussion

If you don't specify a list in this property, by default only the root user can run the command.

DzshRunAsUser

Gets or sets the user under which the command runs when executed using dzsh.

Syntax

```
string DzshRunAsUser {get; set}
```

Property value

The user name of a user authorized to run the sh command.

The default value is the current user.

Guid

Gets the GUID of the command right.

Syntax

```
Guid Guid {get;}
```

Property value

The GUID of the command right.

IsResetVariables

Determines whether to reset environment variables when running the command.

Syntax

```
bool IsResetVariables {get; set;}
```

Property value

Set `true` to reset environment values when the user runs the command.

Discussion

The `dzdo.env_keep` configuration parameter in the `centrifydc.conf` file defines a set of environment variables to retain from the current user's environment when the command is run, regardless of whether the `IsResetVariables` property is `true` or `false`. When you set this property true, if you want to specify additional variables to retain from the user's environment, list the variables in the VariablesToKeepOrDelete property.

The dzdo.env_delete configuration parameter in the centrifydc.conf file defines a set of environment variables to delete from the current user's environment when the command is run, regardless of whether the IsResetVariables property is true or false. When you set this property false, if you want to specify additional environment variables to remove, list those variables in the VariablesToKeepOrDelete property.

MatchPath

Gets or sets the match type for the path of the command.

Syntax

```
string MatchPath {get; set;}
```

Property value

The default value is "USERPATH".

Possible values to match:

- "USERPATH" Standard user path, starting with a forward slash (/).
- "SYSTEMPATH" Standard system path, starting with a forward slash (/).
- "SYSTEMSEARCHPATH" System search path, starting with a forward slash (/).
- A custom specific path, starting with a forward slash (/).
- All paths using a single asterisk (*).

PreserveGroupMembership

Determines whether to retain the user's group membership while executing the command.

Syntax

```
bool PreserveGroupMembership {get; set;}
```

Property value

Set `true` to preserve group membership.

The default is `false`.

UMask

Determines the user file-creation mode mask (umask) value to use for the command.

Syntax

```
string UMask {get; set;}
```

Property value

The default Unix file permissions for new files created by the command, expressed as an octal number. For example, `764` or `077`. The default value is `077`.

Exceptions

UMask throws an `ArgumentException` if the specified permissions mask is not valid.

VariablesToAdd

Gets or sets a comma-separated list of environment variable name-value pairs to add when the command is executed.

Syntax

```
string VariablesToAdd {get; set;}
```

Property value

A comma-separated string of name-value pairs (for example, "var1=a,var2=b,var3=c"). If a value of null or empty string is set, no name-value pairs are added. The default is null.

Exceptions

VariablesToAdd throws an ArgumentException if VariablesToAdd contains an empty entry, the name, value, or name-value pair is invalid, or you listed duplicate variables.

VariablesToKeepOrDelete

Get or set a comma-separated list of environment variables to keep or delete, depending on the value of the IsResetVariables property.

Syntax

```
string VariablesToKeepOrDelete {get; set;}
```

Property value

A comma-separated list of environment variables. The default is null.

Discussion

This list is used by the IsResetVariables method to determine which variables should be kept or deleted when the command identified by this Command object is run.

Exceptions

VariablesToKeepOrDelete throws an ArgumentException if the variable name is invalid or you specified duplicate variables.

Weight

Gets or sets the weight of the command.

Syntax

```
int Weight {get; set;}
```

Property value

The command priority. The default value is `0`.

Discussion

This number is when handling multiple matches for commands specified by wild cards. If commands specified by this command object match commands specified by another command object, the command object with the higher command priority prevails. The higher the value of the `Weight` property, the higher the priority.

Commands

The Commands class manages a collection of Command objects.

Syntax

```
public interface ICommands
```

Methods

The Commands class provides the following method:

GetEnumerator	Returns an enumeration of Command objects.

GetEnumerator

Returns an enumeration of Command objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of Command objects.

Computer

The Computer class represents a Delinea-managed computer object.

Syntax

```
public interface IComputer
```

Methods

The Computer class provides the following methods:

Commit	Commits changes to the computer object and saves them in Active Directory.
Delete	Removes the computer profile from Active Directory.
GetDirectoryEntry	Returns the directory entry for a computer object.
Refresh	Reloads the computer object data from the data in Active Directory.

Properties

The Computer class provides the following properties:

AdsiInterface	Gets the IADs interface for the computer object from Active Directory.
ADsPath	Gets the LDAP path to the computer object.
AgentVersion	Gets the version number of the Delinea Agent as it is stored in Active Directory.
CanonicalName	Gets the canonical name of the computer object.
IsOrphan	Indicates whether the computer profile has a computer object associated with it.
IsReadable	Indicates whether the computer object is readable.
IsWritable	Indicates whether the computer object is writable.
JBossEnabled	Gets or sets the attribute that enables JBoss access for a computer account.
Name	Gets the computer name of the computer object.
ProfileADsPath	Gets the LDAP path to the computer profile associated with a computer object.
SchemaVersion	Gets the version of the Active Directory schema.
TomcatEnabled	Gets or sets the attribute that enables Tomcat access for a computer account.
Version	Gets the version number of the Active Directory schema.
WebLogicEnabled	Gets or sets the attribute that enables WebLogic access for a computer account.
WebSphereEnabled	Gets or sets the attribute that enables WebSphere access for a computer account

Zone	Gets the zone associated with the Computer object.
ZoneMode	Gets the zone mode of the computer.

Commit

Commits any changes or updates to the computer object and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

When you use this method, it checks and validates the computer properties before saving the object in Active Directory. For example, before saving, the method validates that the computer name doesn't exceed the maximum length or contain invalid characters.

Exceptions

`Commit` may throw one of the following exceptions:

- `ApplicationException` if the changes you are attempting to save contain one or more errors.
- `COMException` if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- `InvalidOperationException` if the computer profile cannot be found. This usually indicates that the computer is not in a zone.
- `UnauthorizedAccessException` if there are insufficient permissions to commit the Active Directory computer account object.

Example

The following code sample illustrates using `Commit` for a computer object in a script:

```
...
set objZone = cims.GetZone("sierra.com/Performix/Zones/HongKong")
'Identify the computer account
Set objComp = cims.GetComputer("sierra.com/Performix/Computers/chu")
'Set a property and save the changes to the computer account
Set objComp.WebSphereEnabled = true
objComp.Commit
...
```

Delete

Removes the computer profile from Active Directory.

Syntax

```
void Delete()
```

Discussion

The computer profile is the service connection point associated with the computer object. This method does not remove the computer object itself from Active Directory.

Exceptions

`Delete` may throw one of the following exceptions:

- `InvalidOperationException` if the computer profile cannot be found. This usually indicates that the computer is not in a zone.
- `UnauthorizedAccessException` if there are insufficient permissions to delete the Active Directory computer profile.

Example

The following code sample illustrates using `Delete` for a computer object in a script:

```
...
set objZone = cims.GetZone("sierra.com/Performix/Zones/HongKong")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aix_fr03,
cn=Performix,CN=Computers,DC=sierra,DC=com")
'Delete the profile for the computer account
objComp.Delete
...
```

GetDirectoryEntry

Returns the directory entry for the computer object.

Syntax

```
DirectoryEntry GetDirectoryEntry ()
```

Return value

The DirectoryEntry attribute of the computer object.

Discussion

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Example

The following code sample illustrates using GetDirectoryEntry for a computer object in a script:

```
...
'Identify the computer account
IComputer computer = cims.GetComputerByPath("LDAP://CN=sage,
CN=Computers,DC=arcade,DC=com");
'Get the directory entry for the computer account
DirectoryEntry computerEntry = computer.GetDirectoryEntry();
'Rename the computer account
computerEntry.Rename("CN=sagebrush");
...
```

Refresh

Reloads the Computer object data from the data in Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the computer properties in the cached object to ensure it is synchronized with the latest information in Active Directory.

Exceptions

`Refresh` may throw one of the following exceptions:

- `InvalidOperationException` if the computer profile cannot be found. This usually indicates that the computer is not in a zone.
- `COMException` if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using `Refresh` for a computer object in a script:

```
...
set objZone = cims.GetZone("sierra.com/Performix/Zones/HongKong")
'Identify the computer account
Set objComp = cims.GetComputer("sierra.com/Performix/Computers/chu”)
'Set a property and save the changes to the computer account
Set objComp.WebSphereEnabled = true
objComp.Commit
'Refresh the computer object and display the result
objComp.Refresh
wScript.Echo objComp.WebSphereEnabled
...
```

AdsiInterface

Gets the IADs interface for the computer object from Active Directory.

Syntax

IADs AdsiInterface {get;}

Property value

The IADs interface for the computer object.

Example

The following code sample illustrates using AdsiInterface for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=Centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aixserver,
CN=computers,DC=sierra,DC=com")
'Display the LDAP path of the parent container
wScript.Echo objComp.AdsiInterface.Parent
...
```

ADsPath

Returns the LDAP path to the computer object.

Syntax

```
string ADsPath {get;}
```

Property value

The LDAP path to the computer object in the following format:

```
LDAP://CN=aixserver,CN=computers,DC=sierra,DC=com
```

Returns `null` if the computer profile is an orphan.

Example

The following code sample illustrates using `ADsPath` for a computer object in a script:

```
...
set objZone = cims.GetZone("ajax.org/UNIX/Zones/")
'Identify the computer account
Set objComp = cims.GetComputer("ajax.org/Computers/backup78")
wScript.Echo "LDAP path: " & objComp.ADsPath
...
```

AgentVersion

Gets the version number of the Delinea Agent as it is stored in Active Directory.

Syntax

```
string AgentVersion {get;}
```

Property value

The version number of the Delinea Agent.

Example

The following code sample illustrates using AgentVersion for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=Centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aixserver,
CN=computers,DC=sierra,DC=com")
wScript.Echo "Centrify Agent: " & objComp.AgentVersion
...
```

CanonicalName

Gets the Active Directory canonical name of the computer object.

Syntax

```
string CanonicalName {get;}
```

Property value

The canonical name of the computer object.

Example

The following code sample illustrates using CanonicalName for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=solaris10-dev,
CN=computers,DC=sierra,DC=com")
wScript.Echo "Canonical name: " & objComp.CanonicalName
...
```

IsOrphan

Indicates whether the Delinea profile associated with a computer object is an orphan.

Syntax

```
bool IsOrphan {get;}
```

Property value

Returns `true` if the computer profile is an orphan, or `false` if the object is not an orphan.

Discussion

A Delinea computer profile can become an orphan if the computer object it is associated with is deleted manually using Active Directory Users and Computers or ADSI. Orphan data can consume disk space and reduce performance for directory services and should be removed.

Example

The following code sample illustrates using `IsOrphan` for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Check for orphan profiles
for each computer in objZone.GetComputers
    If computer.IsOrphan then
        wScript.Echo computer.Name
    end if
next
...
```

IsReadable

Indicates whether the data associated with the computer object is readable using the current permissions.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns true if the computer object is readable, or false if the object is not readable.

Discussion

This property returns a value of true if the user accessing the computer object in Active Directory has sufficient permissions to read its properties.

Example

The following code sample illustrates using IsReadable for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputer("ajax.org/Computers/backup78")
If not objComp.IsReadable then
    wScript.Echo “Computer account is not readable!”
end if
...
```

IsWritable

Indicates whether the data associated with the computer object is writable by the current user.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns true if the computer object is writable, or false if the object is not writable.

Discussion

This property returns a value of true if the user accessing the computer object in Active Directory has sufficient permissions to change the computer object's properties.

Example

The following code sample illustrates using IsWritable for a computer object in a script:

```
...
set objZone = cims.GetZone("ajax.org/UNIX/Zones/Pilot zone")
'Identify the computer account
Set objComp = cims.GetComputer("ajax.org/Computers/backup78")
If not objComp.IsWritable then
    wScript.Echo "You cannot save changes to this computer account!"
end if
...
```

BossEnabled

Gets or sets the attribute that indicates whether the computer is enabled as a server for JBoss applications.

Syntax

```
bool JBossEnabled {get; set;}
```

Property value

Set to true if access to JBoss applications is enabled for the computer account, or false if access to JBoss applications is not enabled.

Exceptions

JBossEnabled throws an InvalidOperationException if you try to set this property when the computer is not in a zone. For example, if you are using Delinea Express or have joined the domain using the --workstation option, you should not use this property.

Example

The following code sample illustrates using JBossEnabled for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,CN=zones,
CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aixserver,
CN=computers,DC=sierra,DC=com")
Set objComp.JBossEnabled = false
objComp.Commit
...
```

Name

Gets the computer name of the computer object.

Syntax

```
string Name {get;}
```

Property value

The computer name of the computer object.

Example

The following code sample illustrates using Name for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,CN=zones,
CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=magnolia,
CN=computers,DC=sierra,DC=com")
'Display the computer account name
wScript.Echo "Computer name: " & objComp.Name
...
```

ProfileADsPath

Gets the LDAP path to a computer object's UNIX profile.

Syntax

```
string ProfileADsPath {get;}
```

Property value

The LDAP path for the computer profile associated with the computer object.

Example

The following code sample illustrates using ProfileADsPath for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,CN=zones,
CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=magnolia,
CN=computers,DC=sierra,DC=com")
'Display the LDAP path to the computer's UNIX profile
wScript.Echo "LDAP path: " & objComp.ProfileADsPath
...
```

SchemaVersion

Gets the version of the Active Directory data schema.

Syntax

```
int SchemaVersion {get;}
```

Property value

The version of the schema as an integer (int).

Discussion

This property is used internally by the Delinea .NET module to identify the Active Directory schema being used.

> **Note**: This property is designed for COM-based programs that support a 32-bit signed number. The property Version can be used in place of this property in .NET programs because .NET supports 64-bit signed numbers.

Example

The following code sample illustrates using SchemaVersion for a computer object in a script:

```
...
set objZone = cims.GetZone("ajax.org/UNIX/Zones/Pilot zone
)
'Identify the computer account
Set objComp = cims.GetComputer("ajax.org/Computers/backup78")
wScript.Echo “Schema version: “ & objComp.SchemaVersion
...
```

TomcatEnabled

Determines whether the computer is enabled as a server for Tomcat applications.

Syntax

```
bool TomcatEnabled {get; set;}
```

Property value

Set to `true` if access to Tomcat applications is enabled for the computer account, or `false` if not.

Exceptions

`TomcatEnabled` throws an `InvalidOperationException` if you try to set this property when the computer is not in a zone. For example, if you are using Delinea Express or have joined the domain using the `--workstation` option, you should not use this property.

Example

The following code sample illustrates using `TomcatEnabled` for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aixserver,
CN=computers,DC=sierra,DC=com")
Set objComp.TomcatEnabled = true
objComp.Commit
...
```

Version

Gets the version number of the Active Directory data schema.

Syntax

```
long Version {get;}
```

Property value

The version number of the Active Directory schema as a long integer value.

Discussion

This property can be used only in .NET programs because .NET supports 64-bit signed numbers. This property cannot be used in COM-based programs. For COM-based programs, use the SchemaVersion property instead.

Example

The following code sample illustrates using Version for a computer object in a script:

```
...
// Create the top-level object
Cims cims = new Cims()
// Identify the computer account
IComputer computer = cims.GetComputer("ajax.org/Computers/backup78")
Console WriteLine "Schema version number: " + computer.Version
...
```

WebLogicEnabled

Determines whether the computer is enabled as a server for WebLogic applications.

Syntax

```
bool WebLogicEnabled {get; set;}
```

Property value

Set to true if access to WebLogic applications is enabled for the computer account or false if not.

Exceptions

WebLogicEnabled throws an InvalidOperationException if you try to set this property when the computer is not in a zone. For example, if you are using Delinea Express or have joined the domain using the --workstation option, you should not use this property.

Example

The following code sample illustrates using WebLogicEnabled for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aixserver,
CN=computers,DC=sierra,DC=com")
Set objComp.WebLogicEnabled = true
objComp.Commit
...
```

WebSphereEnabled

Determines whether the computer is enabled as a server for WebSphere applications.

Syntax

```
bool WebSphereEnabled {get; set;}
```

Property value

Set to true if access to WebSphere applications is enabled for the computer account, or false if not.

Exceptions

WebSphereEnabled throws an InvalidOperationException if you try to set this property when the computer is not in a zone. For example, if you are using Delinea Express or have joined the domain using the --workstation option, you should not use this property.

Example

The following code sample illustrates using WebSphereEnabled for a computer object in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,CN=zones,
CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aixserver,
CN=computers,DC=sierra,DC=com")
Set objComp.WebSphereEnabled = false
objComp.Commit
...
```

Zone

Gets or sets the zone object associated with the computer object.

Syntax

```
IZone Zone {get; set;}
```

Property value

The zone object for the zone of the computer account.

Discussion

Each computer object can only be associated with one zone: the zone used to join the computer to its Active Directory domain. This property gets or sets the zone object for the zone to which the computer is currently joined.

Exceptions

`Zone` may throw one of the following exceptions:

- `ApplicationException` if the zone you specify is `null`, an unsupported type, or already in use; or if you were trying to move the computer object to a new domain and the operation failed.
- `InvalidOperationException` if the computer is not zoned.

Example

The following code sample illustrates using `Zone` for a computer object in a script:

```
…
set objZone = cims.GetZoneByPath("LDAP://CN=research,CN=zones,
CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the computer account
Set objComp = cims.GetComputerByPath("LDAP://CN=aixserver,
CN=computers,DC=sierra,DC=com")
‘Display the zone name
wScript.Echo objComp.Zone.Name
…
```

ZoneMode

Gets the zone mode of the computer; used internally by the .NET module.

Syntax

```
ComputerZoneMode ZoneMode {get;}
```

Property value

The zone mode of the computer.

Possible values:

```
public enum ComputerZoneMode
{
    // Unknown
       Unknown = 0,
    // The computer is joined to a zone
       Zoned = 1,
    // The computer is in workstation mode
       Workstation = 2,
    // The computer is in express mode
       Express = 4,
    // The computer is in null zone mode (no pam or nss)
       NullZone = 8,
};
```

ComputerGroupUnixProfiles

Enumerates groups under a computer zone.

Syntax

```
public interface IComputerGroupUnixProfiles : IGroupUnixProfiles
```

Methods

The ComputerGroupUnixProfiles class provides the following methods:

Find	Finds the group added to the computer.
GetEnumerator	Returns the enumeration of GroupUnixProfile objects. (Inherited from GroupUnixProfiles.)
Refresh	Reloads the cached GroupUnixProfile objects. (Inherited from GroupUnixProfiles.)

Properties

The ComputerGroupUnixProfiles class provides the following properties:

Count	Gets the number of GroupUnixProfile objects in this set. (Inherited from GroupUnixProfiles.)
IsEmpty	Determines whether the collection of UNIX group profiles is empty. (Inherited from GroupUnixProfiles.)

Find

Finds the group added to the computer.

Syntax

```
IHierarchicalGroup Find(IHierarchicalZoneComputer computer)
```

Parameter

Specify the following parameter when using this method:

computer	The computer to search.

Return value

The hierarchical group added to the computer, if any, or `null` if no group is found.

ComputerRole

This class represents a computer role.

Syntax

public interface IComputerRole

Methods

The ComputerRole class provides the following methods:

AddAccessGroup	Adds a user group to this computer role.
AddRoleAssignment	Adds an empty role assignment.
AddUser	Adds a user role assignment to this computer role.
ClearCustomAttributes	VBScript interface to clear the custom attributes for this class.
Commit	Saves changes.
Delete	Deletes this computer role.
GetAccessGroup	Gets a user group assigned to this computer role.
GetAccessGroups	Gets the user groups assigned to this computer role.
GetCustomAttributeContainer	Gets the directory entry for the parent container object for the custom attributes for this class.
GetGroup	Gets the AD computer group associated with this computer role.
GetRoleAssignment	Gets the role assignment for a specified role and user.
GetRoleAssignmentById	Gets the role assignment, given a GUID.
GetRoleAssignments	Returns all the user role assignments under this computer role.
GetRoleAssignmentToAllADUsers	Returns the role assignment given to all Active Directory users who have a specified role.
GetRoleAssignmentToEveryone	Returns the role assignment given to all users who have a specified role.
GetUser	Gets a user assigned to this computer role.
GetUsers	Gets the collection of users assigned to this computer role.
ICustomAttributeContainer GetCustomAttributeContainer	.NET interface that returns the directory entry for the parent container object for the custom attributes for this class.
SetCustomAttribute	VBScript interface to set the custom attributes for this class.
Validate	Validates the changes made to this computer role.

Properties

The ComputerRole class provides the following properties:

CustomAttributes	VBScript only: Gets or sets custom attributes for this computer role.
Description	Gets or sets the description of this computer role.
Group	Gets or sets the AD computer group associated with this computer role.
IsOrphan	Indicates whether this computer role is an orphan.
Name	Gets or sets the name of this computer role.
Zone	Gets the zone of this computer role.

Discussion

A computer role describes the intended use of a group of computers; for example, the set of computers dedicated as database servers. Each computer role has one associated Active Directory computer group, which identifies the computers that have that use. You can assign any number of users or user groups to a computer role, with each user or user group having the permissions necessary to perform a set of functions on computers in that computer role.

> **Note**: Although there are conceptual similarities, a computer role is not a variety of access role. Whereas an access role is a set of permissions assigned to an Active Directory user or user group, a computer role defines the intended use of a group of computers. For example, the DBServer computer role might be associated with the Active Directory DatabaseServers computer group. Two user groups might be assigned to the DBServer computer role: DBUsers, which has the DatabaseUsers access role; and DBAdmins, which has the DatabaseAdmins role.

You can add custom attributes to role definitions and role assignments. For example, you might want to use a custom attribute to reference a ticket number associated with a specific type of access request, role definition, or temporary role assignment. Custom attributes are optional and you can use them to capture any kind of information that is meaningful to your organization.

You can add custom attributes when defining or modifying a role, defining or modifying a computer role, or when modifying role assignment properties.

The key point is that you can use the field for any type of information you might find useful. Customers most often want to reference a trouble/request ticket but the field can contain whatever you want.

AddAccessGroup

Adds a user group to this computer role.

Syntax

```
IAzRoleAssignment AddAccessGroup(DirectoryEntry group)
IAzRoleAssignment AddAccessGroup(SearchResult groupSr)
IAzRoleAssignment AddAccessGroup(string groupDn)
IAzRoleAssignment AddAccessGroup(IADsGroup grouplads)
```

Parameters

Specify one of the following parameters when using this method.

group	The directory entry for the group you want to add.
groupSr	The directory entry for a group specified as a search result.
groupDn	The group specified as a distinguished name.
grouplads	The IADs interface to the group.

Discussion

The AddAccessGroup(DirectoryEntry group) and AddAccessGroup(SearchResult group) methods are available only for .NET-based programs; call AddRoleAssignment for VBScript.

Return value

The computer role assignment that includes the new group.

Exceptions

AddAccessGroup may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- ApplicationException if the parameter value is not a valid group or if it failed to create a role assignment because it cannot find the group.

AddRoleAssignment

Adds an empty user role assignment to the computer role.

Syntax

```
IRoleAssignment AddRoleAssignment()
```

Return value

Returns an empty role assignment. This role assignment is not stored in Active Directory until you call the RoleAssignment:Commit method.

Discussion

Any number of users can be assigned to a computer role and each of those users can have more than one role. Use this method to get an empty user role assignment for a computer role.

AddUser

Adds a user to this computer role.

Syntax

```
IAzRoleAssignment AddUser(DirectoryEntry user)
IAzRoleAssignment AddUser(SearchResult userSr)
IAzRoleAssignment AddUser(string userDn)
IAzRoleAssignment AddUser(IADsUser userIads)
```

Parameters

Specify one of the following parameters when using this method.

user	The directory entry for the user you want to add.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The computer role assignment that includes the new user.

Discussion

The AddUser(DirectoryEntry user) and AddAccessGroup(SearchResult user) methods are available only for .NET-based programs. Call AddRoleAssignment for VBScript.

Exceptions

AddUser may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- ApplicationException if the parameter value is not a valid user or if it failed to create a role assignment because it cannot find the user.

ClearCustomAttributes

Clears the custom attributes for this computer role.

Syntax

```
void ClearCustomAttributes()
```

Commit

Commits any changes or updates to a computer role and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

This method does not validate changes. Call the Validate method before calling the `Commit` method.

Exceptions

`Commit` throws an `ApplicationException` if it could not find the computer role, could not find authorization data for the role, or failed to commit the computer role due to a communication error.

Delete

Marks the computer role for deletion from Active Directory.

Syntax

```
void Delete()
```

Exceptions

`Delete` throws an `ApplicationException` if it can't find the computer role, can't find authorization data for the zone, or failed to delete the role for another reason.

GetAccessGroup

Gets a user group assigned to this computer role given a specific role.

Syntax

```
IAzRoleAssignment GetAccessGroup(IRole role, DirectoryEntry group)
IAzRoleAssignment GetAccessGroup(IRole role, SearchResult groupSr)
IAzRoleAssignment GetAccessGroup(IRole role, string groupDn)
IAzRoleAssignment GetAccessGroup(IRole role, IADsGroup groupIAds)
```

Parameters

Specify the following parameter when using this method:

role	The role of the group.

Specify one of the following parameters when using this method.

group	The directory entry for the group.
groupSr	The directory entry for a group specified as a search result.
groupDn	The group specified as a distinguished name.
groupIads	The IADs interface to the group.

Return value

The computer role assignment that includes the specified group (IAzRoleAssignment.TrusteeType==Group).

Discussion

Any number of user groups can be assigned to a computer role and each of those groups can have more than one role. Use this method to get the computer role assignment for a specific group and role.

The GetAccessGroup(IRole role, DirectoryEntry group) and GetAccessGroup(IRole role, SearchResult groupSr) methods are available only for .NET-based programs; call AddRoleAssignment for VBScript.

Exceptions

GetAccessGroup may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- ApplicationException if the parameter value is not a valid group; or if it failed to get a role assignment because it cannot find the group.

GetAccessGroups

Gets the user groups assigned to this computer role.

Syntax

```
IRoleAssignments GetAccessGroups()
```

Return value

The collection of computer role assignments. Enumerate this object to get all of the `IRoleAssignment` objects for this computer role that represent groups (`IRoleAssignment.TrusteeType==Group`).

GetCustomAttributeContainer

Returns the directory entry for the parent container object for the custom attributes for this computer role.

Syntax

```
ICustomAttributeContainer GetCustomAttributeContainer()
```

Return value

The directory entry for the parent container object for the custom attributes for this computer role.

Discussion

The `GetCustomAttributeContainer` method is available only for .NET-based programs.

GetGroup

Returns the computer group associated with this computer role.

Syntax

```
DirectoryEntry GetGroup()
```

Return value

The directory entry for the computer group associated with the computer role.

Discussion

The GetGroup method is available only for .NET-based programs; call Group for VBScript.

GetRoleAssignment

Returns the user role assignment for a specified role and user.

Syntax

```
IRoleAssignment GetRoleAssignment(IRole role, string dn)
```

Parameters

Specify the following parameters when using this method.

role	The role for which you want a role assignment.
dn	The distinguished name of the user for which you want a role assignment.

Return value

The role assignment for the specified role and user.

Discussion

Any number of users can be assigned to a computer role and each of those users can have more than one role. Use this method to get the user role assignment for a specific user and role. To get the computer role assignment for a specific user, call the GetUser method.

Exceptions

`GetRoleAssignment` throws an `ArgumentNullException` if one of the specified parameter values is `null`.

GetRoleAssignmentById

Returns a role assignment, given a GUID.

Syntax

```
IRoleAssignment GetRoleAssignmentById(Guid id)
```

Parameter

Specify the following parameter when using this method:

id	The GUID of the role assignment.

Return value

The role assignment that has the specified GUID.

Discussion

This method returns a role assignment object given the GUID of the object.

Exceptions

`GetRoleAssignmentById` throws an `ArgumentNullException` if the specified parameter value is `null`.

GetRoleAssignments

Returns all the user role assignments under this computer role.

Syntax

```
IRoleAssignments GetRoleAssignments()
```

Return value

The collection of user role assignments for this computer role.

GetRoleAssignmentToAllADUsers

Returns the role assignment given to all Active Directory users who have a specified role.

Syntax

```
IRoleAssignment GetRoleAssignmentToAllADUsers(IRole role)
```

Parameter

Specify the following parameter when using this method:

role	The user role for which you want the role assignment.

Return value

The role assignment for the specified role.

Exceptions

GetRoleAssignmentToAllADUsers throws an ArgumentNullException if the specified parameter value is null.

GetRoleAssignmentToEveryone

Returns the role assignment given to all users who have a specified role.

Syntax

```
IRoleAssignment GetRoleAssignmentToEveryone(IRole role)
```

Parameter

Specify the following parameter when using this method:

role	The user role for which you want the role assignment.

Return value

The role assignment for the specified role.

Discussion

This method returns the role assignment for everyone with the specified role, including local users and groups.

Exceptions

`GetRoleAssignmentToEveryone` throws an `ArgumentNullException` if the specified parameter value is `null`.

GetUser

Gets a user assigned to this computer role.

Syntax

```
IAzRoleAssignment GetUser(IRole role, DirectoryEntry user)
IAzRoleAssignment GetUser(IRole role, SearchResult userSr)
IAzRoleAssignment GetUser(IRole role, string userDn)
IAzRoleAssignment GetUser(IRole role, IADsUser userIads)
```

Parameters

Specify the following parameter when using this method:

role	The role of the user.

Specify one of the following parameters when using this method.

user	The directory entry for the user you want to add.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The computer role assignment for the specified user and role.

Discussion

Any number of users can be assigned to a computer role and each of those users can have more than one role. Use this method to get the computer role assignment for a specific user and role. To get the user role assignment for a specific user, call the GetRoleAssignment method.

The GetUser(IRole role, DirectoryEntry user) and GetUser(IRole role, SearchResult userSr) methods are available only for .NET-based programs; call User for VBScript.

Exceptions

GetUser may throw the following exceptions:

- ApplicationException if cannot find the computer role in the zone; if it cannot find the specified role; if it cannot find authorization information for the zone; or if it failed to get the role assignment for some other reason.
- ArgumentNullException if a specified parameter value is null.

GetUsers

Gets the users assigned to this computer role.

Syntax

```
IRoleAssignments GetUsers()
```

Return value

The collection of computer roles. Enumerate this object to get all of the `IRoleAssignment` objects for this computer role that represent users (`IRoleAssignment.TrusteeType==User`).

SetCustomAttribute

Sets the custom attribute for this computer role.

Syntax

```
void SetCustomAttribute(string name, string value)
```

Parameters

Specify the following parameters when using this method:

name	The name of the custom attribute.
value	The value of the custom attribute

Return value

The collection of computer roles. Enumerate this object to get all of the IRoleAssignment objects for this computer role that represent users (IRoleAssignment.TrusteeType==User).

Validate

Validates the data in the ComputerRole object before any changes are committed to Active Directory. The method validates the following:

- The computer role name is not empty.
- The computer role name does not duplicate an existing computer role name in the zone.
- The computer role exists in the zone.
- An Active Directory computer group has been specified for the computer role.
- The specified computer group exists.

If the ComputerRole object is marked for deletion, the method skips validation tests.

Syntax

```
void Validate()
```

Exceptions

If the validation fails, Validate may throw an ApplicationException with a message indicating which test failed.

CustomAttributes

Syntax

```
string CustomAttributes {get; set;}
```

Property value

The custom attribute for this computer role.

Description

Gets or sets the description of this computer role.

Syntax

```
string Description {get; set;}
```

Property value

A string describing the computer role.

Group

Syntax

```
string Group {get; set;}
```

Property value

The Active Directory name of the computer group.

IsOrphan

Indicates whether the computer role is an orphan.

Syntax

```
bool IsOrphan {get;}
```

Property value

Returns `true` if this computer role cannot link to its Active Directory group.

Name

Gets or sets the name of the computer role.

Syntax

```
string Name {get; set;}
```

Property value

The name of the computer role.

Zone

Gets the zone of the computer role.

Syntax

```
IHierarchicalZone Zone {get;}
```

Property value

The zone in which the computer role is defined.

ComputerRoles

The ComputerRoles class manages a collection of computer roles.

Syntax

```
public interface IComputerRoles
```

Methods

The ComputerRoles class provides the following method:

GetEnumerator	Gets the enumerator you can use to enumerate all computer roles.

Properties

The ComputerRoles class provides the following property:

IsEmpty	Determines whether the collection is empty.

GetEnumerator

Returns an enumeration of ComputerRole objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

Returns an enumerator you can use to list all the ComputerRole objects.

IsEmpty

Indicates whether the collection of computer roles is empty.

Syntax

```
bool IsEmpty {get;}
```

Property value

Returns `true` if there are no `ComputerRole` objects in the `ComputerRoles` object.

Computers

The Computers class manages a collection of Computer objects.

Syntax

```
public interface IComputers
```

Methods

The Computers class provides the following method:

GetEnumerator	Gets an enumerator you can use to enumerate all computer objects.

Properties

The ComputerRoles class provides the following property:

IsEmpty	Determines whether the collection is empty.

GetEnumerator

Returns an enumeration of Computer objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

Returns an enumerator you can use to list all the Computer objects.

IsEmpty

Determines whether the collection of computer objects is empty.

Syntax

```
bool IsEmpty {get;}
```

Property value

Returns true if there are no Computer objects in the Computers object.

Delinea

ComputerUserUnixProfiles

The ComputerUserUnixProfiles class manages a collection of UserUnixProfile objects that represent computer users.

Syntax

```
public interface IComputerUserUnixProfiles : IUserUnixProfiles
```

Methods

The ComputerUserUnixProfiles class provides the following methods:

Find	Finds the user added to the specified computer.
GetEnumerator	Returns the enumeration of user profiles. (Inherited from UserUnixProfiles.)
Refresh	Reloads the cached user UNIX profiles. (Inherited from UserUnixProfiles.)

Properties

The ComputerUserUnixProfiles class provides the following properties:

Count	Gets the number of UserUnixProfile objects in this collection. (Inherited from UserUnixProfiles.)
IsEmpty	Determines whether the collection is empty. (Inherited from UserUnixProfiles.)

Find

Finds the UNIX user profile of the user of a specified computer.

Syntax

```
IHierarchicalUser Find(IHierarchicalZoneComputer computer)
```

Parameter

Specify the following parameter when using this method:

computer	The computer to search.

Return value

The UNIX user profile of the user of the specified computer; `null` if none exists. If there is more than one user, the first UNIX profile found is returned.

CustomAttribute

The CustomAttribute class contains a custom attribute. Available for .NET only.

Properties

The CustomAttribute class provides the following properties:

Name	The name of the custom attribute, specified as a string.
Value	The value of the custom attribute, specified as a string.

CustomAttributeContainer

The CustomAttributeContainer class contains a collection of custom attributes. Available for .NET only.

Methods

The CustomAttributeContainer class provides the following methods:

ClearCustomAttributes	Clears the custom attributes.
ICustomAttributes GetCustomAttributes	Interface to return the custom attributes.
SetCustomAttribute	Interface to set the custom attributes for this class.
ValidateCustomAttributes	Validates the custom attributes.

GetCustomAttributes

Gets the CustomAttributes.

Syntax

```
ICustomAttributes GetCustomAttributes(IHierarchicalZoneComputer computer)
```

Parameter

Specify the following parameter when using this method:

computer	The computer to search.

Return value

The custom attributes of the specified computer; `null` if none exists.

ValidateCustomAttributes

Validates the CustomAttributes.

Syntax

```
ValidateCustomAttributes(IHierarchicalZoneComputer computer)
```

Parameter

Specify the following parameter when using this method:

computer	The computer to search.

Return value

A boolean value; true if the custom attributes are valid. Otherwise, false.

CustomAttributes

The CustomAttributes class contains a set of custom attributes. Available for .NET only.

Methods

The CustomAttributeContainer class provides the following methods:

IEnumerator GetEnumerator	Interface to enumerate the custom attributes.

GetEnumerator

Returns an enumeration of CustomAttributes objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of CustomAttributes objects.

Entry

The Entry class contains methods and properties used to manage individual NIS map entries stored in Active Directory. This class is defined in the Centrify.DirectControl.NISMap.API namespace rather than the Centrify.DirectControl.API namespace.

Syntax

```
public class IEntry : ICloneable, IDisposable
```

Discussion

Each map entry consists of three primary fields: a key field, a value field, and an optional comment field.

The Entry class supports the methods and properties that apply to all .NET objects. In addition to those methods and properties, the Entry class provides some Delinea-specific methods and properties for managing the fields in NIS map records. Only the Delinea-specific methods and properties are described in this reference.

Methods

The Entry class provides the following Delinea-specific methods:

Clone	Makes a clone of the NIS map entry. Inherited from ICloneable.
Commit	Commits changes to the NIS map entry object and saves them in Active Directory.
Dispose	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.
GetDirectoryEntry	Returns the DirectoryEntry attribute for the NIS map entry object.

Properties

The Entry class provides the following Delinea-specific properties:

Comment	Gets or sets the comment field associated with a specific key in a map entry.
IsReadable	Indicates whether the map entry is readable.
IsWritable	Indicates whether the map entry is writable.
Key	Gets or sets the key field in a map entry.
Map	Gets the NIS map associated with the map entry.
Value	Gets or sets the value field associated with a specific key in a map entry.

Commit

Commits the settings or changes for the map entry object to Active Directory.

Syntax

```
void Commit();
```

Exceptions

Commit throws an ApplicationException if it can't find the DirectoryEntry value or if the key or value is invalid.

Example

The following code sample illustrates using Commit to make changes to an existing NIS map entry to Active Directory:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach zone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the generic map type named "Workstations IDs"
Set map = store.open("Workstations IDs")
'Modify the value field for the “Workstation” map entry:
set entry = map.get("128.10.12.1")
entry.Value = "satellite1"
'Commit the changes to Active Directory
entry.Commit
wScript.Echo "NIS map entry “ & entry.Key & “: " & entry.Value
...
```

GetDirectoryEntry

Returns the DirectoryEntry object for the map entry object.

Syntax

```
DirectoryEntry GetDirectoryEntry ()
```

Return value

The directory entry for the map entry object.

Discussion

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Comment

Gets or sets the comment field for a specific NIS map entry.

Syntax

```
string Comment {get; set;}
```

Property value

The contents of the comment field for a specific NIS map entry.

Discussion

Each map entry consists of three primary fields: a key field, a value field, and an optional comment field. To use this property, you must be able to identify the map and the entry—the specific record in the map—for which you are setting or retrieving the comment.

Exceptions

`Comment` throws an `ArgumentException` if you try to set a value greater than 2048 characters.

Example

The following code sample illustrates using `Comment` to change the comment field in an existing NIS map entry:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach zone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the generic map type named "Workstations IDs"
Set map = store.open("Workstations IDs")
'Modify the Comment field for Workstation ”128.10.12.1” map entry:
set entry = map.get("128.10.12.1")
entry.Comment = "San Francisco, 5th floor, Accounting Dept."
'Commit the changes to Active Directory
entry.Commit
...
```

IsReadable

Indicates whether the map entry is readable for the user credentials presented to connect to Active Directory.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns true if the map entry object is readable by the user, or false if the map entry object is not readable.

Discussion

This property returns a value of true if the user accessing the map entry object in Active Directory has sufficient permissions to read the entry properties.

Example

The following code sample illustrates using this property in a script:

```
…
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=qa-slovenia,CN=unix,DC=quantum,DC=net")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach objZone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the generic map type named "Workstations IDs"
Set map = store.open("Workstations IDs")
'Get the map entry specified
Set entry = map.get("128.10.12.1")
'Check whether the record is readable
If not entry.IsReadable then
    wScript.Echo “No read permission for this record”
end if
…
```

IsWritable

Indicates whether the map entry is writable for the user credentials presented to connect to Active Directory.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns true if the map entry object is writable by the user, or false if the map entry object is not writable.

Discussion

This property returns a value of true if the user accessing the map entry object in Active Directory has sufficient permissions to change the entry object's properties.

Example

The following code sample illustrates using this property in a script:

```
…
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=qa-slovenia,CN=unix,DC=quantum,DC=net")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach objZone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the generic map type named "Workstations IDs"
Set map = store.open("Workstations IDs")
'Get the map entry specified
Set entry = map.get("128.10.12.1")
'Check whether the record is writable
If not entry.IsWritable then
    wScript.Echo “No write permission for this record”
end if
…
```

Key

Gets or sets the key field for a NIS map entry.

Syntax

```
string Key {get; set;}
```

Property value

The contents of the key field for a NIS map entry.

Discussion

Each map entry consists of three primary fields: a key field, a value field, and an optional comment field.

Exceptions

`Key` throws an `ArgumentException` if you try to set a value that is null, empty, or greater than 1024 characters.

Example

The following code sample illustrates using `Key` to make changes to an existing NIS map entry and commit the changes to Active Directory.

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the NIS map named "generic map"
Set map = store.open("generic map")
'Modify the map entry fields for the “Key_Name” map record:
'entry.key = Key_Name
'entry.Value = Key_Value
'entry.comment = This is a sample generic map entry"
set entry = map.get("Key_Name")
entry.Key = "Modified_Key"
entry.Value = "Modified_Value"
entry.Comment = "Modified comment for the sample map entry"
'Commit the changes to Active Directory
entry.Commit
wScript.Echo "NIS map entry has been modified."
...
```

Map

Syntax

```
Map Map {get;}
```

Property value

The map containing this entry.

Value

Gets or sets the value field associated with a specific NIS map entry key.

Syntax

```
string Value {get; set;}
```

Property value

The value field associated with a specific NIS map entry key.

Discussion

Each map entry consists of three primary fields: a key field, a value field, and an optional comment field. The content and format of the value field depends on the type of NIS map you are working with. For example, if you are setting the value field in a generic map, the field can contain virtually any string that you want served for a corresponding key name.

If you are setting the value field in a netgroup map, the field lists the members of the group, separated by a blank space. Each member can be either a group name or a triple of the form (hostname,username,domainname). For example:

```
set map = store.open("netgrouop")
set entry = map.get("db_users")
entry.Value = "fin hr (,dean,ajax.org) (clone\*,,)"
```

If you are defining the value field in an auto.mount map entry, the field consists of the mount options, a tab character, and the network path to the file to consult for the mount point being defined. For example:

```
set map = store.open("auto.mount")
'Modify the value field of the “cdrom” mount point entry
set entry = map.get("cdrom")
entry.Value = "-fstype=nsfs,ro" & Chr(11) & ":/dev/sr0"
```

If you are defining the value field in an auto.master map entry, the field consists of the map file to consult, a tab character, and the mount options for the mount point being defined. For example:

```
set map = store.open("auto.mount")
'Modify the value field of the “/net” mount point entry
set entry = map.get("/net")
entry.Value = "-hosts" & Chr(11) & "-nosuid,nobrowse"
```

Exceptions

Value throws an ArgumentException if you try to set a value that is null, empty, or greater than 1024 characters.

Example

The following code sample illustrates using Value to set the value associated with a specified NIS map entry in a netgroup map:

```
…
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone.
'Provide the path to the zone and user credentials
store.Attach zone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the NIS map named “netgroup”
set map = store.open("netgroup")
'Modify the value field of the “db_admins” entry
set entry = map.Get("db_admins")
entry.Value = "dbas dbowners (,dean,) (firebird,jon,)"
…
```

Group

Delinea uses existing Active Directory groups to manage the members of UNIX groups.

Syntax

```
public interface IGroup
```

Discussion

The Group class provides access to methods and properties that enable UNIX group profiles to be linked to Active Directory groups and that you can use to manage UNIX profiles associated with Active Directory groups. The additional UNIX-specific attributes that make up the UNIX profile for a group are stored and managed within the GroupUnixProfile object.

Methods

The Group class provides the following methods:

AddUnixProfile	Adds a new UNIX group profile to a zone.
Commit	Validates and saves changes to the Group object in Active Directory.
CommitWithoutCheck	Saves changes to the Group object in Active Directory without performing any validation.
GetDirectoryEntry	Returns the directory entry for an Active Directory group object from Active Directory.
GetRoleAssignmentsFromDomain	Returns the collection of all role assignments for a group in a specified domain.
GetRoleAssignmentsFromForest	Returns the collection of all role assignments for a group in a specified forest.
Refresh	Reloads the Group object data from the data in Active Directory.

Properties

The Group class provides the following properties:

AdsiInterface	Gets the IADs interface for an Active Directory group.
ADsPath	Gets the LDAP path for an Active Directory group.
ID	Gets the unique identifier for an Active Directory group.
UnixProfiles	Gets the GroupUnixProfiles object associated with an Active Directory group.

AddUnixProfile

Adds a new UNIX group profile to a zone.

Syntax

IGroupUnixProfile AddUnixProfile(IZone zone, int gid, string name)

IGroupUnixProfile AddUnixProfile(IZone zone, long gid, string name)

Parameters

Specify the following parameters when using this method.

zone	The individual zone to which you are adding a new UNIX group profile.
gid	The GID of the new UNIX group profile.
name	The name of the new UNIX group profile.

Return value

The UNIX group object created.

Discussion

The UNIX group profile includes the group name and the numeric group identifier (GID).

> **Note**: There are two versions of this method: one designed for COM-based programs that supports a 32-bit signed number for the gid argument and one designed for .NET-based programs that allows a 64-bit signed number for the gid argument.

Exceptions

AddUnixProfile may throw one of the following exceptions:

- ArgumentNullException if the zone parameter value is null.
- NotSupportedException if the specified zone has an unrecognized schema.

Example

The following code sample illustrates using AddUnixProfile in a script:

```
...
if (objGroup.UnixProfiles.Find(objZone) == null)
{
    long next_gid = 10000; // use 10000 as default gid
// Get the next available GID for this zone
if (objZone.NextAvailableGID \>= 0)
{
    next_gid = objZone.NextAvailableGID;
}
// Add this zone to the group
objGroupUnixProfile = objGroup.AddUnixProfile(objZone, next_gid, strUnixGroup);

// Save
objGroupUnixProfile.Commit();
...
```

Commit

Commits any changes or updates to the group object and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

When you use this method, it checks and validates the data before saving it in Active Directory. Before saving, the method validates the following:

- The group name is a valid string that contains only letters (upper- or lowercase), numerals 0 through 9, and the hyphen (-) and underscore (_) characters.
- The GID value is a positive integer. Negative numbers are not allowed.
- The group name does not duplicate an existing group name.

Exceptions

`Commit` may throw one of the following exceptions:

- `ApplicationException` if any field in the UNIX group profile is invalid.
- `COMException` if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- `UnauthorizedAccessException` if you have insufficient permissions to commit the group object to Active Directory.

Example

The following code sample illustrates using `Commit` in a script:

```
...
if (objGroup.UnixProfiles.Find(objZone) == null)
{
    Console.WriteLine( strGroup + " was not a member of " + strZone);
    return;
}
else
    // Remove group
    objGroup.RemoveGroupUnixProfile(objZone);
    objGroup.Commit();
}
...
```

CommitWithoutCheck

Commits any changes or updates to the Group object and saves the changes to Active Directory without validating any of the data fields.

Syntax

void CommitWithoutCheck()

Discussion

Because this method does not perform any validation checking, it commits changes faster than the Group.Commit method.

Exceptions

CommitWithoutCheck may throw one of the following exceptions:

- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- UnauthorizedAccessException if you have insufficient permissions to commit the group object to Active Directory.

Example

The following code sample illustrates using CommitWithoutCheck in a script:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("ajax.org/UNIX/Zones/eur007")
'Identify the Active Directory group
set group = cims.GetGroupByPath("LDAP://CN=Subcontractors,
CN=EuropeanDiv,DC=ajax,DC=org")
'Set the UNIX profile associated with the group
group.SetGroupUnixProfile(zone, 8234, "subs")
'Update Active Directory without validation
group.CommitWithoutCheck
...
```

GetDirectoryEntry

Returns a DirectoryEntry object for the Active Directory group account from Active Directory.

Syntax

```
DirectoryEntry GetDirectoryEntry()
```

Return value

The directory entry for the UNIX group profile associated with the Active Directory group.

Discussion

The DirectoryEntry object represents the service connection point associated with the group in the zone.

> **Note**: This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Exceptions

GetDirectoryEntry throws an ApplicationException if the directory object cannot be retrieved—for example, if it has not been committed.

Example

The following code sample illustrates using GetDirectoryEntry in a script:

```
...
//Identify the group you want to work with
IGroup group = cims.GetGroup("LDAP://CN=oracle1, CN=Users, DC=ajax, DC=org");
// Get the directory entry
DirectoryEntry groupEntry = group.GetDirectoryEntry();
// Rename the group
groupEntry.Rename("CN=oracle_dbas");
...
```

GetRoleAssignmentsFromDomain

Returns the collection of all role assignments explicitly assigned to a specified group—regardless of whether the role assignment is in a zone, computer-specific (computer override) zone, or computer role—within a specified domain.

Syntax

```
IRoleAssignments GetRoleAssignmentsFromDomain(string domain)
```

Parameters

Specify the following parameter when using this method:

domain	The domain to search for the group's role assignments.

Return value

A collection of role assignment objects representing all of the role assignments explicitly assigned to this group in the specified domain or in the currently joined domain.

Discussion

This method only returns role assignments explicitly assigned to the group. The method does not expand the group membership or return role assignments for groups nested under the specified group.

The method will look for stored credentials to access the specified domain. If there are no stored credentials, it uses the default credentials for the current user.

If you don't specify a domain by passing an empty string ("") to the method, the method returns role assignments from the currently joined domain.

Example

The following code sample illustrates using `GetRoleAssignmentsFromDomain` in a script:

```
...
// New Cims object
$cims = New-Object ("Centrify.DirectControl.API.Cims");
// Get IGroup object
$objGroupDn = "CN=group1,CN=Users,DC=domain,DC=com";
$objGroup = \$cims.GetGroup(\$objGroupDn);
// Get role assignments from domain
$objGroup.GetRoleAssignmentsFromDomain("domain.com")
...
```

GetRoleAssignmentsFromForest

Returns the collection of all role assignments explicitly assigned to a specified group—regardless of whether the role assignment is in a zone, computer-specific (computer override) zone, or computer role—within a specified forest.

Syntax

```
IRoleAssignments GetRoleAssignmentsFromForest(string forest)
```

Parameters

Specify the following parameter when using this method:

forest	The forest to search for the group's role assignments.

Return value

A collection of role assignments objects representing all of the role assignments explicitly assigned to this group in the specified forest or in the currently joined forest.

Discussion

This method only returns role assignments explicitly assigned to the group. The method does not expand the group membership or return role assignments for groups nested under the specified group.

The method will look for stored credentials to access the specified forest. If there are no stored credentials, it uses the default credentials for the current user.

If you don't specify a forest by passing an empty string ("") to the method, the method returns role assignments from the currently joined forest.

Example

The following code sample illustrates using `GetRoleAssignmentsFromForest` in a script:

```
...
// New Cims object
$cims = New-Object ("Centrify.DirectControl.API.Cims");
// Get IGroup object
$objGroupDn = "CN=group1,CN=Users,DC=domain,DC=com";
$objGroup = \$cims.GetGroup(\$objGroupDn);
// Get role assignments from forest
$objGroup.GetRoleAssignmentsFromForest("forest.com")
...
```

Refresh

Reloads the group object data from the data in Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the group information in the cached object to ensure it is synchronized with the latest information in Active Directory.

Example

The following code sample illustrates using Refresh in a script:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("ajax.org/UNIX/Zones/eur007")
'Identify the Active Directory group
set group = cims.GetGroupByPath("LDAP://CN=Subcontractors,
CN=EuropeanDiv,DC=ajax,DC=org")
'Modify the UNIX profile associated with the group
group.SetGroupUnixProfile(zone, 8234, "subcon07")
group.Commit
'Reload the group object from Active Directory
group.Refresh
wScript.Echo "Group Unix Profile Name: " & group.Name
...
```

AdsiInterface

Gets the IADsGroup interface for the group object from Active Directory.

Syntax

IADsGroup AdsiInterface {get;}

Property value

The IADsGroup interface for the group object.

Example

The following code sample illustrates using AdsiInterface in a script:

```
...
'Identify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://cn=eur007,cn=Zones,
cn=UNIX,dc=ajax,dc=org")
'Identify the Active Directory group
set objGroup =
cims.GetGroupByPath("LDAP://cn=Subcontractors,cn=EuropeanDiv,dc=ajax,dc=org")
'Get ADSI interface associated with the group
Set objAdsi = objGroup.AdsiInterface
...
```

ADsPath

Gets the LDAP path for the specified Active Directory group.

Syntax

```
string ADsPath {get;}
```

Property value

The LDAP path for the Active Directory group object.

Example

The following code sample illustrates using ADsPath for a group in a script:

```
…
'Identify the zone you want to work with
set objZone = cims.GetZone("sierra.com/program data/centrify/zones/market
research")
'Identify the Active Directory group
Set objGroup = cims.GetGroup("sierra.com/Groups/Managers")
‘Display the LDAP for the specified group
wScript.Echo "LDAP path: " & objGroup.ADsPath
…
```

ID

Gets the unique identifier for the specified Active Directory group.

Syntax

```
string ID {get;}
```

Property value

The GUID for the specified Active Directory group.

Example

The following code sample illustrates using ID for a group in a script:

```
...
'Identify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the Active Directory group
Set objGroup = cims.GetGroupByPath("LDAP://CN=managers,
CN=Groups,DC=sierra,DC=com")
‘Display the ID for the specified group
wScript.Echo "Unique ID: " & objGroup.ID
...
```

UnixProfiles

Gets the GroupUnixProfiles object associated with a specified Active Directory group.

Syntax

IGroupUnixProfiles UnixProfiles {get;}

Property value

The GroupUnixProfiles object associated with the specified Active Directory group.

Discussion

The GroupUnixProfiles object contains information about the collection of group profiles associated with the Active Directory group in different zones.

Example

The following code sample illustrates using UnixProfiles in a script:

```
...
// Create a CIMS object to interact with AD
ICims cims = new Cims();
// Note: There is no cims.connect function.
// By default, this application will use the connection to the domain controller

// and existing credentials from the computer already logged in.
// Get the group object
IGroup objGroup = cims.GetGroupByPath(strGroup);
// Get the zone object
IZone objZone = cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN);
// Determine if the specified group is already a member of the zone.
// This method will either return a blank objGroupUnixProfile
// or one containing data
if (objGroup.UnixProfiles.Find(objZone) == null)
{
    Console.WriteLine( strGroup + " was not a member of " + strZone);
    return;
}
else
{
    // Remove group
    objGroup.RemoveGroupUnixProfile(objZone);
    objGroup.Commit();
}
...
```

Delinea

GroupInfo

The GroupInfo class contains methods and properties used to import and map UNIX group profiles to Active Directory groups. This class is defined in the Centrify.DirectControl.API.Import namespace.

Syntax

```
public interface IGroupInfo : IDisposable
```

Methods

The GroupInfo class provides the following methods:

Unexpected Link Text	Commits changes to the pending group object and saves them in Active Directory.
Unexpected Link Text	Marks the pending group profile for deletion from Active Directory.
Dispose	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.
Unexpected Link Text	Returns the members of a pending import group.
Unexpected Link Text	Links the pending import group profile with the specified Active Directory group account.
Unexpected Link Text	Checks Active Directory for groups that match or conflict with a pending import group.

Properties

The GroupInfo class provides the following properties:

Unexpected Link Text	Gets the distinguished name (DN) of the import candidate.
Unexpected Link Text	Gets or sets the UNIX group identifier (GID) for the pending import group profile.
Unexpected Link Text	Gets the unique ID of the pending import group object.
Unexpected Link Text	Indicates whether the pending import group has been successfully imported.
Unexpected Link Text	Gets all of a pending import group's members.
Unexpected Link Text	Gets or sets the UNIX group name for a pending import group.
Unexpected Link Text	Gets the text string that describes the source of the pending import data.
Unexpected Link Text	Gets the status of the pending import group.
Unexpected Link Text	Gets a text string that provides detailed information about the status of the pending import group.

Unexpected Link Text	Gets the date and time that the pending group profiles were imported from the data source.

Commit

Commits any changes or updates to the pending group object and saves them in Active Directory.

Syntax

```
void Commit()
```

Delete

Marks the pending group profile object for deletion from Active Directory.

Syntax

```
void Delete()
```

Discussion

This method does not delete the pending group profile. After you mark the object for deletion, you must use the Unexpected Link Text method to commit changes to the object to Active Directory. When the Commit method is executed, the pending group profile is deleted from Active Directory to complete the operation.

Exceptions

Delete throws an UnauthorizedAccessException if you have insufficient access rights to remove the UNIX profile in the zone.

GetMembers

Returns the members of a pending import group.

Syntax

```
string GetMembers()
```

Return value

The collection of user profiles in the UserInfos object for the members of the pending import group.

Discussion

This method returns the collection of user profiles that are members of the pending import group.

Import

Imports the pending import group profile by associating the UNIX properties for the group with the specified Active Directory group account.

Syntax

```
void Import(IGroup group)
```

Parameter

Specify the following parameter when using this method:

group	The group for which you want to retrieve profile information.

Discussion

This method links the pending import group to an Active Directory account and removes the group from the pending import list.

UpdateStatus

Checks the Active Directory forest for matching or conflicting information that will allow or prevent a pending import group being imported.

Syntax

```
void UpdateStatus()
```

Discussion

This method searches Active Directory for a group name that matches the pending import group name and updates the pending import group properties with the results of the search. For example, if no Active Directory match is found or a UNIX profile already exists for the matching Active Directory group, the method updates the pending group's properties with that information.

> **Note:** Checking the Active Directory forest for potential matching candidates or conflicts can be a time-intensive operation. Therefore, you should consider the size and distribution of the forest and limit the number of pending import groups you are working with when using this method.

CandidateDN

Gets or sets the distinguished name (DN) of the import candidate.

Syntax

```
string CandidateDN {get; set;}
```

Property value

The matching Active Directory group object for the pending group profile, if one is found. If there's no matching candidate in Active Directory, null is returned.

Discussion

This property returns the Active Directory group account that appears to match the pending group profile. If there's an existing Active Directory group that matches the pending group, the pending import group can be mapped to that account. If no matching candidate is found in Active Directory, this property returns a null value.

GID

Gets or sets the UNIX group identifier (GID) for the pending import group profile.

Syntax

```
int GID {get; set;}

long GID {get; set;}
```

Property value

The UNIX group identifier (GID) for the pending group profile.

Discussion

There are two versions of this property: one designed for COM-based programs that supports a 32-bit signed number one designed for .NET-based programs that allows a 64-bit signed number. Therefore, the data type for the property can be an integer (int) or a long integer (long) depending on the programming language you use.

ID

Gets the unique ID of the pending import group object.

Syntax

```
string ID {get;}
```

Property value

The unique ID for the pending import group object.

IsImported

Determines whether the pending import group has been successfully imported.

Syntax

```
bool IsImported {get;}
```

Property value

Returns `true` if the pending import group has been imported, or `false` if the group has not been successfully imported.

Discussion

This property returns `true` if the pending import group has been imported, or `false` if the group has not been imported.

Members

Gets all of a pending import group's members.

Syntax

```
IGroupMembers Members {get;}
```

Property value

The user names for the members of a pending import group.

Name

Gets or sets the UNIX group name for a pending import group.

Syntax

```
string Name {get; set;}
```

Property value

The UNIX group name of a pending import group.

Source

Gets the text string that describes the source of the pending import data.

Syntax

```
string Source {get;}
```

Property value

A text string that describes the source of the pending import data.

Discussion

If the pending data was imported from a file, the property returns the source as File followed by the path to the file name imported. If the source of the pending import data was a NIS server, the property returns the NIS server name and domain. For example, if the source of the data was a file, the property returns a string similar to this:

```
File: C:\\Migration\\magnolia_groups
```

Status

Gets the status of the pending import group.

Syntax

```
StatusType Status {get;}
```

Property value

The status message for the pending import group.

Discussion

The status is determined by checking Active Directory for existing groups that match or conflict with the pending import group. The property returns a number that determines the icon displayed for the group in the console. The icons indicate whether a group is:

Ready to import	Info	
Has potential issues that should be resolved	Warning	
Cannot be imported	Error	

StatusDescription

Gets a text string that provides detailed information about the status of the pending import group.

Syntax

```
string StatusDescription {get;}
```

Property value

The status message for the pending import group.

Discussion

The status is determined by checking Active Directory for existing groups that match or conflict with the pending import group. The results are displayed in Access manager and in the Status tab of a pending group's Properties dialog box. The status description can also include details about the members of the group. For example, if checking the Active Directory forest revealed a group name or GID conflict with an existing group or another pending import group, the StatusDescription property might include information similar to this:

```
There is another pending imported group using the same GID.
There is another pending imported group using the same group name.
Group member:'alan' cannot be associated.
Group member:'rae' cannot be associated.
```

TimeStamp

Gets the date and time that the pending group profiles were imported from the data source.

Syntax

```
DateTime TimeStamp {get;}
```

Property value

The date and time that the pending group data was imported.

Example

The following code sample illustrates using this property in a script:

```
…
'Specify the zone you want to work with
Set objZone = cims.GetZone("w2k3.net/Acme/Zones/default")
‘Display the time groups where imported
Set objPendingGrps = objZone.GetImportPendingGroups
If not objPendingGrps is nothing then
wScript.Echo "Imported from source: ", objPendingGrps.TimeStamp
End if
…
```

Delinea

GroupInfos

The GroupInfos class contains methods and properties used to manage a collection of pending import group profiles. This class is defined in the Centrify.DirectControl.API.Import namespace.

Syntax

```
public interface IGroupInfos : IEnumerable\<IGroupInfo\>, IDisposable
```

Methods

The GroupInfos class provides the following methods:

Dispose	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.
Unexpected Link Text	Returns the pending import group with the specified identifier from the collection of group profiles.
Unexpected Link Text	Returns an enumeration of GroupInfo objects.

Properties

The GroupInfos class provides the following properties:

Unexpected Link Text	Determines the total number of pending import group profiles defined in the collection represented by the GroupInfos object.
Unexpected Link Text	Determines whether the collection of pending import group profiles is empty.

Find

Returns the pending import group with the specified identifier from the collection of group profiles.

Syntax

```
IGroupInfo Find(string id)
```

Parameter

Specify the following parameter when using this method:

id	The unique identifier of the pending group profile for which you want to retrieve information.

Return value

The GroupInfo object for the specified pending import group.

GetEnumerator

Returns an enumeration of IGroupInfo objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of GroupInfo objects.

Count

Determines the total number of pending import group profiles defined in the GroupInfos collection.

Syntax

```
int Count {get;}
```

Property value

The number of pending import group profiles in the set.

Discussion

This property enumerates all of the profiles in the collection before it returns the Count value. If you only need to determine whether any import groups are pending, you should use the IsEmpty property for a faster response time.

IsEmpty

Determines whether the collection of pending import group profiles is empty.

Syntax

```
bool IsEmpty {get;}
```

Property value

Returns `true` if there are no pending import group profiles in the `GroupInfos` object, or `false` if there is at least one pending import group profile in the object.

Discussion

Unlike the Count property, the `IsEmpty` property does not enumerate all of the pending import profiles in the collection before it returns a value. If you only need to determine whether any profiles are defined, you should call this property for a faster response.

GroupMember

The GroupMember class contains properties for working with the individual members of a pending import group. This class is defined in the Centrify.DirectControl.API.Import namespace.

Syntax

```
public interface IGroupMember : IDisposable
```

Methods

The GroupMember class provides the following method:

Dispose	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.

Properties

The GroupMember class provides the following properties:

CandidateDN	Gets or sets the distinguished name (DN) of the pending import group members.
Name	Gets or sets the UNIX user name for a pending import group member.

CandidateDN

Gets or sets the distinguished name (DN) of the pending import group members.

Syntax

```
string CandidateDN {get; set;}
```

Property value

The matching Active Directory group object for pending group profile, if one is found. If there's no matching candidate in Active Directory, nothing is returned.

Discussion

This property returns the Active Directory user account that appears to match the pending group member. If there's an existing Active Directory user that matches the pending import group member, the pending import group member can be mapped to that account.

Name

Gets or sets the UNIX user name for a pending import group member.

Syntax

```
string Name {get; set;}
```

Property value

The UNIX group name of a pending import group member.

GroupMembers

The GroupMembers class contains properties used to manage a collection of pending import group members. This class is defined in the Centrify.DirectControl.API.Import namespace.

Syntax

```
public interface IGroupMembers : IEnumerable\<IGroupMember\>, IDisposable
```

Methods

The GroupMembers class provides the following methods:

Add	Adds a new UNIX user as a member of the pending import group.
AddRange	Adds a list of new UNIX users as members of the pending import group.
Clear	Removes all of the group members from a pending import group.
Dispose	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.
GetEnumerator	Returns an enumeration of GroupMember objects. Inherited from IEnumerable.
Remove	Removes the specified group member from the list of members in a pending import group.

Properties

The GroupMembers class provides the following properties:

Count	Determines the total number of group members in the pending import group.

Add

Adds a new UNIX user account as a member with the specified member name to the pending import group.

Syntax

IGroupMember Add(string memberName)

Parameter

Specify the following parameter when using this method:

memberName	The UNIX user name of the account you want to add to the pending import group.

Return value

The UNIX user you are adding as a member of the pending import group.

AddRange

Adds a list of new UNIX user profiles as members of the pending import group.

Syntax

```
void AddRange(ICollection string memberNames)
```

Parameter

Specify the following parameter when using this method:

memberNames	The list of UNIX user names you want to add as members of the pending import group.

Clear

Removes all of the group members from a pending import group.

Syntax

```
void Clear()
```

Discussion

This method enables you to import a pending import group profile without resolving membership conflicts or mapping group members to Active Directory users.

Remove

Removes the specified group member from the list of members in a pending import group.

Syntax

```
void Remove(IGroupMember member)
```

Parameter

Specify the following parameter when using this method:

member	The member you want to remove from the pending import group

Count

Determines the total number of group members in the pending import group.

Syntax

```
int Count {get;}
```

Property value

The number of group members in the pending import group.

Discussion

This property enumerates the list of members defined in the collection represented by the GroupMembers object.

Delinea

GroupUnixProfile

The GroupUnixProfile class manages the UNIX group profile information of an Active Directory group or a local group in a given zone.

Syntax

public interface IGroupUnixProfile

Discussion

An Active Directory or local group's zone-specific UNIX profile includes the numeric GID value and profile name directory.

Methods

The GroupUnixProfile class provides the following methods:

Commit	Commits changes to the GroupUnixProfile object to Active Directory.
Delete	Marks the UNIX group profile object for deletion from Active Directory.
GetDirectoryEntry	Returns the DirectoryEntry for a UNIX group profile from Active Directory.
Refresh	Reloads the GroupUnixProfile object data from the data in Active Directory.
Validate	Validates data in the GroupUnixProfile object before the changes are committed to Active Directory.

Properties

The GroupUnixProfile class provides the following properties:

ADsPath	Gets the LDAP path to the UNIX group profile.
Cims	Gets the Cims data for the group profile.
Group	Gets the Active Directory group to which the GroupUnixProfile object belongs (Active Directory groups only).
GroupID	Gets or sets the numeric group identifier (GID) for the group profile.
ID	Gets the unique identifier for the UNIX group profile.
IsForeign	Indicates whether the UNIX profile for a group is in a different forest than its corresponding Active Directory group (Active Directory groups only).
IsMembershipRequired	Determines whether an Active Directory group is a required group (Active Directory groups only).
IsOrphan	Indicates whether this UNIX group profile is an orphan (Active Directory groups only).
IsReadable	Indicates whether the Active Directory object is readable.
IsSFU	Indicates whether this UNIX group is an SFU zone profile (Active Directory groups only).
IsWritable	Indicates whether the Active Directory object is writable.

Members	Gets or sets the local group members of the UNIX group profile (local groups only).
Name	Gets or sets the group name of the UNIX group profile.
ProfileState	Gets or sets the profile state of the local group profile (local groups only).
Type	Gets the type of the UNIX group profile.
UnixEnabled	Determines whether the UNIX information is enabled.
Zone	Gets the zone object for the current GroupUnixProfile object.

Commit

Commits any changes or updates to the GroupUnixProfile object and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

This method commits to Active Directory any new or changed values in the group UNIX profile. If an object is marked for deletion, calling this method completes the operation and deletes the object from Active Directory. The method also increments the next available group identifier (GID) by one, if applicable and permitted. The method does not validate the data before saving it in Active Directory.

Exceptions

Commit may throw one of the following exceptions:

- ApplicationException if it failed to get the directory entry of the group profile.
- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- ObjectAlreadyExistsException if the method receives a COMException with an LDAP object already exists error code.

Example

The following code sample illustrates using Commit in a script:

```
...
'Identify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://cn=onsite,cn=Zones,
cn=UNIX,dc=arcade,dc=com")
'Identify the Active Directory group
Set objGroup = cims.GetGroupByPath("CN=escalation,CN=support, DC=arcade,DC=com")

'Remove the membership requirement for the group
Set objGroup.IsMembershipRequired = false
'Save the changes in Active Directory
objGroup.commit
...
```

Delete

Marks the UNIX group profile object for deletion from Active Directory.

Syntax

```
void Delete()
```

Discussion

This method does not delete the group profile-- it only marks it for deletion. After you mark an object for deletion, you must call the Commit method to complete the operation.

Example

The following code sample illustrates using Delete in a script:

```
...
'Identify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://cn=eur007,cn=Zones,
cn=UNIX,dc=ajax,dc=org")
'Get the UNIX group profile you want to delete
set objProfile = objZone.GetGroupUnixProfileByGid(“905”)
objProfile.Delete
...
```

GetDirectoryEntry

Returns an instance of the directory entry for the group's UNIX profile from Active Directory.

Syntax

```
DirectoryEntry GetDirectoryEntry ()
```

Return value

The DirectoryEntry object for the UNIX group profile associated with the Active Directory group.

Discussion

The DirectoryEntry object represents the service connection point associated with the group in the zone.

> **Note:** This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Example

The following code sample illustrates using GetDirectoryEntry in a script:

```
...
// Identify the zone you want to work with
IZone zone = cims.GetZone("ajax.org/UNIX/Zones/NW_Support")
// Display the access control list
foreach (IGroupUnixProfile gpProfile in zone.GetGroupUnixProfiles))
{
// Get the directory entry
DirectoryEntry scp = gpProfile.GetDirectoryEntry();
Console WriteLine(scp.ObjectSecurity.GetSecurityDescriptorSddlForm
(AccessControlSections.Access));
}
...
```

Refresh

Reloads the GroupUnixProfile object data from the data in Active Directory.

Syntax

void Refresh()

Discussion

This method refreshes the group profile information in the cached object to ensure it is synchronized with the latest information in Active Directory.

Example

The following code sample illustrates using Refresh in a script:

```
…
'Identify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://cn=eur007,cn=Zones,
cn=UNIX,dc=ajax,dc=org")
'Get the UNIX group profile you want to work with
set objProfile = objZone.GetGroupUnixProfileByGid(“905”)
'Reload the group profile object from Active Directory
objProfile.Refresh
…
```

Validate

Validates the data in the GroupUnixProfile object before any changes are committed to Active Directory.

Syntax

```
void Validate()
```

Discussion

The method validates the following:

- The group name is a valid string that can contain only letters (upper- or lowercase), numerals 0 through 9, and the hyphen (-) and underscore (_) characters.
- The GID value is a positive integer. Negative numbers are not allowed.
- The group profile does not duplicate an existing group identifier (GID) or group name.

If the GroupUnixProfile object is marked for deletion, the method skips validation tests.

Exceptions

Validate throws an ApplicationException if any field in the UNIX group profile is invalid.

Example

The following code sample illustrates using Validate in a script:

```
...
'Identify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://cn=eur007,cn=Zones,
cn=UNIX,dc=ajax,dc=org")
'Get the UNIX group profile you want to work with
set objProfile = objZone.GetGroupUnixProfileByGid(“905”)
'Validate the UNIX profile associated with the group
objProfile.Validate
...
```

ADsPath

Gets the LDAP path to the UNIX group profile object.

Syntax

```
string ADsPath {get;}
```

Property value

The LDAP path to the UNIX group profile.

Example

The following code sample illustrates using `ADsPath in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the Active Directory group
Set objGroup = cims.GetGroupByPath("LDAP://CN=managers,CN=groups,
DC=sierra,DC=com")
'Get the UNIX profile for the group in the zone
set objGroupUnixProfile = objGroupUnixProfiles.Find(objZone)
'Display the LDAP path for this group profile
wScript.Echo "LDAP Path: " & objGroupUnixProfile.ADsPath
...
```

Cims

Gets the Cims object for the group profile.

Syntax

```
Cims Cims {get;}
```

Property value

The Cims object for the group profile.

Discussion

This property serves as a shortcut for retrieving data.

Example

The following code sample illustrates using Cims in a script:

```
...
function doThings(gp2)
set objZone2 = gp2.Cims.GetZone("ajax.org/Zones/test")
gp2.Group.AddUnixProfile objZone2,objProfile.Gid,objProfile.Name
end function
set cims = CreateObject("Centrify.DirectControl.Cims3")
set objZone = cims.GetZone("ajax.org/Zones/default")
for each gp2 in objZone.GetGroupUnixProfiles
doThings gp2
next
...
```

Group

Gets the Active Directory group object associated with the specified GroupUnixProfile object.

Syntax

IGroup Group {get;}

Property value

The Active Directory group object associated with the UNIX group profile.

Example

The following code sample illustrates using Group in a script:

```
...
'Identify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/eur007")
'Get the UNIX group profile you want to work with
set objProfile = objZone.GetGroupUnixProfileByGid("905")
'Display the LDAP path to the profile's Active Directory group
wScript.Echo "LDAP path: " & objProfile.Group.ADsPath
...
```

GroupID

Gets the numeric group identifier (GID) for the group profile or sets a new GID for the specified Active Directory group in the specified zone.

Syntax

```
long GroupID {get; set;}
```

Property value

The numeric value of the UNIX GID for the UNIX profile in the zone.

Discussion

This property supports a 64-bit signed number for .NET modules.

Exceptions

`GroupID` throws and `InvalidOperationException` if the GID is `null` (that is, there is only a partial profile).

ID

Gets the unique identifier for the UNIX group profile from Active Directory.

Syntax

```
string ID {get;}
```

Property value

The unique identifier for this UNIX group profile.

Example

The following code sample illustrates using ID in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,CN=zones,
CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the Active Directory group
Set objGroup = cims.GetGroupByPath("LDAP://CN=managers,CN=groups,
DC=sierra,DC=com")
'Get the UNIX profile for the group in the zone
set objGroupUnixProfile = objGroupUnixProfiles.Find(objZone)
'Display the unique ID for this group
wScript.Echo "Unique ID: " & objGroupUnixProfile.ID
...
```

IsForeign

Indicates whether the corresponding Active Directory group for a UNIX profile is in a different Active Directory forest than the forest associated with the group profile in the zone.

Syntax

```
bool IsForeign {get;}
```

Property value

Returns true if the UNIX profile is associated with an Active Directory group in a different forest.

Discussion

If the Active Directory group is in a different forest than the one associated with a top-level Delinea data object (Cims object), the property returns true.

> **Note:** This property is always false for newly-created groups before the group object is committed to Active Directory.

Example

The following code sample illustrates using IsForeign in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Check the forest for groups in the zone
For each profile in objZone.GetGroupUnixProfiles
if profile.IsForeign then
wScript.Echo profile.Name
end if
next
...
```

IsMembershipRequired

Determines whether the Active Directory group is a required group for its members.

Syntax

```
bool IsMembershipRequired {get; set;}
```

Property value

Returns true if the UNIX profile associated with an Active Directory group is marked as a required group.

Discussion

If this property is true, users cannot use the adsetgroups command to remove the group from the currently active set of groups. If this property is false, users who are members of the group can add or remove the group from their list of active groups at any time.

For more information about making a group required, see the *Administrator's Guide for Linux and UNIX*.

Exceptions

IsMembershipRequired throws an InvalidOperationException if there is only a partial profile.

Example

The following code sample illustrates using IsMembershipRequired in a script:

```
...
Set objZone = cims.GetZoneByPath("LDAP://CN=research,CN=zones,
CN=centrify,CN=program data,DC=sierra,DC=com")
'Get the UNIX group profile you want to work with
set objProfile = objZone.GetGroupUnixProfileByGid("905")
'Make this group a required group for its members
Set objProfile.IsMembershipRequired = true
...
```

IsOrphan

Indicates whether this UNIX group profile is an orphan.

Syntax

```
bool IsOrphan {get;}
```

Property value

Returns `true` if the GroupUnixProfile object has no corresponding Active Directory group object, or `false` if the object has a corresponding Active Directory group object.

Discussion

The UNIX group profile is an orphan if the corresponding Active Directory group object is missing.

Exceptions

`IsOrphan` throws an `ApplicationException` if the group profile does not exist.

Example

The following code sample illustrates using `IsOrphan in a script:

```
...
'Identify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/eur007")
'Check for orphan profiles
for each profile in objZone.GetGroupUnixProfiles
If profile.IsOrphan then
wScript.Echo profile.Name
end if
next
...
```

IsReadable

Indicates whether the group profile object in Active Directory is readable for the current user credentials.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns true if the GroupUnixProfile object is readable, or false if the object is not readable.

Discussion

This property returns a value of true if the user accessing the group profile object in Active Directory has sufficient permissions to read its properties.

Example

The following code sample illustrates using IsReadable in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the Active Directory group
Set objGroup =
cims.GetGroupByPath("LDAP://CN=testers,CN=groups,DC=sierra,DC=com")
'Get the UNIX profile for the group in the zone
set objGroupUnixProfile = objGroupUnixProfiles.Find(objZone)
'Check whether the object is readable
if not objGroupUnixProfile.IsReadable then
wScript.Echo "Denied read access. Exiting ...."
wScript.Quit
else
wScript.Echo "Read permission granted. Continuing ...."
wScript.Echo "Group Profile GID: " & objGroupUnixProfile.GID
end if
...
```

IsSFU

Indicates whether this group profile is an SFU zone profile.

Syntax

```
bool IsSFU {get;}
```

Property value

Returns `true` if the `GroupUnixProfile` object is an SFU zone profile.

Discussion

See Data storage for Delinea zones for a discussion of SFU zones.

IsWritable

Indicates whether the group profile object in Active Directory is writable for the current user's credentials.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns `true` if the `GroupUnixProfile` object is writable, or `false` if the object is not writable.

Discussion

This property returns a value of `true` if the user accessing the group profile object in Active Directory has sufficient permissions to change the group profile object's properties.

Example

The following code sample illustrates using `IsWritable` in a script:

```
...
set objZone =
cims.GetZoneByPath("LDAP://CN=research,CN=zones,CN=centrify,CN=program
data,DC=sierra,DC=com")
'Identify the Active Directory group
Set objGroup =
cims.GetGroupByPath("LDAP://CN=testers,CN=groups,DC=sierra,DC=com")
'Get the UNIX profile for the group in the zone
set objGroupUnixProfile = objGroupUnixProfiles.Find(objZone)
'Check whether the object is writable
if not objGroupUnixProfile.IsWritable then
wScript.Echo "Denied write access. Exiting ...."
wScript.Quit
else
wScript.Echo "Write permission granted. Continuing ...."
wScript.Echo "Group Profile GID: " & objGroupUnixProfile.GID
end if
...
```

Members

Gets an existing list of members or sets a new list of members for the UNIX group profile associated with the specified local group.

Syntax

```
string[] Members{get; set;}
```

Property value

The members of a local group.

Exceptions

Members throws an InvalidOperationException if the group you specify is not a local group.

Delinea

ProfileState

Gets the profile state of an existing local group or sets the profile of the specified local group.

Syntax

```
GroupProfileState ProfileState{get; set;}
```

Property value

The profile state of the specified local group.

Exceptions

ProfileState throws an InvalidOperationException if the group you specify is not a local group.

Name

Gets an existing name or sets a new name for the UNIX group profile associated with the specified Active Directory group in the specified zone.

Syntax

```
string Name {get; set;}
```

Property value

The UNIX group name for the UNIX profile in the zone.

Example

The following code sample illustrates using Name in a script:

```
…
set objZone =
cims.GetZoneByPath("LDAP://CN=research,CN=zones,CN=centrify,CN=program
data,DC=sierra,DC=com")
'Identify the Active Directory group
Set objGroup =
cims.GetGroupByPath("LDAP://CN=managers,CN=groups,DC=sierra,DC=com”)
'Get the UNIX profile for the group in the zone
set objGroupUnixProfile = objGroupUnixProfiles.Find(objZone)
wScript.Echo "Group Profile Name: " & objGroupUnixProfile.Name
…
```

`[title]: # (Type) [tags]: # (windows api) [priority]: # (21)

Type

Gets the type of the UNIX group profile.

Syntax

GroupUnixProfileType Type {get;}

Property value

Returns one of the following numeric values depending on how the UNIX group profile is stored:

- 0 indicates the group profile is a standard Delinea UNIX profile.
- 1 indicates the profile is a private group stored in a Private Groups container.
- 2 indicates the profile is a Delinea SFU profile.
- 3 indicates the profile is a local group.

Discussion

The Private group type is only applicable to early versions of Delinea software. It is not a valid group profile type in version 4.0 and later.

Example

The following code sample illustrates using Type in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data,DC=sierra,DC=com")
'Identify the Active Directory group
Set objGroup =
cims.GetGroupByPath("LDAP://CN=escalation,CN=support,DC=sierra,DC=com")
'Get the UNIX profile for the group in the zone
set objGroupUnixProfile = objGroupUnixProfiles.Find(objZone)
Select Case objGroupUnixProfile.Type
Case 0
wScript.Echo "Standard group"
Case 1
wScript.Echo "Private group"
Case 2
wScript.Echo "SFU group"
End Select
...
```

UnixEnabled

Determines whether the UNIX information is enabled.

Syntax

```
bool UnixEnabled {get; set;}
```

Property value

Set `true` if the UNIX information is enabled.

Example

For a code sample that uses the `UnixEnabled` property, see AddUnixProfile.

Zone

Gets the zone object for the current group unix profile.

Syntax

IZone Zone {get;}

Property value

The zone object for the UNIX group profile.

Discussion

This property serves as a shortcut for retrieving data.

GroupUnixProfiles

The GroupUnixProfiles class manages a collection of group profiles in a zone.

Syntax

```
public interface IGroupUnixProfiles
```

Discussion

The content of the collection of group profiles contained in the object depends on how the object was obtained:

- When you use GetUserUnixProfiles, the GroupUnixProfiles object returned enumerates all of the profiles defined for a specific Active Directory user across all zones in the current domain.
- When you use GetGroupUnixProfiles, the GroupUnixProfiles object returned enumerates all of the profiles defined for a specific Active Directory group in a specific zone.

Methods

The GroupUnixProfiles class provides the following methods:

GetEnumerator	Returns an enumeration of GroupUnixProfile objects.
Refresh	Reloads the GroupUnixProfiles object data from the data in Active Directory.

Properties

The GroupUnixProfiles class provides the following properties:

Count	Gets the total number of UNIX group profiles in the collection of GroupUnixProfiles for an Active Directory group.
IsEmpty	Indicates whether the GroupUnixProfiles object contains any UNIX group profiles.

GetEnumerator

Returns an enumeration of GroupUnixProfile objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

An enumeration of GroupUnixProfile objects.

Refresh

Reloads the GroupUnixProfiles object data from the data in Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the collection of group profiles in the cached object to ensure it is synchronized with the latest information in Active Directory.

Count

Gets the total number of UNIX group profiles defined in the GroupUnixProfiles collection for an Active Directory group or zone.

Syntax

```
int Count {get;}
```

Property value

The number of UNIX group profiles in the GroupUnixProfiles collection.

Discussion

This property enumerates all of the profiles in the collection before it returns the Count value. If you only need to determine whether any profiles are defined, use the IsEmpty property for a faster response time.

Example

The following code sample illustrates using Count in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data, DC=sierra, DC=com")
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data, DC=sierra, DC=com")
If objGroupUnixProfiles.IsEmpty then
wscript.echo "No profiles defined"
Else
wscript.echo objGroupUnixProfiles.Count & " profiles defined"
End if
...
```

IsEmpty

Indicates whether the collection of UNIX group profiles is empty.

Syntax

```
bool IsEmpty {get;}
```

Property value

Returns true if there are no group profiles in the GroupUnixProfiles object, or false if there is at least one UNIX group profile in the object.

Discussion

Unlike the Count property, the IsEmpty property does not query all of the profiles in the collection before it returns a value. If you only need to determine whether any profiles are defined, call this property for a faster response.

Example

The following code sample illustrates using IsEmpty in a script:

```
...
set objZone = cims.GetZoneByPath("LDAP://CN=research,
CN=zones,CN=centrify,CN=program data, DC=sierra, DC=com")
If objGroupUnixProfiles.IsEmpty then
wscript.echo "No profiles defined”
Else
wscript.echo objGroupUnixProfiles.Count & " profiles defined”
End if
...
```

HierarchicalGroup

The HierarchicalGroup class manages the UNIX group profile information of an Active Directory group in a hierarchical zone, as well as local groups.

Syntax

```
public interface IHierarchicalGroup : IGroupUnixProfile
```

Methods

The HierarchicalGroup class provides the following methods:

Unexpected Link Text	Commits changes to the GroupUnixProfile object to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Marks the UNIX group profile object for deletion from Active Directory. (Inherited from Unexpected Link Text).
Unexpected Link Text	Returns the computer to which this group profile belongs.
Unexpected Link Text	Returns the directory entry for a UNIX group profile from Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Clears all property values so that all UNIX attributes for this user are inherited from the parent zone.
Unexpected Link Text	Reloads the GroupUnixProfile object data from the data in Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Resolves the effective profile.
Unexpected Link Text	Validates data in the GroupUnixProfile object before the changes are committed to Active Directory. (Inherited from Unexpected Link Text.)

Properties

The HierarchicalGroup class provides the following properties:

Unexpected Link Text	Gets the LDAP path to the UNIX group profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the Cims data for the group profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the effective GID of the group.
Unexpected Link Text	Indicates whether members of this group can remove the group from their currently active set of groups (not applicable to local groups).

Unexpected Link Text	Gets members of the local group (local groups only).
Unexpected Link Text	Gets the UNIX name of the group (not applicable to local groups).
Unexpected Link Text	Gets the profile state of the local group (local groups only).
Unexpected Link Text	Gets the Active Directory group to which the GroupUnixProfile object belongs (not applicable to local groups). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the numeric group identifier (GID) for the group profile. (Unexpected Link Text.)
Unexpected Link Text	Gets the unique identifier for the UNIX group profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether there is an effective GID for this group.
Unexpected Link Text	Indicates whether there is an effective membership requirement for this group (not applicable to local groups).
Unexpected Link Text	Indicates whether EffectiveMembers is defined for this group (local groups only).
Unexpected Link Text	Indicates whether there is an effective name for this group.
Unexpected Link Text	Indicates whether there is an effective profile state defined for this group (local groups only).
Unexpected Link Text	Determines whether the profile state is defined for this group (local groups only).
Unexpected Link Text	Indicates whether the UNIX profile for a group is in a different forest than its corresponding Active Directory group (not applicable to local groups). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the GID is defined for this group.
Unexpected Link Text	Determines whether Members is defined for this local group (local groups only).
Unexpected Link Text	Determines whether an Active Directory group is a required group (not applicable to local groups). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the membership requirement is defined for this group (not applicable to local groups).
Unexpected Link Text	Determines whether a name is defined for this group.
Unexpected Link Text	Indicates whether this UNIX group profile is an orphan (not applicable to local groups). (Inherited from Unexpected Link Text.)

Unexpected Link Text	Determines whether the Active Directory object is readable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether this UNIX group is an SFU zone profile (not applicable to local groups). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the Active Directory object is writable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets an existing list of members or sets a new list of members for the UNIX group profile associated with the specified local group (local groups only). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the group name of the UNIX group profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the profile state of a local group (local groups only). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the type of the UNIX group profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the UNIX information is enabled. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the zone associated with the UNIX group (inherited from Unexpected Link Text)
Unexpected Link Text	Gets the zone to which this group profile belongs.

GetComputer

Returns the computer to which this group profile belongs.

Syntax

```
IHierarchicalZoneComputer GetComputer()
```

Return value

Returns a hierarchical zone computer object specifying the computer to which this group profile belongs. Returns `null` if the group profile is not associated with a specific computer.

InheritFromParent

This method clears all current-level property values so that all property values are inherited from ancestor zones or from defaults.

Syntax

```
void InheritFromParent()
```

Discussion

This method clears all current-level property values so that all property values are inherited from ancestor zones or from defaults. This is a convenience method that is equivalent to resetting all properties to `null`.

ResolveEffectiveProfile

Resolves the effective profile for the group.

Syntax

```
void ResolveEffectiveProfile()
```

Discussion

This method resolves profiles of the group defined in the current zone, in parent zones, and in zone default values to determine the effective profile. If an error occurs, such as one of the parent zones not being accessible, the effective profile properties show the best-effort data retrieved before the error occurred.

EffectiveGid

Gets the GID of the group.

Syntax

```
long EffectiveGid {get;}
```

Property value

The GID in the UNIX group profile.

Exceptions

EffectiveGid throws an InvalidOperationException if the UNIX group profile does not include a GID.

EffectiveMembers

Gets the members of the local group.

Syntax

```
string[] EffectiveMembers {get;}
```

Property value

The members of the group.

Exceptions

EffectiveGid throws an InvalidOperationException if the UNIX group profile does not have members defined, or if this is not a local group profile and you attempt to set or get this property.

EffectiveIsMembershipRequired

Indicates whether members of this group can remove the group from their currently active set of groups.

Syntax

```
bool EffectiveIsMembershipRequired {get;}
```

Property value

Returns true if you can use the adsetgroups command to remove this group from your currently active set of groups.

Discussion

On most UNIX systems, a user can be a member of only a limited number of groups at one time. Because of this limitation, it is useful to be able to change a user's group membership by adding and removing groups when necessary.

You can use the adsetgroups command to manage the set of Active Directory groups that are available to a UNIX account. You also have the option to specify that membership in a specific group is required in a zone.

If you specify that a group is required, users who are members of the group cannot remove that group from their currently active set of groups. In that case, the EffectiveIsMembershipRequired property returns false.

Exceptions

IsEffectiveMembershipRequired throw an InvalidOperationException if there is only a partial profile.

EffectiveName

Gets the UNIX name of the group.

Syntax

```
string EffectiveName {get;}
```

Property value

The group name in the UNIX group profile.

EffectiveProfileState

Gets the profile state of the local group.

Syntax

```
GroupProfileState EffectiveProfileState {get;}
```

Property value

The profile state of the local group.

Exceptions

`EffectiveProfileState` throws an `InvalidOperationException` if the UNIX group profile does not have a profile state defined, or if this is not a local group profile and you attempt to get this property.

IsEffectiveGidDefined

Indicates whether there is an effective GID for this group.

Syntax

```
bool IsEffectiveGidDefined {get;}
```

Property value

Returns true if there is a UNIX group identifier (GID) in the UNIX group profile.

Discussion

If the Unexpected Link Text method has not been called, the value is resolved the first time this property is accessed.

IsEffectiveIsMembershipRequiredDefined

Indicates whether there is an effective membership requirement for this group.

Syntax

```
bool IsEffectiveIsMembershipRequiredDefined {get;}
```

Property value

Returns `true` if there is an effective membership requirement for this group.

Discussion

If the Unexpected Link Text method has not been called, the value is resolved the first time this property is accessed.

IsEffectiveMembersDefined

Indicates whether there is an effective members requirement for this local group.

Syntax

```
bool IsEffectiveMembersDefined {get;}
```

Property value

Returns `true` if there is an effective members requirement for this group.

Discussion

If the Unexpected Link Text method has not been called, the value is resolved the first time this property is accessed.

Exceptions

`IsEffectiveMembersDefined` throws an `InvalidOperationException` if this is not a local group profile and you attempt to get this property.

This property is only applicable to local groups.

IsEffectiveNameDefined

Indicates whether there is an effective name for this group.

Syntax

```
bool IsEffectiveNameDefined {get;}
```

Property value

Returns true if there is an effective name for this group.

Discussion

If the Unexpected Link Text method has not been called, the value is resolved the first time this property is accessed.

IsEffectiveProfileStateDefined

Indicates whether there is an effective profile state for this local group.

Syntax

```
bool IsEffectiveProfileStateDefined {get;}
```

Property value

Returns `true` if there is an effective profile state for this group.

Discussion

If the Unexpected Link Text method has not been called, the value is resolved the first time this property is accessed.

This property is only applicable to a local group profile.

Exceptions

`IsEffectiveProfileStateDefined` throws an `InvalidOperationException` if this is not a local group profile and you attempt to get this property.

IsGidDefined

Determines whether there is a GID defined for this group.

Syntax

```
bool IsGidDefined {get; set;}
```

Property value

Returns `true` if there is a GID defined for this group. Set this property false to clear the GID.

Exceptions

`IsGidDefined` throws an `InvalidOperationException` if the GID has not been defined and you attempt to set this property true.

IsMembersDefined

Indicates whether Members is defined for this local group.

Syntax

```
bool IsMembersDefined {get; set;}
```

Property value

Returns true if Unexpected Link Text is defined for this group. Set this property false to clear Unexpected Link Text.

Exceptions

IsMembers throws an InvalidOperationException if:

- Unexpected Link Text has not been defined and you attempt to set this property true.
- If this is not a local group and you attempt to set or get this property.

IsMembershipRequiredDefined

Determines whether the membership requirement is defined for this group.

Syntax

```
bool IsMembershipRequiredDefined {get; set;}
```

Property value

Returns true if the membership requirement is defined for this group. Set this property false to clear the Unexpected Link Text flag.

Exceptions

IsMembershipRequiredDefined throws an InvalidOperationException if the Unexpected Link Text flag has not been defined and you attempt to set this property true.

IsNameDefined

Determines whether the name is defined for this group.

Syntax

```
bool IsNameDefined {get; set;}
```

Property value

Returns `true` if the name is defined for this group. Set this property `false` to clear the name.

Exceptions

`IsNameDefined` throws an `InvalidOperationException` if the name has not been defined and you attempt to set this property true.

IsProfileStateDefined

Indicates whether there is a profile state defined for this local group.

Syntax

```
bool IsProfileStateDefined {get;}
```

Property value

Returns `true` if there is an a profile state defined for this group.

Discussion

Setting this property to `false` will clear Unexpected Link Text.

Exceptions

`IsProfileStateDefined` throws an `InvalidOperationException` if:

- Unexpected Link Text is not defined and you attempt to set this property to true.
- This is not a local group profile and you attempt to set or get this property.

Zone

Gets the zone to which this group profile belongs.

Syntax

```
IHierarchicalZone Zone {get;}
```

Property value

The zone to which this group profile belongs; `null` if this is a computer-specific profile.

Delinea

HierarchicalUser

The HierarchicalUser class manages the UNIX user profile information of an Active Directory user in a hierarchical zone.

Syntax

```
public interface IHierarchicalUser : IUserUnixProfile
```

Discussion

In hierarchical zones, both identity (profile data) and access (authorization data) are inherited, such that a user's effective identity or access are determined by all the profile data and all the access data at all levels of the hierarchy.

Profile data can be defined at any level: parent, child, or computer. It is possible to define a partial profile at any level — that is, leave one or more of the NSS fields blank. Although a complete profile is required to have access to a machine, a profile in a child zone can complete the missing fields from the parent zone. In the case of conflict, profile definitions in a child zone override the definition in the parent zone and computer-level definitions override all zone-level definitions.

On the other hand, role assignments do not override each other. Rather, they accumulate, such that a user's potential rights include all the rights granted by all the role assignments in the access tree. These are *potential* rights because rights granted to a user by a role assignment are effective only if the user has a complete profile defined for a zone.

In other words, when a computer joins a zone, the profile tree determines a pool of potential users, the access tree determines a different set of users with rights, and where the two intersect is the set of effective users.

See the Unexpected Link Text class for a user's Windows profile.

Methods

The HierarchicalUser class provides the following methods:

Unexpected Link Text	Returns a new user role assignment.
Unexpected Link Text	Commits changes to the userUnixProfile object to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Marks the UNIX user profile object for deletion from Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the computer to which this user profile belongs.
Unexpected Link Text	Returns the directory entry for a UNIX user profile from Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the effective user role assignments.
Unexpected Link Text	Returns the UNIX profile of the primary group of the user. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns a user role assignment for this UNIX user.
Unexpected Link Text	Returns all the user role assignments for this UNIX user.

Unexpected Link Text	Clears all property values so that all UNIX attributes for this user are inherited from the parent zone.
Unexpected Link Text	Reloads the userUnixProfile object data from the data in Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Resolves the effective profile to be used when the user logs on to the computer.
Unexpected Link Text	Resolves the effective roles for this user.
Unexpected Link Text	Validates data in the userUnixProfile object before the changes are committed to Active Directory. (Inherited from Unexpected Link Text.)

Properties

The HierarchicalUser class provides the following properties:

Unexpected Link Text	Gets the LDAP path to the UNIX user profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the Cims data for the user profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the contents of the effective GECOS field of the user profile.
Unexpected Link Text	Gets the hierarchical zone of the effective GECOS.
Unexpected Link Text	Gets the effective home directory of the user.
Unexpected Link Text	Gets the zone of the user's home directory.
Unexpected Link Text	Indicates whether this user uses an auto private group (not applicable to local user profiles).
Unexpected Link Text	Gets the user's effective logon name.
Unexpected Link Text	Gets the zone of the user's effective UNIX name.
Unexpected Link Text	Gets the effective primary group GID of the user.
Unexpected Link Text	Gets the zone of the primary group GID.

Unexpected Link Text	Gets the effective profile state of the local user (local user profiles only).
Unexpected Link Text	Gets the zone which defines the effective profile state
Unexpected Link Text	Gets the effective logon shell of the user.
Unexpected Link Text	Gets the zone of the effective logon shell.
Unexpected Link Text	Gets the effective UID of the user.
Unexpected Link Text	Gets the zone of the user's effective UID.
Unexpected Link Text	Gets or sets the contents of the GECOS field explicitly set in the user profile of the current zone.
Unexpected Link Text	Gets or sets the home directory of the user. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the unique identifier for the UNIX user profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether there is an effective GECOS for this user.
Unexpected Link Text	Indicates whether there is an effective home directory defined for this user.
Unexpected Link Text	Indicates whether there is an effective name for this user.
Unexpected Link Text	Indicates whether a primary group is defined for this user.
Unexpected Link Text	Indicates whether there is an effective profile state for this local user (local user profiles only).
Unexpected Link Text	Indicates whether there is an effective shell defined for this user.
Unexpected Link Text	Indicates whether the user has an effective UID.
Unexpected Link Text	Indicates whether the auto private group flag is defined for this user (not applicable to local user profiles).
Unexpected Link Text	Indicates whether the UNIX profile for a user is in a different forest than its corresponding Active Directory user (not applicable to local user profiles). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the GECOS is defined in this profile.

Unexpected Link Text	Determines whether the home directory is defined in this profile.
Unexpected Link Text	Determines whether a name is defined in this profile.
Unexpected Link Text	Indicates whether this UNIX user profile is an orphan (not applicable to local user profiles). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether there is a GID defined for this user in this zone.
Unexpected Link Text	Gets or sets whether the profile state is defined in this local user profile (local user profiles only).
Unexpected Link Text	Determines whether the Active Directory object is readable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether this is a secondary profile (not applicable to local user profiles).
Unexpected Link Text	Indicates whether this user object uses the Microsoft Services for UNIX (SFU) schema extension (not applicable to local user profiles). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the shell is defined in this profile.
Unexpected Link Text	Determines whether the ID is defined in this profile.
Unexpected Link Text	Determines whether this user uses auto private groups (not applicable to local user profiles).
Unexpected Link Text	Determines whether the auto private group flag is defined (not applicable to local user profiles).
Unexpected Link Text	Determines whether the Active Directory object is writable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the user name of the UNIX user profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the GID of the user's primary group. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the profile state of a local user profile (local user profiles only). (Inherited from Unexpected Link Text)
Unexpected Link Text	Gets or sets the user's default shell. (Inherited from UserUnUnexpected Link TextixProfile.)
Unexpected Link Text	Gets the type of the UNIX user profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the UNIX information is enabled. (Inherited from Unexpected Link Text.)

Unexpected Link Text	Gets the user to whom this UNIX profile belongs (not applicable to local user profiles). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the user identifier (UID) for the user profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the zone associated with the UNIX user (inherited from Unexpected Link Text) Gets the zone to which this user profile belongs.

AddUserRoleAssignment

Adds a user role assignment to the user profile.

Syntax

IRoleAssignment AddUserRoleAssignment()

Return value

An empty user role assignment object. This role assignment is not stored in Active Directory until you call the RoleAssignment:[Commit](dev/windows-api/object-reference/computerrole/commit.md) method.

Discussion

This object is not saved to Active Directory until you set at least one property value and call the Unexpected Link Text method.

Example

The following code sample illustrates using AddUserRoleAssignment in a script:

```
...
IHierarchicalUser objUserUnixProfile = (IHierarchicalUser)
objZone.GetUserUnixProfile(objUser);
if (objUserUnixProfile == null)
{
    // New user for the zone
    objUserUnixProfile = objZone.AddUserPartialProfile(strUser);
}
IRole objRole = objZone.GetRole(strRole);
if (objRole == null)
{
    Console.WriteLine("Role " + strRole + " does not exist.");
    return;
}
IRoleAssignment asg = objUserUnixProfile.GetUserRoleAssignment(objRole);
if (asg != null)
{
    Console.WriteLine("Assignment already exist.");
    return;
}
else
{
    // assigning role to user
    asg = objUserUnixProfile.AddUserRoleAssignment();
    asg.Role = objZone.GetRole(strRole);
    asg.Commit();
    Console.WriteLine("Role " + strRole + " was successfully assigned to " + strUser
        \+ ".");
}
...
```

GetComputer

Returns the computer to which this user profile belongs.

Syntax

```
IHierarchicalZoneComputer GetComputer ()
```

Return value

Returns a hierarchical zone computer object specifying the computer to which this user profile belongs. Returns `null` if the user profile is not associated with a specific computer.

GetEffectiveUserRoleAssignments

Returns an enumeration of the effective user role assignments.

Syntax

```
IRoleAssignments GetEffectiveUserRoleAssignments()
```

Return value

An enumeration of the effective user role assignments for this user.

Discussion

The collection of effective role assignments is a combination of all the role assignments for this user in this zone and all parent zones. See the Unexpected Link Text class for a more complete discussion.

GetUserRoleAssignment

Returns the role assignment for a specific role for this user.

Syntax

```
IRoleAssignment GetUserRoleAssignment(IRole role)
```

Parameter

Specify the following parameter when using this method:

role	The role for which you want the role assignment.

Return value

The role assignment that associates this user with the specified role. Returns null if none exists.

Exceptions

GetUserRoleAssignment throws an ArgumentNullException if you pass null for the role parameter.

Example

The following code sample illustrates using GetUserRoleAssignment in a script:

```
...
// Create a CIMS object to interact with AD'
ICims cims = new Cims();
// Note: There is no cims.connect function.'
// By default, this application will use the connection to the domain controller

// and existing credentials from the computer already logged in.
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

IUser objUser = cims.GetUserByPath(strUser);
if (objUser == null)
{
    Console.WriteLine("User " + strUser + " does not exist.");
    return;
}
IHierarchicalUser objUnixUser = objZone.GetUserUnixProfile(objUser) as
IHierarchicalUser;
if (objUnixUser == null)
{
    objUnixUser = objZone.AddUserPartialProfile(strUser);
}
IRole objRole = objZone.GetRole(strRoleName);
if (objRole == null)
{
    Console.WriteLine("Role " + strRoleName + " does not exist.");
    return;
}
IRoleAssignment objAsg = objUnixUser.GetUserRoleAssignment(objRole);
if (objAsg == null)
{
    Console.WriteLine("Role assginment does not exist.");
    return;
}
else
{
    objAsg.Delete();
    Console.WriteLine("Role " + strRoleName + " was successfully removed from user "
        \+ strUser);
}
...
```

GetUserRoleAssignments

Returns an enumeration of the role assignments for this UNIX user.

Syntax

```
IRoleAssignments GetUserRoleAssignments()
```

Return value

An enumeration of the role assignments for this user in this zone.

Discussion

Call the Unexpected Link Text method to get the effective collection of role assignments, including those defined for this user in parent zones.

InheritFromParent

Clears all property values so that all UNIX attributes for this user are inherited from the parent zone.

Syntax

```
void InheritFromParent()
```

Discussion

This method clears all current-level property values so that all property values are inherited from ancestor zones or from defaults. This is a convenience method that is equivalent to resetting all properties to `null`.

ResolveEffectiveProfile

Resolves the profile for the user that is effective when the user logs on to the computer.

Syntax

```
void ResolveEffectiveProfile()
```

Discussion

This method resolves the profiles of the user in the current zone and parent zones, plus zone default values (if any), to determine effective profile values. If an error occurs, such as one of the parent zones not being accessible, the effective profile properties show the best-effort data retrieved before the error occurred.

You must call this method before calling any of the properties that return effective profile values.

ResolveEffectiveRoles

Resolves the effective roles for the user.

Syntax

```
void ResolveEffectiveRoles(IHierarchicalZone zone)
void ResolveEffectiveRoles(IHierarchicalZoneComputer computer)
```

Parameters

Specify one of the following parameters when using this method.

zone	The zone for which you want the group and user role assignments.
computer	The computer for which you want the group and user role assignments.

Discussion

This method resolves the groups and roles of the user in the specified zone or computer and parent zones. If you specify a zone, the method ignores computer-level roles and groups. If you specify a computer, the method considers only roles and groups defined for that computer. For a discussion of roles in hierarchical zones, see the Unexpected Link Text class.

EffectiveGecos

Gets the effective GECOS field of the user profile.

Syntax

```
string EffectiveGecos {get;}
```

Property value

The contents of the GECOS field of the effective profile for this user.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns the unresolved value at the current hierarchical level, or `null` if there is none.

EffectiveGecosZone

Gets the zone in which the effective GECOS field is defined.

Syntax

```
IHierarchicalZone EffectiveGecosZone {get;}
```

Property value

The lowest-level hierarchical zone where the GECOS field is defined. This value overrides any definitions in higher-level zones.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns null.

Call the Unexpected Link Text method to get or set the GECOS field for the current zone.

EffectiveHomeDirectory

Gets the effective home directory of the user.

Syntax

```
string EffectiveHomeDirectory {get;}
```

Property value

The contents of the home directory field of the effective profile for this user.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns the unresolved value at the current hierarchical level, or `null` if there is none.

EffectiveHomeDirectoryZone

Gets the zone in which the effective home directory of the user is defined.

Syntax

```
IHierarchicalZone EffectiveHomeDirectoryZone {get;}
```

Property value

The lowest-level hierarchical zone where the home directory field is defined. This value overrides any definitions in higher-level zones.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns `null`.

EffectiveIsUseAutoPrivateGroup

Indicates whether the effective user profile enables auto private groups.

Syntax

```
bool EffectiveIsUseAutoPrivateGroup {get;}
```

Property value

Returns `true` if the effective profile for this user enables auto private groups.

Discussion

Auto private group sets the user's UNIX profile name as the group name and the user's UID as the group GID.

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns the unresolved value at the current hierarchical level, or `null` if there is none.

EffectiveName

Gets the user's effective logon name.

Syntax

```
string EffectiveName {get;}
```

Property value

The contents of the logon name field of the effective profile for this user.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns the unresolved value at the current hierarchical level, or `null` if there is none.

EffectiveNameZone

Gets the zone in which the effective logon name of the user is defined.

Syntax

```
IHierarchicalZone EffectiveNameZone {get;}
```

Property value

The lowest-level hierarchical zone where the logon name field is defined. This value overrides any definitions in higher-level zones.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns `null`.

EffectivePrimaryGroup

Gets the GID of the effective primary group from the user profile.

Syntax

```
long EffectivePrimaryGroup {get;}
```

Property value

The contents of the primary group field of the effective profile for this user.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns the unresolved value at the current hierarchical level, or `null` if there is none.

EffectiveProfileState

Gets the effective profile state of the local user.

Syntax

```
UserProfileState EffectiveProfileState{get;}
```

Property value

The contents of the profile state filed of the effective profile for this local user.

Discussion

If `ResolveEffectiveProfile()` has not been called, this property will return either null, or the explicit value.

Exceptions

`EffectiveProfileState` throws an `InvalidOperationException` if this is not a local user profile and you attempt to get this property.

EffectiveProfileStateZone

Gets the zone which defines the effective profile state.

Syntax

```
IHierarchicalZone EffectiveProfileStateZone{get;}
```

Property value

The lowest-level hierarchical zone where the profile state field is defined. This value overrides any definitions in higher-level zones.

Discussion

If `ResolveEffectiveProfile()` has not been called, this property will always return null.

Exceptions

`EffectiveProfileStateZone` throws an `InvalidOperationException` if this is not a local user profile and you attempt to get this property.

Delinea

EffectivePrimaryGroupZone

Gets the zone in which the GID of the effective primary group of the user is defined.

Syntax

```
IHierarchicalZone EffectivePrimaryGroupZone {get;}
```

Property value

The lowest-level hierarchical zone where the primary group field is defined. This value overrides any definitions in higher-level zones.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns `null`.

EffectiveShell

Gets the user's effective logon shell.

Syntax

```
string EffectiveShell {get;}
```

Property value

The contents of the logon shell field of the effective profile for this user.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns the unresolved value at the current hierarchical level, or `null` if there is none.

EffectiveShellZone

Gets the zone in which the user's effective logon shell is defined.

Syntax

```
IHierarchicalZone EffectiveShellZone {get;}
```

Property value

The lowest-level hierarchical zone where the logon shell field is defined. This value overrides any definitions in higher-level zones.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns `null`.

EffectiveUid

Gets the user's effective UID.

Syntax

```
long EffectiveUID {get;}
```

Property value

The contents of the UID field of the user's effective profile.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns the unresolved value at the current hierarchical level, or `null` if there is none.

EffectiveUidZone

Gets the zone in which the user's effective UID is defined.

Syntax

```
IHierarchicalZone EffectiveUIDZone {get;}
```

Property value

The lowest-level hierarchical zone where the UID field is defined. This value overrides any definitions in higher-level zones.

Discussion

You must call the Unexpected Link Text method before calling this property. If you don't do so, this property returns `null`.

Gecos

Gets or sets the GECOS field of the user profile in the current zone.

Syntax

```
string Gecos {get; set;}
```

Property value

The contents of the GECOS field.

Discussion

Call the Unexpected Link Text method to get the effective GECOS for this zone.

IsEffectiveGecosDefined

Indicates whether there is an effective value for the GECOS field for this user.

Syntax

```
bool IsEffectiveGecosDefined {get;}
```

Property value

Returns `true` if an effective value for the GECOS field exists for this user.

Discussion

See the discussion of the Unexpected Link Text method.

IsEffectiveHomeDirectoryDefined

Indicates whether there is an effective home directory for this user.

Syntax

```
bool IsEffectiveHomeDirectoryDefined {get;}
```

Property value

Returns `true` if an effective home directory exists for this user.

Discussion

See the discussion of the Unexpected Link Text method.

IsEffectiveNameDefined

Indicates whether there is an effective logon name for this user.

Syntax

```
bool IsEffectiveNameDefined {get;}
```

Property value

Returns `true` if an effective name exists for this user.

Discussion

See the discussion of the Unexpected Link Text method.

IsEffectivePrimaryGroupDefined

Indicates whether there is an effective GID for this user.

Syntax

```
bool IsEffectivePrimaryGroupDefined {get;}
```

Property value

Returns `true` if an effective GID exists for this user.

Discussion

See the discussion of the Unexpected Link Text method.

IsEffectiveProfileStateDefined

Indicates whether there is an effective profile state for this local user.

Syntax

```
bool IsEffectiveProfileStateDefined {get;}
```

Property value

Returns `true` if an effective profile state exists for this local user.

Exceptions

`IsEffectiveProfileStateDefined` throws an `InvalidOperationException` if this is not a local user profile and you attempt to get this property.

IsEffectiveShellDefined

Indicates whether there is an effective logon shell for this user.

Syntax

```
bool IsEffectiveShellDefined {get;}
```

Property value

Returns `true` if an effective logon shell exists for this user.

Discussion

See the discussion of the Unexpected Link Text method.

IsEffectiveUidDefined

Indicates whether there is an effective UID for this user.

Syntax

```
bool IsEffectiveUidDefined {get;}
```

Property value

Returns true if there is an effective UNIX user identifier (UID) for this user.

Discussion

See the discussion of the Unexpected Link Text method.

IsEffectiveUseAutoPrivateGroupDefined

Indicates whether there is an effective auto private group flag setting for this user.

Syntax

```
bool IsEffectiveUseAutoPrivateGroupDefined {get;}
```

Property value

Returns `true` if there is an effective auto private group flag for this user.

Discussion

When auto private groups are enabled, the user's UNIX profile name is automatically used as the group name and the user's UID is used as the GID.

See the discussion of the `ResolveEffectiveProfile' method.

IsGecosDefined

Determines whether there is a GECOS field defined for this user in this zone.

Syntax

```
bool IsGecosDefined {get; set;}
```

Property value

Returns `true` if there is a GECOS field defined for this user. Set this property `false` to clear the GECOS field.

Exceptions

`IsGecosDefined` throws an `InvalidOperationException` if the GECOS field has not been defined and you attempt to set this property `true`.

IsHomeDirectoryDefined

Determines whether there is a home directory defined for this user in this zone.

Syntax

```
bool IsHomeDirectoryDefined {get; set;}
```

Property value

Returns `true` if there is a home directory defined for this user. Set this property `false` to clear the home directory.

Exceptions

`IsHomeDirectoryDefined` throws an `InvalidOperationException` if the home directory has not been defined and you attempt to set this property `true`.

IsNameDefined

Determines whether there is a logon name defined for this user in this zone.

Syntax

```
bool IsNameDefined {get; set;}
```

Property value

Returns `true` if there is a logon name defined for this user. Set this property `false` to clear the logon name.

Exceptions

`IsNameDefined` throws an `InvalidOperationException` if the name has not been defined and you attempt to set this property `true`.

IsProfileStateDefined

Determines whether the profile state is defined for this local user profile.

Syntax

```
bool IsProfileStateDefined {get; set;}
```

Property value

Returns `true` if there is a profile state defined for this user. Set this property `false` to clear the profile state.

Exceptions

`IsProfileStateDefined` throws an `InvalidOperationException` if:

- The profile state has not been defined and you attempt to set this property to `true`.
- This is not a local user profile and you attempt to set or get this property.

IsPrimaryGroupDefined

Determines whether there is a primary GID defined for this user in this zone.

Syntax

```
bool IsPrimaryGroupDefined {get; set;}
```

Property value

Returns `true` if there is a primary GID defined for this user. Set this property `false` to clear the GID.

Discussion

The user's primary group identifier (GID) can be associated with an Active Directory group or be a separate "dedicated-user" group that is only used in the UNIX operating environment. This property indicates whether a group profile for that GID has been defined in the zone.

Exceptions

`IsPrimaryGroupDefined` throws an `InvalidOperationException` if the primary GID has not been defined and you attempt to set this property `true`.

IsSecondary

Indicates whether the profile in this zone is a secondary profile.

Syntax

```
bool IsSecondary {get;}
```

Property value

Returns `true` if this is a secondary profile. Returns `false` if this is a primary profile.

IsShellDefined

Determines whether there is a logon shell defined for this user in this zone.

Syntax

```
bool IsShellDefined {get; set;}
```

Property value

Returns `true` if there is a logon shell defined for this user. Set this property `false` to clear the shell.

Exceptions

`IsShellDefined` throws an `InvalidOperationException` if the logon shell has not been defined and you attempt to set this property `true`.

IsUidDefined

Determines whether there is a UID defined for this user in this zone.

Syntax

```
bool IsUidDefined {get; set;}
```

Property value

Returns `true` if there is a UID defined for this user. Set this property `false` to clear the UID.

Exceptions

`IsUidDefined` throws an `InvalidOperationException` if the UID has not been defined and you attempt to set this property `true`.

IsUseAutoPrivateGroup

Determines whether the user uses auto private groups.

Syntax

```
bool IsUseAutoPrivateGroup {get; set;}
```

Property value

Returns `true` if this user uses an auto private group.

Discussion

When auto private groups are enabled, the user's UNIX profile name is automatically used as the group name and the user's UID is used as the GID.

IsUseAutoPrivateGroupDefined

Determines whether the auto private group flag is defined for this user in this zone.

Syntax

```
bool IsUseAutoPrivateGroupDefined {get; set;}
```

Property value

Returns `true` if the auto private group flag is defined for this user. Set this property `false` to remove the flag definition from the profile.

Discussion

When auto private groups are enabled, the user's UNIX profile name is automatically used as the group name and the user's UID is used as the GID.

Exceptions

`IsUseAutoPrivateGroupDefined` throws an `InvalidOperationException` if the auto private group flag has not been defined and you attempt to set this property `true`.

Zone

Gets the zone to which this user profile belongs.

Syntax

```
IHierarchicalZone Zone {get;}
```

Property value

The zone to which this user profile belongs; `null` if this is a computer-specific profile.

Delinea

HierarchicalZone

The HierarchicalZone class represents a hierarchical zone.

Syntax

```
public interface IHierarchicalZone : IZone
```

Discussion

The HierarchicalZone class inherits many methods and properties from the Zone class, but adds support for partial profiles and inheritable roles. Under hierarchical zones, both identity (profile data) and access (authorization data) are inherited, such that a user's effective identity or access are determined by all the profile data and all the access data at all levels of the hierarchy.

See Unexpected Link Text for a discussion of profile and access inheritance.

Methods

The HierarchicalZone class provides the following methods:

Unexpected Link Text	Adds an empty role assignment to a group
Unexpected Link Text	Creates a computer role under this zone.
Unexpected Link Text	Adds a partial profile for a specified group.
Unexpected Link Text	Adds a partial profile for a specified local group.
Unexpected Link Text	Adds a partial profile for a specified local user.
Unexpected Link Text	Adds an MIT Kerberos realm trusted user to this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Adds an empty role assignment.
Unexpected Link Text	Adds a partial profile for a specified user.
Unexpected Link Text	Commits changes to the group object to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Creates a command right for the zone.
Unexpected Link Text	Creates a pending imported group in this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Creates a pending imported user in this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Creates a network application access right.
Unexpected Link Text	Creates a PAM application access right.
Unexpected Link Text	Creates a role in the zone.
Unexpected Link Text	Creates an SSH application access right.
Unexpected Link Text	Creates a Windows application access right.
Unexpected Link Text	Creates a Windows Desktop access right.

Unexpected Link Text	Marks the zone for deletion from Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Generates predefined SSH and PAM rights in this zone.
Unexpected Link Text	Generates predefined user roles in this zone.
Unexpected Link Text	Returns a group assigned to this zone given a role for the group.
Unexpected Link Text	Returns an enumeration of groups in the zone.
Unexpected Link Text	Returns an enumeration of this zone's child zones.
Unexpected Link Text	Returns the privileged command right with a specific name or GUID.
Unexpected Link Text	Returns an enumeration of all the privileged command rights in the zone.
Unexpected Link Text	Returns the computer profile in the zone given the distinguished name of the profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns a specific computer role under this zone.
Unexpected Link Text	Returns an enumeration of all the computer roles under this zone.
Unexpected Link Text	Returns an enumeration of all the computers in the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the Active Directory object for the Computers node. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the Active Directory object for the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the display name of this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns all the command rights that can be assigned to users in the zone, including inherited rights.
Unexpected Link Text	Returns all the network access rights that can be assigned to users in the zone, including inherited rights.
Unexpected Link Text	Returns all the PAM application access rights that can be assigned to users in the zone, including inherited rights.
Unexpected Link Text	Returns all the user roles that can be assigned to users in the zone, including inherited roles.
Unexpected Link Text	Returns all the SSH application access rights that can be assigned to users in the zone, including inherited rights.
Unexpected Link Text	Returns an enumeration of effective users under this zone.
Unexpected Link Text	Returns all the Windows application access rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.
Unexpected Link Text	Returns all the Windows desktop access rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.
Unexpected Link Text	Returns all the Windows users in the zone, including users inherited from zones higher in the hierarchy.
Unexpected Link Text	Returns the DirectoryEntry of the local groups container. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the local UNIX group profile for a specified group name in the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns a local group profile using the distinguished name (DN) of the profile. (Inherited from Unexpected Link Text.)

Unexpected Link Text (Int32)	Returns the local group profile using the Group Identifier (GID). This method is exposed to the .COM interface. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns a list of the local group profiles in the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the directory entry of the local users container. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the local user profile using the specified user name. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the local user profile specified by the distinguished name (DN) of the profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text (Int32)	Returns the local user profile using the User Identifier (UID). This method is exposed to the .COM interface (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns a list of the local user profiles in the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the specified network access right.
Unexpected Link Text	Returns all the network access rights that can be assigned to users in the zone.
Unexpected Link Text	Returns the Active Directory object for the Groups container. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the UNIX group profile in this zone for the specified Active Directory group. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the UNIX group profile in this zone for the Active Directory group specified by distinguished name. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the UNIX group profile in this zone for the Active Directory group specified by group name. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns an enumeration of the UNIX groups in the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the group with the specified ID pending import. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns an enumeration of groups pending import to this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the user with the specified ID pending import. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns an enumeration of users pending import to this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	VBScript interface to access NSS variables.
Unexpected Link Text	VBScript interface to obtain all NSS variable names.
Unexpected Link Text	Returns the PAM application access right with the specified name.
Unexpected Link Text	Returns an enumeration of all the PAM application rights in the zone.
Unexpected Link Text	Returns the primary profile for the specified user.
Unexpected Link Text	Returns the role with the specified name or GUID.
Unexpected Link Text	Returns the role assignment for the specified role and trustee.
Unexpected Link Text	Returns the role assignment for the specified GUID.

Unexpected Link Text	Returns an enumeration of all the role assignments in the zone.
Unexpected Link Text	Returns the role assignment given to all Active Directory users who have a specified role.
Unexpected Link Text	Returns the role assignment given to all UNIX users who have a specified role.
Unexpected Link Text	Returns an enumeration of all the roles in the zone.
Unexpected Link Text	Returns an enumeration of the secondary profiles for the specified user.
Unexpected Link Text	Returns the SSH application access right with the specified name.
Unexpected Link Text	Returns an enumeration of all the SSH application rights in the zone.
Unexpected Link Text	Returns all role assignments under this zone, including role assignments for computer roles and computers.
Unexpected Link Text	Returns an enumeration of all the user profiles for the specified user.
Unexpected Link Text	Returns an enumeration of all the user role assignments in the zone.
Unexpected Link Text	Returns the specified Windows application right.
Unexpected Link Text	Returns all the Windows application rights in the zone.
Unexpected Link Text	Returns all the Windows computers in the zone.
Unexpected Link Text	Returns the specified Windows desktop right.
Unexpected Link Text	Returns all the Windows desktop rights in the zone.
Unexpected Link Text	Returns the directory entry of the Users container. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the UNIX user profile in this zone for the user specified by distinguished name. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns the UNIX user profile in this zone for the user specified by user name. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns an enumeration of all the UNIX user profiles in the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the group has a profile in this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether a UNIX profile exists in the zone for the specified local group. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether a UNIX profile exists in the zone for the specified local user. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Adds a computer zone to a computer object in this zone.
Unexpected Link Text	Refreshes the data in this object instance from the data stored in Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	VBScript interface to set the values of NSS variables.
Unexpected Link Text	Indicates whether the specified user has a profile in this zone. (Inherited from Unexpected Link Text.)

Properties

The HierarchicalZone class provides the following properties:

Unexpected Link Text	Gets the IADs interface of the zone object in Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the LDAP path to the zone object. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the attribute used to store the password hash for an agentless client. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets an enumeration of available user login shells. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the Cims object managing this zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the default group for new users. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the default login directory for new users. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the default login shell for new users. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the zone to use for default zone values. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the description of the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the full name of the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether auto-provisioning of group profiles is enabled for the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the default group name.
Unexpected Link Text	Gets the unique identifier for the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether this is a child zone.
Unexpected Link Text	Indicates whether the group default name is defined.
Unexpected Link Text	Indicates whether this is a hierarchical zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets whether Next GID value is configured for this zone.
Unexpected Link Text	Gets or sets whether Next UID value is configured for this zone.

Unexpected Link Text	Indicates whether this zone object in Active Directory is readable with the current user credentials. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the zone uses the Microsoft Services for UNIX (SFU) schema extension. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether this is a TruncateName zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the UseAutoPrivateGroup flag is defined.
Unexpected Link Text	Determines whether the user default GECOS is defined in this profile.
Unexpected Link Text	Determines whether the user default home directory is defined in this profile.
Unexpected Link Text	Determines whether the user default name is defined in this profile.
Unexpected Link Text	Determines whether the user default primary group is defined in this profile.
Unexpected Link Text	Determines whether the user default role is defined in this profile.
Unexpected Link Text	Determines whether the user default login shell is defined in this profile.
Unexpected Link Text	Indicates whether this zone object is writable using the provided credential. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the license container for the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the master domain controller for the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether Active Directory group membership must be maintained. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the name of the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the next GID to be used when adding a group (32-bit for COM programs). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the next UID to be used when adding a user (32-bit for COM programs). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the next GID to be used when adding a group (64-bit for .NET modules). (Inherited from Unexpected Link Text.)

Unexpected Link Text	Gets or sets the next UID to be used when adding a user (64-bit for .NET modules). (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the NIS domain associated with this SFU zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the map of profile variables.
Unexpected Link Text	Gets or sets the parent of this zone.
Unexpected Link Text	Gets or sets the list of GIDs not to be used when adding groups. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the list of UIDs not to be used when adding users. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the schema of the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the Active Directory domain associated with this SFU zone for retrieving SFU information. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether to use the Apple algorithm to automatically generate the GID when adding a group. The Apple algorithm is based on the globally unique identifier (GUID) for the object.
Unexpected Link Text	Determines whether to use the Apple algorithm to automatically generate the UID when adding a user. The Apple algorithm is based on the globally unique identifier (GUID) for the object.
Unexpected Link Text	Determines whether to use the Delinea algorithm to automatically generate the GID when adding a group. The Delinea algorithm is based on the security identifier (SID) for the object.
Unexpected Link Text	Determines whether this zone defaults to use an auto private group when adding a zone user.
Unexpected Link Text	Determines whether to use the Delinea algorithm to automatically generate the UID when adding a user. The Delinea algorithm is based on the security identifier (SID) for the object.
Unexpected Link Text	Determines whether to use the NextGID property when adding a group.
Unexpected Link Text	Determines whether to use the NextUID property when adding a user.
Unexpected Link Text	Indicates whether auto-provisioning of user profiles is enabled for the zone. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the default GECOS field for new user profiles.
Unexpected Link Text	Gets or sets the user default GID when adding a new user profile.
Unexpected Link Text	Gets or sets the default user name for a new user profile.

Unexpected Link Text	Gets or sets the user default GID for new user profiles; for use in VBScript scripts.
Unexpected Link Text	Gets or sets the default role for a new user profile.
Unexpected Link Text	Gets the version number of the data schema. (Inherited from Unexpected Link Text.)

AddAccessGroup

Adds an empty role assignment to a group.

Syntax

```
IHzRoleAssignment AddAccessGroup(DirectoryEntry groupDE)
IHzRoleAssignment AddAccessGroup(SearchResult groupSR)
IHzRoleAssignment AddAccessGroup(string groupDn)
IHzRoleAssignment AddAccessGroup(IAdsGroup groupIAds)
```

Parameters

Specify one of the following parameters when using this method.

groupDE	The directory entry for the group.
groupSr	The directory entry for the group specified as a search result.
groupDn	The group specified as a distinguished name.
groupIads	The IADs interface to the group.

Return value

The computer role assignment.

Discussion

The role assignment is not stored in Active Directory until you call the Unexpected Link Text method.

The AddAccessGroup(DirectoryEntry groupDE) and AddAccessGroup(SearchResult groupSR) methods are available only for .NET-based programs; call Unexpected Link Text for VBScript.

Exceptions

AddAccessGroup may throw one of the following exceptions:

- ApplicationException if the specified parameter is not a group or the method cannot find the group.
- ArgumentNullException if you pass a null parameter.

Example

The following code sample illustrates using the AddAccessGroup and GetAccessGroup methods in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
   return;
}
IRole role = objZone.GetRole(strRole);
if (role == null)
{
```

```
    Console.WriteLine(strRole + " does not exist in zone.");
}
else if (objZone.GetAccessGroup(role, strGroup) != null)
{
    Console.WriteLine("Role assignment already exist.");
}
else
{
    // assign a role to the group
    IRoleAssignment zag = objZone.AddAccessGroup(strGroup);
    zag.Role = role;
    zag.Commit();
}
…
```

AddComputerRole

Creates a computer role under this zone.

Syntax

```
IComputerRole AddComputerRole(string name)
```

Parameters

Specify the following parameter when using this method:

name	The name of the computer role you want to add.

Return value

AddGroupPartialProfile

Adds a partial profile for the specified group to the zone.

Syntax

IHierarchicalGroup AddGroupPartialProfile(DirectoryEntry groupDE)

IHierarchicalGroup AddGroupPartialProfile(SearchResult groupSR)

IHierarchicalGroup AddGroupPartialProfile(string groupDn)

IHierarchicalGroup AddGroupPartialProfile(IAdsGroup groupIAds)

Parameters

Specify one of the following parameters when using this method.

groupDE	The directory entry for the group for which you want a partial profile.
groupSr	The directory entry for a group specified as a search result.
groupDn	The group specified as a distinguished name.
groupIads	The IADs interface to the group.

Return value

The hierarchical group object that represents the group profile.

Discussion

This method creates a new group profile with values set for the Cims and Group properties. If the zone is an SFU zone, then this method also sets a value for the NISDomain property. You can then add other properties to the profile.

The profile is not stored in Active Directory until you call the Unexpected Link Text method.

The AddAccessGroup(DirectoryEntry groupDE) and AddAccessGroup(SearchResult groupSR) methods are available only for .NET-based programs; call Unexpected Link Text for VBScript.

Exceptions

If you pass a null parameter, AddGroupPartialProfile throws the exception ArgumentNullException.

Example

The following code sample illustrates using the AddGroupPartialProfile method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone = cims.GetZoneByPath("cn=" + strZone + "," +
strContainerDN) as
IHierarchicalZone;
// Load the unix profiles associated with the group
// Determine if the specified group is already a member of the zone.
// This method will either return a blank objGroupUnixProfile
// or one containing data
IGroupUnixProfile objGroupUnixProfile;
if (objZone.GetGroupUnixProfileByName(strUnixGroup) == null)
{
    // Add this zone to the group
    objGroupUnixProfile = objZone.AddGroupPartialProfile(strGroup);
    objGroupUnixProfile.Name = strUnixGroup;
    // Save
```

```
    objGroupUnixProfile.Commit();
}
...
```

AddRoleAssignment

Adds an empty role assignment to the zone.

Syntax

```
IRoleAssignment AddRoleAssignment()
```

Return value

An empty role assignment object. This role assignment is not stored in Active Directory until you call the RoleAssignment:[Commit](dev/windows-api/object-reference/computerrole/commit.md) method.

AddLocalGroupPartialProfile

Adds a partial profile for the specified group to the zone.

Syntax

```
IHierarchicalUser AddlocalGroupPartialProfile(string groupName)
```

Parameters

Specify groupName; the name of the local group.

Return value

The hierarchical group object that represents the local group profile.

Exceptions

If you pass a null parameter, AddLocalGroupPartialProfile throws the exception ArgumentNullException.

AddLocalUserPartialProfile

Adds a partial profile for the specified user to the zone.

Syntax

```
IHierarchicalUser AddLocalUserPartialProfile(string userName)
```

Parameters

Specify `userName`; the user name of the local user.

Return value

The hierarchical user object that represents the local user profile.

Exceptions

If you pass a `null` parameter, `AddLocalUserPartialProfile` throws the exception `ArgumentNullException`.

AddUserPartialProfile

Adds a partial profile for the specified user to the zone.

Syntax

IHierarchicalUser AddUserPartialProfile(DirectoryEntry userDE)

IHierarchicalUser AddUserPartialProfile(SearchResult userSR)

IHierarchicalUser AddUserPartialProfile(string userDn)

IHierarchicalUser AddUserPartialProfile(IAdsUser userIAds)

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want a partial profile.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The hierarchical user object that represents the user profile.

Discussion

This method creates a new user profile with values set for the Cims and User properties. If the zone is an SFU zone, then this method also sets a value for the NISDomain property. You can then add other properties to the profile.

The profile is not stored in Active Directory until you call the Unexpected Link Text method.

Exceptions

If you pass a null parameter, AddUserPartialProfile throws the exception ArgumentNullException.

Example

The following code sample illustrates using the AddUserPartialProfile method in a script:

```
...
// Create a CIMS object to interact with AD
ICims cims = new Cims();
// Note: There is no cims.connect function.
// By default, this application will use the connection to the domain controller

// and existing credentials from the computer already logged in.
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
   return;
}
IUser objUser = cims.GetUserByPath(strUser);
if (objUser == null)
{
```

```
    Console.WriteLine("User " + strUser + " does not exist.");
    return;
}
IHierarchicalUser objUserUnixProfile = (IHierarchicalUser)
objZone.GetUserUnixProfile(objUser);
if (objUserUnixProfile == null)
{
    // New user for the zone
    objUserUnixProfile = objZone.AddUserPartialProfile(strUser);
}
IRole objRole = objZone.GetRole(strRole);
if (objRole == null)
{
    Console.WriteLine("Role " + strRole + " does not exist.");
    return;
}
IRoleAssignment asg = objUserUnixProfile.GetUserRoleAssignment(objRole);
if (asg != null)
{
    Console.WriteLine("Assignment already exist.");
    return;
}
else
{
    // assigning role to user
    asg = objUserUnixProfile.AddUserRoleAssignment();
    asg.Role = objZone.GetRole(strRole);
    asg.Commit();
}
…
```

CreateCommand

Creates a command right for the zone.

Syntax

ICommand CreateCommand ()

Return value

A command right for the zone.

Discussion

A command right controls who has permission to run a specific command in a zone.

The profile is not stored in Active Directory until you call the Unexpected Link Text method.

Example

The following code sample illustrates using the CreateCommand method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
   ICommand objCmd = objZone.GetCommand(strCmd);
   if (objCmd != null)
   {
      Console.WriteLine("Command " + strCmd + " already exists.");
   }
   else
   {
      objCmd = objZone.CreateCommand();
      objCmd.Name = strCmd;
      objCmd.CommandPattern = strPattern;
      objCmd.Description = "optional description";
      objCmd.Commit();
      Console.WriteLine("Command " + strCmd + " was created successfully.");
   }
}
...
```

CreateNetworkAccess

Creates a network application access right.

Syntax

INetworkAccess CreateNetworkAccess ()

Return value

A network application access right for the zone.

Discussion

A network access right enables a user to run an application on a remote computer as another user. For example, a network access right can give a user the ability to run as an SQL Administrator on a remote server.

The right is not stored in Active Directory until you call the Unexpected Link Text method.

Example

The following code sample illustrates using the CreateNetworkAccess method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
   INetworkAccess objNetworkAccess = objZone.GetNetworkAccess(strName);
   if (objNetworkAccess != null)
   {
      Console.WriteLine("NetworkAccess " + strName + " already exist.");
   }
   else
   {
      objNetworkAccess = objZone.CreateNetworkAccess();
      objNetworkAccess.Name = strName;
      objNetworkAccess.RunAsType = WindowsRunAsType.User;
      objNetworkAccess.Priority = 0;
      objNetworkAccess.Description = "optional description";
      string userPath = DirectoryServices.GetLdapPathFromDN(cims.Server, strUser);
      DirectoryEntry userEntry = DirectoryServices.GetDirectoryEntry(userPath,
      cims.UserName, cims.Password);
      SecurityIdentifier m_userSid = new
      SecurityIdentifier(DirectoryServices.GetStringSid(userEntry));
      objNetworkAccess.RunAsList = new List\<SecurityIdentifier\>{ m_userSid };
      objNetworkAccess.Commit();
      Console.WriteLine("NetworkAccess " + strName + " is created successfully.");
   }
}
...
```

CreatePamAccess

Creates a PAM application access right.

Syntax

IPam CreatePamAccess ()

Return value

A PAM application access right for the zone.

Discussion

A PAM (Pluggable Authentication Module) application right gives a user the ability to access the authorized PAM-enabled application.

The right is not stored in Active Directory until you call the 'Commit` method.

Example

The following code sample illustrates using the CreatePamAccess method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
    Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
    IPam objPam = objZone.GetPamAccess(strName);
    if (objPam != null)
    {
    Console.WriteLine("PAM " + strName + " already exists.");
    }
    else
    {
      objPam = objZone.CreatePamAccess();
      objPam.Name = strName;
      objPam.Application = strApp;
      objPam.Description = "optional description";
      objPam.Commit();
    }
}
...
```

CreateRole

Creates a role in the zone.

Syntax

```
IRole CreateRole (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the role.

Return value

A role with the specified name.

Discussion

The role is not stored in Active Directory until you call the Unexpected Link Text method.

Example

The following code sample illustrates using the CreateRole method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

// create the role
if (objZone == null)
{
    Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
    IRole role = objZone.CreateRole(strRole);
    role.Description = "optional description";
    role.Commit();
}
...
```

CreateSshRight

Creates an SSH application access right.

Syntax

```
ISsh CreateSshRight ()
```

Return value

An SSH application access right for the zone.

Discussion

An SSH (Secure Shell) application right gives a user the ability to access the authorized SSH-enabled application.

The right is not stored in Active Directory until you call the Unexpected Link Text method.

CreateWindowsApplication

Creates a Windows application access right.

Syntax

```
IWindowsApplication CreateWindowsApplication ()
```

Return value

A Windows application access right for the zone.

Discussion

A Windows application right gives a user the ability to access the authorized Windows application.

The right is not stored in Active Directory until you call the Unexpected Link Text method.

Example

The following code sample illustrates using the CreateWindowsApplication method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
    Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
    IWindowsApplication objWindowsApplication =
    objZone.GetWindowsApplication(strName);
    if (objWindowsApplication != null)
    {
        Console.WriteLine("WindowsApplication " + strName + " already exists.");
    }
    else
    {
        objWindowsApplication = objZone.CreateWindowsApplication();
        objWindowsApplication.Name = strName;
        objWindowsApplication.RunAsType = WindowsRunAsType.Self;
        objWindowsApplication.Priority = 0;
        objWindowsApplication.Description = "optional description";
        objWindowsApplication.Command = strApplication;
        objWindowsApplication.Commit();
        Console.WriteLine("Windows Application " + strName + " has been created
            successfully.");
    }
}
...
```

CreateWindowsDesktop

Creates a Windows Desktop access right.

Syntax

```
IWindowsDesktop CreateWindowsDesktop ()
```

Return value

A Windows desktop access right for the zone.

Discussion

A Windows desktop right provides a complete desktop that behaves as if the user had logged in as specific privileged user. For example, if you have an SQL Administrator login, you can give an ordinary user an SQL Administrator desktop so they can operate in that role when necessary.

The right is not stored in Active Directory until you call the Unexpected Link Text method.

Example

The following code sample illustrates using the CreateWindowsDesktop method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
   IWindowsDesktop objWindowsDesktop = objZone.GetWindowsDesktop(strName);
   if (objWindowsDesktop != null)
   {
      Console.WriteLine("WindowsDesktop " + strName + " already exists.");
   }
   else
   {
      objWindowsDesktop = objZone.CreateWindowsDesktop();
      objWindowsDesktop.Name = strName;
      objWindowsDesktop.RunAsType = WindowsRunAsType.Self;
      objWindowsDesktop.Priority = 0;
      objWindowsDesktop.Description = "optional description";
      objWindowsDesktop.Commit();
      Console.WriteLine("Windows Desktop " + strName + " has been created
          successfully.");
}
}
...
```

GeneratePredefinedRights

Generates predefined SSH and PAM rights in this zone.

Syntax

```
Void GeneratePredefinedRights ()
```

Discussion

This method calls the Unexpected Link Text and Unexpected Link Text methods for a predefined list of SSH and PAM applications. You can call the Unexpected Link Text and Unexpected Link Text methods to get lists of the SSH and PAM rights that have been created in the zone. The rights are stored in Active Directory; you do not have to call the Unexpected Link Text method.

GeneratePredefinedRoles

Generates predefined roles.

Syntax

Void GeneratePredefinedRoles ()

Discussion

This method calls the Unexpected Link Text method for a predefined list of user roles, such as the Windows Login and UNIX Login roles. You can call the Unexpected Link Text method to get a list of the roles that have been created in the zone. The roles are stored in Active Directory; you do not have to call the Unexpected Link Text ` method.

GetAccessGroup

Gets a user group assigned to this zone given a specific role.

Syntax

```
IHzRoleAssignment GetAccessGroup(IRole role, DirectoryEntry group)
IHzRoleAssignment GetAccessGroup(IRole role, SearchResult groupSr)
IHzRoleAssignment GetAccessGroup(IRole role, string groupDn)
IHzRoleAssignment GetAccessGroup(IRole role, IADsGroup groupIAds)
```

Parameters

Specify the following parameter when using this method:

role	The role of the group.

Specify one of the following parameters when using this method.

group	The directory entry for the group.
groupSr	The directory entry for the group specified as a search result.
groupDn	The group specified as a distinguished name.
groupIads	The IADs interface to the group.

Return value

The computer role assignment that includes the specified group (IHzRoleAssignment.TrusteeType==Group).

Discussion

Any number of user groups can be assigned to a computer role and each of those groups can have more than one role. Use this method to get the computer role assignment for a specific group and role.

The GetAccessGroup(IRole role, DirectoryEntry group) and GetAccessGroup(IRole role, SearchResult groupSr) methods are available only for .NET-based programs; call Unexpected Link Text VBScript.

Exceptions

GetAccessGroup may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- ApplicationException if the parameter value is not a valid user; or if it failed to create a role assignment because it cannot find the user.

Example

See Unexpected Link Text for an example of using the GetAccessGroup method in a script:

GetAccessGroups

Returns the computer roles assigned to this zone.

Syntax

```
IRoleAssignments GetAccessGroups()
```

Return value

The collection of computer roles. Enumerate this object to get all of the `IAzRoleAssignment` objects in this zone.

GetChildZones

Returns the child zones of this zone.

Syntax

```
IEnuerable GetChildZones()
```

Return value

The collection of child zones.

Exceptions

`GetChildZones` throws an `ApplicationException` if it can't find the zone. For example, `GetChildZones` throws an `ApplicationException` if the zone has been removed or the server is not available.

GetCommand

Returns the command right with a specified name or GUID.

Syntax

ICommand GetCommand (string name)

ICommand GetCommand (Guid id)

Parameter

Specify one of the following parameters when using this method:

name	The name of the command.
id	The GUID of the command.

Return value

A command right with the specified name or GUID, or null if no match is found.

Exceptions

GetCommand may throw one of the following exceptions:

- ApplicationException if it can't find authorization data for the zone or if it failed to get the command right (see the message returned by the exception for the reason).
- ArgumentException if the name or id parameter is null or empty.

Example

The following code sample illustrates using the GetCommand method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
   ICommand objCmd = objZone.GetCommand(strCmd);
   if (objCmd != null)
   {
      Console.WriteLine("Command " + strCmd + " already exists.");
   }
   else
   {
      objCmd = objZone.CreateCommand();
      objCmd.Name = strCmd;
      objCmd.CommandPattern = strPattern;
      objCmd.Description = "optional description";
      objCmd.Commit();
   }
}
...
```

GetCommands

Returns all the command rights in the zone.

Syntax

```
ICommands GetCommands()
```

Return value

The collection of commands in the zone.

GetComputerRole

Returns the computer role with a specified name.

Syntax

IComputerRole GetComputerRole (string name)

Parameter

Specify the following parameter when using this method:

name	The name of the computer role.

Return value

The computer role with the specified name, or null if no match is found.

Exceptions

GetComputerRole throws an ApplicationException if it can't find authorization data for the zone or if it failed to get the computer role (see the message returned by the exception for the reason).

Example

The following code sample illustrates using the GetComputerRole method in a script:

```
...
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
IComputerRole compRole = objZone.GetComputerRole(strName);
if (compRole != null)
{
Console.WriteLine("Computer role " + strName + " already exist.");
}
else
{
compRole = objZone.AddComputerRole(strName);
compRole.Group = strGroup;
compRole.Validate();
compRole.Commit();
Console.WriteLine("Computer role " + strName + " is created successfully.");
}
}
...
```

GetComputerRoles

Returns all the computer roles in the zone.

Syntax

```
IComputerRoles GetComputerRoles()
```

Return value

The collection of computer roles in the zone.

GetEffectiveCommands

Returns all the command rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.

Syntax

```
ICommands GetEffectiveCommands()
```

Return value

The collection of effective command rights in the zone.

Exceptions

`GetEffectiveCommands` throws an `ApplicationException` if it failed to get the effective command rights (see the message returned by the exception for the reason).

GetEffectiveNetworkAccesses

Returns all the network access rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.

Syntax

```
INetworkAccesses GetEffectiveNetworkAccesses()
```

Return value

The collection of effective network access rights in the zone.

Exceptions

`GetEffectiveNetworkAccesses` throw an `ApplicationException` if it failed to get the effective network access rights (see the message returned by the exception for the reason).

GetEffectivePamAccesses

Returns all the PAM application access rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.

Syntax

```
IPams GetEffectivePamAccesses()
```

Return value

The collection of effective PAM application access rights in the zone.

Exceptions

`GetEffectivePamAccesses` throws an `ApplicationException` if it failed to get the effective command rights (see the message returned by the exception for the reason).

GetEffectiveRoles

Returns all the roles that can be assigned to users in the zone, including roles inherited from zones higher in the hierarchy.

Syntax

```
IRoles GetEffectiveRoles()
```

Return value

The collection of effective roles in the zone.

Exceptions

`GetEffectiveRoles` throws an `ApplicationException` if it failed to get the effective command rights (see the message returned by the exception for the reason).

GetEffectiveSshs

Returns all the SSH application access rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.

Syntax

```
ISshs GetEffectiveSshs()
```

Return value

The collection of effective SSH application access rights in the zone.

Exceptions

`GetEffectiveSshs` throws an `ApplicationException` if it fails to get the effective command rights (see the message returned by the exception for the reason).

GetEffectiveUserUnixProfiles

Returns all the users in the zone, including users inherited from zones higher in the hierarchy.

Syntax

```
IUserUnixProfiles GetEffectiveUserUnixProfiles()
```

Return value

The collection of effective users in the zone.

GetEffectiveWindowsApplications

Returns all the Windows application access rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.

Syntax

```
IWindowsApplications GetEffectiveWindowsApplications()
```

Return value

The collection of effective Windows application access rights in the zone.

Exceptions

`GetEffectiveWindowsApplications` throws an `ApplicationException` if it fails to get the effective access rights (see the message returned by the exception for the reason).

GetEffectiveWindowsDesktops

Returns all the Windows desktop access rights that can be assigned to users in the zone, including rights inherited from zones higher in the hierarchy.

Syntax

```
IwindowsDesktops GetEffectiveWindowsDesktops()
```

Return value

The collection of effective Windows desktop access rights in the zone.

Exceptions

`GetEffectiveWindowsDesktops` throws an `ApplicationException` if it failed to get the effective access rights (see the message returned by the exception for the reason).

GetEffectiveWindowsUsers

Returns all the Windows users in the zone, including users inherited from zones higher in the hierarchy.

Syntax

```
IWindowsUsers GetEffectiveWindowsUsers()
```

Return value

The collection of effective Windows users in the zone.

GetNetworkAccess

Returns the specified network access right.

Syntax

```
INetworkAccess GetNetworkAccess (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the access right.

Return value

The network access right with the specified name.

Exceptions

GetNetworkAccess may throw one of the following exceptions:

- ArgumentException if the parameter value is null or empty.
- ApplicationException if cannot find authorization for the zone, or if it failed to get the network access right (see the message returned by the exception for the reason).

Example

For an example of the use of the GetNetworkAccess method, see Unexpected Link Text.

GetNetworkAccesses

Returns all the network access rights that can be assigned to users in the zone.

Syntax

```
INetworkAccesses GetNetworkAccesses()
```

Return value

The collection of NSS variable names.

Discussion

This method returns only the network access rights assigned in the current zone. Call `GetEffectiveNetworkAccesses` to return all the network access rights including those inherited from zones higher in the hierarchy.

GetNSSVariable

Returns the specified NSS environment variable; VBScript only.

Syntax

```
string GetNssVariable (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the variable.

Return value

The value of the variable, or null if name is not a defined variable.

GetNSSVariables

Returns the names of all NSS variables; VBScript only.

Syntax

```
IEnumerable GetNSSVariables()
```

Return value

The collection of NSS variable names.

GetPamAccess

Returns the specified PAM application access right.

Syntax

```
IPam GetPamAccess (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the PAM access right.

Return value

The PAM application access right with the specified name, or null if name is not in use.

Exceptions

GetPamAccess may throw one of the following exceptions:

- ApplicationException if it can't find authorization data for the zone or if it failed to get the PAM application access right (see the message returned by the exception for the reason).
- ArgumentException if the name parameter is null or empty.

Example

For sample code using the GetPamAccess method in a script, see Unexpected Link Text.

GetPamAccesses

Returns all the PAM application access rights in the zone.

Syntax

```
IPams GetPamAccesses()
```

Return value

The collection of PAM application access rights in the zone.

GetPrimaryUser

Returns the primary profile for the specified user.

Syntax

```
IHierarchicalUser GetPrimaryUser(DirectoryEntry userDE)
IHierarchicalUser GetPrimaryUser(SearchResult userSR)
IHierarchicalUser GetPrimaryUser(string userDn)
IHierarchicalUser GetPrimaryUser(IAdsUser userIAds)
```

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want the primary profile.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The hierarchical user object that represents the user profile.

Discussion

The primary profile is the profile at the highest level in the zone hierarchy where the user's profile is defined. All or part of the primary profile can be overridden by secondary profiles farther down in the hierarchy.

The `GetPrimaryUser(DirectoryEntry userDE)` and `GetPrimaryUser(SearchResult userSr)` methods are available only for .NET-based programs.

Exceptions

`GetPrimaryUser` throws an `ArgumentNullException` if the specified parameter value is `null` or empty, or if the user does not exist.

GetRole

Returns the role with a specified name or GUID.

Syntax

IRole GetRole (string name)

IRole GetRole (Guid id)

Parameter

Specify the following parameter when using this method:

name	The name of the role.
id	The GUID of the role.

Return value

The role with the specified name, or null if no match is found.

Exceptions

GetRole may throw one of the following exceptions:

- ApplicationException if it can't find authorization data for the zone or if it failed to get the role (see the message returned by the exception for the reason).
- ArgumentException if the parameter is null or empty.

Example

The following code sample illustrates using the GetRole method in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
    Console.WriteLine("Zone " + strZone + " does not exist.");
    return;
}
IRole role = objZone.GetRole(strRole);
if (role == null)
{
    Console.WriteLine(strRole + " does not exist in zone.");
}
else if (objZone.GetAccessGroup(role, strGroup) != null)
{
    Console.WriteLine("Role assignment already exist.");
}
else
{
    // assign a role to the group
    IRoleAssignment zag = objZone.AddAccessGroup(strGroup);
    zag.Role = role;
    zag.Commit();
}
...
```

GetRoleAssignment

Returns a role assignment given a role and trustee.

Syntax

```
IRoleAssignment GetRoleAssignment (IRole role, string dn)
```

Parameter

Specify the following parameters when using this method.

role	The role for which you want the assignment.
dn	The distinguished name of the user or group to whom the role is assigned.

Return value

The role assignment, or `null` if no match is found.

Exceptions

`GetRoleAssignment` throws an `ArgumentNullException` if either parameter is `null` or empty.

GetRoleAssignmentById

Returns a role assignment given an ID.

Syntax

```
IRoleAssignment GetRoleAssignmentById (Guid id)
```

Parameter

Specify the following parameter when using this method:

id	The GUID of the role assignment.

Return value

The role assignment, or `null` if no match is found.

Exceptions

`GetRoleAssignment` throws an `ArgumentException` if the parameter is empty.

GetRoleAssigments

Returns all the role assignments in the zone.

Syntax

```
IRoleAssignments GetRoleAssignments()
```

Return value

The collection of role assignments in the zone.

GetRoleAssignmentToAllADUsers

Returns the role assignment given to all Active Directory users who have a specified role.

Syntax

```
IRoleAssignment GetRoleAssignmentToAllADUsers(IRole role)
```

Parameter

Specify the following parameter when using this method:

role	The user role for which you want the role assignments.

Return value

The role assignment for the specified role.

Exceptions

GetRoleAssignmentToAllADUsers throws an ArgumentNullException if the parameter is null.

GetRoleAssignmentToAllUnixUsers

Returns the role assignment given to all UNIX users who have a specified role.

Syntax

```
IRoleAssignment GetRoleAssignmentToAllUnixUsers(IRole role)
```

Parameter

Specify the following parameter when using this method:

role	The user role for which you want the role assignments.

Return value

The role assignment for the specified role.

Discussion

This method returns the role assignment for local UNIX users with the specified role.

Exceptions

GetRoleAssignmentToAllUnixUsers throws an ArgumentNullExceptionif the parameter is null.

GetRoles

Returns all the roles in the zone.

Syntax

```
IRoles GetRoles()
```

Return value

The collection of computer roles in the zone.

GetSecondaryUsers

Returns the secondary profiles for the specified user.

Syntax

```
IUserUnixProfiles GetSecondaryUsers(DirectoryEntry userDE)
IUserUnixProfiles GetSecondaryUsers(SearchResult userSR)
IUserUnixProfiles GetSecondaryUsers(string userDn)
IUserUnixProfiles GetSecondaryUsers(IAdsUser userIAds)
```

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want the secondary profiles.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The collection of secondary user UNIX profiles.

Discussion

The primary profile is the profile at the highest level in the zone hierarchy where the user's profile is defined. All or part of the primary profile can be overridden by secondary profiles farther down in the hierarchy.

The `GetSecondaryUser(DirectoryEntry userDE)` and `GetSecondaryUser(SearchResult userSr)` methods are available only for .NET-based programs.

Exceptions

`GetSecondaryUsers` throws an `ArgumentNullException` if the parameter is `null` or the user does not exist.

GetSshRight

Returns the specified SSH application access right.

Syntax

```
ISsh GetSshRight (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the SSH access right.

Return value

The SSH application access right with the specified name, or `null` if name is not in use.

Exceptions

`GetSshRight` may throw one of the following exceptions:

- `ApplicationException` if it can't find authorization data for the zone or if it failed to get the right (see the message returned by the exception for the reason).
- `ArgumentException` if the parameter is `null` or empty.

GetSshRights

Returns all the SSH application access rights in the zone.

Syntax

```
ISshs GetSshRights()
```

Return value

The collection of SSH application access rights in the zone.

GetSubTreeRoleAssignments

Returns all the role assignments under this zone, including role assignments for computer roles and computers.

Syntax

```
IRoleAssignments GetSubTreeRoleAssignments()
```

Return value

The collection of role assignments in the zone.

Exceptions

`GetSubTreeRoleAssignments` throws an `ApplicationException` if the method fails to find the authorization store.

GetUserProfiles

Returns all the profiles for the specified user.

Syntax

```
IUserUnixProfiles GetUserProfiles(DirectoryEntry userDE)
IUserUnixProfiles GetUserProfiles(SearchResult userSR)
IUserUnixProfiles GetUserProfiles(string userDn)
IUserUnixProfiles GetUserProfiles(IAdsUser userIAds)
```

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want the profiles.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The collection of user UNIX profiles.

Exceptions

GetUserProfiles throws an ArgumentNullException if the parameter is null or the user does not exist.

GetUserRoleAssignments

Returns all the user role assignments in the zone, or for a specific user in the zone.

Syntax

```
IRoleAssignments GetUserRoleAssignments()
IRoleAssignments GetUserRoleAssignments(DirectoryEntry userDE)
IRoleAssignments GetUserRoleAssignments(SearchResult userSR)
IRoleAssignments GetUserRoleAssignments(string userDn)
IRoleAssignments GetUserRoleAssignments(IAdsUser userIAds)
IRoleAssignments GetUserRoleAssignments(IUser user)
```

Parameters

Specify no parameters to return all the role assignments in the zone.

Specify one of the following parameters to return all the role assignments for a specific user:

userDE	The directory entry for the user for which you want the role assignments.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.
user	The user specified as a CIMS user object.

Return value

The collection of role assignments as `IRoleAssignment` objects.

Exceptions

`GetUserRoleAssignments` throws an `ArgumentNullException` if the required parameter is `null` or empty.

GetWindowsApplication

Returns the specified Windows application right.

Syntax

```
IWindowsApplication GetWindowsApplication (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the Windows application.

Return value

The Windows application right with the specified name, or `null` if name is not in use.

Exceptions

`GetWindowsApplication` may throw one of the following exceptions:

- `ApplicationException` if it can't find authorization data for the zone or if it failed to get the right (see the message returned by the exception for the reason).
- `ArgumentException` if the parameter is null or empty.

GetWindowsApplications

Returns all the Windows application rights in the zone.

Syntax

```
IWindowsApplications GetWindowsApplications()
```

Return value

The collection of Windows application rights in the zone.

GetWindowsComputers

Returns all the Windows computers in the zone.

Syntax

```
IComputers GetWindowsComputers()
```

Return value

The collection of Windows computers in the zone.

GetWindowsDesktop

Returns the specified Windows desktop right.

Syntax

```
IWindowsDesktop GetWindowsDesktop (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the Windows desktop.

Return value

The Windows desktop right with the specified name, or `null` if name is not in use.

Exceptions

`GetWindowsDesktop` may throw one of the following exceptions:

- `ApplicationException` if it can't find authorization data for the zone or if it failed to get the right (see the message returned by the exception for the reason).
- `ArgumentException` if the parameter is null or empty.

GetWindowsDesktops

Returns all the Windows desktop rights in the zone.

Syntax

```
IWindowsDesktops GetWindowsDesktops()
```

Return value

The collection of Windows desktop rights in the zone.

PrecreateComputerZone

Adds a computer zone to a computer object in this zone.

Syntax

```
IHierarchicalZoneComputer PrecreateComputerZone(string dnsname, DirectoryEntry trustee)
IHierarchicalZoneComputer PrecreateComputerZone(string dnsname, string trusteeDn)
IHierarchicalZoneComputer PrecreateComputerZone (string dnsName, DirectoryEntry trustee, bool skipPermissionSetting);
```

Parameters

Specify the following parameters when using this method.

dnsname	The DNS host name of the Active Directory computer object to which you wish to add a computer zone.
trustee	The user or group to which the computer-level overrides will be assigned.
trusteeDn	The user or group to which the computer-level overrides will be assigned, specified as a distinguished name.
skipPermissionSetting	Specifies if permission delegation is skipped when precreating computer zones.

Return value

The hierarchical computer object that contains the computer zone.

Discussion

Computer-level overrides for user, group, or computer role assignments are contained in a *computer zone*, which is a special type of zone that contains properties that are specific to only one computer. Computer zones are an internal data structure that are not exposed as zone in Access Manager.

This method adds a computer zone to a computer object in a hierarchical zone. You can then assign roles to that trustee.

Use `PrecreateComputerZone(string dnsname, DirectoryEntry trustee)` for .NET programs and `PrecreateComputerZone(string dnsname, string trusteeDn)` for VBScript.

Exceptions

`PrecreateComputerZone` throws an `ApplicationException` if the method fails to delegate computer zone permissions (see the message returned by the exception for the reason).

SetNSSVariable

Sets the value of the specified NSS environment variable; VBScript only.

Syntax

string SetNssVariable (string name, string value)

Parameter

Specify the following parameters when using this method.

name	The name of the variable.
value	The value of the variable.

GroupDefaultName

Gets or sets the default name for new group profiles.

Syntax

```
string GroupDefaultName {get; set;}
```

Property value

The default group profile name.

IsChild

Indicates whether this is a child zone.

Syntax

```
bool IsChild {get;}
```

Property value

Returns `true` if this zone is designated a child zone.

Discussion

Delinea allows a child zone to have no parent, so that you can preload all the child zone profiles and role assignments before assigning the zone to a parent zone. This property identifies a zone as a parent zone if it has no link to a parent zone and has a child zone pointing to it. If the zone is not a parent zone according to those criteria, then this property returns `true`, identifying it as a child zone.

IsGroupDefaultNameDefined

Determines whether the group default name has been defined.

Syntax

```
bool IsGroupDefaultNameDefined {get; set;}
```

Property value

Returns `true` if a group default name has been defined. Set this value false to clear this property. Call the Unexpected Link Text property to set a value for this property.

Exceptions

`IsGroupDefaultNameDefined` throws an `InvalidOperationException` if the group default name has not been defined and you attempt to set this property `true`.

IsNextGidDefined

Determines whether the NextGID property has been defined for this zone.

Syntax

```
bool IsNextGidDefined {get; set;}
```

Property value

Returns true if the NextGID property has been defined. Set this value false to clear this property. Call the Unexpected Link Text property to set a value for this property.

Exceptions

IsNextGidDefined throws an InvalidOperationException if the NextGID property has not been defined and you attempt to set this property true.

IsNextUidDefined

Determines whether the NextUID property has been defined for this zone.

Syntax

```
bool IsNextUidDefined {get; set;}
```

Property value

Returns true if the Unexpected Link Text property has been defined. Set this value false to clear this property. Call the Unexpected Link Text property to set a value for this property.

Exceptions

IsNextUidDefined throws an InvalidOperationException if the NextUID property has not been defined and you attempt to set this property true.

IsUseAutoPrivateGroupDefined

Determines whether the UseAutoPrivateGroup property has been defined for this zone.

Syntax

```
bool IsUseAutoPrivateGroupDefined {get; set;}
```

Property value

Returns true if the UseAutoPrivateGroup property has been defined. Set this value false to clear this property. Call the Unexpected Link Text property to set a value for this property.

Discussion

When auto private groups are enabled, the user's UNIX profile name is automatically used as the group name and the user's UID is used as the GID.

Exceptions

IsUseAutoPrivateGroupDefined throws an InvalidOperationException if the UseAutoPrivateGroup property has not been defined and you attempt to set this property true.

IsUserDefaultGecosDefined

Determines whether the UserDefaultGecos property has been defined for this zone.

Syntax

```
bool IsUserDefaultGecosDefined {get; set;}
```

Property value

Returns true if the UserDefaultGecos property has been defined. Set this value false to clear this property. Call the Unexpected Link Text property to set a value for this property.

Exceptions

IsUserDefaultGecosDefined throws an InvalidOperationException if the UserDefaultGecos property has not been defined and you attempt to set this property true.

IsUserDefaultHomeDirectoryDefined

Determines whether the UserDefaultHomeDirectory property is defined for this zone.

Syntax

```
bool IsUserDefaultHomeDirectoryDefined {get; set;}
```

Property value

Returns true if the UserDefaultHomeDirectory property is defined. Set this value false to clear this property. Call the Unexpected Link Text property to set a value for this property.

Exceptions

IsUserDefaultHomeDirectoryDefined throws an InvalidOperationException if the UserDefaultHomeDirectory property has not been defined and you attempt to set this property true.

IsUserDefaultNameDefined

Determines whether the UserDefaultName property is defined for this zone.

Syntax

```
bool IsUserDefaultNameDefined {get; set;}
```

Property value

Returns true if the user default name property is defined. Set this value false to clear this property. Call the UserDefaultName property to set a value for this property.

Exceptions

IsUserDefaultNameDefined throws an InvalidOperationException if the UserDefaultName property has not been defined and you attempt to set this property true.

IsUserDefaultPrimaryGroupDefined

Determines whether the UserDefaultPrimaryGroup property is defined for this zone.

Syntax

```
bool IsUserDefaultPrimaryGroupDefined {get; set;}
```

Property value

Returns true if the user default primary group property is defined. Set this value false to clear this property. Call the UserDefaultPrimaryGroup property to set a value for this property.

Exceptions

IsUserDefaultPrimaryGroupDefined throws an InvalidOperationException if the UserDefaultPrimaryGroup property has not been defined and you attempt to set this property true.

IsUserDefaultRoleDefined

Determines whether the UserDefaultRole property is defined for this zone.

Syntax

```
bool IsUserDefaultRoleDefined {get; set;}
```

Property value

Returns true if the user default role property is defined. Set this value false to clear this property. Call the UserDefaultRole property to set a value for this property.

Exceptions

IsUserDefaultRoleDefined throws an InvalidOperationException if the UserDefaultRole property has not been defined and you attempt to set this property true.

IsUserDefaultShellDefined

Determines whether the UserDefaultShell property is defined for this zone.

Syntax

```
bool IsUserDefaultShellDefined {get; set;}
```

Property value

Returns true if the user default shell property is defined. Set this value false to clear this property. Call the DefaultShell property to set a value for this property.

Exceptions

IsUserDefaultShellDefined throws an InvalidOperationException if the UserDefaultShell property has not been defined and you attempt to set this property true.

NssVariables

Gets all the NSS environment variables.

Syntax

IDictionary\<string, string\> NssVariables {get;}

Property value

A dictionary of key-value pairs that define all the profile variables.

Discussion

The NSSVariables property is available only for .NET-based programs; call Unexpected Link Text for VBScript.

Example

The following code sample illustrates using the NssVariables property in a script:

```
...
IHierarchicalZone objParent =
cims.GetZoneByPath("cn=" + strParentZone + "," + strContainerDN) as
IHierarchicalZone;
if (objParent == null)
{
    Console.WriteLine("Parnet zone " + strParentZone + " does not exist.");
}
else
{
    IHierarchicalZone objZone = cims.CreateZone(objContainer, strZone) as IHierarchicalZone;
    // set the starting UID and GID for the zone
    objZone.NextUID = 10000;
    objZone.NextGID = 10000;
    objZone.UseNextUid = true;
    objZone.UseNextGid = true;
    objZone.AvailableShells = new string[] { "/bin/bash", "/bin/shell" };
    objZone.DefaultShell = "%{shell}";
    objZone.DefaultHomeDirectory = "%{home}/%{user}";
    objZone.UserDefaultGecos = "%{u:description}";
    objZone.Parent = objParent;
    objZone.NssVariables.Add("shell", "/bin/bash" );
    objZone.Commit();
}
...
```

Parent

Gets or sets the parent of the current zone.

Syntax

```
IHierarchicalZone Parent {get; set;}
```

Property value

The parent zone.

Discussion

Delinea allows a child zone to have no parent, so that you can preload all the child zone profiles and role assignments before assigning the zone to a parent zone. See also the discussion under the Unexpected Link Text property.

SFU zones cannot be child zones. See Data storage for Delinea zones for information about different zone types.

Exceptions

Parent throws an ApplicationException if you attempt to assign a parent to an SFU zone.

Example

The following code sample illustrates using the Parent property in a script:

```
...
IHierarchicalZone objParent =
cims.GetZoneByPath("cn=" + strParentZone + "," + strContainerDN) as
IHierarchicalZone;
if (objParent == null)
{
    Console.WriteLine("Parent zone " + strParentZone + " does not exist.");
}
else
{
    IHierarchicalZone objZone = cims.CreateZone(objContainer, strZone) as IHierarchicalZone;
    // set the starting UID and GID for the zone
    objZone.NextUID = 10000;
    objZone.NextGID = 10000;
    objZone.UseNextUid = true;
    objZone.UseNextGid = true;
    objZone.AvailableShells = new string[] { "/bin/bash", "/bin/shell" };
    objZone.DefaultShell = "%{shell}";
    objZone.DefaultHomeDirectory = "%{home}/%{user}";
    objZone.UserDefaultGecos = "%{u:description}";
    objZone.Parent = objParent;
    objZone.NssVariables.Add("shell", "/bin/bash" );
    objZone.Commit();
}
...
```

UseAppleGid

Determines whether to use the Apple algorithm to automatically generate the GID when adding a group to the zone. The Apple algorithm uses the globally unique identifier (GUID) for the object to generate a unique numeric identifier for each group.

Syntax

```
bool UseAppleGid {get; set;}
```

Property value

If this value is set to true, Delinea uses the Apple algorithm to generate the numeric group identifier (GID) when adding a group.

UseAppleUid

Determines whether to use the Apple algorithm to automatically generate the UID when adding a user to the zone. The Apple algorithm uses the globally unique identifier (GUID) for the object to generate a unique numeric identifier for each user.

Syntax

```
bool UseAppleUid {get; set;}
```

Property value

If this value is set to true, Delinea uses the Apple algorithm to generate the numeric user identifier (UID) when adding a user.

UseAutoGid

Determines whether to use the Delinea algorithm to automatically generate the GID when adding a group to the zone.an auto-generated GID when adding a group to the zone. The Delinea algorithm uses the domain-wide security identifier (SID) and the relative identifier (RID) to generate a unique numeric identifier for each group.

Syntax

```
bool UseAutoGid {get; set;}
```

Property value

If this value is set to true, Delinea automatically generates a GID from the domain-wide security identifier (SID) and the relative identifier (RID) when adding a group.

UseAutoPrivateGroup

Determines whether to use a private group when adding a user to the zone.

Syntax

```
bool UseAutoPrivateGroup {get; set;}
```

Property value

When this value is `true`, Delinea uses a private group when adding a user to the zone.

Discussion

A private group automatically sets the user's UNIX profile name as the user's primary group name and the user's UID as the user's primary group GID. Automatically-generated groups are not stored or managed in Active Directory.

Call the `IsUseAutoPrivateGroupDefined` property before attempting to get the value for this property.

Exceptions

`UseAutoPrivateGroup` may throw one of the following exceptions:

- `FormatException` if the GID is not a number.
- `InvalidOperationException` if the `UseAutoPrivateGroup` property has not been defined.

UseAutoUid

Determines whether to use the Delinea algorithm to automatically generate the UID when adding a user to the zone.The Delinea algorithm uses the domain-wide security identifier (SID) and the relative identifier (RID) to generate a unique numeric identifier for each user.

Syntax

```
bool UseAutoUid {get; set;}
```

Property value

If this value is set to `true`, Delinea automatically generates a UID from the domain-wide security identifier (SID) and the relative identifier (RID) when adding a user.

UseNextGid

Determines whether to automatically increment the GID when adding a group to the zone.

Syntax

```
bool UseNextGid {get; set;}
```

Property value

When this value is true, Delinea automatically increments the GID when adding a group to the zone.

Discussion

There is no guarantee that the GIDs generated using this method are unique with regard to GIDs in other zones.

Example

For a code sample illustrating the use of this property, see Unexpected Link Text.

UseNextUid

Determines whether to automatically increment the UID when adding a user to the zone.

Syntax

```
bool UseNextUid {get; set;}
```

Property value

When this value is true, Delinea automatically increments the UID when adding a user to the zone.

Discussion

There is no guarantee that the UIDs generated using this method are unique with regard to UIDs in other zones.

Example

For a code sample illustrating the use of this property, see Unexpected Link Text.

UserDefaultGecos

Gets or sets the default GECOS field for new user profiles in the zone.

Syntax

```
string UserDefaultGecos {get; set;}
```

Property value

The contents of the GECOS field.

Example

For a code sample illustrating the use of this property, see Unexpected Link Text.

UserDefaultGid

Gets or sets the default GID (32-bit) for new user profiles in the zone.

Syntax

```
int UserDefaultGid {get; set;}
```

Property value

The GID. If set to -1, Delinea uses auto private group for new user profiles (see Unexpected Link Text).

Discussion

This property returns an error if the default GID has not been defined. Call the Unexpected Link Text property to determine whether the default GID is defined.

This property uses a 32-bit value for use in VBScript scripts. Use the Unexpected Link Text property for 64-bit GIDs.

Exceptions

UserDefaultGid may throw one of the following exceptions:

- InvalidOperationException if you try to get the default GID and it has not been defined.
- FormatException if the default GID value is not valid.

UserDefaultName

Gets or sets the default name for new user profiles in the zone.

Syntax

```
string UserDefaultName {get; set;}
```

Property value

The default name.

UserDefaultPrimaryGroup

Gets or sets the default GID (64-bit) for new user profiles in the zone.

Syntax

```
long UserDefaultPrimaryGroup {get; set;}
```

Property value

The GID. If set to -1, Delinea uses private groups for new user profiles (see Unexpected Link Text).

Discussion

This property returns an error if the default GID has not been defined. Call the Unexpected Link Text property to determine whether the default GID is defined.

This property uses a 64-bit value for use in .NET modules. Use the Unexpected Link Text property for VBScript.

Exceptions

`UserDefaultPrimaryGroup` may throw one of the following exceptions:

- `InvalidOperationException` if you try to get the default GID and it has not been defined.
- `FormatException` if the default GID value is not valid.

UserDefaultRole

Gets or sets the default role for new user profiles in the zone.

Syntax

```
IRole UserDefaultRole {get; set;}
```

Property value

The default role.

Delinea

HzRoleAssignment

Represents a zone-level role assignment.

Syntax

public interface IRoleAssignment

Methods

The HzRoleAssignment class provides the following methods:

Unexpected Link Text	VBScript interface to clear the custom attributes for this class. Inherited from Unexpected Link Text
Unexpected Link Text	Commits changes in the role assignment to Active Directory. Inherited from Unexpected Link Text
Unexpected Link Text	Deletes the role. Inherited from Unexpected Link Text
ICustomAttributeContainer Unexpected Link Text	.NET interface that returns the directory entry for the parent container object for the custom attributes for this class. Inherited from Unexpected Link Text
Unexpected Link Text	Returns the trustee being assigned. Inherited from Unexpected Link Text
Unexpected Link Text	VBScript interface to set the custom attributes for this class. Inherited from Unexpected Link Text
Unexpected Link Text	Validates the role assignment. Inherited from Unexpected Link Text

Properties

The HzRoleAssignment class provides the following properties:

Unexpected Link Text	VBScript only: Gets or sets custom attributes for this class. Inherited from Unexpected Link Text
Unexpected Link Text	Determines the time at which this role becomes inactive. Inherited from Unexpected Link Text
Unexpected Link Text	Gets the GUID of the role assignment. Inherited from Unexpected Link Text
Unexpected Link Text	Indicates whether the role assignment is orphaned due to a missing or invalid role. Inherited from Unexpected Link Text
Unexpected Link Text	Indicates whether the role assignment is orphaned due to a missing or invalid trustee. Inherited from Unexpected Link Text
Unexpected Link Text	Gets the local trustee being assigned. Inherited from Unexpected Link Text
Unexpected Link Text	Gets the role the trustee is assigned to. Inherited from Unexpected Link Text
Unexpected Link Text	Specifies the time from which this role becomes effective. Inherited from Unexpected Link Text
Unexpected Link Text	Gets the distinguished name of the trustee assigned this role. Inherited from Unexpected Link Text
Unexpected Link Text	Gets the trustee type of the role assignment. Inherited from Unexpected Link Text
Unexpected Link Text	Gets the zone in which the role assignment is made.

Zone

Gets the zone in which the role assignment is made.

Syntax

IZone Zone {get;}

Property value

The zone of the role assignment.

InheritedRoleAsg

The InheritedRoleAsg class represents a virtual role assignment constructed by inheritance from parent zones and the current zone or computer. A role assignment object contains information about an Active Directory object (trustee) that has been added to a role.

Syntax

public interface IInheritedRoleAsg

Methods

The InheritedRoleAsg class provides the following method:

Unexpected Link Text	Returns the user associated with the role.

Properties

The InheritedRoleAsg class provides the following properties:

Unexpected Link Text	Determines the time at which this role becomes inactive.
Unexpected Link Text	Indicates whether the role assignment is orphaned due to missing or invalid data.
Unexpected Link Text	Indicates whether the role assignment is orphaned due to a missing trustee.
Unexpected Link Text	Gets the role the trustee is assigned to.
Unexpected Link Text	Gets the role assignment that is the source for this inherited role assignment.
Unexpected Link Text	Specifies the time from which this role becomes effective.
Unexpected Link Text	Gets the distinguished name of the trustee assigned this role.

GetTrustee

Returns the user associated with the role.

Syntax

```
DirectoryEntry GetTrustee()
```

Return value

The Active Directory object representing the user.

EndTime

Determines the time from which this role becomes inactive.

Syntax

```
DateTime EndTime {get; set;}
```

Property value

The time at which the role ceases to be active. A value of `DateTime.MaxValue` means the role never expires. The time must be later than 1/1/1970 00:00.

IsRoleOrphaned

Indicates whether the role assignment is orphaned due to a missing or invalid role.

Syntax

```
bool IsRoleOrphaned {get;}
```

Property value

Returns `true` if this role assignment is an orphan.

IsTrusteeOrphaned

Indicates whether the role assignment is orphaned due to a missing or invalid user.

Syntax

```
bool IsTrusteeOrphaned {get;}
```

Property value

Returns `true` if this role assignment is an orphan.

Role

Syntax

IRole Role {get;}

Property value

The object representing the role.

Source

Gets the role assignment that is the source for this inherited role assignment.

Syntax

```
IRoleAssignment Source {get;}
```

Property value

The original role assignment that is the source for this inherited role assignment.

StartTime

Gets the time from which this role becomes effective.

Syntax

```
DateTime StartTime {get;}
```

Property value

The time at which the role becomes active. A value of `DateTime.MinValue` means the role becomes effective immediately. The time must be later than 1/1/1970 00:00.

TrusteeDn

Gets the user associated with the role.

Syntax

```
string TrusteeDn {get;}
```

Property value

The distinguished name of the user.

Key

The Key class provides access to individual license key properties.

Syntax

public interface IKey

Discussion

A Key object represents a single license key provided by Delinea. The license key is an encrypted string that encapsulates information such as the license type, number of allowed computers, a serial number, and whether the license is an evaluation or permanent license. For example, a single license key might authorize access for 25 servers for the organization with the serial number defined as 317.

Properties

The Key class provides the following properties:

Unexpected Link Text	Gets the number of licenses provided by a specific key.
Unexpected Link Text	Gets the date a specific license key is set to expire.
Unexpected Link Text	Determines whether the license key is an evaluation license.
Unexpected Link Text	Determines whether the license key being checked is a valid license.
Unexpected Link Text	Gets the serial number of the license key.
Unexpected Link Text	Gets the license type for a specific license key.

Count

Gets the number of licenses provided by a specific license key.

Syntax

```
int Count {get;}
```

Property value

The number of licenses provided in a license key.

Discussion

Each license key specifies the number of workstations or servers for which you have purchased licenses. This property indicates the total number of licenses defined for the key. It does not indicate the number currently in use or available to be used.

Example

The following code sample illustrates using the license key `Count` property in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
wscript.echo "Number of licenses:", objLics.Count
for each objLic in objLics
wScript.Echo "License Type:", objLic.Type
wScript.Echo "Seats:", objLic.Count
wScript.Echo "Used:", objLic.usedCount
set objKeys = objLic.keys
i = 0
do while i \< objKeys.Count
set objKey = objKeys(0)
if objKey.isEval then
wScript.Echo "-- [Eval] ", objKey.ExpiryDate
else
wscript.Echo "--", "Serial \#:", objKey.SerialNumber
wScript.Echo "Seats:", objKey.Count
end if
i = i + 1
loop
next
wScript.Echo ""
next
...
```

ExpiryDate

Gets the date a specific license key is set to expire.

Syntax

DateTime ExpiryDate {get;}

Property value

The date on which a specified license key expires.

Discussion

If a license key is defined as an evaluation license, it includes a timestamp that determines when the license will expire. You can use this property to retrieve this expiration date.

Example

The following code sample illustrates using ExpiryDate in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
wscript.echo "Number of licenses:", objLics.Count
for each objLic in objLics
wScript.Echo "License Type:", objLic.Type
wScript.Echo "Seats:", objLic.Count
wScript.Echo "Used:", objLic.usedCount
‘Display the expiration for eval licenses
set objKeys = objLic.keys
i = 0
do while i \< objKeys.Count
set objKey = objKeys(0)
if objKey.isEval then
wScript.Echo "-- [Eval] ", objKey.ExpiryDate
end if
i = i + 1
loop
next
wScript.Echo ""
next
...
```

IsEval

Determines whether the license key is an evaluation license.

Syntax

```
bool IsEval {get;}
```

Property value

Returns `true` if the license is a temporary evaluation license, or `false` if the license key is a permanent license.

Discussion

An evaluation license provides full use of Delinea software for a limited period of time. This property returns `true` if the license is a temporary evaluation license, or `false` if the license key is a permanent license.

Example

The following code sample illustrates using `IsEval` in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
for each objLic in objLics
set objKeys = objLic.keys
i = 0
do while i \< objKeys.Count
set objKey = objKeys(0)
‘Check for evaluation license keys
if objKey.isEval then
wScript.Echo "-- [Eval] ", objKey.ExpiryDate
end if
i = i + 1
loop
next
wScript.Echo ""
next
...
```

IsValid

Determines whether the license key being checked is a valid license.

Syntax

```
bool IsValid {get;}
```

Property value

Returns `true` if the license is valid, or `false` if the license key is not valid or has expired.

Discussion

This property returns `true` if the license key is a valid license, or `false` if the license key is invalid. The property also returns `false` if the license key checked is an expired evaluation license.

Example

The following code sample illustrates using `IsValid` in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
for each objLic in objLics
set objKeys = objLic.keys
i = 0
do while i \< objKeys.Count
set objKey = objKeys(0)
If not objKey.isValid then
wScript.Echo "Invalid License Key"
wscript.Quit
end if
i = i + 1
loop
next
wScript.Echo ""
next
...
```

SerialNumber

Gets the serial number of the license key.

Syntax

```
int SerialNumber {get;}
```

Property value

The serial number for a specified license key.

Discussion

The serial number provides a mechanism for tracing which license keys were issued to a recipient.

Example

The following code sample illustrates using SerialNumber in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
for each objLic in objLics
set objKeys = objLic.keys
i = 0
do while i \< objKeys.Count
set objKey = objKeys(0)
if objKey.isValid then
wscript.Echo "--", "Serial \#:", objKey.SerialNumber
wScript.Echo "Seats:", objKey.Count
end if
i = i + 1
loop
next
wScript.Echo ""
next
...
```

Type

Gets the license type for a specific license key.

Syntax

```
LicenseType Type {get;}
```

Property value

The license type for a license key.

See Unexpected Link Text for possible values.

Discussion

The license type indicates whether a specific license key is intended for workstation computers or application servers.

Example

The following code sample illustrates using `Type` in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
for each objLic in objLics
set objKeys = objLic.keys
i = 0
do while i \< objKeys.Count
set objKey = objKeys(0)
if objKey.isValid then
wScript.Echo "License Type", objKey.Type
wscript.Echo "Serial \#:", objKey.SerialNumber
wScript.Echo "Seats:", objKey.Count
end if
i = i + 1
loop
next
wScript.Echo ""
next
...
```

Keys

The Keys class is used to manage a set of license keys.

Syntax

```
public interface IKeys
```

Discussion

This class allows you to retrieve a set of license keys of a particular license type. For example, if you have one or more encrypted license keys (xxxx-xxxx-xxxx) that provide up to 100 licenses of the same license type, such as 100 workstation, server, or application licenses, the Keys object can be used to retrieve the Key objects that provide those 100 workstation, server, or application licenses.

Methods

The Keys class provides the following methods:

Unexpected Link Text	Adds a license key to the set.
Unexpected Link Text	Returns an enumeration of Key objects.
Unexpected Link Text	Removes a license key from the set.

Properties

The Keys class provides the following properties:

Unexpected Link Text	Gets the number of license keys stored in the set.
Unexpected Link Text	Gets the license key object using a specific index identifier.

Add

Adds a license key to the set of keys of a particular type.

Syntax

```
Key Add(string key)
```

Parameter

Specify the following parameter when using this method:

key	The license key string to add to the set.

Return value

The added license key object.

Exceptions

`Add` may throw one of the following exceptions:

- `ApplicationException` if the license key has expired, is invalid, or is a non-FIPS 140 key on a system that requires FIPS 140 keys.
- `ArgumentException` if the parameter is `null` or empty or if the key already exists.

GetEnumerator

Returns an enumeration of Key objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of Key objects.

Remove

Removes a license key from the set of license keys of a particular type.

Syntax

```
void Remove(string key)
```

Parameter

Specify the following parameter when using this method:

key	The license key string to remove from the set.

Return value

The license key string to be removed.

Exceptions

`Remove` may throw one of the following exceptions:

- `ApplicationException` if the license key cannot be found.
- `ArgumentException` if the parameter is null or empty.

Count

Determines the total number of license keys defined in the collection of keys for a particular type of license.

Syntax

```
int Count {get;}
```

Property value

The number of individual license keys included in the Keys collection.

Item

Gets the license key object found at the index point you specify.

Syntax

```
IKey this[int i] {get;}
```

Parameter

Specify the following parameter when using this property.

i	The index number to use for retrieving the license key object from the set.

Property value

The license key object.

Delinea

License

The License class provides access to Delinea license properties.

Syntax

```
public interface ILicense
```

Discussion

This class represents the keys of the same license type in the same license container. For example, the License object can contain the collection of server, workstation, or application licenses for one license container, such as the default parent container domain/Program Data/Centrify/Licenses.

Properties

The License class provides the following properties:

Unexpected Link Text	Determines the total number of licenses of a particular type.
Unexpected Link Text	Determines whether the license is an evaluation license.
Unexpected Link Text	Gets the license keys associated with the license object.
Unexpected Link Text	Gets the license type for the license object.
Unexpected Link Text	Gets the total number of licenses that are currently in use.

Count

Determines the total number of licenses of a particular type.

Syntax

```
int Count {get;}
```

Property value

The number of licenses provided in the License object.

Example

The following code sample illustrates using Count in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
for each objLic in objLics
wScript.Echo "License Type:", objLic.Type
wScript.Echo "Seats:", objLic.Count
wScript.Echo "Used:", objLic.usedCount
next
wScript.Echo ""
next
...
```

IsEval

Determines whether the license is an evaluation license.

Syntax

```
bool IsEval {get;}
```

Property value

Returns `true` if the license is a temporary evaluation license, or `false` if it is a permanent license.

Discussion

An evaluation license provides full use of Delinea software for a limited period of time. This property returns `true` if the license is a temporary evaluation license, or `false` if the license is permanent.

Keys

Gets the license keys associated with the license object.

Syntax

```
Keys Keys {get;}
```

Property value

The Keys object that contains the set of individual license keys for this license object.

Type

Gets the license type for the license object.

Syntax

```
LicenseType Type {get;}
```

Property value

The license type.

Possible values:

```
public enum LicenseType
{
    // Not defined
       NotDefined = -1,
    // UNIX Workstation license
       Workstation = 110,
    // UNIX Server license
       Server = 111,
    // Windows Server license
       WindowsServer = 112,
    // Windows Workstation license
       WindowsWorkstation = 113,
    // Application license for Tomcat
       Tomcat = 210,
    // Application license for JBoss
       JBoss = 211,
    // Application license for WebLogic
       WebLogic = 212,
    // Application license for WebSphere
       WebSphere = 213,
    // Application license for Apache
       Apache = 214,
    // Application license for DB2
       DB2 = 215,
    // Install evaluation license
       InstallEval = 310,
    // Specific date evaluation license
       SpecificEval = 311
}
```

Discussion

The license type indicates whether a specific license is intended for workstation computers or application servers.

Example

The following code sample illustrates using `Type` in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
for each objLic in objLics
wScript.Echo "License Type:", objLic.Type
wScript.Echo "Seats:", objLic.Count
wScript.Echo "Used:", objLic.usedCount
next
wScript.Echo ""
next
...
```

UsedCount

Gets the total number of licenses that are currently in use.

Syntax

```
int UsedCount {get;}
```

Property value

The total number of licenses that are currently in use.

Discussion

Available licenses become used licenses when computers join the domain.

Exceptions

`UsedCount` throws an `ApplicationException` if license information is unavailable because an LDAP error occurred.

Example

The following code sample illustrates using `UsedCount` in a script:

```
...
set objCollection cims.LoadLicenses
for each objLics in objCollection
for each objLic in objLics
wScript.Echo "License Type:", objLic.Type
wScript.Echo "Seats:", objLic.Count
wScript.Echo "Used:", objLic.usedCount
next
wScript.Echo ""
next
...
```

Licenses

The Licenses class is used to manage a set of licenses in a particular license container object.

Syntax

public interface ILicenses

Discussion

This class represents the collection of License objects that have been added to this parent container object. The Licenses object represents one container in the LicensesCollection object.

Methods

The Licenses class provides the following methods:

Unexpected Link Text	Adds a license key to the set of licenses in the license container.
Unexpected Link Text	Commits any changes to the Licenses object to Active Directory.
Unexpected Link Text	Returns an instance of the directory entry for the Licenses parent container object.
Unexpected Link Text	Reloads the Licenses object data from the data in Active Directory.
Unexpected Link Text	Removes a license key from the set.

Properties

The Licenses class provides the following properties:

Unexpected Link Text	Gets the number of license objects stored in this Licenses container.
Unexpected Link Text	Indicates whether any generated license key installed in the Licenses parent container is an evaluation license.
Unexpected Link Text	Indicates whether any computer license is installed.
Unexpected Link Text	Gets the ID from this Licenses object.
Unexpected Link Text	Indicates whether the Licenses parent object in Active Directory is readable.
Unexpected Link Text	Indicates whether the Licenses parent object in Active Directory is writable.
Unexpected Link Text	Gets the License object for a specific type of license.

AddLicenseKey

Adds a license key to the set of licenses in a particular Licenses parent container.

Syntax

```
IKey AddLicenseKey(string key)
```

Parameter

Specify the following parameter when using this method:

key	The license key string to add to the parent container.

Return value

The added key object.

Exceptions

`AddLicenseKey` may throw one of the following exceptions:

- `ApplicationException` if the license key has expired, is invalid, or is a non-FIPS 140 key on a system that requires FIPS 140 keys.
- `ArgumentException` if the parameter is `null` or empty or if the key already exists.

Commit

Commits any changes or updates to the Licenses object and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

The method does not validate the data before saving it in Active Directory.

Exceptions

Commit throws an `ApplicationException` if the Active Directory domain controller is readonly.

GetDirectoryEntry

Returns an instance of the DirectoryEntry object for the Licenses parent container object from Active Directory.

Syntax

```
DirectoryEntry GetDirectoryEntry ()
```

Return value

The DirectoryEntry object for the Licenses parent container object.

Discussion

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Refresh

Reloads the Licenses object data from the data in Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the collection of licenses in the cached object to ensure it is synchronized with the latest information in Active Directory.

RemoveLicenseKey

Removes a license key from the set of license objects for a particular Licenses parent container.

Syntax

```
void RemoveLicenseKey(string key)
```

Parameter

Specify the following parameter when using this method:

key	The license key string to remove from the set.

Return value

The license key object to be removed.

Exceptions

RemoveLicenseKey may throw one of the following exceptions:

- ApplicationException if the license key cannot be found.
- ArgumentException if the parameter is null or empty.

Count

Gets the total number of licenses for a particular Licenses parent container.

Syntax

```
int Count {get;}
```

Property value

The number of licenses provided in the Licenses object.

HasEvaluation

Indicates whether any license key installed in the `Licenses` parent container is an evaluation license.

Syntax

```
bool HasEvaluation {get;}
```

Property value

Returns `true` if any generated license key is a temporary evaluation license, or `false` if there are no evaluation license keys installed.

HasMachineLicense

Indicates whether any computer license is installed.

Syntax

```
bool HasMachineLicense {get;}
```

Property value

Returns `true` if any computer license is installed, or `false` if there are no computer licenses installed.

ID

Gets the ID from the Licenses object.

Syntax

```
string ID {get;}
```

Property value

The ID.

IsReadable

Indicates whether the Licenses parent object in Active Directory is readable for the current user credentials.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns true if the Licenses parent object is readable, or false if the object is not readable.

Discussion

This property returns a value of true if the user accessing the Licenses object in Active Directory has sufficient permissions to read its properties.

IsWritable

Indicates whether the Licenses parent object in Active Directory is writable for the current user credentials.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns true if the Licenses parent object is writable, or false if the object is not writable.

Discussion

This property returns a value of true if the user accessing the Licenses object in Active Directory has sufficient permissions to write its properties.

Item

Gets the License object for a specific type of license.

Syntax

```
ILicense this[LicenseType type] {get;}
```

Parameter

Specify the following parameter when using this property.

type	The type of License object to retrieve from the Licenses object.

See Unexpected Link Text for possible values.

Return value

The Unexpected Link Text object of the specified type.

Discussion

This property enables you to retrieve the License object for a collection of licenses of a particular type, such as the collection of server licenses or the collection of licenses for a specific application.

Delinea

LicensesCollection

The LicensesCollection class is used to manage all of the licenses in all of the Licenses parent containers defined for a forest.

Syntax

```
public interface ILicensesCollection
```

Discussion

The LicensesCollection object is retrieved using the Cims.[LoadLicenses](dev/windows-api/object-reference/cims/loadlicenses.md) method.

Methods

The LicensesCollection class provides the following methods:

Unexpected Link Text	Returns the specific parent container object from the collection of all parent license containers in the forest.
Unexpected Link Text	Returns an enumeration of Licenses objects.
Unexpected Link Text	Returns the total number of licenses of the specified license type that have been installed.
Unexpected Link Text	Returns the total number of licenses of the specified license type that are currently being used.

Properties

The LicensesCollection class provides the following properties:

Unexpected Link Text	Gets the number of license container objects stored in the Active Directory forest.
Unexpected Link Text	Indicates whether there are any evaluation licenses in the forest.
Unexpected Link Text	Indicates whether any computer license is installed.
Unexpected Link Text	Gets the parent license container object by index number.

Find

Returns the specific parent container object from the collection of all parent license containers in the forest.

Syntax

```
ILicenses Find(DirectoryEntry licenseContainer)
```

Parameter

Specify the following parameter when using this method:

licenseContainer	The Licenses parent container object to retrieve.

Return value

The specified Licenses container object. The container contains the \$CimsLicenseVersionX object.

Discussion

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

GetEnumerator

Returns an enumeration of Licenses objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of Licenses objects.

GetLicensedCount

Returns the total number of licenses of the specified license type that have been installed in an Active Directory forest.

Syntax

```
int GetLicensedCount(LicenseType type)
```

Parameter

Specify the following parameter when using this method:

type	The license type for which you want to get a complete count.

See Unexpected Link Text for possible values.

Return value

Returns a value that represents the number of licenses installed of the specified type.

GetUsedCount

Returns the total number of licenses of the specified license type that are currently being used in an Active Directory forest.

Syntax

```
int GetUsedCount(LicenseType type)
```

Parameter

Specify the following parameter when using this method:

type	The license type for which you want to determine the number being used.

See Unexpected Link Text for possible values.

Return value

Returns a value that represents the number of licenses of the specified type that are currently in use.

Exceptions

`GetUsedCount` throws an `ApplicationException` if license information is unavailable because an LDAP error occurred.

Count

Gets the total number of parent license containers in the Active Directory forest.

Syntax

```
int Count {get;}
```

Property value

The number of parent license containers in the collection of parent containers.

HasEvaluation

Indicates whether any generated license key installed in any of the parent license containers is an evaluation license.

Syntax

```
bool HasEvaluation {get;}
```

Property value

Returns `true` if any evaluation license is installed, or `false` if there are no evaluation licenses installed.

HasMachineLicense

Indicates whether any computer license is installed.

Syntax

```
bool HasMachineLicense {get;}
```

Property value

Returns `true` if any computer license is installed, or `false` if there are no computer licenses installed.

Item

Gets the parent license container object by index number.

Syntax

```
ILicenses this[int index] {get;}
```

Parameter

Specify the following parameter when using this property.

index	The index number for retrieving the parent license container object

Return value

The parent container object found at the specified index number.

Map

The Map class contains methods and properties used to manage individual NIS map entries stored in Active Directory. This class is defined in the Centrify.DirectControl.NISMap.API namespace rather than the Centrify.DirectControl.API namespace.

Syntax

```
public class IMap : ICloneable, IDisposable
```

Discussion

The Map class supports the methods and properties that apply to all .NET objects. In addition to those methods and properties, the Map class provides some Delinea-specific methods and properties for managing individual NIS map records. Only the Delinea-specific methods and properties are described in this reference.

Methods

The Map class provides the following Delinea-specific methods:

| Method | Description | | ----- | ----- | | Unexpected Link Text | Adds a new map entry with the specified key to the NIS map. | | Clone | Makes a clone of the NIS map entry. Inherited from ICloneable. | | Unexpected Link Text | Commits changes to the NIS map and saves them in Active Directory. | | 2 Dispose | Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable. | | Unexpected Link Text | Checks whether there is an entry with a specific key-value pair. | | Unexpected Link Text | Removes the map entry with the specified ID |

Properties

The Map class provides the following Delinea-specific properties:

Unexpected Link Text	Indicates whether the map object is readable.
Unexpected Link Text	Indicates whether the map object is writable.
Unexpected Link Text	Gets or sets the map name of the NIS map.
Unexpected Link Text	Gets the Store instance associated with the map object.
Unexpected Link Text	Gets or sets the NIS map type.

Add

Adds a new map entry, or individual map record, with the specified key.

Syntax

```
Entry Add(string key, string value, string comment);

Entry Add(string key);
```

Parameters

Specify the following parameters when using this method.

key	String	The key field that uniquely defines this entry in the NIS map.
value	String	The value associated with the key field for this entry in the NIS map.
comment	String	Any optional text string to store in the comment field for this entry in the NIS map.

Return value

An entry object instance for the map entry added.

Discussion

Each map entry consists of three primary fields: a key field, a value field, and an optional comment field. The content and format of the value field depends on the type of NIS map you are working with. For example, if you are setting the value field in a generic map, the field can contain virtually any string that you want served for a corresponding key name. If you are adding a map entry to a netgroup, auto.mount, or auto.master map, the single value field defined in Active Directory may consist of multiple, concatenated fields appropriate for the map type.

Because of potential API name conflict, the Add(string key) method can be used with .NET programs only.

Example

The following code sample illustrates using Add to add new NIS entries to different types of NIS maps:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone.
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the generic NIS map named "Remote servers"
Set map = store.open("Remote servers")
'Add an entry to the "Remote servers" NIS map. The input format is:
'map.add "\<key\>", "\<value\>", "\<comment\>"
map.add "mirage", "127.67.10.1", "Server located in Toledo office"
'Open the NIS map named “auto.master”
Set map = store.open("auto.master")
'Add an entry to the "auto.master" NIS map. The input format is: 'map.add
"\<mount point\>", "\<map\>" & Chr(11) & "\<Options\>", "\<comment\>"
'where:
'\<mount point\> - mount point name (key field)
'\<map\> - the map file to consult for this mount point
'\<options\> - mount options
'\<comment\> - text comments
'NOTE: The \<map\> and \<options\> are separated by a tab character, 'Chr(11),
and form the value field for the entry.
map.add "/net", "-hosts" & Chr(11) & "-nosuid,nobrowse", "sample mount"
'Open the NIS map named “auto.mount”
Set map = store.open("auto.mount")
'Add an entry to “auto.mount" NIS map. The input format is:
```

```
'map.add "\<name\>", "\<Options\>" & Chr(11) & "\<network path\>",
""\<comment\>"
'where:
'\<name\> - mount point name (key field)
'\<options\> - mount options
'\<network path\> - the network path to consult for this mount point
'\<comment\> - text comments
'NOTE: The \<options\> and \<network path\> are separated by a tab 'character,
Chr(11), and form the value field for the entry.
map.add "cdrom", "-fstype=nsfs,ro" & Chr(11) & ":/dev/sr0", "sample mount"
'Open the NIS map named “netgroup”
set map = store.open("netgroup")
'Add entries to the “netgroup” NIS map. The input format is:
'map.add "\<group_name\>", "\<member_name\>", "comment"
'where:
'\<group_name\> - defines the unique key of this group
'\<member_name\> - lists the members of the group. Each \<member_name\>
' is either another group name, all of whose members
' are to be included in the group being defined,
' or a triple of the form:
' (hostname,username,domainname)
'\<comment\> - comments of this user
'Add a group "db_admin" with three members: dbas, dean, jon
map.add "db_admin", "dbas (,dean,) (firebird,jon,)", "All DBAs"
wScript.Echo "NIS map entries added."
...
```

Commit

Commits the settings or changes for the map object to Active Directory.

Syntax

```
void Commit();
```

Discussion

The Commit method saves the settings of the map, but not the entries in the map.

Exceptions

Commit throws an ApplicationException if access is denied.

Example

The following code sample illustrates using Commit in a script:

```
SET cims = CreateObject("Centrify.DirectControl.Cims3")
SET zone = cims.GetZone("example.org/Zones/default")
SET store = CreateObject("Centrify.DirectControl.Nis.Store")
store.Attach zone.ADsPath, "username", "password"
SET map = store.Open("computers")
map.Name = "hosts"
map.Commit
```

Exists

Checks whether there is an entry with a specific key-value pair.

Syntax

```
bool Exists(string key, string value)
```

Parameter

Specify the following parameters when using this method:

key	The key you want to check for.
value	The value you want to check for.

Return value

Returns `true` if the specified entry exists.

Get

Returns the map entry, or individual map record, with the specified key.

Syntax

```
Entry Get(string key);
```

Parameter

Specify the following parameter when using this method:

key	The key field that uniquely defines this entry in the NIS map.

Return value

An entry object instance for the NIS map and key specified.

Example

The following code sample illustrates using Get to retrieve an existing NIS map entry from a specific map.

```
...
'Specify the zone you want to work with
set zone = cims.GetZoneByPath("LDAP://CN=qa-slovenia,CN=unix,DC=quantum,DC=net")

'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "nate.james", "my3w0rds"
'Open the NIS map named "Remote servers"
Set objMap = store.open("Remote servers")
'Specify the map entry key field
set objEntry = objMap.Get("helios")
wScript.Echo “IP: “ & objEntry.Value
…
```

GetByID

Returns the map entry, or individual map record, with the specified ID.

Syntax

```
Entry GetByID(string id);
```

Parameter

Specify the following parameter when using this method:

id	The ID that uniquely defines this entry in the NIS map.

Return value

The entry object instance with the specified ID.

GetDirectoryEntry

Returns the directory entry for the NIS map object.

Syntax

```
DirectoryEntry GetDirectoryEntry ()
```

Return value

The directory entry for the map object.

Discussion

This method can only be used in .NET programs because `DirectoryEntry` is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

GetEnumerator

Returns an enumeration of IMap objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of map entries.

GetRedirectMap

Returns the redirect target NIS map.

Syntax

```
Entry GetRedirectMap(Connection connection);
```

Parameter

Specify the following parameter when using this method:

connection	The Cims connection.

Return value

The redirect target NIS map.

Import

Imports a new map entry, or individual map record, with the specified key into Active Directory.

Syntax

```
Entry Import(string key, string value, string comment);
```

Parameters

Specify the following parameters when using this method.

key	The key field that uniquely defines this entry in the NIS map.
value	The value associated with the key field for this entry in the NIS map.
comment	Any optional text string to store in the comment field for this entry in the NIS map.

Return value

An entry object for the map entry imported.

Discussion

The difference between the Import and Add methods is that the Import method performs minimal checking and validation of data to maximize performance.

Exceptions

Import throws an ApplicationException if the key or value is invalid.

Example

The following code sample illustrates using Import to retrieve an existing NIS map entry from a specific map.

```
...
'Specify the zone you want to work with
set zone = cims.GetZoneByPath("LDAP://CN=qa-slovenia,CN=unix,DC=quantum,DC=net")

'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone.
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the NIS map named "Remote servers"
Set map = store.open("Remote servers")
'Add an entry to the "Remote servers" NIS map. The input format is:
map.import "oaxaca", "127.67.32.10", "Latin America Support office"
...
```

Remove

Removes the map entry with the specified key.

Syntax

```
void Remove(string key);
```

Parameter

Specify the following parameter when using this method:

key	The key field that uniquely defines this entry in the NIS map.

Exceptions

Remove throws an ApplicationException if it can't find the DirectoryEntry value.

Example

The following code sample illustrates using Remove to remove an existing NIS map entry by key name from a specific map:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and user credentials
store.Attach zone.ADsPath, "jae.smith", "pas\$w0rd"
'Remove the “Modified_Key” map entry from the "generic map" NIS map
set map = store.Open("generic map")
map.Remove "Modified_Key"
wScript.Echo "NIS map entry removed."
...
```

RemoveByID

Removes the map entry with the specified ID.

Syntax

```
void Remove(string id);
```

Parameter

Specify the following parameter when using this method:

id	The ID that uniquely defines this entry in the NIS map.

Exceptions

RemoveByID throws an ApplicationException if it can't find the DirectoryEntry object.

IsReadable

Indicates whether the NIS map in the attached zone is readable.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns true if the map object is readable by the user, or false if the map object is not readable.

Discussion

This property returns a value of true if the user accessing the map entry object in Active Directory has sufficient permissions to read the entry properties.

Example

The following code sample illustrates using this property in a script:

```
…
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=offshore,CN=unix,DC=quantum,DC=net")

'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach objZone.ADsPath, "tae.parker", "9days\^"
'Open the generic map type named "Workstations IDs"
Set map = store.open("Workstations IDs")
'Check whether the map is readable
if not map.IsReadable then
wScript.Echo “No read permission. Quitting application ...”
wScript.Quit
end if
…
```

IsWritable

Indicates whether the map object is writable.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns true if the map object is writable by the user, or false if the map object is not writable.

Discussion

This property returns a value of true if the user accessing the map object in Active Directory has sufficient permissions to change the map object's properties.

Example

The following code sample illustrates using this property in a script:

```
…
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=pilot,CN=unix,DC=quantum,DC=net")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach objZone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the generic map type named "Workstations IDs"
Set map = store.open("Workstations IDs")
'Check whether the map is writable
If not map.IsWritable then
wScript.Echo “No write permission for ” & map.Name
wScript.Quit
end if
…
```

Name

Gets or sets the map name.

Syntax

```
string Name {get; set;}
```

Property value

The map name.

Discussion

You can specify any string for this property regardless of the type of NIS map.

Exceptions

`Name` throws an `ArgumentException` if you try to set a value that is `null`, empty, or greater than 64 characters.

Example

The following code sample illustrates using this property in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=pilot,CN=unix,DC=quantum,DC=net")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
objStore.Attach objZone.ADsPath, "jae.smith", "pas\$w0rd"
'List map names
For each map in objStore
wScript.Echo map.Name
end if
...
```

Store

Gets the store object instance for the map object.

Syntax

```
Store Store {get;}
```

Property value

The Store instance for the map object.

Type

Gets or sets the map type for the map object.

Syntax

```
string Type {get; set;}
```

Property value

The map type for the map object.

Discussion

Internally, the map type defines how fields are parsed and interpreted for standard network maps and generic maps. the type value is used by Access Manager to identify the map type. Access Manager can recognize all of the common NIS map types.

Example

The following code sample illustrates using this property in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=pilot,CN=unix,DC=quantum,DC=net")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
objStore.Attach objZone.ADsPath, "jae.smith", "pas\$w0rd"
'Open the map type named "Workstations IDs"
Set objMap = objStore.Open("Workstations IDs")
'Check the map type
wScript.Echo “Map Type: ” & objMap.Type
...
```

Delinea

MzRoleAssignment

Represents a computer-level role assignment.

Syntax

public interface IMzRoleAssignment : IRoleAssignment

Methods

The MzRoleAssignment class provides the following methods:

| Method | Description | | ----- | ----- | | Unexpected Link Text | VBScript interface to clear the custom attributes for this class. (Inherited from Unexpected Link Text.) | | Unexpected Link Text | Commits changes in the role assignment to Active Directory. (Inherited from RoleAssignment.) | | Unexpected Link Text | Deletes the role. (Inherited from Unexpected Link Text.) |

Properties

The MzRoleAssignment class provides the following properties:

Unexpected Link Text	VBScript only: Gets or sets custom attributes for this class.
Unexpected Link Text	Determines the time at which this role becomes inactive. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the GUID of the role assignment. (Inherited from RoleAssignment.)
Unexpected Link Text	Indicates whether the role assignment is orphaned due to a missing or invalid role. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the role assignment is orphaned due to a missing or invalid trustee. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the local trustee being assigned. (Inherited from RoleAssignment.)
Unexpected Link Text	Gets or sets the role the trustee is assigned to. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the time from which this role becomes effective. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the distinguished name of the trustee assigned this role. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the trustee type of the role assignment. (Inherited from Unexpected Link Text.)

GetComputer

Returns the computer for which the role assignment is made.

Syntax

```
IComputer GetComputer()
```

Return value

The computer object representing the computer for which the role assignment is made.

Exceptions

`GetComputer` throws an `ApplicationException` if there are multiple computers, computer service connection points (SCPs), or zones that have the same DNS host name; if the method failed to find the computer; or if the method failed to get the computer profile from the role assignment.

NetworkAccess

This class represents a network access right.

Syntax

```
public interface INetworkAccess:IRight
```

The NetworkAccess class provides the following methods:

Unexpected Link Text	Commits changes in the right to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Removes the right. (Inherited from Unexpected Link Text.)

Properties

The NetworkAccess class provides the following properties:

Unexpected Link Text	Gets or sets the description of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is readable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is writable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the name of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the priority of this right.
Unexpected Link Text	Gets or sets whether the user's password is required when this right is used.
Unexpected Link Text	Gets or sets the SID for the run-as user or an SID for the user assigned the right (VBScript).
Unexpected Link Text	Gets or sets the SID for the run-as user or a list of SIDs for the users assigned the right (.NET).
Unexpected Link Text	Gets or sets the run-as type for the right.
Unexpected Link Text	Gets the zone this right belongs to. (Inherited from Unexpected Link Text.)

Discussion

A network access right enables a user to run an application on a remote computer as another user. For example, a network access right can give a user the ability to run as an SQL Administrator on a remote server.

Priority

Gets or sets the priority of this right.

Syntax

```
int Priority {get; set;}
```

Property value

The priority of the right. Default is 0.

Discussion

This number is used when handling multiple matches for rights specified by wild cards. If rights specified by this property object match rights specified by another property object, the object with the higher priority prevails. The higher the value of the Priority property, the higher the priority.

RequirePassword

Gets or sets whether the logged-in user's password is required when this right is used.

Syntax

```
bool RequirePassword {get; set;}
```

Property value

Set to `true` if the right requires the logged-in user's password.

RunAs

Gets or sets the run-as property for this right.

Syntax

```
string RunAs {get; set;}
```

Property value

The run-as property for a single user.

Discussion

If the Unexpected Link Text property is set to Self, the remote application is run under the logged-in user account, but with the additional privileges of the user whose SID is listed in the RunAs property. For example, if the NetworkAccess right is set to run as Self and RunAs contains the SID of the Network Admins group, then this application runs with the permissions of the logged-in user plus the permissions of the Network Admins group.

If the RunAsType property is set to User, the remote application is run under the user whose SID is listed in the RunAs property. For example, if the NetworkAccess right is set to run as User and RunAs contains the SID of the user NetAdmin, then this application runs with the permissions of the NetAdmin user.

If the RunAs property is empty, this right is invalid and an exception is thrown when you call the Unexpected Link Text method.

> **Note**: This property is for use in VBScript programs. Use the RunAsList property for .NET.

RunAsList

Gets or sets the run-as list for this right.

Syntax

IList\<SecurityIdentifier\> RunAsList {get; set;}

Property value

The run-as list for the right.

Discussion

If the Unexpected Link Text property is set to Self, the remote application is run under the logged-in user account, but with the additional privileges of the groups whose SIDs are listed in the RunAsList property. For example, if the NetworkAccess right is set to run as Self and RunAsList contains the SID of the Network Admins group, then this application runs with the permissions of the logged-in user plus the permissions of the Network Admins group.

If the RunAsType property is set to User, the remote application is run under the user whose SID is listed in the RunAsList property. In this case, the RunAsList property contains only a single SID. For example, if the NetworkAccess right is set to run as User and RunAsList contains the SID of the user NetAdmin, then this application runs with the permissions of the NetAdmin user.

If the RunAsList property is empty, this right is invalid and an exception is thrown when you call the Unexpected Link Text method.

Note: This property can only be used in .NET programs. Use the RunAs property for VBScript.

RunAsType

Gets or sets the run-as type for this right.

Syntax

```
WindowsRunAsType RunAsType {get; set;}
```

Property value

The run-as type of the right.

Possible values:

```
public enum WindowsRunAsType
{
    // Run as self
    Self,
    // Run as another user
    User
}
```

Discussion

If the RunAsType property is set to Self, the remote application runs as the logged-in user with the additional privileges of the groups whose SIDs are listed in the Unexpected Link Text. For example, if the NetworkAccess right is set to run as Self and RunAsList contains the SID of the Network Admins group, then this application runs with the permissions of the logged-in user plus the permissions of the Network Admins group.

If the RunAsType property is set to User, the application is run as the user whose SID is listed in the RunAsList property. For example, if the NetworkAccess right is set to run as User and RunAsList contains the SID of the user NetAdmin, then this application runs as NetAdmin with the permissions of that user.

NetworkAccesses

The NetworkAccesses class manages a collection of network access rights.

Syntax

public interface INetworkAccesses

Methods

The NetworkAccesses class provides the following method:

Unexpected Link Text	Gets the enumerator you can use to enumerate all network access rights.

GetEnumerator

Returns an enumeration of NetworkAccess objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

Returns an enumerator you can use to list all the NetworkAccess objects.

Pam

Represents a PAM application access right.

Syntax

```
public interface IPam: IRight
```

Discussion

A PAM (Pluggable Authentication Module) application right gives a user the ability to access the authorized PAM-enabled application.

Methods

The Pam class provides the following methods:

Unexpected Link Text	Commits changes in the right to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Deletes the right. (Inherited from Unexpected Link Text.)

Properties

The Pam class provides the following properties:

Unexpected Link Text	Gets or sets the PAM application.
Unexpected Link Text	Gets or sets the description of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is readable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is writable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the name of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the zone this right belongs to. (Inherited from Unexpected Link Text.)

Application

Gets or sets the PAM application for which this is a right.

Syntax

```
string Application {get; set;}
```

Property value

The file path of the application.

Exceptions

Application throws an ArgumentException if you try to set the property and the string is null or empty.

Example

The following code sample illustrates using Application in a script:

```
...
string strParent = "CN=zones,CN=Centrify,CN=Program Data";
if (args.Length != 3)
{
   Console.WriteLine("Usage:");
   Console.WriteLine(" test_add_pam.exe \\"zone-name\\" \\"pam-name\\"
      \\"pam-application\\"");
   return;
}
string strZone = args[0];
string strName = args[1];
string strApp = args[2];
// Need to obtain an active directory container object
DirectoryEntry objRootDSE = new DirectoryEntry("LDAP://rootDSE");
DirectoryEntry objContainer = new DirectoryEntry("LDAP://" + strParent + "," +
objRootDSE.Properties["defaultNamingContext"].Value.ToString());
string strContainerDN = objContainer.Properties["DistinguishedName"].Value as
string;
// Create a CIMS object to interact with AD
ICims cims = new Cims();
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
}
else
{
   IPam objPam = objZone.GetPamAccess(strName);
   if (objPam != null)
   {
      Console.WriteLine("PAM " + strName + " already exist.");
   }
   else
   {
      objPam = objZone.CreatePamAccess();
      objPam.Name = strName;
      objPam.Application = strApp;
      objPam.Description = "optional description";
      objPam.Commit();
   }
}
...
```

Pams

The Pams class manages a collection of PAM application access rights.

Syntax

```
public interface IPams
```

Methods

The Pams class provides the following method:

Unexpected Link Text	Returns the enumerator you can use to enumerate all PAM rights.

GetEnumerator

Returns an enumeration of PAM access rights.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

An enumerator you can use to list all the Pam objects.

Right

This class provides a base class for all rights.

Syntax

public interface IRight

Methods

The Right class provides the following methods:

Unexpected Link Text	Commits changes in the right to Active Directory.
Unexpected Link Text	Deletes the right.

Properties

The Right class provides the following properties:

Unexpected Link Text	Gets or sets the description of the right.
Unexpected Link Text	Indicates whether the right is readable.
Unexpected Link Text	Indicates whether the right is writable.
Unexpected Link Text	Gets or sets the name of the right.
Unexpected Link Text	Gets the zone this right belongs to.

Commit

Commits any changes or updates to the Right object and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

The method does not validate the data before saving it in Active Directory.

Exceptions

Commit throws an ApplicationException if:

- The command right name or command pattern is null, empty, or invalid.
- The command name is null or empty.
- The command path is null or empty.
- The method cannot find the command right or authorization data for the zone.

If the Commit method fails, see the message returned by the exception for more specific information about the reason for the failure.

Delete

Deletes the right from Active Directory.

Syntax

```
void Delete()
```

Exceptions

Delete throws an ApplicationException if the method cannot find the command right to delete or cannot find authorization data for the zone.

If the Delete method fails, see the message returned by the exception for more specific information about the reason for the failure.

Description

Gets or sets the description of the right.

Syntax

```
string Description {get; set;}
```

Property value

A string describing the right.

IsReadable

Indicates whether the right is readable.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns `true` if the right is readable.

IsWritable

Indicates whether the right is writable.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns `true` if the right is writable.

Name

Gets or sets the name of the right.

Syntax

```
string Name {get; set;}
```

Property value

The name of the right. The name can contain only letters (upper- or lowercase), numerals 0 through 9, and the hyphen (-) and underscore (_) characters.

Exceptions

`Name` throws an `ArgumentException` if the name is `null`, empty, or contains invalid characters.

Zone

Indicates the zone to which this right belongs.

Syntax

IZone Zone {get;}

Property value

The zone.

Delinea

Role

The Role class represents a user access role.

Syntax

public interface IRole

Methods

The Role class provides the following methods:

Unexpected Link Text	Adds a command right to the role.
Unexpected Link Text	Adds a network application access right to the role.
Unexpected Link Text	Adds a PAM application access right to the role.
Unexpected Link Text	Adds an SSH application access right to the role.
Unexpected Link Text	Adds a Windows application right to the role.
Unexpected Link Text	Adds a Windows desktop right to the role.
Unexpected Link Text	Adds a trustee to the role at the zone or computer level.
Unexpected Link Text	VBScript interface to clear the custom attributes for this class.
Unexpected Link Text	Commits changes to the role to Active Directory.
Unexpected Link Text	Deletes the role from Active Directory.
Unexpected Link Text	Returns all command rights added to the role.
ICustomAttributeContainer Unexpected Link Text	.NET interface that returns the directory entry for the parent container object for the custom attributes for this class.
Unexpected Link Text	Returns the collection of all network application access rights added to this role.
Unexpected Link Text	Returns all PAM application access rights added to the role.
Unexpected Link Text	Returns all SSH application access rights added to the role.
Unexpected Link Text	Returns the collection of all Windows application rights added to this role.
Unexpected Link Text	Returns the collection of all Windows desktop rights added to this role.
Unexpected Link Text	Indicates whether the role is valid in a specified time period.
Unexpected Link Text	Removes all rights from the role.
Unexpected Link Text	Removes a specific command right from the role.
Unexpected Link Text	Removes a specific PAM application right from the role.
Unexpected Link Text	Removes a specific PAM application right from the role.

Unexpected Link Text	Removes a specific SSH application right from the role.
Unexpected Link Text	Removes a specific Windows application access right from the role.
Unexpected Link Text	Removes a specific Windows desktop right from the role.
Unexpected Link Text	Sets a day of the week on which the role is active or inactive.
Unexpected Link Text	Sets a day and hour of the week for which the role is active or inactive.
Unexpected Link Text	VBScript interface to set the custom attributes for this class.

Properties

The Role class provides the following properties:

Unexpected Link Text	Determines whether the role allows local users.
Unexpected Link Text	Gets or sets the time at which the role is active, in hex format.
Unexpected Link Text	VBScript only: Gets or sets custom attributes for this class.
Unexpected Link Text	Gets or sets the description of the role.
Unexpected Link Text	Gets the GUID for this role.
Unexpected Link Text	Indicates whether the role is readable.
Unexpected Link Text	Indicates whether the role is writable.
Unexpected Link Text	Gets or sets the name of the role.
Unexpected Link Text	Gets or sets the system rights granted to the role.
Unexpected Link Text	Gets the zone to which this role belongs.

AddCommand

Adds a command right to the role.

Syntax

```
void AddCommand(Icommand command)
```

Parameter

Specify the following parameter when using this method:

command	The command right you want to add to the role.

Discussion

This command right is not stored in Active Directory until you call the Unexpected Link Text method.

Exceptions

AddCommand throws an ApplicationException if the command right is not in the current or parent zone.

Example

The following code sample illustrates using AddCommand in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
   Console.WriteLine("Zone " + strZone + " does not exist.");
   return;
}
IRole objRole = objZone.GetRole(strRole);
if (objRole == null)
{
   Console.WriteLine("Role " + strRole + " does not exist.");
   return;
}
ICommand objCmd = objZone.GetCommand(strCmd);
if (objCmd == null)
{
   Console.WriteLine("Command " + strCmd + " does not exist.");
   return;
}
objRole.AddCommand(objCmd);
objRole.Commit();
...
```

AddNetworkAccess

Adds a network application access right to the role.

Syntax

```
void AddNetworkAccess(INetworkAccess networkAccess)
```

Parameter

Specify the following parameter when using this method:

networkAccess	The network application right you want to add to the role.

Discussion

This right is not stored in Active Directory until you call the Unexpected Link Text method.

Exceptions

AddNetworkAccess throws an ApplicationException if the network access right is not in the current or parent zone.

AddPamAccess

Adds a PAM application access right to the role.

Syntax

```
void AddPamAccess(IPam pam)
```

Parameter

Specify the following parameter when using this method:

pam	The PAM application right you want to add to the role.

Discussion

This right is not stored in Active Directory until you call the Unexpected Link Text method.

Exceptions

AddPamAccess throws an ApplicationException if the PAM application access right is not in the current or parent zone.

AddSsh

Adds an SSH application access right to the role.

Syntax

```
void AddSsh(ISsh ssh)
```

Parameter

Specify the following parameter when using this method:

ssh	The SSH application right you want to add to the role.

Discussion

This right is not stored in Active Directory until you call the Unexpected Link Text method.

Exceptions

`AddSsh` throws an `ApplicationException` if the SSH application right is not in the current or parent zone.

AddWindowsApplication

Adds a Windows application right to the role.

Syntax

```
void AddWindowsApplication(IWindowsApplication windowsApplication)
```

Parameter

Specify the following parameter when using this method:

windowsApplication	The Windows application right you want to add to the role.

Discussion

This right is not stored in Active Directory until you call the Unexpected Link Text method.

Exceptions

AddWindowsApplication throws an ApplicationException if the Windows application right is not in the current or parent zone.

AddWindowsDesktop

Adds a Windows desktop right to the role.

Syntax

```
void AddWindowsDesktop(IWindowsDesktop windowsDesktop)
```

Parameter

Specify the following parameter when using this method:

windowsDesktop	The Windows desktop right you want to add to the role.

Discussion

This right is not stored in Active Directory until you call the Unexpected Link Text method.

Exceptions

AddWindowsDesktop throws an ApplicationException if the Windows desktop right is not in the current or parent zone.

Example

The following code sample illustrates using AddWindowsDesktop in a script:

```
...
// Get the zone object
IHierarchicalZone objZone =
cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN) as IHierarchicalZone;

if (objZone == null)
{
    Console.WriteLine("Zone " + strZone + " does not exist.");
    return;
}
IRole objRole = objZone.GetRole(strRole);
if (objRole == null)
{
    Console.WriteLine("Role " + strRole + " does not exist.");
    return;
}
IWindowsDesktop objWindowsDesktop =
objZone.GetWindowsDesktop(strWindowsDesktop);
if (objWindowsDesktop == null)
{
    Console.WriteLine("WindowsDesktop " + strWindowsDesktop + " does not exist.");
    return;
}
objRole.AddWindowsDesktop(objWindowsDesktop);
objRole.Commit();
...
```

Assign

Assigns a trustee to a role at the zone or computer level.

Syntax

```
IRoleAssignment Assign(DirectoryEntry trusteeDE, IComputer computer)
IRoleAssignment Assign(DirectoryEntry trusteeDE, IZone zone)
IRoleAssignment Assign(SearchResult trusteeSR, Icomputer computer)
IRoleAssignment Assign(SearchResult trusteeSR, IZone zone)
IRoleAssignment Assign(string trusteeDN, IComputer computer)
IRoleAssignment Assign(string trusteeDN, IZone zone)
```

Parameters

Use the following parameters with this method.

trusteeDE	The directory entry for the trustee (user or group) you want to add.
trusteeSR	The directory entry for a trustee specified as a search result.
trusteeDn	The trustee specified as a distinguished name.
computer	The computer to which you want to add the role.
zone	The zone to which you want to add the role.

Return value

The role assignment that includes the specified trustee. This role assignment is not stored in Active Directory until you call the Unexpected Link Text method.

Discussion

The `Assign(DirectoryEntry trusteeDE, IComputer computer)`, `Assign(SearchResult trusteeSr, IComputer computer)`, `Assign(DirectoryEntry trusteeDE, IZone zone)` and `Assign(SearchResult trusteeSr, IZone zone)` methods are available only for .NET-based programs.

Exceptions

Assign may throw one of the following exceptions:

- `ApplicationException` if the trustee is not a user or a group, you attempt to assign a role to a zone other than the containing or child zone, the method fails to create a role assignment (see the message returned by the exception for the reason), the method cannot find the trustee object or distinguished name in the specified search result, or the method cannot find the trustee.
- `ArgumentException` if any parameter is `null` or empty.

Commit

Commits any changes or updates to the Role object and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

The method does not validate the data before saving it in Active Directory.

Exceptions

`Commit` throws an `ApplicationException` if:

- The role name is `null`, empty, or invalid.
- The method cannot find the role or command right.
- The method cannot find authorization data for the zone.

If the `Commit` method fails, see the message returned by the exception for more specific information about the reason for the failure.

Delete

Deletes the role from Active Directory.

Syntax

```
void Delete()
```

Exceptions

Delete throws an ApplicationException if the method cannot find the role or authorization data for the zone.

If the Delete method fails, see the message returned by the exception for more specific information about the reason for the failure.

GetCommands

Returns all the command rights added to this role.

Syntax

```
ICommands GetCommands()
```

Return value

The collection of command rights. Enumerate this object to get all of the ICommand objects for this role.

GetNetworkAccesses

Returns the collection of all network application access rights added to this role.

Syntax

```
INetworkAccesses GetNetworkAccesses()
```

Return value

A collection of NetworkAccess objects representing all the network application access rights in this role.

GetPamAccesses

Returns the collection of all PAM application rights added to this role.

Syntax

```
IPams GetPamAccesses()
```

Return value

A collection of Unexpected Link Text objects representing all the PAM application rights in this role.

GetSshRights

Returns the collection of all SSH application rights added to this role.

Syntax

```
ISshs GetSshRights()
```

Return value

A collection of Unexpected Link Text objects representing all the SSH application rights in this role.

GetWindowsApplications

Returns the collection of all Windows application rights added to this role.

Syntax

```
IWindowsApplications GetWindowsApplications()
```

Return value

A collection of Unexpected Link Text objects representing all the Windows application rights in this role.

GetWindowsDesktops

Returns the collection of all Windows desktop rights added to this role.

Syntax

```
IWindowsDesktops GetWindowsDesktops()
```

Return value

A collection of Unexpected Link Text objects representing all the Windows desktop rights in this role.

IsApplicable

Checks to see if the role is valid at a specified time.

Syntax

```
bool IsApplicable(int dayOfWeek, int hourOfDay)
```

Parameter

Specify the following parameters when using this method.

dayOfWeek	The day of the week, where 0 is Sunday and 6 is Saturday.
hourOfDay	The hour of the day, where 0 is midnight and 23 is 11:00 PM

Return value

Returns `true` if the role is valid at the specified time.

Discussion

If the role is active at a particular hour, it is active for that entire hour. To set a specific hour, see Unexpected Link Text. To set an entire day, see Unexpected Link Text. To set up an entire schedule with one call, see Unexpected Link Text.

RemoveAllRights

Removes all rights from the role.

Syntax

```
void RemoveAllRights()
```

Discussion

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

RemoveCommand

Removes a specific command right from the role.

Syntax

```
void RemoveCommand(ICommand command)
```

Parameter

Specify the following parameter when using this method:

command	The command right you want to remove.

Discussion

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

RemoveNetworkAccess

Removes a specific network access right from the role.

Syntax

```
void RemoveNetworkAccess(INetworkAccess networkAccess)
```

Parameter

Specify the following parameter when using this method:

networkAccess	The network application access right you want to remove.

Discussion

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

RemovePamAccess

Removes a specific PAM application access right from the role.

Syntax

```
void RemovePamAccess(IPam pam)
```

Parameter

Specify the following parameter when using this method:

pam	The PAM application access right you want to remove.

Discussion

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

RemoveSshRight

Removes a specific SSH application access right from the role.

Syntax

```
void RemoveSshRight(ISsh ssh)
```

Parameter

Specify the following parameter when using this method:

ssh	The SSH application access right you want to remove.

Discussion

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

RemoveWindowsApplication

Removes a specific Windows application access right from the role.

Syntax

```
void RemoveWindowsApplication(IWindowsApplication windowsApplication)
```

Parameter

Specify the following parameter when using this method:

windowsApplication	The Windows application access right you want to remove.

Discussion

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

RemoveWindowsDesktop

Removes a specific Windows desktop right from the role.

Syntax

```
void RemoveWindowsDesktop(IWindowsDesktop windowsDesktop)
```

Parameter

Specify the following parameter when using this method:

windowsDesktop	The Windows desktop right you want to remove.

Discussion

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

SetApplicableDay

Sets a day of the week on which the role is active or inactive.

Syntax

```
void SetApplicableDay(int dayOfWeek, bool isApplicable)
```

Parameter

Specify the following parameters when using this method.

dayOfWeek	The day of the week on which you want the role to be active or inactive, where 0 is Sunday and 6 is Saturday.
isApplicable	Set true to make the role active on the specified day, or false to make the role inactive on that day.

Discussion

If you set the role active on Monday, it is active all day each Monday. To set a specific hour, see Unexpected Link Text. To set up an entire schedule with one call, see Unexpected Link Text. To check whether the role is active at a given time, see Unexpected Link Text.

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

SetApplicableHour

Sets a day and hour of the week for which the role is active or inactive.

Syntax

```
void SetApplicableHour(int dayOfWeek, int hourOfDay, bool isApplicable)
```

Parameter

Specify the following parameters when using this method.

dayOfWeek	The day of the week on which you want the role to be active or inactive, where 0 is Sunday and 6 is Saturday.
hourOfDay	The hour of the day at which you want the role to be active or inactive, where 0 is midnight and 23 is 11:00 PM
isApplicable	Set true to make the role active on the specified day and hour, or false to make the role inactive.

Discussion

If you set the role active on Monday at 10 AM, it is active every Monday from 10:00 to 10:59. To set an entire day, see Unexpected Link Text. To set up an entire schedule with one call, see Unexpected Link Text. To check whether the role is active at a given time, see Unexpected Link Text.

Changes to the role assignments are not stored in Active Directory until you call the Unexpected Link Text method.

AllowLocalUser

Determines whether the role allows local users.

Syntax

```
bool AllowLocalUser {get; set;}
```

Property value

Set to `true` if the role allows local users. The default is `false`.

ApplicableTimeHexString

Gets or sets the time at which the role is active, specified as a hexadecimal number.

Syntax

```
string ApplicableTimeHexString {get; set;}
```

Property value

The times at which the role is active or inactive.

Discussion

This is a 42-character (21-byte) hexadecimal value stored as a string. When the hex value is converted to a binary value, its 168 bits each map to a single hour within the week. If a bit is set to 1, its corresponding hour is enabled for the role. If set to 0, its corresponding hour is disabled.

For details of how the bits are mapped to the hours of the week, see Reading and setting timebox values

To set a specific hour, see Unexpected Link Text. To set an entire day, see Unexpected Link Text. To check whether the role is active at a given time, see Unexpected Link Text.

Exceptions

`ApplicableTimeHexString` throws an `ArgumentException` if the hex string is invalid.

Description

Gets or sets a description of the role.

Syntax

```
string Description {get; set;}
```

Property value

A description of the role.

Guid

Gets the GUID for this role.

Syntax

```
Guid Guid {get;}
```

Property value

The GUID. If the role has not been saved, this property returns Guid.Empty.

IsReadable

Indicates whether the role is readable.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns `true` if the role is readable.

Discussion

This property returns a value of true if the user accessing the `Role` object in Active Directory has sufficient permissions to read its properties.

IsWritable

Indicates whether the role is writable.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns `true` if the role is writable.

Discussion

This property returns a value of true if the user accessing the `Role` object in Active Directory has sufficient permissions to write its properties.

Name

Gets or sets the name of the role.

Syntax

```
string Name {get; set;}
```

Property value

The name of the role. The name can contain only letters (upper- or lowercase), numerals 0 through 9, and the hyphen (-) and underscore (_) characters.

Exceptions

`Name` throws an `ArgumentException` if the name is `null` or empty or contains invalid characters.

SystemRights

Gets or sets system rights granted to the role.

Syntax

```
SystemRight SystemRights {get; set;}
```

Property value

A byte indicating which system rights are granted.

Possible values:

```
public enum SystemRight
{
    // No system rights
       None = 0,
    // Log in with password
       LoginWithPassword = 1,
    // Log in without password (single sign-on)
       LoginWithoutPassword = 2,
    // Ignore disabled status in Active Directory and log in anyway
       IgnoreDisabled = 4,
    // Allow using a full shell
       AllowNonRestrictedShell = 8,
    // NoAudit
       NoAudit = 16,
    // Audit always required
       AuditRequired = 32
    // Multi-factor authentication required
       MfaRequired = 512,
    // Permit login when running in emergency mode
       Rescue = 64
    // Allow logging in from the console
       ConsoleLogon = 128
    // Allow logging in remotely (RDP)
       RemoteLogon = 256
    // Allow powershell remote access
       PsRemote = 1024
}
```

Discussion

The Rescue system right allows the user to log in when there are problems with the authorization cache or the auditing service that are preventing all other users from logging in. For example, if auditing is required but the auditing service is not running or not available, only users with the rescue system right will be allowed to log in. The rescue system right requires the Delinea NSS module to be running in “emergency” mode because the adclient process is not running.

Zone

Gets the zone to which this role belongs.

Syntax

```
IZone Zone {get;}
```

Property value

The zone.

Delinea

RoleAssignment

This class represents a zone-level role assignment.

Syntax

```
public interface IRoleAssignment
```

Methods

The RoleAssignment class provides the following methods:

Unexpected Link Text	VBScript interface to clear the custom attributes for this class.
Unexpected Link Text	Commits changes in the role assignment to Active Directory.
Unexpected Link Text	Deletes the role assignment.
ICustomAttributeContainer Unexpected Link Text	.NET interface that returns the directory entry for the parent container object for the custom attributes for this class.
Unexpected Link Text	Returns the trustee being assigned.
Unexpected Link Text	VBScript interface to set the custom attributes for this class.
Unexpected Link Text	Validates the role assignment

Properties

The RoleAssignment class provides the following properties:

Unexpected Link Text	VBScript only: Gets or sets custom attributes for this class.
Unexpected Link Text	Determines the time at which this role assignment becomes inactive.
Unexpected Link Text	Gets the GUID of the role assignment.
Unexpected Link Text	Indicates whether the role assignment is orphaned due to a missing or invalid role.
Unexpected Link Text	Indicates whether the role assignment is orphaned due to a missing or invalid trustee.
Unexpected Link Text	Gets or sets the local trustee being assigned.
Unexpected Link Text	Gets or sets the role the trustee is assigned to.
Unexpected Link Text	Gets or sets the time from which this role assignment becomes effective.
Unexpected Link Text	Gets or sets the distinguished name of the trustee assigned this role.
`TrusteeType	Gets or sets the trustee type of the role assignment.

Commit

Commits any changes or updates to the role assignment and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

The method does not validate the data before saving it in Active Directory. Call the Unexpected Link Text method before calling the Commit method to make sure the data is valid.

Exceptions

Commit throws an ApplicationException if:

- The role assignment already exists.
- The method cannot find the role assignment or the role.
- The method cannot find authorization data for the zone.

If the Commit method fails, see the message returned by the exception for more specific information about the reason for the failure.

Delete

Deletes the role assignment from Active Directory.

Syntax

```
void Delete()
```

Exceptions

`Delete` throws an `ApplicationException` if the method cannot find the role assignment or authorization data for the zone.

If the `Delete` method fails, see the message returned by the exception for more specific information about the reason for the failure.

GetTrustee

Returns the trustee assigned to the role.

Syntax

```
DirectoryEntry GetTrustee()
```

Return value

The directory entree of the user or group assigned by this role assignment.

Exceptions

`GetTrustee` throws an `ApplicationException` if the method fails to get the trustee object from directory services.

Validate

Validates the data in the role assignment object before any changes are committed to Active Directory.

Syntax

```
void Validate()
```

Exceptions

Validate throws an ApplicationException if:

- The role assignment already exists.
- The role is null.
- The method cannot find the role assignment or the role.
- The method cannot find authorization data for the zone.
- The start time is later than the end time.

If the Validate method fails, see the message returned by the exception for more specific information about the reason for the failure.

EndTime

Gets or sets the time after which this role assignment is inactive.

Syntax

```
DateTime EndTime {get; set;}
```

Property value

The time at which the role assignment ceases to be active. A value of `DateTime.MaxValue` means the role assignment never expires. The time must be later than 1/1/1970 00:00.

Exceptions

`EndTime` throws an `ArgumentException` if you try to set the end time earlier than the start time or earlier than 2400 hours UTC, 1 January, 1970.

Id

Gets the GUID of the role assignment.

Syntax

```
Guid Id {get;}
```

Property value

The GUID of the role assignment.

IsRoleOrphaned

Indicates whether the role assignment is orphaned due to a missing or invalid role.

Syntax

```
bool IsRoleOrphaned {get;}
```

Property value

Returns `true` if this role assignment is an orphan.

IsTrusteeOrphaned

Indicates whether the role assignment is orphaned due to a missing or invalid user or group.

Syntax

```
bool IsTrusteeOrphaned {get;}
```

Property value

Returns `true` if this role assignment is an orphan.

LocalTrustee

Gets or sets the local user or group being assigned.

Syntax

```
string LocalTrustee {get; set;}
```

Property value

The local trustee; either a group or user. You can set either a name or ID for a local user. A local group string begins with the type flag %. You cannot specify a null or empty string. A user or group name string must match the regular expression (Regex):

@"^%?[\.a-zA-Z0-9_-]+\$?@localhost$"

A user ID string must match the regular expression:

@"^#[0-9]+@localhost$"

Exceptions

LocalTrustee may throw one of the following exceptions:

- ArgumentException if the local trustee string is null or empty.
- ApplicationException if the method fails to update the role assignment (see the message returned by the exception for the reason).

Role

Gets or sets the role.

Syntax

```
IRole Role {get; set;}
```

Property value

The object representing the role.

Exceptions

`Role` throws an `ApplicationException` if the role you specify is not in the current or parent zone.

If the `Role` property fails, see the message returned by the exception for more specific information about the reason for the failure.

StartTime

Gets or sets the time from which this role assignment becomes effective.

Syntax

```
DateTime StartTime {get; set;}
```

Property value

The time at which the role assignment becomes active. A value of `DateTime.MinValue` means the role becomes effective immediately. The time must be later than 1/1/1970 00:00.

Exceptions

`StartTime` throws an `ArgumentException` if you try to set the start time later than the end time or earlier than 2400 hours UTC, 1 January, 1970.

TrusteeDn

Gets or sets the user associated with the role.

Syntax

```
string TrusteeDn {get; set;}
```

Property value

The distinguished name of the user.

Exceptions

`TrusteeDn` may throw one of the following exceptions:

- `ArgumentException` if the trustee string is null or empty.
- `ApplicationException` if the method fails to update the role assignment trustee (see the message returned by the exception for the reason).

TrusteeType

Gets or sets the trustee type of the role assignment.

Syntax

```
TrusteeType TrusteeType {get; set;}
```

Property value

The type of trustee.

Possible values:

```
public enum TrusteeType
{
    // Unknown
       Unknown = 0,
    // AD User
       User = 1,
    // AD group
       Group = 2,
    // Local UNIX user
       LocalUser = 4,
    // Local UNIX group
       LocalGroup = 8,
    // All AD Users
       AllADUsers = 16,
    // All local UNIX accounts
       AllUnixUser = 32
    // Local Windows user
       LocalWindowsUser = 64
    // Local Windows group
       LocalWindowsGroup = 128
    // All local Windows users
       AllWindowsUsers = 256
};
```

Exceptions

`TrusteeType` throws an `ArgumentException` if you try to set the trustee type to any value other than `AllADUsers` or `AllUnixUser`.

RoleAssignments

The RoleAssignments class manages a collection of Role Assignment objects.

Syntax

```
public interface IRoleAssignments
```

Methods

The RoleAssignments class provides the following method:

Unexpected Link Text	Returns an enumeration of role assignments.

GetEnumerator

Returns an enumeration of role assignments.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of RoleAssignment objects.

Exceptions

GetEnumerator throws an ApplicationException if it cannot find the scope in the zone, cannot find the role, or cannot find authorization data for the zone.

If the GetEnumerator method fails, see the message returned by the exception for more specific information about the reason for the failure.

Delinea

Roles

The Roles class manages a collection of Role objects.

Syntax

```
public interface IRoles
```

Methods

The Roles class provides the following method:

Unexpected Link Text	Returns an enumeration of roles.

GetEnumerator

Returns an enumeration of roles.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of Role objects.

Exceptions

GetEnumerator throws an ApplicationException if it cannot find authorization data for the zone.

If the GetEnumerator method fails, see the message returned by the exception for more specific information about the reason for the failure.

Ssh

Represents an SSH application access right.

Syntax

```
public interface ISsh: IRight
```

Discussion

An SSH (Secure Shell) application right gives a user the ability to access the authorized SSH-enabled application.

Methods

The Ssh class provides the following methods:

Unexpected Link Text	Commits changes in the right to Active Directory. (Inherited from Right
Unexpected Link Text	Deletes the right. (Inherited from Right.)

Properties

The Ssh class provides the following properties:

Unexpected Link Text	Gets or sets the SSH application.
Unexpected Link Text	Gets or sets the description of the right. (Inherited from Right.)
Unexpected Link Text	Indicates whether the right is readable. (Inherited from Right.)
Unexpected Link Text	Indicates whether the right is writable. (Inherited from Right.)
Unexpected Link Text	Gets or sets the name of the right. (Inherited from Right.)
Unexpected Link Text	Gets the zone this right belongs to. (Inherited from Right.)

Application

Gets or sets the SSH application for which this is a right.

Syntax

```
string Application {get; set;}
```

Property value

The file path of the application.

Exceptions

`Application` throws an `ArgumentException` if the application string is `null` or empty.

Sshs

The Sshs class manages a collection of SSH application access rights.

Syntax

```
public interface ISshs
```

Methods

The Sshs class provides the following method:

Unexpected Link Text	Returns the enumerator you can use to enumerate all SSH rights.

GetEnumerator

Returns an enumeration of SSH access rights.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

An enumerator you can use to list all the Ssh objects.

Store

The Store class contains methods and properties used to manage a zone's NIS maps stored in Active Directory. This class is defined in the Centrify.DirectControl.NISMap.API namespace rather than the Centrify.DirectControl.API namespace.

Syntax

```
public class IStore : ICloneable, IDisposable
```

Discussion

The Store class supports the methods and properties that apply to all .NET objects. In addition to those methods and properties, the Store class provides some Delinea-specific methods and properties for managing network or generic NIS maps in a zone. Only Delinea-specific methods and properties are described in this reference.

Methods

The Store class provides the following Delinea-specific methods:

Unexpected Link Text	Links the Store object to the specified zone.
Unexpected Link Text	Makes a copy of the current Store object instance. Inherited from ICloneable.
Unexpected Link Text	Creates a new NIS map object in the zone in Active Directory.
Unexpected Link Text	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.
Unexpected Link Text	Removes the specified NIS map from the zone and Active Directory.
Unexpected Link Text	Checks whether there is a NIS map with the specified name.
Unexpected Link Text	Gets the directory entry for the NIS map container.
Unexpected Link Text	Opens the NIS map with the specified name.

Properties

The Store class provides the following Delinea-specific properties:

Unexpected Link Text	Indicates whether the NIS map store is readable.
Unexpected Link Text	Indicates whether the NIS map store is writable.

Attach

Attaches the Centrify.DirectControl.NisMap.API namespace storage object to the specified zone.

Syntax

```
void Attach(string zonePath, string username, string password)

void Attach(DirectoryEntry zoneEntry)
```

Parameters

Specify the following parameters when using this method.

zonePath	The LDAP path to the zone to which you want to attach the NIS map storage object.
username	The user name to use when linking the NIS map storage object to the specified zone.
password	The user password to use when linking the NIS map storage object to the specified zone.
zoneEntry	The directory entry for the zone to which you want to attach the NIS map storage object. (.NET only)

Exceptions

Attach may throw the following exception:

- COMException if an error occurs in a call to the underlying interface.
- ApplicationException if it fails to locate the NIS map store, the domain controller is read-only, access is not authorized, or an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using Attach to create a map storage object and attach it to a zone:

```
...
'Identify the zone in which the NIS maps will be created
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone.
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "jae.smith", "pas$w0rd"
'Use store.Create to add a generic NIS map in this zone.
store.Create "generic map","Generic Map"
'Use store.Create to also add two auto_master NIS maps
store.Create "auto.master","AutoMaster Map"
store.Create "auto_master","AutoMaster Map"
'Use store.Create to add a automount NIS map
store.Create "auto.mount","Automount Map"
'Use store.Create to add a netgroup NIS map
store.Create "netgroup","Netgroup Map"
wScript.Echo "NIS Maps added to " & zone.Name
...
```

Create

Creates a new NIS map with the specified name.

Syntax

```
Map Create(string mapName, string type)
```

Parameters

Specify the following parameters when using this method.

mapName	The name of the NIS map you want to create.
type	The type of NIS map to create.

Return value

The map object created.

Discussion

When you use this method to create NIS maps, you can specify just the map name or the map name and map type. Internally, however, the map name and type defines how fields are parsed and interpreted for standard network maps and generic maps. For example, the netgroup map name can only be used to create a netgroup type of NIS map. In most cases, you should only create generic maps (key value pairs) using this method to prevent NIS maps from becoming unusable due to unexpected formatting.

Exceptions

Create may throw one of the following exceptions:

- COMException if there is an LDAP error. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- ArgumentException if the map name is not valid.

Example

The following code sample illustrates using Create to add new NIS maps to a zone:

```
...
'Identify the zone in which the NIS maps will be created
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone.
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "jae.smith", "pas$w0rd"
'Use store.Create to add a generic NIS map in this zone.
store.Create "Contact List","Generic Map"
'Use store.Create to also add the auto_master NIS maps
store.Create "auto_master","AutoMaster Map"
'Use store.Create to add a automount NIS map
store.Create "automounts","Automount Map"
'Use store.Create to add a netgroup NIS map
store.Create "netgroup","Netgroup Map"
wScript.Echo "NIS Maps added to " & zone.Name
```

Delinea

...

Delete

Deletes the specified NIS map.

Syntax

```
void Delete(string mapName)
void Delete(IMap map)
```

Parameter

Specify the following parameter when using this method:

mapName	The name of the NIS map you want to remove.
map	The NIS map you want to remove. (.NET only)

Exceptions

Delete throws a COMException if there is an LDAP error. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using Delete to remove NIS maps from a zone:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "jae.smith", "pas$w0rd"
'Use store.Delete to delete the generic map named "generic map"
store.Delete "generic map"
wScript.Echo "NIS map deleted."
...
```

Exists

Checks whether there is a NIS map with the specified name.

Syntax

```
bool Exists(string mapName)
```

Parameter

Specify the following parameter when using this method:

mapName	The map name whose existence you want to check for.

Return value

Returns true if the specified NIS map exists.

Exceptions

Exists throws a COMException if an error occurs during a call to the underlying interface.

Example

The following code sample illustrates the use of Store.Exists:

```
SET cims = CreateObject("Centrify.DirectControl.Cims3")
SET zone = cims.GetZone("example.org/Zones/default")
SET store = CreateObject("Centrify.DirectControl.Nis.Store")
store.Attach zone.ADsPath, "username", "password"
IF NOT store.Exists("netgroup") THEN
store.Create "netgroup", "408EE104-1864-41fa-B346-19FED4092E68"
END IF
```

GetDirectoryEntry

Returns the directory entry for the NIS map container.

Syntax

```
DirectoryEntry GetDirectoryEntry ()
```

Return value

The DirectoryEntry attribute of the NIS map container.

Discussion

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Open

Opens the NIS map with the specified name.

Syntax

```
Map Open(string mapName);
```

Parameter

Specify the following parameter when using this method:

mapName	The name of the NIS map you want to remove.

Return value

The `map` object instance of the specified map, or `null` if the specified map is not found.

Exceptions

`Open` throws a `COMException` if there is an LDAP error. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using `Open` to access a specific NIS map:

```
...
'Identify the zone you want to work with
set zone = cims.GetZone("sample.com/centrify/zones/default")
'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone.
'Provide the path to the zone and user credentials (username and 'password).
store.Attach zone.ADsPath, "jae.smith", "pas$w0rd"
'Open the NIS map named "Remote servers"
Set map = store.Open("Remote servers")
...
```

IsReadable

Indicates whether the NIS map storage object is readable.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns `true` if the map storage object is readable by the user, or `false` if the map storage object is not readable.

Discussion

This property returns a value of true if the user accessing the NIS map storage object in Active Directory has sufficient permissions to read its properties.

Exceptions

`IsReadable` may throw one of the following exceptions:

- `ApplicationException` if the store entry cannot be located.
- `COMException` if there is an error in a call to the underlying interface.

Example

The following code sample illustrates using this property in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=offshore,CN=unix,DC=quantum,DC=net")

'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach objZone.ADsPath, "tae.parker", "9days^"
'Check whether the map node is readable
if not store.IsReadable then
wScript.Echo "No read permission. Quitting application ..."
wScript.Quit
end if
...
```

IsWritable

Indicates whether the NIS map storage object is writable.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns true if the map storage object is writable by the user, or false if the map storage object is not writable.

Discussion

This property returns a value of true if the user accessing the NIS map storage object in Active Directory has sufficient permissions to change the storage object's properties.

Exceptions

IsWritable throws a COMException if there is an LDAP error. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using this property in a script:

```
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=offshore,CN=unix,DC=quantum,DC=net")

'Create the Store object
Set store = CreateObject("Centrify.DirectControl.Nis.Store")
'Attach to the target zone
'Provide the path to the zone and username and password.
store.Attach objZone.ADsPath, "tae.parker", "9days^"
'Check whether the map node is writable
if not store.IsWritable then
wScript.Echo "No write permission. Quitting application ..."
wScript.Quit
end if
...
```

User

The User class enables Delinea to associate existing Active Directory user accounts with UNIX profiles that contain the attributes required for users to log on to UNIX computers.

Syntax

public interface IUser

Discussion

These additional UNIX-specific attributes that make up the UNIX profile for an Active Directory user are stored and managed within the UserUnixProfile object.

Methods

The User class provides the following methods:

AddUnixProfile	Adds a new UNIX profile for a user to the specified zone.
Commit	Commits the changes to the User object and saves them in Active Directory.
CommitWithoutCheck	Commits the changes to the User object without validating any of the data before saving.
GetDirectoryEntry	Returns an instance of the DirectoryEntry for the user from Active Directory.
GetRoleAssignmentsFromDomain	Returns the collection of all role assignments for a user in a specified domain.
GetRoleAssignmentsFromForest	Returns the collection of all role assignments for a user in a specified forest.
Refresh	Reloads the data in the cache from Active Directory.

Properties

The User class provides the following properties:

AdsiInterface	Gets the ADSI interface of the user object in Active Directory.
ADsPath	Gets the LDAP path to the Active Directory user object.
ID	Gets the UID for the user as a string.
UnixProfiles	Gets the collection of UNIX profiles for the user.

AddUnixProfile

Adds a new UNIX profile for an existing Active Directory user account to the specified zone.

Syntax

IUserUnixProfile AddUnixProfile (IZone zone, int uid, string name, string shell, string homeDir, int primaryGroup)

IUserUnixProfile AddUnixProfile (IZone zone, long uid, string name, string shell, string homeDir, long primaryGroup)

Parameters

Specify the following parameters when using this method.

zone	The destination zone for the new user information.
uid	The UID of the user associated with the profile.
name	The UNIX login name of the user associated with the profile.
shell	The default shell of the user associated with the profile.
homeDir	The default home directory of the user associated with the profile.
primaryGroup	The GID of the primary group of the user associated with the profile.

Return value

A new UserUnixProfile object.

Discussion

There are two versions of this method: one designed for COM-based programs that supports a 32-bit signed number for the uid and primaryGroup arguments and one designed for .NET-based programs that allows a 64-bit signed number for the arguments.

Exceptions

AddUnixProfile throws a NotSupportedException if the zone schema is not supported.

Example

The following code sample illustrates using AddUnixProfile in a script:

```
...
// Create a CIMS object to interact with AD
ICims cims = new Cims();
// Note: There is no cims.connect function.
// By default, this application will use the connection to the domain controller

// and existing credentials from the computer already logged in.
// Get the user object
IUser objUser = cims.GetUserByPath(strUser);
// Get the zone object
IZone objZone = cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN);
IUserUnixProfile objUserUnixProfile;
if (objUser.UnixProfiles.Find(objZone) == null)
{
    // New user for the zone
    long lngUID = objZone.NextUID;
    string strShell = objZone.DefaultShell;
    string strHome = objZone.DefaultHomeDirectory;
    if (bool.Parse(bPrivate))
```

```
    {
        // Create the user as a member of a private group
        objUserUnixProfile = objUser.AddUnixProfile(objZone, lngUID, strUnixAccount,
        strShell, strHome, lngUID);
    }
    else
    {
        // Create the user as a member of the default group
        IGroupUnixProfile objDefaultGroup = objZone.DefaultGroup;
        long lngGID = 10000; // use 10000 as default
        if (objDefaultGroup != null)
        {
            lngGID = objDefaultGroup.GroupId;
        }
        objUserUnixProfile = objUser.AddUnixProfile(objZone, lngUID, strUnixAccount,
            strShell, strHome, lngGID);
    }
    // Enable the UNIX profile for the end user
    objUserUnixProfile.UnixEnabled = true;
    objUserUnixProfile.Commit();
}
else
{
    Console.WriteLine(strUser + " is already a member of " + strZone);
    return;
}
Console.WriteLine("User " + strUser + " was successfully added to zone " +
    strZone + ".");
...
```

Commit

Commits any changes or updates to the User object and saves the changes to Active Directory.

Syntax

```
void Commit()
```

Discussion

When you use this method, it checks and validates the data before saving it in Active Directory.

Exceptions

Commit may throw one of the following exceptions:

- ApplicationException if any field in the UNIX profile is not valid.
- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- UnauthorizedAccessException if you have insufficient access rights to commit changes to the Active Directory object.

Example

The following code sample illustrates using Commit in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the user object
set objUser = cims.GetUserByPath("LDAP://CN=pat.hu,CN=Users, DC=ajax,DC=org")
'Add the UNIX profile for the user
set objUserUnixProfile = objUser.AddUnixProfile(objZone, 623, "pat_hu",
"/bin/bash", "/home/pat_hu", 623)
'Enable the user's UNIX profile
objUserUnixProfile.UnixEnabled = True
'Update Active Directory
objUserUnixProfile.commit
...
```

CommitWithoutCheck

Commits any changes or updates to the User object and saves the changes to Active Directory.

Syntax

```
void CommitWithoutCheck()
```

Discussion

When you use this method, it does not validate any of the data before saving.

Exceptions

CommitWithoutCheck may throw one of the following exceptions:

- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.
- UnauthorizedAccessException if you have insufficient access rights to commit changes on the Active Directory object.

Example

The following code sample illustrates using CommitWithoutCheck in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the user object
set objUser = cims.GetUserByPath("LDAP://CN=pat.hu,CN=Users, DC=ajax,DC=org")
'Add the UNIX profile for the user
set objUserUnixProfile = objUser.AddUnixProfile(objZone, nextuid, unixlogin,
defaultshell, homedir, admingid)
'Enable the user's UNIX profile
objUserUnixProfile.UnixEnabled = True
'Update Active Directory without validating the UNIX profile
objUserUnixProfile.CommitWithoutCheck
...
```

GetDirectoryEntry

Returns the directory entry for the user from Active Directory.

Syntax

```
DirectoryEntry GetDirectoryEntry()
```

Return value

A directory entry for the service connection point that represents the user's UNIX profile.

Discussion

The `DirectoryEntry` object represents the directory object for the user and its associated attributes.

> **Note**: This method can only be used in .NET programs because `DirectoryEntry` is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Exceptions

`GetDirectoryEntry` throws an `ApplicationException` if it cannot get the directory object.

GetRoleAssignmentsFromDomain

Returns the collection of all role assignments associated with a user in a specified domain.

Syntax

```
IRoleAssignments GetRoleAssignmentsFromDomain(string domain)
```

Parameters

Specify the following parameter when using this method:

domain	The domain to search for the user's role assignments.

Return value

A collection of role assignment objects representing all of the role assignments explicitly assigned to this user in the specified domain or in the currently joined domain.

Discussion

This method only returns the role assignments that have been explicitly assigned to the user. The method will look for stored credentials to access the specified domain. If there are no stored credentials, the method uses the default credentials for the current user.

If you don't specify a domain by passing an empty string ("") to the method, the method returns role assignments from the currently joined domain.

Example

The following code sample illustrates using GetRoleAssignmentsFromDomain in a script:

```
...
\# New Cims object
\$cims = New-Object ("Centrify.DirectControl.API.Cims");
\# Get IUser object
\$objUserDn = "CN=user1,CN=Users,DC=domain,DC=com";
\$objUser = \$cims.GetUser(\$objUserDn);
\# Get role assignments from domain
\$objUser.GetRoleAssignmentsFromDomain("domain.com")
...
```

GetRoleAssignmentsFromForest

Returns the collection of all role assignments associated with a user in a specified Active Directory forest.

Syntax

```
IRoleAssignments GetRoleAssignmentsFromForest(string forest)
```

Parameters

Specify the following parameter when using this method:

forest	The forest to search for the user's role assignments.

Return value

A collection of role assignment objects representing all of the role assignments explicitly assigned to this user in the specified forest or in the currently joined forest.

Discussion

This method only returns the role assignments that have been explicitly assigned to the user. The method will look for stored credentials to access the specified forest. If there are no stored credentials, the method uses the default credentials for the current user.

If you don't specify a forest by passing an empty string ("") to the method, the method returns role assignments from the currently joined forest.

Example

The following code sample illustrates using GetRoleAssignmentsFromForest in a script:

```
...
\# New Cims object
\$cims = New-Object ("Centrify.DirectControl.API.Cims");
\# Get IUser object
\$objUserDn = "CN=user1,CN=Users,DC=domain,DC=com";
\$objUser = \$cims.GetUser(\$objUserDn);
\# Get role assignments from forest
\$objUser.GetRoleAssignmentsFromForest("forest.com")
...
```

Refresh

Reloads the User object data from the data in Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the user information in the cached object to ensure it is synchronized with the latest information in Active Directory.

Exceptions

Refresh throws a COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using Refresh in a script:

```
...
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=corporate,CN=zones,CN=centrify,CN=program
data,DC=sierra,DC=com")
'Get the user object
set objUser = cims.GetUserByPath("LDAP://CN=pat.hu,CN=Users,DC=ajax,DC=org")
'Get the UNIX profile for the user
profile = objUser.UnixProfiles
'Enable the user's UNIX profile
profile.UnixEnabled = True
'Reload the user object
objUser.Refresh
...
```

AdsiInterface

Gets the ADSI interface of the user object in Active Directory.

Syntax

IADsUser AdsiInterface {get;}

Property value

The ADSI interface of the user object in Active Directory.

Example

The following code sample illustrates using AdsiInterface in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfiles
'Display the ADSI interfce for the user
wScript.Echo “ADSI: “ & profile.AdsiInterface
...
```

ADsPath

Gets the LDAP path to the Active Directory user object.

Syntax

```
string ADsPath {get;}
```

Property value

The LDAP path to the Active Directory user object.

Discussion

The basic format for the LDAP path is:

```
LDAP://[\<domain\>/]\<attr\>=\<name\>...,dc=\<domain part\>...
```

For example, if the user object is `john.doe` in the organizational unit consultants and the domain is `acme.com`, the LDAP path to the object looks like this:

```
LDAP://cn=john.doe,ou=consultants,dc=acme,dc=com
```

Example

The following code sample illustrates using `ADsPath` in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfiles
'Display the LDAP path for the user
wScript.Echo “LDAP Path: “ & profile.ADsPath
...
```

ID

Gets the unique identifier for the user as a string value.

Syntax

```
string ID {get;}
```

Property value

The unique identifier for the user as a string.

Example

The following code sample illustrates using ID in a script:

```
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfiles
'Display the UID for the user
wScript.Echo “User Identifier (UID): “ & profile.ID
…
```

UnixProfiles

Gets all of the UNIX profiles for a specified Active Directory user in the current domain.

Syntax

IUserUnixProfiles UnixProfiles {get;}

Property value

The collection of UNIX profiles for the user.

Discussion

The resulting object, UserUnixProfiles, is the collection of UNIX profiles that have been defined for the user across all zones.

Example

The following code sample illustrates using UnixProfiles in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the user object
set objUser = cims.GetUserByPath("LDAP://CN=tai.wu,CN=Users, DC=ajax,DC=org")
'Look up the user's UNIX profile in the zone
dim objUserUnixProfiles
set objUserUnixProfiles = objUser.UnixProfiles
set objUserUnixProfile = objUserUnixProfiles.Find(objZone)
```

UserInfo

The UserInfo class contains methods and properties used to import and map UNIX user profiles to Active Directory user accounts. This class is defined in the Centrify.DirectControl.API.Import namespace.

Syntax

public interface IUserInfo : IDisposable

Methods

The UserInfo class provides the following methods:

Commit	Commits any changes to the pending import user object and saves them in Active Directory.
Delete	Marks the pending user profile object for deletion from Active Directory.
Dispose	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.
GetCandidate	Returns the directory object of a user pending import.
Import	Links the pending import user profile with the specified Active Directory user account.
SetCandidate	Sets the directory object of a user pending import.
UpdateStatus	Checks the Active Directory forest for matching or conflicting information that will allow or prevent a pending import user being imported.

Properties

The UserInfo class provides the following properties:

CandidateDN	Gets the distinguished name (DN) of the import candidate.
Gecos	Gets or sets the GECOS field of the UNIX profiles for the pending import user.
HomeDirectory	Gets or sets the home directory for the pending import user.
ID	Gets the unique ID of the pending import user object.
Name	Gets or sets the UNIX user name for a pending import user.
PrimaryGroupID	Gets or sets the UNIX group identifier (GID) of the primary group for the pending import user profile.
Shell	Gets or sets the default login shell for the pending import user.
Source	Gets the text string that describes the source of the pending import data.
Status	Gets the status of the pending import user.
StatusDescription	Gets a text string that provides detailed information about the status of the pending import user.
TimeStamp	Gets the date and time that the pending user profiles were imported from the data source.

UID	Gets or sets the UNIX user identifier (UID) for the pending import user profile.

Commit

Commits any changes or updates to the pending import user object and saves them in Active Directory.

Syntax

```
void Commit()
```

Delete

Marks the pending user profile object for deletion from Active Directory.

Syntax

```
void Delete()
```

Discussion

This method does not delete the pending user profile. After you mark the object for deletion, you must use the Commit method to commit changes to the object to Active Directory. When the Commit method is executed, the pending user profile is deleted from Active Directory to complete the operation.

Exceptions

Delete throws an `UnauthorizedAccessException` if you have insufficient access rights to remove the UNIX profile in the zone. s

GetCandidate

Returns the directory object of a user pending import.

Syntax

```
DirectoryEntry GetCandidate()
```

Return value

The directory object of a user that is a candidate for import. Returns `null` if the candidate cannot be found.

Import

Imports the pending import user profile by associating the UNIX properties for the user with the specified Active Directory user account.

Syntax

```
void Import(IUser user)
```

Parameter

Specify the following parameter when using this method:

user	The user for which you want to retrieve profile information.

Discussion

This method links the pending import user to an Active Directory account and removes the user from the pending import list.

SetCandidate

Sets the directory object of a user pending import.

Syntax

```
void SetCandidate(DirectoryEntry entry)
```

Parameters

Specify the following parameter when using this method.

entry	The directory entry for the user that is a candidate for import.

Discussion

This method updates the CandidateDN property,

UpdateStatus

Checks the Active Directory forest for matching or conflicting information that will allow or prevent a pending import user being imported.

Syntax

```
void UpdateStatus()
```

Discussion

This method searches Active Directory for a user name that matches the pending import user name and updates the pending import user properties with the results of the search. For example, if no Active Directory match is found or a UNIX profile already exists for the matching Active Directory user, the method updates the pending user's properties with that information.

> **Note**: Checking the Active Directory forest for potential matching candidates or conflicts can be a time-intensive operation. Therefore, you should consider the size and distribution of the forest and limit the number of pending import users you are working with when using this method.

CandidateDN

Gets or sets the distinguished name (DN) of the import candidate.

Syntax

```
string CandidateDN {get; set;}
```

Property value

The matching Active Directory user object for pending user profile, if one is found. If there's no matching candidate in Active Directory, nothing is returned.

Discussion

This property returns the Active Directory user account that appears to match the pending user profile. If there's an existing Active Directory user that matches the pending user, the pending import user can be mapped to that account. If no matching candidate is found in Active Directory, this property returns a null value.

Gecos

Gets or sets the GECOS field of the UNIX profile for the pending import user.

Syntax

```
string Gecos {get; set;}
```

Property value

The text string value of the GECOS field in the UNIX profile for the pending import user.

HomeDirectory

Gets or sets the home directory field of the UNIX profile for the pending import user.

Syntax

```
string HomeDirectory {get; set;}
```

Property value

The text string value of the home directory field in the UNIX profile for the pending import user.

ID

Gets the unique ID of the pending import user object.

Syntax

```
string ID {get;}
```

Property value

The unique ID for the pending import group object.

Name

Gets or sets the UNIX user name for a pending import user.

Syntax

```
string Name {get; set;}
```

Property value

The UNIX user name of a pending import user.

PrimaryGroupID

Gets or sets the UNIX group identifier (GID) of the primary group for the pending import user profile.

Syntax

```
int PrimaryGroupID {get; set;}
```

Property value

The UNIX group identifier (GID) of the primary group for the pending import user profile.

Discussion

There are two versions of this property: one designed for COM-based programs that supports a 32-bit signed number one designed for .NET-based programs that allows a 64-bit signed number. Therefore, the data type for the property can be an integer (`int`) or a long integer (`long`) depending on the programming language you use.

Shell

Gets or sets the default login shell for the pending import user.

Syntax

```
string Shell {get; set;}
```

Property value

The text string value of the default login shell in the UNIX profile for the pending import user.

Source

Gets the text string that describes the source of the pending import data.

Syntax

```
string Source {get;}
```

Property value

A text string that describes the source of the pending import data.

Discussion

If the pending data was imported from a file, the property returns the source as File: followed be the path to the file name imported. If the source of the pending import data was a NIS server, the property returns the NIS server name and domain. For example, if the source of the data was a file, the property returns a string similar to this:

```
File: C:\\Migration\\magnolia_passwd
```

Status

Gets the status of the pending import user.

Syntax

```
StatusType Status {get;}
```

Property value

The status message for the pending import user.

Discussion

The status is determined by checking Active Directory for existing users that match or conflict with the pending import user. The property returns a number that determines the icon displayed for the user in the console. The icons indicate whether a pending user is:

Ready to import	Info	
Has potential issues that should be resolved	Warning	
Cannot be imported	Error	

StatusDescription

Gets a text string that provides detailed information about the status of the pending import user.

Syntax

```
string StatusDescription {get;}
```

Property value

The detailed status message for the pending import user.

Discussion

The status is determined by checking Active Directory for existing users that match or conflict with the pending import user. The results are displayed in **Access Manager** and in the **Status** tab of a pending user's **Properties** dialog box. The status description can also include details about the user's primary group. For example, if checking the Active Directory forest revealed a user name or UID conflict with an existing user or another pending import user, the StatusDescription property might include information similar to this:

```
No group with the corresponding GID found in Active Directory.
There is another pending imported user using the same UID.
There is another pending imported user using the same user name.
```

TimeStamp

Gets the date and time that the pending user profiles were imported from the data source.

Syntax

```
DateTime TimeStamp {get;}
```

Property value

The date and time that the pending user data was imported.

Example

The following code sample illustrates using this property in a script:

```
'Specify the zone you want to work with
Set objZone = cims.GetZone("w2k3.net/Acme/Zones/default")
‘Display the time users where imported
Set objPendUsers = objZone.GetImportPendingUsers
If not objPendUsers is nothing then
wScript.Echo "Imported from source: ", objPendUsers.TimeStamp
End if
…
```

UID

Gets or sets the UNIX user identifier (UID) for the pending import user profile.

Syntax

```
int UID {get; set;}
```

Property value

The UNIX user identifier (UID) for the pending import user profile.

Discussion

There are two versions of this property: one designed for COM-based programs that supports a 32-bit signed number one designed for .NET-based programs that allows a 64-bit signed number. Therefore, the data type for the property can be an integer (int) or a long integer (long) depending on the programming language you use.

UserInfos

The UserInfos class contains methods and properties used to manage a collection of pending import user profiles. This class is defined in the Centrify.DirectControl.API.Import namespace.

Syntax

```
public interface IUserInfos : IDisposable
```

Methods

The UserInfos class provides the following methods:

Dispose	Performs application-defined tasks associated with freeing, releasing, or resetting unmanaged resources. Inherited from IDisposable.
Find	Returns the pending import user with the specified identifier from the collection of pending user profiles.
GetEnumerator	Returns an enumeration of UserInfo objects.

Properties

The UserInfos class provides the following properties:

Count	Gets the total number of pending import user profiles defined in the collection represented by the UserInfos object.
IsEmpty	Indicates whether the collection of pending import users is empty.

Find

Returns the pending import user with the specified identifier from the collection of pending user profiles.

Syntax

```
IUserInfo Find(string id)
```

Parameter

Specify the following parameter when using this method:

id	The unique identifier of the pending user profile for which you want to retrieve information.

Return value

The UserInfo object for the specified pending import user.

GetEnumerator

Returns an enumeration of IUserInfo objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of UserInfo objects.

Count

Gets the total number of pending import user profiles defined in the collection represented by the UserInfos object.

Syntax

```
int Count {get;}
```

Property value

The number of pending import user profiles in the set.

Discussion

This property enumerates all of the profiles in the collection before it returns the Count value. If you only need to determine whether any pending import groups, you should use the [IsEmpty](property for a faster response time.

IsEmpty

Determines whether the collection of pending import user profiles is empty.

Syntax

```
bool IsEmpty {get;}
```

Property value

Returns `true` if there are no pending import user profiles in the `UserInfos` object, or `false` if there is at least one pending import user profile in the object.

Discussion

If there are no pending import user profiles in the `UserInfos` object, this property returns `true`. If these is at least one pending import user profile, the property returns `false`. Unlike the `Count` property, the `IsEmpty` property does not enumerate all of the pending import profiles in the collection before it returns a value. If you only need to determine whether any profiles are defined, you should call this property for a faster response.

UserUnixProfile

The UserUnixProfile class is an information class for managing user information in a specific zone.

Syntax

```
public interface IUserUnixProfile
```

Discussion

A user's zone-specific UNIX profile includes the numeric UID value, numeric GID value, default login shell, and default home directory. The GID can be associated with a standard Active Directory group, a standalone UNIX-only group profile not associated with any Active Directory group, and a local user profile.

Methods

The UserUnixProfile class provides the following methods:

Commit	Commits changes to the user profile to Active Directory.
Delete	Marks the user profile for deletion from Active Directory.
GetDirectoryEntry	Returns the directory entry for the UNIX user profile from Active Directory.
GetPrimaryGroup	Returns the UNIX profile of the primary group of the user.
Refresh	Reloads cached object data from Active Directory.
Validate	Checks whether the user profile contains valid data and can be committed to Active Directory.

Properties

The UserUnixProfile class provides the following properties:

ADsPath	Gets the LDAP path to the UNIX data object.
Cims	Gets the Cims object for the user.
HomeDirectory	Gets or sets the home directory for the user.
ID	Gets the unique identifier for the UserUnixProfile data object.
IsForeign	Indicates whether the Active Directory user associated with a UNIX profile is defined in a different forest than the zone (not applicable to local user profiles).
IsOrphan	Indicates whether this UNIX user is not associated with a corresponding Active Directory user (not applicable to local user profiles).
IsReadable	Indicates whether the Active Directory object is readable.
IsSFU	Indicates whether this UNIX user is an SFU zone profile (not applicable to local user profiles).
IsWritable	Determines whether the Active Directory object is writable.

Name	Gets or sets the UNIX login name of the user.
PrimaryGroup	Gets or sets the GID of the user's primary group.
ProfileState	Gets or sets the profile state of the local user profile (local user profiles only).
Shell	Gets or sets the default shell for the user.
Type	Gets the UserUnixProfile type for the user.
UnixEnabled	Determines whether the user's UNIX profile is enabled for access to the zone.
User	Gets the user object associated with this user UNIX profile (not applicable to local user profiles).
UserId	Gets or sets the UNIX user identifier (UID).
Zone	Gets the zone object associated with the user.

Commit

Commits changes to the user profile object and saves the changes in Active Directory.

Syntax

```
void Commit()
```

Discussion

If you are creating a new UNIX profile or updating a user's primary group or other attributes, you must use this method to complete the operation. If you have marked an object for deletion, this method deletes the object from Active Directory.

Exceptions

`Commit` may throw one of the following exceptions:

- `UnauthorizedAccessException` if your permissions are not sufficient to commit the Active Directory data object.
- `COMException` if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using `Commit` in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Set the UNIX profile for the user
set profile = objUser.SetUnixProfile(objZone, 10001, "pat", "/bin/bash",
"/home/pat", 10001)
'Validate the user's UNIX profile
profile.Validate
profile.Commit
...
```

Delete

Marks the user profile object for deletion from Active Directory.

Syntax

```
void Delete()
```

Discussion

This method does not delete the user profile. After you mark an object for deletion, you must use the Commit method to commit changes to the user object to Active Directory. When the Commit method is executed, the UNIX profile is deleted from Active Directory to complete the operation.

Example

The following code sample illustrates using Delete in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfiles
'Mark the user profile for deletion
profile.Delete
...
```

GetDirectoryEntry

Returns an instance of the directory entry for the user's UNIX profile from Active Directory.

Syntax

```
DirectoryEntry GetDirectoryEntry()
```

Return value

A directory entry for the service connection point that represents the user's UNIX profile in the zone.

Discussion

This method can only be used in .NET programs because `DirectoryEntry` is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

GetPrimaryGroup

Returns the UNIX profile of the primary group of the user.

Syntax

IGroupUnixProfile GetPrimaryGroup()

Return value

The UNIX profile of the user's primary group.

Example

The following code sample illustrates using GetPrimaryGroup in a script:

```
…
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfiles
'Display the LDAP path for the user
wScript.Echo “Primary GID: “ & profile.GetPrimaryGroup().GID
…
```

Refresh

Reloads UNIX profile data from the data in Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the UNIX profile information in the cached object to ensure it is synchronized with the latest information in Active Directory.

Example

The following code sample illustrates using Refresh in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfiles
'Reload the user's UNIX profile
profile.Refresh
...
```

Validate

Checks whether the user profile contains valid data and can be committed to Active Directory.

Syntax

```
void Validate()
```

Discussion

This method checks for errors in the UNIX profile fields and verifies that the profile includes a valid primary group, user name, UID, home directory, shell, and zone type. The method also verifies that the entry is not a duplicate of any existing profile in the zone. The method does not perform any of these checks, however, if the user profile is marked for deletion or if the profile has not been modified.

Exceptions

Validate throws an ApplicationException if the UNIX profile is missing data or contains invalid data.

Example

The following code sample illustrates using Validate in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Set the UNIX profile for the user
set profile = objUser.SetUnixProfile(objZone, 10001, "pat", "/bin/bash",
"/home/pat", 10001)
'Validate the user's UNIX profile
profile.Validate
...
```

ADsPath

Gets the LDAP path to the UNIX profile data object.

Syntax

```
string ADsPath {get;}
```

Property value

The LDAP path to the UNIX profile data object.

Example

The following code sample illustrates using ADsPath in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Display the LDAP for the user's UNIX profile
wScript.Echo "LDAP Path: " & profile.ADsPath
...
```

Cims

Gets the Cims object for the user.

Syntax

```
Cims Cims {get;}
```

Property value

The Cims object.

Discussion

This property serves as a shortcut for retrieving data.

HomeDirectory

Gets or sets the home directory for the user.

Syntax

```
string HomeDirectory {get; set;}
```

Property value

A string that defines the path to the default home directory for the user from the user's UNIX profile.

Example

The following code sample illustrates using HomeDirectory in a script:

```
…
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Change the default home directory in the user's UNIX profile
set profile.HomeDirectory = "/home/all_users/pathu"
…
```

ID

Gets the unique identifier for the UserUnixProfile data object.

Syntax

```
string ID {get;}
```

Property value

The unique identifier for the UserUnixProfile data object.

Example

The following code sample illustrates using ID in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Display the unique identifier for the user's UNIX profile
wScript.Echo "Unique ID: " & profile.ID
...
```

IsForeign

Indicates whether the corresponding Active Directory user for a UNIX profile is in a different Active Directory forest than the forest associated with the user's UNIX profile in the zone.

Syntax

```
bool IsForeign {get;}
```

Property value

Returns true if the UNIX profile is associated with an Active Directory user in a different forest.

Discussion

If the Active Directory user is in a different forest than the one associated with a top-level Cims object, the property returns true.

Example

The following code sample illustrates using IsForeign in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Check the forest for Users in the zone
For each profile in objZone.GetUserUnixProfiles
if profile.IsForeign then
wScript.Echo “Foreign user: ” & profile.Name
end if
next
...
```

IsOrphan

Indicates whether this UNIX user is not associated with a corresponding Active Directory user.

Syntax

```
bool IsOrphan {get;}
```

Property value

Returns `true` if the corresponding Active Directory user for a UNIX profile is not found, or `false` if the corresponding Active Directory user for the UNIX profile exists.

Discussion

This property can be used to determine whether the Active Directory user associated with a UNIX profile has been deleted from Active Directory.

Example

The following code sample illustrates using `IsOrphan` in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Check for Orphan Users in the zone
For each profile in objZone.GetUserUnixProfiles
if profile.IsOrphan then
wScript.Echo “Orphan user: ” & profile.Name
end if
next
...
```

IsReadable

Indicates whether the user profile object in Active Directory is readable for the current user credentials.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns true if the UserUnixProfile object is readable, or false if the object is not readable.

Discussion

This property returns a value of true if the user accessing the user profile object in Active Directory has sufficient permissions to read its properties.

Example

The following code sample illustrates using IsReadable in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Check whether the user's UNIX profile is readable
if not profile.IsReadable then
wScript.Echo "No permission to read the UNIX profile!"
else
wScript.Echo "UNIX login name: " & profile.Name
end if
...
```

IsSFU

Indicates whether the UNIX user profile is in a Services for UNIX (SFU) zone.

Syntax

```bool IsSFU {get;}```

Property value

Returns true if the user profile is a Services for UNIX (SFU) profile.
```

IsWritable

Indicates whether the user profile object is writable for the current user's credentials.

Syntax

```
bool IsWritable {get;}
```

Property value

Returns `true` if the `UnixUserProfile` object is writable, or `false` if the object is not writable.

Discussion

This property returns a value of `true` if the user accessing the user profile object in Active Directory has sufficient permissions to change the user profile object's properties.

Example

The following code sample illustrates using `IsWritable` in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Check whether the user's UNIX profile is writable
if not profile.IsWritable then
wScript.Echo "No permission to change the UNIX profile!"
end if
...
```

Name

Gets or sets the UNIX login name of the user in the user's UNIX profile.

Syntax

```
string Name {get; set;}
```

Property value

The UNIX login name from the user's UNIX profile.

Example

The following code sample illustrates using Name in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Set the UNIX profile for the user
set profile = objUser.SetUnixProfile(objZone, 10001, "pat", "/bin/bash",
"/home/pat", 10001)
'Display the user's UNIX login name
profile.Name
...
```

PrimaryGroup

Gets or sets the group identifier (GID) of the primary group for the user.

Syntax

```
long PrimaryGroup {get; set;}
```

Property value

The value used as the GID for the user's primary group.

Discussion

This method is used internally by .NET modules.

Example

The following code sample illustrates using PrimaryGroup in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Set the GID for the user's primary group
Set objUser.PrimaryGroup = 490007
...
```

ProfileState

Gets the profile state of an existing local user or sets the profile of the specified local user.

Syntax

```
UserProfileState ProfileState{get; set;}
```

Property value

The profile state of the specified local user.

Exceptions

`ProfileState` throws an `InvalidOperationException` if the user you specify is not a local user.

Shell

Gets or sets the default shell for the user.

Syntax

```
string Shell {get; set;}
```

Property value

A string that defines the path to the default shell for the user from the user's UNIX profile.

Example

The following code sample illustrates using Shell in a script:

```
…
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Change the default shell in the user's UNIX profile
set profile.Shell = "bin/sh"
…
```

Type

Gets the user UNIX profile type for the user.

Syntax

```
UserUnixProfileType Type {get;}
```

Property value

A numeric value that indicates whether the UNIX profile is a standard Delinea profile or a Service for UNIX (SFU) profile.

Possible values:

```
public enum UserUnixProfileType
{
    // Centrify user
    Centrify = 0,
    // Microsft Service for Unix type
    Sfu = 1,
    // MIT Kerberos-realm trusted user
    MIT = 2
}
```

Discussion

There is no AD User object corresponding to an MIT user type of profile.

Example

The following code sample illustrates using Type in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Check the profile type in the user's UNIX profile
if profile.Type = 0
    wScript.Echo "Standard UNIX profile"
else
    wScript.Echo "SFU user UNIX profile"
end if
...
```

UnixEnabled

Determines whether the user's UNIX profile is enabled for access to the zone. This attribute is only applicable in classic zones and for backwards compatibility.

Syntax

```
bool UnixEnabled {get; set;}
```

Property value

Returns true if the user's UNIX profile is enabled for access in a classic zone, or false if the UNIX profile is not enabled for access to the zone.

Discussion

The UnixEnabled attribute determines whether a specific profile is enabled or disabled for access to the zone. If this property is set to true, the user's UNIX profile can be used to access the current zone. If this property is set false, the user cannot log on to computers in the zone using the disabled UNIX profile.

Exceptions

UnixEnabled throws an InvalidOperationException if the user is assigned to a hierarchical zone.

Example

The following code sample illustrates using UnixEnabledv in a script:

```
...
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the user object
set objUser = cims.GetUserByPath("LDAP://CN=pat.hu,CN=Users,DC=ajax,DC=org")
'Disable the user's UNIX profile in this zone
objUserUnixProfile.UnixEnabled = False
...
```

User

Gets the Active Directory user object associated with this user UNIX profile.

Syntax

IUser User {get;}

Property value

The user object.

UserId

Gets or sets the UID of the user.

Syntax

```
long UserId {get; set;}
```

Property value

The UID of the user.

Zone

Gets the zone object associated with the user.

Syntax

IZone Zone {get;}

Property value

The zone object associated with the user.

Example

The following code sample illustrates using Zone in a script:

```
…
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
'Get the Active Directory user object
set objUser = cims.GetUser("ajax.org/Users/pat.hu")
'Get the UNIX profile for the user
profile = objUser.UnixProfileByUid(10001)
'Display the zone associated with the user's UNIX profile
wScript.Echo "Zone: " & profile.Zone
…
```

UserUnixProfiles

The UserUnixProfiles class is used to manage a collection of user profiles.

Syntax

```
public interface IUserUnixProfiles
```

Discussion

The collection of user profiles contained in the object depend on how the object was obtained:

- When you call User.UnixProfiles, the UserUnixProfiles object returned enumerates all of the profiles defined for a specific Active Directory user across all zones in the current domain.
- When you call Zone.GetUserUnixProfiles, the UserUnixProfiles object returned enumerates all of the profiles defined for a specific Active Directory user in a specific zone.

Methods

The UserUnixProfiles class provides the following methods:

GetEnumerator	Returns an enumeration of user profiles.
Refresh	Reloads the collection of UNIX profiles from Active Directory.

Properties

The UserUnixProfiles class provides the following properties:

Count	Gets the number of UNIX profiles defined in the collection of UserUnixProfiles.
IsEmpty	Indicates whether the UserUnixProfiles object contains any profiles.

GetEnumerator

Returns an enumeration of user profiles.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

The set of user profile objects.

Refresh

Reloads the collection of UNIX profiles from Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the collections of UNIX profiles in the cached object to ensure the object is synchronized with the latest information in Active Directory.

Count

Determines the total number of UNIX profiles defined in the UserUnixProfiles collection.

Syntax

```
int Count {get;}
```

Property value

The number of UNIX profiles in the set.

Example

The following code sample illustrates using Count in a script:

```
…
'Get the zone object
Set objZone = cims.GetZone("ajax.org/UNIX/Zones/pilot")
Set objUserUnixProfiles = objUser.UnixProfiles
wScript.Echo "Profile count: " & objUserUnixProfiles.Count
…
```

IsEmpty

Determines whether the collection of UNIX user profiles is empty.

Syntax

```
bool IsEmpty {get;}
```

Property value

Returns `true` if there are no user profiles in the `UserUnixProfiles` object.

Discussion

Unlike the `Count` property, the `IsEmpty` property does not query all of the profiles in the collection before it returns a value. If you only need to determine whether any profiles are defined, you should call this property for a faster response.

WindowsApplication

This class represents a Windows application right.

Syntax

public interface IWindowsApplication:IRight

Methods

The WindowsApplication class provides the following methods:

Unexpected Link Text	Commits changes in the right to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Creates the match criteria used to identify the Windows application to which you want to grant a right.
Unexpected Link Text	Removes the right. (Inherited from Unexpected Link Text.)

Properties

The WindowsApplication class provides the following properties:

Unexpected Link Text	Gets or sets the properties that are used to identify a specific Windows application.
Unexpected Link Text	Gets or sets the description of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is readable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is writable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the name of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the priority of this right.
Unexpected Link Text	Gets or sets whether the user's password is required when this right is used.
Unexpected Link Text	Gets or sets the SID for the run-as user or an SID for the user assigned the right (VBScript).
Unexpected Link Text	Gets or sets the SID for the run-as user or a list of SIDs for the users assigned the right (.NET).
Unexpected Link Text	Gets or sets the run-as type for the right.
Unexpected Link Text	Gets the zone this right belongs to. (Inherited from Unexpected Link Text.)

Discussion

A Windows application right enables a user to run a Windows application with the privileges of another user or as a member of an Active Directory or built-in group. For example, you can use a Windows application right to give a standard Windows user elevated privileges to run an database management application as a database administrator.

CreateApplicationCriteria

Creates the match criteria to identify the Windows application and related requirements to which you want to grant a right.

Syntax

```
void CreateApplicationRight()
```

Discussion

This method initiates the collection of the set of match criteria, defined using the properties of the WindowsApplicationCriteria class, to identify a specific Windows application to which you want to grant a right.

Example

See Unexpected Link Text for a code sample that illustrates using CreateApplicationRight in a script.

ApplicationCriteriaList

Gets or sets the list of properties that are used to identify a specific Windows application.

Syntax

In .NET:

```
IEnumerable\<IWindowsApplicationCriteria\> ApplicationCriteriaList {get; set;}
```

In VBScript:

```
object[] ApplicationCriteriaList {get; set;}
```

Property value

The complete match criteria defined to identify a specific Windows application.

Example

The following code sample illustrates using ApplicationCriteriaList in a script:

```
// Create a new Windows application right with some basic properties.
$objWindowsApplication = $objZone.CreateWindowsApplication();
$objWindowsApplication.Name = $strWindowsApplication;
$objWindowsApplication.RunAsType = $runAsType;
$objWindowsApplication.RunAsString = $strDnList;
$objWindowsApplication.RequirePassword = $requirePassword;
$objWindowsApplication.Description = "optional description";
$objWindowsApplication.Priority = 0;
// Specify the criteria used to identify the Windows application.
$listType = ("System.Collections.Generic.List\`1" -as "Type");
$listType = $listType.MakeGenericType( @(
("Centrify.DirectControl.API.IWindowsApplicationCriteria" -as "Type")));
$criteriaList = [Activator]::CreateInstance($listType);
$objApplicationCriteria = $objWindowsApplication.CreateApplicationCriteria();

$objApplicationCriteria.FileType =
[Centrify.DirectControl.API.WindowsFileType]::EXE;
$objApplicationCriteria.FileName = "calc.exe";
$objApplicationCriteria.Path = "SYSTEMPATH";
$objApplicationCriteria.FileDescription = "Windows Calculator";
$objApplicationCriteria.FileDescriptionMatchOption =
[Centrify.DirectControl.API.StringMatchOption]::ExactMatch;
$objApplicationCriteria.FileVersion = "6.1";
$objApplicationCriteria.FileVersionMatchOption =
[Centrify.DirectControl.API.VersionMatchOption]::LaterThanOrEqualTo;
$objApplicationCriteria.Description = "Match criteria for Windows Calc";
$objWindowsApplication.ApplicationCriteriaList = $criteriaList;
$objWindowsApplication.Commit();
Write-Host("WindowsApplication {0} has been added to zone {1} successfully." -f
$strWindowsApplication, $strZone);
exit 0;
}
```

Priority

Gets or sets the priority of this right.

Syntax

```
int Priority {get; set;}
```

Property value

The priority of the right. Default is 0.

Discussion

This number is used when handling multiple matches for rights specified by wild cards. If rights specified by this property object match rights specified by another property object, the object with the higher priority prevails. The higher the value of the Priority property, the higher the priority.

Example

See Unexpected Link Text for a code sample that illustrates using Priority in a script.

RequirePassword

Gets or sets whether the logged-in user's password is required when this right is used.

Syntax

```
bool RequirePassword {get; set;}
```

Property value

Set to true if the right requires the logged-in user's password.

Example

See Unexpected Link Text for a code sample that illustrates using RequirePassword in a script.

RunAs

Gets or sets the run-as property for this right.

Syntax

```
string RunAs {get; set;}
```

Property value

The run-as property for a single user.

Discussion

If the Unexpected Link Text property is set to Self, the remote application is run under the logged-in user account, but with the additional privileges of the user whose SID is listed in the RunAs property. For example, if the WindowsApplication right is set to run as Self and RunAs contains the SID of the Network Admins group, then this application runs with the permissions of the logged-in user plus the permissions of the Network Admins group.

If the RunAsType property is set to User, the remote application is run under the user whose SID is listed in the RunAs property. For example, if the WindowsApplication right is set to run as User and RunAs contains the SID of the user NetAdmin, then this application runs with the permissions of the NetAdmin user.

If the RunAs property is empty, this right is invalid and an exception is thrown when you call the Unexpected Link Text method.

> **Note**: This property is for use in VBScript programs. Use the RunAsList property for .NET.

RunAsList

Gets or sets the run-as list for this right.

Syntax

```
IList\<SecurityIdentifier\> RunAsList {get; set;}
```

Property value

The run-as list for the right.

Discussion

If the Unexpected Link Text property is set to Self, the application is run under the logged-in user account, but with the additional privileges of the groups whose SIDs are listed in the RunAsList property. For example, if the WindowsApplication right is set to run as Self and RunAsList contains the SID of the Local Admins group, then this application runs with the permissions of the logged-in user plus the permissions of the Local Admins group.

If the RunAsType property is set to User, the application is run under the user whose SID is listed in the RunAsList property. In this case, the RunAsList property contains only a single SID. For example, if the WindowsApplication right is set to run as User and RunAsList contains the SID of the user Admin, then this application runs with the permissions of the Admin user.

If the RunAsList property is empty, this right is invalid and an exception is thrown when you call the Unexpected Link Text method.

> **Note**: This property can only be used in .NET programs. Use the RunAs property for VBScript.

RunAsType

Gets or sets the run-as type for this right.

Syntax

```
WindowsRunAsType RunAsType {get; set;}
```

Property value

The run-as type of the right.

Possible values:

```
public enum WindowsRunAsType
{
    // Run as self
    Self,
    // Run as another user
    User
}
```

Discussion

If the Unexpected Link Text property is set to Self, the application runs as the logged-in user with the additional privileges of the groups whose SIDs are listed in the RunAsList property. For example, if the WindowsApplication right is set to run as Self and RunAsList contains the SID of the Local Admins group, then this application runs with the permissions of the logged-in user plus the permissions of the Local Admins group.

If the RunAsType property is set to User, the application is run as the user whose SID is listed in the [RunAsList(../networkaccess/runaslist.md) property. For example, if the WindowsApplication right is set to run as User and RunAsList contains the SID of the user Admin, then this application runs as Admin with the permissions of that user.

Example

See ApplicationCriteriaList for a code sample that illustrates using RunAsType in a script.

WindowsApplicationCriteria

This class represents the match criteria for identifying a Windows application right.

Syntax

```
public interface IWindowsApplicationCriteria
```

Methods

The WindowsApplicationCriteria class provides the following method.

Unexpected Link Text	Determines whether the match criteria is valid.

Properties

The WindowsApplicationCriteria class provides the following match criteria properties that correspond to the fields displayed on the Match Criteria tab in Access Manager:

Unexpected Link Text	Gets or sets the arguments allowed with this Windows application right.
Unexpected Link Text	Gets or sets the company name to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies whether the string specified for the CompanyName property must be an exact match or a partial match.
Unexpected Link Text	Gets or sets the description for the match criteria defined for a specific application right.
Unexpected Link Text	Gets or sets the file description to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies whether the string specified for the FileDescription property must be an exact match or a partial match.
Unexpected Link Text	Gets or sets the encrypted file hash to match to identify the Windows application associated with this right. The file hash is generated using the SHA-1 encryption algorithm, which is FIPS-compliant.
Unexpected Link Text	Gets or sets the file name to match to identify the Windows application associated with this right.
Unexpected Link Text	Gets or sets the type of executable file to match to identify the Windows application associated with this right.
Unexpected Link Text	Gets or sets the file version to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies whether the version must be equal to, earlier than or equal to, or later than or equal to the version specified for the FileVersion property.

Unexpected Link Text	Specifies whether arguments for the Argument property are case-sensitive.
Unexpected Link Text	Specifies whether the string specified for the Argument property must be an exact match or a partial match.
Unexpected Link Text	Gets or sets the local user name or group name to match to allow the use of this Windows application right.
Unexpected Link Text	Specifies the distinguished name of the Active Directory user or group who is the file owner to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies the security identifier of the Active Directory user or group who is the file owner to match to identify the Windows application associated with this right.
Unexpected Link Text	Gets or sets the type of owner to match to allow the use of this Windows application right.
Unexpected Link Text	Gets or sets the path to the executable to match to identify the Windows application associated with this right.
Unexpected Link Text	Gets or sets the product name to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies whether the string specified for the ProductName property must be an exact match or a partial match.
Unexpected Link Text	Gets or sets the product version to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies whether the version must be equal to, earlier than or equal to, or later than or equal to the version specified for the ProductVersion property.
Unexpected Link Text	Gets or sets the publisher name to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies whether the publisher must be an exact match, partial match, start with, or end with the string specified for the Publisher property.
Unexpected Link Text	Specifies whether the Windows application associated with this right requires an administrative user account.
Unexpected Link Text	Gets or sets the volume serial number to match to identify the Windows application associated with this right.
Unexpected Link Text	Specifies whether the volume serial number must be an exact match, partial match, start with, or end with the string specified for the SerialNumber property.

Discussion

A Windows application right enables a user to run a Windows application with the privileges of another user or as a member of an Active Directory or built-in group. For example, you can use a Windows application right to give a standard Windows user elevated privileges to run an database management application as a database administrator. You can define the criteria to use to identify the Windows application associated with an application right using the WindowsApplicationCriteria properties.

Validate

Determines whether the match criteria is valid.

Syntax

```
void Vallidate()
```

Discussion

This property is only applicable in .NET-compatible programs.

Exception

`Validate` throws an `ApplicationException` if any property specified for the match criteria is not valid.

Argument

Gets or sets the arguments allowed with this Windows application right.

If you specify a file type of .msc, you must also specify the Arguments property. The Arguments property is optional for all other file types. If this property is set to an empty string, no arguments are allowed. Do not specify the Arguments property if you are granting a right to access the application without argument restrictions. If the property is not defined, the application can be executed with any argument or combination of arguments.

Syntax

```
string Argument {get; set;}
```

Property value

A list of arguments that can be used with the application when this application is executed.

CompanyName

Gets or sets the company name to match to identify the Windows application associated with this right.

Syntax

```
string CompanyName {get; set;}
```

Property value

The company name associated with the application.

Example

The following code sample illustrates using CompanyName in a script:

```
...
\$listType = ("System.Collections.Generic.List\``1" -as "Type");
\$listType = \$listType.MakeGenericType( @(
("Centrify.DirectControl.API.IWindowsApplicationCriteria" -as "Type")));
\$criteriaList = [Activator]::CreateInstance(\$listType);
\$objApplicationCriteria = \$objWindowsApplication.CreateApplicationCriteria();

\$objApplicationCriteria.FileType =
[Centrify.DirectControl.API.WindowsFileType]::EXE;
\$objApplicationCriteria.FileName = "filename.exe";
\$objApplicationCriteria.Path = "SYSTEMPATH";
\$objApplicationCriteria.Argument = "Optional arguments 1";
\$objApplicationCriteria.IsArgumentCaseSensitive = \$true;
\$objApplicationCriteria.IsArgumentExactMatch = \$true;
\$objApplicationCriteria.CompanyName = "Cendura Software";
\$objApplicationCriteria.CompanyNameMatchOption =
[Centrify.DirectControl.API.StringMatchOption]::ExactMatch;
...
```

CompanyNameMatchOption

Specifies whether the string specified for the CompanyName property must be an exact match or can be a partial match to identify an application associated with this right.

Syntax

```
StringMatchOption CompanyNameMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the company name field.

Possible values:

```
public enum StringMatchOption
{
    // Exact match
    ExactMatch,
    // Partial match
    Contains
}
```

Example

See Unexpected Link Text for code sample that illustrates using CompanyNameMatchOption in a script.

Description

Gets or sets the description for the set of match criteria defined for a specific application right.

For example, if you are defining match criteria that will grant an application right for multiple versions of SQL Server Management Studio running on different versions of the Windows operating system, you might specify a description such as “SQL Server Management Studio (2005-2012)” to indicate the scope of the right.

Syntax

```
string Description {get; set;}
```

Property value

The descriptive text for a set of match criteria.

Example

The following code sample illustrates using Description in a script:

```
\$objWindowsApplication =
\$objZone.GetWindowsApplication(\$strWindowsApplication);
{
\$objWindowsApplication = \$objZone.CreateWindowsApplication();
\$objWindowsApplication.Name = \$strWindowsApplication;
\$objWindowsApplication.RunAsType = \$runAsType;
\$objWindowsApplication.RunAsString = \$strDnList;
\$objWindowsApplication.RequirePassword = \$requirePassword;
\$objWindowsApplication.Description = "SQL Server Match criteria";
\$objWindowsApplication.Priority = 0;
…
```

FileDescriptionMatchOption

Specifies whether the string specified for the FileDescription property must be an exact match or a partial match to identify an application associated with this right.

Syntax

```
StringMatchOption FileDescriptionMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the file description field.

Possible values:

```
public enum StringMatchOption
{
    // Exact match
    ExactMatch,
    // Partial match
    Contains
}
```

FileDescriptionMatchOption

Specifies whether the string specified for the FileDescription property must be an exact match or a partial match to identify an application associated with this right.

Syntax

```
StringMatchOption FileDescriptionMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the file description field.

Possible values:

```
public enum StringMatchOption
{
    // Exact match
    ExactMatch,
    // Partial match
    Contains
}
```

FileHash

Gets or sets the encrypted file hash to match to identify the Windows application associated with this right. The file hash is generated using the SHA-1 encryption algorithm, which is FIPS-compliant.

Syntax

```
string FileHash {get; set;}
```

Property value

The file hash to match to identify the application.

FileName

Gets or sets the file name to match to identify the Windows application associated with this right.

Syntax

```
string FileName {get; set;}
```

Property value

The file name to match to identify the application.

FileType

Gets or sets the type of executable file to match to identify the Windows application associated with this right. You must specify a file type to define a valid application right.

Syntax

```
WindowsFileType FileType {get; set;}
```

Property value

The executable file type to match.

Possible values:

```
public enum WindowsFileType
{
    // Batch file
       BAT,
    // Command script
       CMD,
    // Command file
       COM,
    // Control Panel Extension
       CPL,
    // Executable file
       EXE
    // Microsoft common console document
       MSC
    // Windows installer package
       MSI
    // Windows installer patch
       MSP
    // Windows PowerShell cmdlet
       PS1
    // VBScript script
       VBS
    // Windows script file
       WSF
}
```

Example

The following code sample illustrates using FileType in a script:

```
$objWindowsApplication =
$objZone.GetWindowsApplication($strWindowsApplication);
{
...
$listType = $listType.MakeGenericType( @
("Centrify.DirectControl.API.IWindowsApplicationCriteria" -as "Type")));
$criteriaList = [Activator]::CreateInstance($listType);
$objApplicationCriteria = $objWindowsApplication.CreateApplicationCriteria();

$objApplicationCriteria.FileType =
[Centrify.DirectControl.API.WindowsFileType]::EXE;
$objApplicationCriteria.FileName = "filename.exe";
...
}
```

FileVersion

Gets or sets the file version to match to identify the Windows application associated with this right.

Syntax

```
string FileVersion {get; set;}
```

Property value

The file version to match to identify the application.

FileVersionMatchOption

Specifies whether the version must be equal to, earlier than or equal to, or later than or equal to the version specified for the FileVersion property.

Syntax

```
VersionMatchOption FileVersionMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the file version field.

Possible values:

```
public enum VersionMatchOption
{
    // Match the version specified
       Equal,
    // Match earlier than or equal to the specified version
       EarlierThanOrEqualTo,
    // Match later than or equal to the specified version
       LaterThanOrEqualTo
}
```

IsArgumentCaseSensitive

Specifies whether the arguments for the Argument property are case-sensitive.

Syntax

```
bool IsArgumentCaseSensitive {get; set;}
```

Property value

Set to true if arguments are case-sensitive. The default is false.

IsArgumentExactMatch

Specifies whether the arguments specified for the Argument property must be an exact match.

Syntax

```
bool IsArgumentExactMatch {get; set;}
```

Property value

Set to true if the arguments must be an exact match. The default is false.

LocalOwner

Gets or sets the local owner to match to allow the use of this Windows application right.

Syntax

```
string LocalOwner {get; set;}
```

Property value

The local owner user name or group to match to execute the application.

OwnerDN

Specifies the distinguished name of the Active Directory user or group who is the file owner to match to identify the Windows application associated with this right.

This property is only applicable in VBScript programs.

Syntax

```
string OwnerDN {get; set;}
```

Property value

The distinguished name of the owner of the file to match.

OwnerSid

Specifies the security identifier of the Active Directory user or group who is the file owner to match to identify the Windows application associated with this right.

This property is only applicable in .NET-compatible programs.

Syntax

```
SecurityIdentifier OwnerSid {get; set;}
```

Property value

The security identifier of the owner of the file to match.

OwnerType

Gets or sets the type of owner to match to allow the use of this Windows application right.

Syntax

In .NET:

```
Nullable\<WindowsFileOwnerType\> OwnerType {get; set;}
```

In VBScript:

```
WindowsFileOwnerType OwnerType {get; set;}
```

Property value

The type of owner to match.

Possible values:

```
public enum WindowsFileOwnerType
{
    // Active Directory group or user SID
    Sid,
    // Local group account
    LocalGroup,
    // Local user account
    LocalUser
}
```

Path

Gets or sets the path to the executable to match to identify the Windows application associated with this right.

Syntax

```
string Path {get; set;}
```

Property value

Path to the executable for the application. You can specify multiple paths separated by semicolons (;). You can specify the standard system path using the SYSTEMPATH keyword, specify a full custom path, such as C:\\Windows\\system32\\inetsrv, or use one of the supported path variables.

The supported path variables are:

- %systemroot%
- %system32%
- %syswow64%
- %program files%
- %program files(x86)%

The space between “program” and “files” is required.

ProductName

Gets or sets the product name to match to identify the Windows application associated with this right.

Syntax

```
string ProductName {get; set;}
```

Property value

The product name to match to identify the application.

ProductNameMatchOption

Specifies whether the string specified for the ProductName property must be an exact match or a partial match.

Syntax

```
StringMatchOption ProductNameMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the product name field.

Possible values:

```
public enum StringMatchOption
{
    // Exact match
       ExactMatch,
    // Partial match
       Contains
}
```

ProductVersion

Gets or sets the product version to match to identify the Windows application associated with this right.

Syntax

```
string ProductVersion {get; set;}
```

Property value

The product version to match to identify the application.

ProductVersionMatchOption

Specifies whether the version must be equal to, earlier than or equal to, or later than or equal to the version specified for the ProductVersion property.

Syntax

```
VersionMatchOption ProductVersionMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the product version field.

Possible values:

```
public enum VersionMatchOption
{
    // Match the version specified
       Equal,
    // Match earlier than or equal to the specified version
       EarlierThanOrEqualTo,
    // Match later than or equal to the specified version
       LaterThanOrEqualTo
}
```

Publisher

Gets or sets the publisher information from a digital certificate to match to identify the Windows application associated with this right.

Syntax

```
string Publisher {get; set;}
```

Property value

The publisher information to match to identify the application.

PublisherMatchOption

Specifies whether the publisher information must be an exact match, partial match, start with, or end with the string specified for the Publisher property.

Syntax

```
StringMatchOption PublisherMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the publisher field.

Possible values:

```
public enum StringMatchOption
{
    // Exact match
       ExactMatch,
    // Partial match
       Contains
    // Starts with match
       StartsWith
    // Ends with match
       EndsWith
}
```

RequireAdministrator

Specifies whether the Windows application associated with this right requires an administrative user account.

Syntax

```
bool RequireAdministrator {get; set;}
```

Property value

Set to true if the application must be executed using an administrative user account. The default is false.

SerialNumber

Gets or sets the volume serial number to match to identify the Windows application associated with this right.

This property is used to match an application located on a CD or DVD media with the specified volume serial number. If the target application is not executed from CD or DVD media, this property does not apply and the application right will not be granted.

Syntax

```
string SerialNumber {get; set;}
```

Property value

The volume serial number information to match to identify the application.

SerialNumberMatchOption

Specifies whether the volume serial number must be an exact match, partial match, start with, or end with the string specified for the SerialNumber property.

Syntax

```
StringMatchOption SerialNumberMatchOption {get; set;}
```

Property value

The match criteria operator, which specifies the type of matching to perform for the volume serial number field.

Possible values:

```
public enum StringMatchOption
{
    // Exact match
       ExactMatch,
    // Partial match
       Contains
    // Starts with match
       StartsWith
    // Ends with match
       EndsWith
}
```

WindowsApplications

The WindowsApplications class manages a collection of Windows application rights.

Syntax

```
public interface IWindowsApplications
```

Methods

The WindowsApplications class provides the following method:

Unexpected Link Text	Gets the enumerator you can use to enumerate all windows application rights.

GetEnumerator

Returns an enumeration of WindowsApplication objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

Returns an enumerator you can use to list all of the WindowsApplication objects.

Delinea

WindowsDesktop

This class represents a Windows desktop right.

Syntax

public interface IWindowsDesktop:IRight

The WindowsDesktop class provides the following methods:

Unexpected Link Text	Commits changes in the right to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Removes the right. (Inherited from Unexpected Link Text.)

Properties

The WindowsDesktop class provides the following properties:

Unexpected Link Text	Gets or sets the description of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is readable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the right is writable. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the name of the right. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the priority of this right.
Unexpected Link Text	Gets or sets whether the user's password is required when this right is used.
Unexpected Link Text	Gets or sets the SID for the run-as user or an SID for the users assigned the right (VBScript).
Unexpected Link Text	Gets or sets the SID for the run-as user or a list of SIDs for the users assigned the right (.NET).
Unexpected Link Text	Gets or sets the run-as type for the right.
Unexpected Link Text	Gets the zone this right belongs to. (Inherited from Unexpected Link Text.)

Discussion

A Windows desktop right provides a complete desktop that behaves as if the user had logged in as specific privileged user with the privileges of another user or as a member of an Active Directory or built-in group. For example, you can use a Windows desktop right to give a standard Windows user elevated privileges to run local applications as a member of the built-in Administrators group.

Priority

Gets or sets the priority of this right.

Syntax

```
int Priority {get; set;}
```

Property value

The priority of the right. Default is 0.

Discussion

This number is used when handling multiple matches for rights specified by wild cards. If rights specified by this property object match rights specified by another property object, the object with the higher priority prevails. The higher the value of the Priority property, the higher the priority.

RequirePassword

Gets or sets whether the logged-in user's password is required when this right is used.

Syntax

```
bool RequirePassword {get; set;}
```

Property value

Set to `true` if the right requires the logged-in user's password.

RunAs

Gets or sets the run-as property for this right.

Syntax

```
string RunAs {get; set;}
```

Property value

The run-as property for a single user.

Discussion

If the Unexpected Link Text property is set to Self, the remote application is run under the logged-in user account, but with the additional privileges of the groups whose SIDs are listed in the RunAs property as a semicolon (;) separated string. For example, if the WindowsDesktop right is set to run as Self and RunAs contains the SID of the Network Admins group, then this application runs with the permissions of the logged-in user plus the permissions of the Network Admins group.

If the RunAsType property is set to User, the remote application is run under the user whose SID is listed in the RunAs property. For example, if the WindowsDesktop right is set to run as User and RunAs contains the SID of the user NetAdmin, then this application runs with the permissions of the NetAdmin user.

If the RunAs property is empty, this right is invalid and an exception is thrown when you call the Unexpected Link Text method.

> **Note**: This property is for use in VBScript programs. Use the RunAsList property for .NET.

RunAsList

Gets or sets the run-as list for this right.

Syntax

```
IList\<SecurityIdentifier\> RunAsList {get; set;}
```

Property value

The run-as list for the right.

Discussion

If the Unexpected Link Text property is set to Self, the desktop runs as the logged-in user with the additional privileges of the groups whose SIDs are listed in the RunAsList property. For example, if the WindowsDesktop right is set to run as Self and RunAsList contains the SID of the Local Admins group, then this desktop runs with the permissions of the logged-in user plus the permissions of the Local Admins group.

If the RunAsType property is set to User, the desktop is run as the user whose SID is listed in the RunAsList property. In this case, the RunAsList property contains only a single SID. For example, if the WindowsDesktop right is set to run as User and RunAsList contains the SID of the user Admin, then this desktop runs as Admin with the permissions of that user.

If the RunAsList property is empty, this right is invalid and an exception is thrown when you call the Unexpected Link Text method.

> **Note**: This property can only be used in .NET programs. Use the RunAs property for VBScript.

RunAsType

Gets or sets the run-as type for this right.

Syntax

```
WindowsRunAsType RunAsType {get; set;}
```

Property value

The run-as type of the right.

Possible values:

```
public enum WindowsRunAsType
{
    // Run as self
    Self,
    // Run as another user
    User
}
```

Discussion

If the RunAsType property is set to Self, the desktop runs as the logged-in user with the additional privileges of the groups whose SIDs are listed in the Unexpected Link Text property. For example, if the WindowsDesktop right is set to run as Self and RunAsList contains the SID of the Local Admins group, then this desktop runs with the permissions of the logged-in user plus the permissions of the Local Admins group.

If the RunAsType property is set to User, the desktop is run as the user whose SID is listed in the RunAsList property. For example, if the WindowsDesktop right is set to run as User and RunAsList contains the SID of the user Admin, then this desktop runs as Admin with the permissions of that user.

WindowsDesktops

The WindowsDesktops class manages a collection of Windows desktop rights.

Syntax

```
public interface IWindowsDesktops
```

Methods

The WindowsDesktops class provides the following method:

Unexpected Link Text	Gets the enumerator you can use to enumerate all windows desktop rights.

GetEnumerator

Returns an enumeration of WindowsDesktop objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

Returns an enumerator you can use to list all the WindowsDesktop objects.

WindowsUser

The WindowsUser class manages the Windows user profile information of a user.

Syntax

```
public interface IWindowsUser
```

Methods

The WindowsUser class provides the following methods:

Unexpected Link Text	Adds a role assignment to the user profile.
Unexpected Link Text	Returns the directory entry for the user from Active Directory.
Unexpected Link Text	Returns an enumeration of the effective user role assignments.

Properties

The WindowsUser class provides the following property:

Unexpected Link Text	Gets the Windows login name of the user.

Discussion

A user's Windows profile consists of the information used by Windows to identify the user. See the HierarchicalUser class for a user's UNIX profile.

The rights you assign to users and group in a particular role apply to Active Directory users and groups. They can also apply to locally-defined users and groups if you configure the role definition to allow local accounts to be assigned to the role. All Windows users, including local users, must be assigned at least one role that allows them log on locally, remotely, or both.

AddUserRoleAssignment

Adds a role assignment to the user profile.

Syntax

```
IRoleAssignment AddUserRoleAssignment(IHierarchicalZone zone)
IRoleAssignment AddUserRoleAssignment(IHierarchicalZoneComputer computer)
```

Parameters

Specify one of the following parameters when using this method.

zone	The zone to which the Windows user belongs.
computer	The computer to which the Windows user belongs.

Return value

An empty user role assignment object. This role assignment is not stored in Active Directory until you call the RoleAssignment:Commit method.

Discussion

When you assign computer-level overrides for user, group, or computer role assignments, internally Delinea creates a *computer zone* object, which is a special type of zone that contains the users, groups, and computer role assignments that are specific to only that one computer. Use the second form of this method to obtain a computer-level role assignment for this user.

Exceptions

AddUserRoleAssignment may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- ApplicationException if the parameter value is not a valid user or if the method failed to create a role assignment because it cannot find the user.

GetDirectoryEntry

Returns the directory entry for the user from Active Directory.

Syntax

```
DirectoryEntry GetDirectoryEntry()
```

Return value

A directory entry for the service connection point that represents the user's Windows profile.

Discussion

The `DirectoryEntry` object represents the directory object for the user and its associated attributes.

> **Note**: This method can only be used in .NET programs because `DirectoryEntry` is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Exceptions

`GetDirectoryEntry` throws an `ApplicationException` if it cannot get the directory object.

Delinea

GetEffectiveUserRoleAssignments

Returns an enumeration of the effective user role assignments.

Syntax

```
IRoleAssignments GetEffectiveUserRoleAssignments()
```

Return value

An enumeration of the effective user role assignments for this user.

Discussion

The collection of effective role assignments is a combination of all the role assignments for this user in this zone and all parent zones. See the Unexpected Link Text class for a more complete discussion.

Name

Gets the Windows login name of the user.

Syntax

```
string Name {get;}
```

Property value

The login name from the user's Windows profile.

WindowsUsers

The WindowsUsers class manages a collection of Windows user objects.

Syntax

```
public interface IWindowsUsers
```

Methods

The WindowsUsers class provides the following method:

Unexpected Link Text	Gets the enumerator you can use to enumerate all Windows user objects.

GetEnumerator

Returns an enumeration of WindowsUser objects.

Syntax

```
IEnumerator GetEnumerator()
```

Return value

Returns an enumerator you can use to list all the WindowsUser objects.

Zone

Manages Delinea zone objects (Centrify.DirectControl.API.IZone).

Syntax

```
public interface IZone
```

Discussion

For each zone you create, you must also define several zone properties. You can also use the Zone class to manage user access rights and the actions users are allowed to perform within a zone. For more information about creating and working with Delinea zones interactively using the Access Manager console, see the *Administrator's Guide for Linux and UNIX*.

Methods

The Zone class provides the following methods:

Unexpected Link Text	Adds an MIT Kerberos realm-trusted user to this zone.
Unexpected Link Text	Commits settings to Active Directory for the zone object.
Unexpected Link Text	Creates a "pending import" group in the zone.
Unexpected Link Text	Creates a "pending import" user in the zone.
Unexpected Link Text	Deletes the zone object from Active Directory.
Unexpected Link Text	Returns the computer profile using the distinguished name (DN) of the profile.
Unexpected Link Text	Returns the list of computers in the zone.
Unexpected Link Text	Returns the directory entry for the Computers parent container object.
Unexpected Link Text	Returns the directory entry for the zone.
Unexpected Link Text	Returns the display name of the zone.
Unexpected Link Text	Returns the directory entry for the Groups parent container object.
Unexpected Link Text	Returns the UNIX group profile for a specified group in the zone.
Unexpected Link Text	Returns the group profile using the distinguished name (DN) of the profile.
Unexpected Link Text	Returns the UNIX group profile for a specified group name in the zone.
Unexpected Link Text	Returns the list of UNIX groups in the zone.
Unexpected Link Text	Returns an individual "pending import" group in the zone.
Unexpected Link Text	Returns the collection of "pending import" groups in the zone.
Unexpected Link Text	Returns an individual "pending import" user in the zone.
Unexpected Link Text	Returns the collection of "pending import" users in the zone.

Unexpected Link Text	Returns the DirectoryEntry of the local groups container.
Unexpected Link Text	Returns the local UNIX group profile for a specified group name in the zone.
Unexpected Link Text	Returns a local group profile using the distinguished name (DN) of the profile.
Unexpected Link Text	Returns the local group profile using the Group Identifier (GID). This method is exposed to the .COM interface.
Unexpected Link Text	Returns a list of the local group profiles in the zone.
Unexpected Link Text	Returns the directory entry of the local users container.
Unexpected Link Text	Returns the local user profile using the specified user name.
Unexpected Link Text	Returns the local user profile specified by the distinguished name (DN) of the profile.
Unexpected Link Text	Returns the local user profile using the User Identifier (UID). This method is exposed to the .COM interface
Unexpected Link Text	Returns a list of the local user profiles in the zone.
Unexpected Link Text	Returns the directory entry for the Users parent container object.
Unexpected Link Text	Returns the user profile using the distinguished name (DN) of the profile.
Unexpected Link Text	Returns the UNIX user profile for a specified user name in the zone.
Unexpected Link Text	Returns the list of UNIX users in the zone.
Unexpected Link Text	Indicates whether a UNIX profile exists for the specified group in the zone.
Unexpected Link Text	Indicates whether a UNIX profile exists in the zone for the specified local group.
Unexpected Link Text	Indicates whether a UNIX profile exists in the zone for the specified local user.
Unexpected Link Text	Adds a computer to the zone.
Unexpected Link Text	Adds a Windows computer to the zone.
Unexpected Link Text	Returns the data stored for the zone object from the data in the Active Directory entry.
Unexpected Link Text	Indicates whether a UNIX profile exists for the specified user in the zone.

Properties

The Zone class provides the following properties:

[AdsiInterfaceadsiinterface.md)	Gets the IADs interface of the zone object in Active Directory.
Unexpected Link Text	Gets the LDAP path to the zone object.
Unexpected Link Text	Gets or sets the Active Directory attribute used for storing the user's password hash.
Unexpected Link Text	Gets or sets the list of available shells for the zone.

Unexpected Link Text	Gets the Cims object managing the zone.
Unexpected Link Text	Gets or sets the default group profile to use as the primary group for new users in the zone.
Unexpected Link Text	Gets or sets the default path to the user's home directory for new users in the zone.
Unexpected Link Text	Gets or sets the default shell assigned to new users in the zone.
Unexpected Link Text	Gets or sets the zone to use for default zone values.
Unexpected Link Text	Gets or sets the description property for the zone.
Unexpected Link Text	Gets the full name of the zone.
Unexpected Link Text	Indicates whether auto-provisioning of group profiles is enabled for the zone.
Unexpected Link Text	Gets the unique identifier for the zone.
Unexpected Link Text	Indicates whether this zone supports hierarchical zone features.
Unexpected Link Text	Indicates whether the zone object's properties are readable.
Unexpected Link Text	Indicates whether the zone uses the Microsoft Services for UNIX (SFU) schema extension.
Unexpected Link Text	Determines whether the zone is a TruncateName zone.
Unexpected Link Text	Indicates whether the zone object's properties are writable.
Unexpected Link Text	Gets or sets the license container associated with this zone.
Unexpected Link Text	Gets or sets the name of the primary domain controller for the zone.
Unexpected Link Text	Determines whether Active Directory group membership must be maintained for UNIX users in the zone.
Unexpected Link Text	Gets or sets the name of the zone.
Unexpected Link Text	Gets or sets the next available GID value for new groups in the zone.
Unexpected Link Text	Gets or sets the next available UID value for new users in the zone.
Unexpected Link Text	Gets or sets the next GID to be used when adding users.
Unexpected Link Text	Gets or sets the next UID to be used when adding users.
Unexpected Link Text	Gets or sets the NIS domain associated with the zone for SFU zones.
Unexpected Link Text	Gets or sets the list of group identifiers (GIDs) that cannot be assigned in the zone.
Unexpected Link Text	Gets or sets the list of User identifiers (UIDs) that cannot be assigned in the zone.
Unexpected Link Text	Gets the schema type of the zone object.
Unexpected Link Text	Gets or sets the Active Directory domain associated with the zone for SFU zones.
Unexpected Link Text	Indicates whether auto-provisioning of user profiles is enabled for the zone.

Unexpected Link Text	Gets the version number of the data schema.

AddMitUser

Adds a UNIX profile for a user in a trusted Kerberos realm to the zone.

Syntax

IUserUnixProfile AddMitUser(string fullMitUserName, int uid, string name, string shell, string homeDir, int primaryGroup)

IUserUnixProfile AddMitUser(string fullMitUserName, long uid, string name, string shell, string homeDir, long primaryGroup)

Parameters

Specify the following parameters when using this method.

fullMitUserName	The full user name of the user and the trusted Kerberos realm. For example: username@mit.realm.name
uid	The value to use as the UID of the user in the specified zone.
name	The UNIX profile name of the user in the specified zone.
shell	The default shell for the user in the specified zone.
homeDir	The default login shell for the user in the specified zone.
primaryGroup	The value to use as the GID for the user's primary group.

Return value

A new UserUnixProfile object.

Discussion

This method creates a UNIX profile object for a user in a trusted realm that is not tied to an Active Directory user object.

There are two versions of this method: one designed for COM-based programs that supports a 32-bit signed number for the uid and primaryGroup arguments and one designed for .NET-based programs that allows a 64-bit signed number for the arguments.

Exceptions

AddMitUser may throw one of the following exceptions:

- ApplicationException if you try to add a Kerberos user to an SFU zone.
- NotSupportedException if the computer zone schema is not supported.

Example

The following code sample illustrates using AddMitUser in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=cohesion_div,
CN=zones,CN=centrify,CN=program data,DC=arcade,DC=com")
'Create the UNIX profile for the Kerberos user “lewis.cain”
set objUserUnixProfile =
objUser.AddMitUser(“lewis.cain@cohesion.org”,98566,”cainl”, “/bin/csh”,
“home/cainl”, 98556)
'Enable the UNIX profile for the new user and update AD
objUserUnixProfile.UnixEnabled = True
objUserUnixProfile.commit
...
```

Delinea

Commit

Commits the settings or changes for a zone object to Active Directory.

Syntax

```
void Commit()
```

Discussion

This method confirms that the zone name and DirectoryEntry attributes are specified before updating Active Directory.

By default, the user who creates the zone object in Active Directory has permission to perform all administrative tasks in the zone. For information about setting and modifying the permissions required to perform specific tasks, see the *Planning and Deployment Guide*.

Exceptions

Commit may throw one of the following exceptions:

- ArgumentException if the zone name is not valid.
- ApplicationException if the container is not a valid zone container, the zone name is already in use, or you have insufficient access rights to modify the zone.
- UnauthorizedAccessException if you have insufficient access rights to commit the data object.
- COMException if an LDAP error occurred. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using this method in a script:

```
...
'Create a new zone.
set objZone = Cims3.CreateZone(objContainer, strZone)
'set the starting UID and GID for the new zone.
objZone.nextAvailableUID = 10000
objZone.nextAvailableGID = 10000
'set the default shell and home directory the new zone.
objZone.DefaultShell = "/bin/bash"
objZone.DefaultHomeDirectory = "/home/\${user}"
'Finalize the transaction and update Active Directory.
objZone.Commit
...
```

CreateImportPendingGroup

Creates a “pending import” group in the zone.

Syntax

IGroupInfo CreateImportPendingGroup (string source, DateTime timestamp)

Parameters

Specify the following parameters when using this method.

source	String	The location of the source data for the group to be imported.
timestamp	DateTime	The date and time at which the data was retrieved.

Return value

The newly created pending import group object.

Discussion

Group profiles in a “pending import” group object needed to be mapped to Active Directory groups before they can be used. Groups in this state are normally imported from NIS domains or from text files and stored temporarily either in Active Directory or XML files until they are mapped to Active Directory accounts. For more information about importing and mapping groups, see the *Administrator's Guide for Linux and UNIX*.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Create the Pending Import group object
set objPendGrp = objZone.CreateImportPendingGroup("script file", now)
objPendGrp.Gid = 500
objPendGrp.Name = "users"
objPendGrp.Commit
...
```

CreateImportPendingUser

Creates a “pending import” user in the zone.

Syntax

IUserInfo CreateImportPendingUser(string source, DateTime timestamp)

Parameters

Specify the following parameters when using this method.

source	The location of the source data for the user to be imported.
timestamp	The date and time at which the data was retrieved.

Return value

The newly created pending import user object.

Discussion

User profiles in a pending import user object need to be mapped to Active Directory groups before they can be used. Users in this state are normally imported from NIS domains or from text files and stored temporarily either in Active Directory or in XML files until they are mapped to Active Directory accounts. For more information about importing and mapping users, see the *Administrator's Guide for Linux and UNIX*.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Create the Pending Import User object
set objPendUsr = objZone.CreateImportPendingUser("script file", now)
objPendiUsr.Uid = 500
objPendUsr.Name = "joe"
objPendUsr.PrimaryGroupId = 500
objPendUsr.HomeDirectory = "/home/joe"
objPendUsr.Shell = "/bin/bash"
objPendUsr.Gecos = "Joe Jane"
objPendUsr.Commit
...
```

Delete

Deletes the zone object from Active Directory.

Syntax

```
void Delete()
```

Discussion

To delete a zone, you must have the DeleteSubTree privilege on the zone's parent container. For example, to delete a zone from the default location for new zones, you must have the right to DeleteSubTree allowed on the domain/Program Data/Acme/Zones container object.

Exceptions

Delete may throw one of the following exceptions:

- UnauthorizedAccessException if you have insufficient access rights to delete the zone.
- COMException if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Delete the zone object
objZone.Delete
...
```

GetComputerByDN

Returns the computer profile for a computer in the zone using the distinguished name (DN) of the profile.

Syntax

```
IComputer GetComputerByDN(string dn)
```

Parameter

Specify the following parameter when using this method:

dn	The distinguished name (DN) of the computer profile.

Return value

The computer profile with the distinguished name (DN) matching the distinguished name specified, or null if no matching computer profile is found.

Discussion

The computer profile is the service connection point associated with the computer object.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=default,CN=zones,CN=centrify,CN=program
data,DC=arcade,DC=com")
'Get the computer profile by DN
set objComputer=
objZone.GetComputerByDN("CN=velvet,CN=Computers,CN=default,CN=Zones,
CN=centrify,CN=program data,DC=arcade,DC=com")
wScript.Echo computer.Name
...
```

GetComputers

Returns the list of computers in the zone.

Syntax

IComputers GetComputers()

Return value

The list of computers for the selected zone object.

Example

The following code sample illustrates using this method in a script:

```
…
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=research,CN=zones,CN=centrify,CN=program
data,DC=arcade,
DC=com")
'Display the list of computers in the zone
wScript.Echo “Computers in zone: “
for each computer in objZone.GetComputers
wScript.Echo computer.Name
next
…
```

GetComputersContainer

Returns the parent container object for computer profiles in the zone.

Syntax

```
DirectoryEntry GetComputersContainer()
```

Return value

The DirectoryEntry object of the zone's Computers container.

Discussion

If the Computers container does not exist, this method creates one for you.

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Exceptions

GetComputersContainer may throw the following exception:

- ApplicationException if you try to use this method in a COM-based program.

GetDirectoryEntry

Returns an instance of the DirectoryEntry object for the zone.

Syntax

```
DirectoryEntry GetDirectoryEntry()
```

Return value

The DirectoryEntry of the zone.

Discussion

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

GetDisplayName

Returns the name displayed for the zone in Access Manager.

Syntax

```
string GetDisplayName()
```

Return value

The DisplayName property for the selected zone object. For example, if using OU=UNIX,OU=Zones for the zone named qa:

```
domain/UNIX/Zones/qa
```

If the zone is defined as a Services for UNIX (SFU) zone, the DisplayName returned ends in SFU. For example:

```
domain/UNIX/Zones/qaSFU
```

Discussion

In most cases, this method returns the same value as the zone. Unexpected Link Text property, for example, domain/UNIX/Zones/testing_lab, and they can be used interchangeably. However, f the zone is defined as a Services for UNIX (SFU) zone supporting the Microsoft Services for UNIX (SFU) schema, this method appends [SFU] to the zone name, for example domain/UNIX/Zones/testing_lab [SFU].

Example

The following code sample illustrates using this method in a script:

```
…
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=research,CN=zones,CN=centrify,CN=program
data,DC=arcade,
DC=com")
'Display the name of the zone
wScript.Echo “Zone name: “ & objZone.GetDisplayName
…
```

GetGroupsContainer

Returns the directory entry for the parent container object for the group profiles in the zone.

Syntax

```
DirectoryEntry GetGroupsContainer()
```

Return value

The directory entry of the zone's Groups container.

Discussion

If the Groups container does not exist, this method creates one for you.

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Exceptions

GetGroupsContainer throws an ApplicationException if you try to use this method in a COM-based program.

GetGroupUnixProfile

Returns the UNIX group profile for a specified group in the zone.

Syntax

```
IGroupUnixProfile GetGroupUnixProfile(IGroup group)
```

Parameter

Specify the following parameter when using this method:

group	The group for which you want to retrieve profile information.

Return value

The Unexpected Link Text object for the specified group in the zone.

Discussion

This method uses the Centrify.DirectControl.API.IGroup group returned by a Unexpected Link Text or Unexpected Link Text call to retrieve the group profile.

Exceptions

GetGroupUnixProfile may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- NotSupportedException if the zone schema is not supported.
- ApplicationException if there is more than one instance of the specified group in the zone.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Identify the Active Directory group object
set objGrp = cims.GetGroupByPath("LDAP://CN=berlin_qa,CN=Users,DC=ajax,DC=org"))

set objGrpProfile = objZone.GetGroupUnixProfile(objGrp)
'Display the UNIX profile name for the group “berlin_qa”
wScript.Echo objGrpProfile.Name
...
```

GetGroupUnixProfileByDN

Returns the UNIX profile for a group in the zone using the distinguished name (DN) of the profile.

Syntax

IGroupUnixProfile GetGroupUnixProfileByDN(string dn)

Parameter

Specify the following parameters when using this method.

dn	The distinguished name (DN) of the group profile.

Return value

The group profile with the distinguished name (DN) matching the distinguished name specified, or null if no matching group profile is found.

Discussion

The group profile is the service connection point associated with the Active Directory group object.

Exceptions

GetGroupUnixProfile throws a NotSupportedException if the zone schema is not supported.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=default,CN=zones,CN=centrify,CN=program
data,DC=arcade,DC=com")
'Get the group profile by DN
set objComputer= objZone.GetGroupUnixProfileByDN(“CN=legal,CN=Groups,CN=default,
CN=Zones,CN=centrify,CN=program data,DC=arcade,DC=com")
...
```

GetGroupUnixProfileByName

Returns the UNIX group profile for a group with the specified name in the zone.

Syntax

```
IGroupUnixProfile GetGroupUnixProfileByName(string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the UNIX group profile for which you want to retrieve information.

Return value

The GroupUnixProfile object for the specified group name in the selected zone, or null if no group unix profile is found.

Discussion

The name you specify should be the UNIX group name for the group if it differs from the Active Directory name for the group.

Exceptions

GetGroupUnixProfileByName may throw one of the following exceptions:

- NotSupportedException if the zone schema is not supported.
- ApplicationException if there is more than one instance of the specified group in the zone.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Get the UNIX profile for the group “berlin_qa”
set objGrp = objZone.GetGroupUnixProfileByName(“berlin_qa”)
'Display the GID for the group “berlin_qa”
wScript.Echo “GID: “ & objGrp.GID
...
```

GetGroupUnixProfiles

Returns the list of UNIX group profiles that have been defined for the zone.

Syntax

IGroupUnixProfiles GetGroupUnixProfiles()

Return value

The GroupUnixProfiles object for the zone.

Example

The following code sample illustrates using this method in a script:

```
…
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=research,CN=zones,CN=centrify,CN=program
data,DC=arcade,
DC=com")
'Display the list of group profiles defined for the zone
set objGroupProfiles = objZone.GetGroupUnixProfiles
for each objProfile in objGroupProfiles
wScript.Echo “Group profile name: “ & objProfile.Name
next
…
```

GetImportPendingGroup

Returns an individual “pending import” group with the specified ID in the zone.

Syntax

```
IGroupInfo GetImportPendingGroup(string id)
```

Parameter

Specify the following parameter when using this method:

id	The GUID of the “pending import” group profile for which you want to retrieve information.

Return value

The IGroupInfo object for the specified ID in the zone.

Discussion

Group profiles that are “pending import” are normally imported from NIS domains or from text files and not yet mapped to Active Directory groups. For more information about importing and mapping groups, see the *Administrator's Guide for Linux and UNIX*.

Example

The following code sample illustrates using this method in a script:

```
...
'Need to obtain an active directory container object
'Configure the test container.
Set objRootDSE = GetObject("LDAP://rootDSE")
set objContainer = GetObject("LDAP://" & strParent & "," &
objRootDSE.Get("defaultNamingContext"))
strContainerDN = objContainer.get("DistinguishedName")
'Get the zone object.
Set objZone = cims.GetZoneByPath("cn=" & strZone & "," & strContainerDN)
Set objGroupInfo = objZone.GetImportPendingGroup(strID)
objGroupInfo.Delete
...
```

GetImportPendingGroups

Returns the list of “pending import” groups for the zone.

Syntax

```
IGroupInfos GetImportPendingGroups()
```

Return value

The collection of “pending import” group profiles for the zone.

Example

The following code sample illustrates using this method in a script:

```
…
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=default,CN=zones,CN=centrify,CN=program data,
DC=arcade,DC=com")
'Get the collection of pending import groups
set objPendingGrps = objZone.GetImportPendingGroups
if not objPendingGrps is nothing then
wScript.Echo "Pending import groups: ", objPendingGrps.Count
for each objPendingGrp in objPendingGrps
wScript.Echo objPendingGrp.Gid, objPendingGrp.Name
if objPendingGrp.Source = "script file" then
objPendingGrp.Delete
end if
next
wScript.Echo ""
end if
…
```

GetImportPendingUser

Returns an individual “pending import” user with the specified ID in the zone.

Syntax

```
IUserInfo GetImportPendingUser(string id)
```

Parameter

Specify the following parameter when using this method:

id	The GUID of the “pending import” user profile for which you want to retrieve information.

Return value

The Unexpected Link Text object for the specified ID in the zone.

Discussion

User profiles that are “pending import” are normally imported from NIS domains or from text files and not yet mapped to Active Directory users. For more information about importing and mapping groups, see the *Administrator's Guide for Linux and UNIX*.

Example

The following code sample illustrates using this method in a script:

```
...
// Get the user object
IUser objUser = cims.GetUserByPath(strUser);
// Get the zone object
IZone objZone = cims.GetZoneByPath("cn=" + strZone + "," + strContainerDN);
Import.IUserInfo objUserInfo = objZone.GetImportPendingUser(strUserInfo);
if (objUser == null)
{
    Console.WriteLine("User " + strUser + " does not exist.");
}
else
{
    objUserInfo.Import(objUser);
}
...
```

GetImportPendingUsers

Returns the list of “pending import” users for the zone.

Syntax

```
IUserInfos GetImportPendingUsers()
```

Return value

The collection of “pending import” user profiles for the zone.

Example

The following code sample illustrates using this method in a script:

```
…
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
‘Get the collection of pending users
set objPendingUsrs = objZone.GetImportPendingUsers
if not objPendingUsrs is nothing then
wScript.Echo "Pending import users: ", objPendingUsrs.Count
for each objPendingUsr in objPendingUsrs
wScript.Echo objPendingUsr.Uid, objPendingUsr.Name
if objPendingUsr.Source = "script file" then
objPendingUsr.Delete
end if
next
wScript.Echo ""
end if
…
```

GetLocalGroupsContainer

Returns the directory entry for the parent container object for the local group profiles.

Syntax

```
DirectoryEntry GetLocalGroupsContainer()
```

Return value

The directory entry of the local group's container.

Discussion

This method can only be used in .NET programs because `DirectoryEntry` is a .NET-specific class for `directory` objects. This method cannot be used in COM-based programs.

Exceptions

`GetLocalGroupsContainer` may throw the following exception:

`ApplicationException` if you try to use this method in a COM-based program.

GetLocalGroupUnixProfile

Returns the UNIX group profile for a specified local group.

Syntax

```
IGroupUnixProfile GetLocalGroupUnixProfile(string groupName)
```

Parameter

Specify the following parameter when using this method:

groupName	The name of the local group for which you want to retrieve profile information.

Return value

The Unexpected Link Text object for the specified local group name. If there is no group, `null` is returned.

Exceptions

`GetGroupUnixProfile` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is null.

GetLocalGroupUnixProfileByDN

Returns the Local UNIX profile for a group in the zone using the distinguished name (DN) of the profile.

Syntax

```
IGroupUnixProfile GetLocalGroupUnixProfileByDN(string dn)
```

Parameter

Specify the following parameters when using this method.

dn	The distinguished name (DN) of the local group profile.

Return value

The local group profile with the distinguished name (DN) matching the distinguished name specified, or null if no matching group profile is found.

GetLocalGroupUnixProfileByGid (Int32)

Returns the Local UNIX profile for a group in the zone using the group identifier (GID) of the profile. This method is exposed to the .COM interface.

Syntax

```
IGroupUnixProfile GetLocalGroupUnixProfileByGid(int gid)
```

Parameter

Specify the following parameters when using this method.

gid	The group identifier (GID) of the local group profile.

Return value

The local group profile with the specified group identifier (GID) or `null` if no matching group profile is found.

GetLocalGroupUnixProfiles

Get the list of local group profiles in the zone.

Syntax

```
IGroupUnixProfiles GetLocalGroupUnixProfiles()
```

Return value

Returns a collection of `GroupUnixProfile` objects. If there are no groups, `null` is returned.

GetLocalUsersContainer

Returns the directory entry for the parent container object for the local user profiles in the zone.

Syntax

```
DirectoryEntry GetLocalUsersContainer()
```

Return value

The directory entry of the zone's users container.

Discussion

If the `Users` container does not exist, this method creates one for you.

This method can only be used in .NET programs because `DirectoryEntry` is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Exceptions

`GetUsersContainer` may throw the following exception:

- `ApplicationException` if you try to use this method in a COM-based program.

GetLocalUserUnixProfile

Returns the UNIX user profile for a specified local group.

Syntax

```
IUserUnixProfile GetLocalUserUnixProfile(string userName)
```

Parameter

Specify the `userName` parameter when using this method.

Return value

Returns the local user profile with the specified user name. If there is no group, `null` is returned.

GetLocalUserUnixProfileByDN

Returns the local UNIX profile for a user in the zone using the distinguished name (DN) of the profile.

Syntax

```
IUserUnixProfile GetLocalUserUnixProfileByDN(string dn)
```

Parameter

Specify the following parameters when using this method.

dn	The distinguished name (DN) of the local user profile.

Return value

Returns the local user profile with the distinguished name (DN) matching the distinguished name specified, or null if no matching group profile is found.

GetLocalUserUnixProfileByUid (Int32)

Returns the local UNIX profile for a user in the zone using the user identifier (GID) of the profile. This method is exposed to the .COM interface.

Syntax

```
IUserUnixProfile GetLocalUserUnixProfileByUid(int uid)
```

Parameter

Specify the following parameters when using this method.

uid	The user identifier (UID) of the local user profile.

Return value

The local user profile with the specified user identifier (UID) or null if no matching user profile is found.

GetLocalUserUnixProfiles

Get a list of local UNIX user profiles in the zone.

Syntax

```
IUserUnixProfiles GetLocalUserUnixProfiles()
```

Return value

Returns a collection of local user profiles in the zone. If there are no users, `null` is returned.

GetUsersContainer

Returns the directory entry for the parent container object for the user profiles in the zone.

Syntax

```
DirectoryEntry GetUsersContainer()
```

Return value

The directory entry of the zone's Users container.

Discussion

If the Users container does not exist, this method creates one for you.

This method can only be used in .NET programs because DirectoryEntry is a .NET-specific class for directory objects. This method cannot be used in COM-based programs.

Exceptions

`GetUsersContainer` may throw the following exception:

- `ApplicationException` if you try to use this method in a COM-based program.

GetUserUnixProfileByDN

Returns the UNIX profile for a user in the zone using the distinguished name (DN) of the profile.

Syntax

IUserUnixProfile GetUserUnixProfileByDN(string dn)

Parameter

Specify the following parameter when using this method:

dn	The distinguished name (DN) of the user profile.

Return value

The user profile with the distinguished name (DN) matching the distinguished name specified, or null if no matching user profile is found.

Discussion

The user profile is the service connection point associated with the Active Directory user object.

Exceptions

GetUserUnixProfileByDN throws a NotSupportedException if the zone schema is not supported.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone =
cims.GetZoneByPath("LDAP://CN=default,CN=zones,CN=centrify,CN=program
data,DC=arcade,DC=com")
'Get the user profile by DN
set objComputer=
objZone.GetUserUnixProfileByDN("CN=yuji,CN=Users,CN=default,CN=Zones,CN=centrify,CN=program
data,DC=arcade,DC=com")
...
```

GetUserUnixProfileByName

Returns the UNIX user profile associated with the specified user name in the zone.

Syntax

```
IUserUnixProfile GetUserUnixProfileByName(string name)
```

Parameter

Specify the following parameter when using this method:

name	The user's UNIX login name.

Return value

The UserUnixProfile object associated with the specified user name in the zone, or null if the UserUnixProfile is not found.

Exceptions

GetUserUnixProfileByName may throw one of the following exceptions:

- NotSupportedException if the zone schema is not supported.
- ApplicationException if there is more than one instance of the specified user in the zone.

Example

The following code sample illustrates using this method in a script:

```
…
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Display the UNIX profile for the group “jae”
wScript.Echo objZone.GetUserUnixProfileByName(“jae”)
…
```

GetUserUnixProfiles

Returns the list of UNIX user profiles for the zone.

Syntax

IUserUnixProfiles GetUserUnixProfiles()

Return value

The Unexpected Link Text object for the zone. This object is a collection of UserUnixProfile objects.

Example

The following code sample illustrates using this method in a script to enumerate all of the user profiles in the default zone:

```
...
'Specify the zone you want to work with
Set objZone = cims.GetZone("acme.com/Program Data/Acme/Zones/default")
'List the UNIX login name for each profile in the zone
Set objProfiles = objZone.GetUserUnixProfiles()
For each profile in objProfiles
wscript.echo profile.Name
next
...
```

GroupUnixProfileExists

Checks whether a UNIX profile exists for the specified group in the zone.

Syntax

```
bool GroupUnixProfileExists(IGroup group)
```

Parameter

Specify the following parameter when using this method:

group	The group name for which you want to check whether a UNIX profile exists.

Return value

Returns true if a UNIX profile is found in the zone for the specified group, or false if no UNIX profile exists for the group in the zone.

Exceptions

GroupUnixProfileExists may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- NotSupportedException if the zone schema is not supported.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Check whether there's a UNIX profile for the group "legal"
if objZone.GroupUnixProfileExists(legal) = true
wScript.Echo "Profile exists in this zone"
else
wScript.Echo "No matching profile in this zone!"
end if
...
```

LocalGroupUnixProfileExists

Checks whether a UNIX profile exists for the specified local group in the zone.

Syntax

```
bool LocalGroupUnixProfileExists(string groupName)
```

Parameter

Specify the following parameter when using this method:

groupName	The group name for which you want to check whether a UNIX profile exists.

Return value

Returns `true` if the local UNIX group profile is found in the zone, or `false` if no UNIX profile exists for the group in the zone.

Exceptions

`LocalGroupUnixProfileExists` may throw the following exception:

- `ArgumentNullException` if the specified parameter value is null.

LocalUserUnixProfileExists

Checks whether a local UNIX profile exists for the specified user in the zone.

Syntax

```
bool LocalUserUnixProfileExists(string userName)
```

Parameter

Specify the following parameter when using this method:

userName	The local user name for which you want to check whether a UNIX profile exists.

Return value

Returns `true` if a UNIX profile is found in the zone for the specified local user, or `false` if no UNIX profile exists for the user in the zone.

Exceptions

`UserUnixProfileExists` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is null.

PrecreateComputer

Adds a computer to a zone.

Syntax

IComputer PrecreateComputer(DirectoryEntry adComputerEntry, string[] spn, DirectoryEntry trustee)

IComputer PrecreateComputer(DirectoryEntry containerEntry, string cn, string dnsName, string[] spn, DirectoryEntry trustee

IComputer PrecreateComputer(DirectoryEntry adComputerEntry, string[] spn, DirectoryEntry trustee, bool skipPermissionSetting);

IComputer PrecreateComputer(DirectoryEntry containerEntry, string cn, string dnsName, string[] spn, DirectoryEntry trustee, bool skipPermissionSetting);

Parameters

Specify the following parameters when using this method.

adComputerEntry	The DNS host name of the Active Directory computer object you wish to add to the zone.
containerEntry	The Directory container for the created computer.
cn	The computer name.
dnsName	The DNS name of the created computer.
skipPermissionSetting	Specifies if permission delegation is skipped when precreating computers.
spn	Service Principal Name. Specify null to use default.
trustee	The user or group to delegate adjoin permissions to, Specify null to delegate the permission for a self-service join.
trusteeDn	The user or group to which the computer-level overrides will be assigned, specified as a distinguished name.

Return value

The computer object that is added to the zone.

Discussion

Use PrecreateComputer(DirectoryEntry, string[], DirectoryEntry) to add an existing Active Directory computer to the zone. Use PrecreateCompute(DirectoryEntry, string, string, string[], DirectoryEntry) to create a new UNIX computer object and add it to the zone.

PrecreateWindowsComputer

Adds an existing Windows computer to a zone.

Syntax

```
IComputer PrecreateWindowsComputer(DirectoryEntry adComputerEntry);
IComputer PrecreateWindowsComputer(DirectoryEntry adComputerEntry, bool skipPermissionSetting);
```

Parameters

Specify the following parameter when using this method.

adComputerEntry	The DNS host name of the Windows computer object you wish to add to the zone.
skipPermissionSetting	Specifies if permission delegation is skipped when precreating computers.

Return value

The computer object that is added to the zone.

Refresh

Reloads the zone object data from the data in Active Directory.

Syntax

```
void Refresh()
```

Discussion

This method refreshes the zone information in the cached object to ensure it is synchronized with the latest information in Active Directory.

Exceptions

`Refresh` may throw the following exception:

- `COMException` if an LDAP error occurs. LDAP errors can occur if the connection to the LDAP server fails, the connection times out, invalid credentials are presented, or there are other problems communicating with Active Directory.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZoneByPath("LDAP://CN=corporate,CN=zones,CN=centrify,
CN=program data,DC=sierra,DC=com")
'Change the zone description
objZone.Description = "Corporate offices, Edinburgh”
objZone.Commit
'Reload the zone object
objZone.Refresh
...
```

UserUnixProfileExists

Checks whether a UNIX profile exists for the specified user in the zone.

Syntax

```
bool UserUnixProfileExists(IUser user)
```

Parameter

Specify the following parameter when using this method:

user	The user name for which you want to check whether a UNIX profile exists.

Return value

Returns true if a UNIX profile is found in the zone for the specified user, or false if no UNIX profile exists for the user in the zone.

Exceptions

UserUnixProfileExists may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- NotSupportedException if the zone schema is not supported.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Check whether there's a UNIX profile for the user "garcia"
if objZone.GroupUnixProfileExists(garcia) = true
wScript.Echo "Profile exists in this zone"
else
wScript.Echo "No matching profile in this zone!"
end if
...
```

AdsiInterface

Gets the IADs interface of the zone object from Active Directory.

Syntax

IADs AdsiInterface {get;}

Property value

The IADs interface of the zone object.

Discussion

This property enables you to perform any operations provided by the underlying Active Directory Service Interfaces (ADSI) for a zone as a directory object. For example, you can use this property to retrieve the IADs properties and methods that enable you to access the security information for the zone object.

Example

The following code sample illustrates using AdsInterface in a script:

```
...
'Specify the zone you want to work with
set zone = GetZoneByPath("LDAP://cn=test_lab,cn=Zones,cn=UNIX,dc=ajax,dc=org")
'Get the IADs for the zone
set secdes = zone.AdsiInterface.Get("ntSecurityDescriptor")
'Display security information for the zone
wScript.Echo secdes.Owner
...
```

ADsPath

Gets the LDAP path to the zone object.

Syntax

```
string ADsPath {get;}
```

Property value

The full LDAP path to the zone object.

Example

The following code sample illustrates using ADsPath in a script:

```
...
'Specify the zone you want to work with
set zone = GetZone("fireball.net/Field/Zones/macs")
'Display the LDAP path for the zone
wScript.Echo zone.ADsPath
...
```

AgentlessAttribute

Gets or sets the Active Directory attribute used for storing the user's password hash if a zone supports agentless NIS client requests.

Syntax

```
string AgentlessAttribute {get; set;}
```

Property value

The Active Directory attribute used for storing the user's password hash.

Discussion

If you have any computers configured to respond to NIS client requests using information stored in Active Directory, this property must be set to enable password synchronization for the zone. Only the following values are valid:

- altSecurityIdentities
- msSFU30Password
- unixUserPassword

Setting this property to an invalid value disables password synchronization.

Exceptions

AgentlessAttribute throws an ApplicationException if the selected attribute cannot store a password hash.

Example

The following code sample illustrates setting this property in a script:

```
...
'Specify the zone you want to work with
set zone = cims.GetZone("zap.org/Program Data/Acme/Zones/default")
'Change the attribute used for the password hash
zone.AgentlessAttribute = "unixUserPassword"
zone.Commit()
...
```

AvailableShells

Gets or sets the list of available shells for this zone.

Syntax

```
string[ ] AvailableShells {get; set;}
```

Property value

The list of available shells for the zone.

Discussion

The values you define for this property are used as the values in the drop-down list of available shells when defining the UNIX profile for a new user in the Access Manager console.

This property requires a strongly-typed array. Because strongly-typed arrays are not supported in VBScript, you cannot use this property in scripts written with VBScript. To use this property, you must use a programming language that allows strongly-typed arrays.

Example

The following code sample illustrates setting this property in a Visual Studio (C#) script:

```
...
// Set the Active Directory container object.
DirectoryEntry objContainer = new
DirectoryEntry("LDAP://cn=Zones,cn=UNIX,dc=ajax,dc=org");
IZone objZone = cims.CreateZone(objContainer, “QA Zone”);

// set the starting UID and GID for the zone
objZone.NextAvailableUID = 10000;
objZone.NextAvailableGID = 10000;

// set the list of available shells and default shell for the zone
objZone.AvailableShells = new string[] {"/bin/bash", "/bin/shell"};
objZone.DefaultShell = "/bin/bash";

// set the default home directory for the zone
objZone.DefaultHomeDirectory = "/home/\${user}";
objZone.Commit();
Console.WriteLine("Zone created successfully.");
...
```

Cims

Gets the Cims object managing the zone.

Syntax

```
Cims Cims {get;}
```

Property value

The Cims object managing this zone.

Discussion

This property serves as a shortcut for retrieving data.

DefaultGroup

Gets or sets the default group profile to use as the primary group for new users in the zone.

Syntax

```
IGroupUnixProfile DefaultGroup{get; set;}
```

Property value

The default group property for the zone.

Discussion

The default group profile for a zone is always associated with an existing Active Directory group. You can, however, define a primary group that is not associated with any Active Directory group.

For more information about defining primary groups for UNIX users, see the *Planning and Deployment Guide* and the *Administrator's Guide for Linux and UNIX*.

Example

The following code sample illustrates using `DefaultGroup` in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Check the default group for the zone
If objZone.DefaultGroup is nothing
'Identify the Active Directory group object
set objGrp = cims.GetGroupByPath("LDAP://CN=IT Interns,CN=Users,DC=ajax,DC=org")

'Get the UNIX profile for the Active Directory group
set objGrpProfile = objZone.GetGroupUnixProfile(objGrp)
'Make this profile the default group
set objZone.DefaultGroup = objGrpProfile
end if
objZone.Commit
...
```

DefaultHomeDirectory

Gets or sets the local file system path to the user's default home directory.

Syntax

```
string DefaultHomeDirectory {get; set;}
```

Property value

The text string that defines the default path to the user's home directory.

Discussion

The only variable permitted is $. The Access Manager console replaces this variable with the user's UNIX login name when you add a UNIX profile for the user to the zone.

Example

The following code sample illustrates using DefaultHomeDirectory in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("zap.org/Program Data/Acme/Zones/default")
'Set zone properties
objZone.DefaultHomeDirectory = "/home/\${user}"
objZone.DefaultShell = "/bin/bash"
objZone.NextAvailableUID = zone.NextAvailableUID + 1
objZone.NextAvailableGID = zone.NextAvailableGID + 1
objZone.DefaultHomeDirectory = "/home/\${user}"
...
```

DefaultShell

Gets or sets the default shell assigned to new users in the zone.

Syntax

```
string DefaultShell {get; set;}
```

Property value

The default shell property for the zone.

Discussion

The value you define for this property is automatically populated as the default shell when defining the UNIX profile for a new user in Access Manager. The value can be overridden by the administrator defining the user's profile.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("zap.org/Program Data/Acme/Zones/default")
'Specify zone properties
objZone.DefaultHomeDirectory = "/home/admin"
objZone.DefaultShell = "/bin/bash"
objZone.NextAvailableUID = zone.NextAvailableUID + 1
objZone.NextAvailableGID = zone.NextAvailableGID + 1
...
```

DefaultValueZone

Gets or sets the zone to use as the “master” zone for setting default zone property values.

Syntax

IZone DefaultValueZone {get; set;}

Property value

The zone object for the zone used to define default values.

Discussion

If this property is set, the profile information and zone properties in the specified zone are used as the default values for the current zone. For example, if you add users or groups that have profiles in the specified zone to the zone context in which you are currently working, their UNIX profiles have the same UIDs and GIDs in both zones by default.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Get the master default values zone for this zone
set objMaster = objZone.DefaultValueZone
wScript.Echo “The master zone is “ & objMaster.Name
...
```

Description

Gets or sets the text string used for the description property of the zone.

Syntax

```
string Description {get; set;}
```

Property value

The description property for the zone.

Discussion

The zone description can consist of any text string up to the number maximum of characters available in the data attribute where zone properties are stored. The maximum number of characters available for the attribute is approximately 850, but the maximum available for the description depends on the other data being stored. For example, the more available shells you have defined for a zone, the shorter the zone description must be.

Example

The following code sample illustrates setting this property in a script:

```
...
'Specify the zone you want to work with
set zone = cims.GetZone("fireball.net/Field/Zones/macs")
'Set the long description for the zone
zone.Description = "Mac OS X computers and users in Fireball field offices"
zone.Commit()
...
```

FullName

Gets the full name of the zone.

Syntax

```
string FullName {get;}
```

Property value

The full, canonical name for the zone.

Discussion

The full name is the canonical name of the zone. The full name is updated when the directory object is updated. Therefore, changes to the Unexpected Link Text property are not reflected in the value retrieved by the FullName property until the changes to the Name property are committed to Active Directory.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Display the full name zone
If objZone.IsReadable = true
wScript.Echo "Zone name: " & objZone.FullName
end if
...
```

GroupAutoProvisioningEnabled

Indicates whether auto-provisioning of group profiles is enabled for the zone.

Syntax

```
bool GroupAutoProvisioningEnabled {get;}
```

Property value

Returns `true` if the zone has auto-provisioning enabled.

Discussion

When automatic provisioning is enabled for groups, the Zone Provisioning Agent can automatically provision new UNIX profiles for groups added to the zone. In addition to enabling provisioning, you must specify a provisioning group to use as the source for provisioning data. For more information about automatic provisioning of users and groups, see the *Planning and Deployment Guide*.

ID

Gets the unique identifier for the zone.

Syntax

```
string ID {get;}
```

Property value

The unique identifier for the zone.

Discussion

This property is used internally to prevent a zone from being listed more than once.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set zone = GetZoneByPath("LDAP://cn=test_lab,cn=Zones,cn=UNIX,dc=ajax,dc=org")
'Display the unique identifier for the zone
wScript.Echo zone.ID
...
```

IsHierarchical

Indicates whether the zone supports hierarchical zone features.

Syntax

```
bool IsHierarchical {get;}
```

Property value

Returns true if the zone is hierarchical.

IsReadable

Determines whether this zone object's properties are readable for the user whose credentials are presented.

Syntax

```
bool IsReadable {get;}
```

Property value

Returns true if the zone object is readable by the user, or false if the zone object is not readable.

Discussion

This property returns a value of true if the user accessing the zone object in Active Directory has sufficient permissions to read zone properties.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Check whether the zone is readable
If not objZone.IsReadable then
wScript.Echo “You do not have read permission for this zone”
end if
...
```

IsSFU

Determines whether the zone uses the Microsoft Services for UNIX (SFU) schema extension.

Syntax

```
bool IsSFU {get;}
```

Property value

Returns true if the zone uses a Services for UNIX (SFU) schema, or false if the zone does not use the SFU schema.

Discussion

If the Microsoft Services for UNIX (SFU) schema extension is installed and being used to store UNIX attributes for the zone, this property returns a value of true.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set zone = GetZoneByPath("LDAP://cn=test_lab,cn=Zones,cn=UNIX,dc=ajax,dc=org")
'Check whether the zone uses the SFU schema
If zone.IsSFU then
wScript.Echo “Zone uses the SFU schema for UNIX attributes”
end if
...
```

IsTruncateName

Determines whether the zone is a TruncateName zone.

Syntax

```
bool IsTruncateName {get; set;}
```

Property value

If this property is true, the zone is a TruncateName zone.

Discussion

If this property is true, the default pre-Windows 2000 name for new users is the computer account name truncated at 15 characters.

IsWritable

Determines whether the zone object's properties are writable properties for the user whose credentials are presented.

Syntax

```
bool isWritable {get;}
```

Property value

Returns true if the zone object is writable by the user, or false if the zone object is not writable.

Discussion

This property returns a value of true if the user accessing the zone object in Active Directory has sufficient permissions to change zone properties.

Example

The following code sample illustrates using this property in a script:

```
…
'Specify the zone you want to work with
set objZone = cims.GetZone("ajax.org/UNIX/Zones/test_lab")
'Check whether the zone is writable
If not objZone.IsWritable then
wScript.Echo “You do not have permission to modify the zone”
end if
…
```

Licenses

Gets or sets the license container associated with this zone.

Syntax

```
ILicenses Licenses {get; set;}
```

Property value

The license container for this zone.

MasterDomainController

Gets or sets the name of the domain controller to use as the primary domain controller for the zone.

Syntax

```
string MasterDomainController {get; set;}
```

Property value

The name of the primary domain controller for the zone.

Example

The following code sample illustrates using MasterDomainController in a script:

```
…
'Specify the zone you want to work with
set zone = GetZone("fireball.net/Field/Zones/macs")
‘Display the domain controller for this zone
wScript.Echo “Main Domain Controller: “ & zone.MasterDomainController
…
```

MustMaintainADGroupMembership

Gets or sets the flag that indicates whether Active Directory group membership must be maintained.

Syntax

```
bool MustMaintainADGroupMembership {get; set;}
```

Property value

Returns true if the Active Directory group membership must be maintained; otherwise, it returns false.

Discussion

By default, setting the primary Active Directory group in a user's UNIX profile does not affect the user's actual Active Directory group membership.

If you want to enforce Active Directory group membership for new users when you add them to the zone, set this property to true. Setting this property to true displays the **Associate Active Directory group membership** option in the Zone Properties dialog box.

Example

The following code sample illustrates using MustMaintainADGroupMembership in a script:

```
...
'Specify the zone you want to work with
set zone = GetZone("fireball.net/Field/Zones/macs")
'Check whether Active Directory group membership is enforced
if zone.MustMaintainADGroupMembership then
wScript.Echo "Active Directory group membership maintained"
else
wScript.Echo "No Active Directory group membership needed"
end if
...
```

Name

Gets or sets the name of the zone.

Syntax

```
string name {get; set;}
```

Property value

The short name of the zone. The name must start with an alphanumeric character or an underscore (*) character and can contain any combination of letters (upper- or lowercase), numerals 0 through 9, and the period (.), hyphen (-) and underscore (*) characters up to a maximum length of 64 characters.

Exceptions

Name throw an ArgumentException if you try to set an invalid name for the zone.

Example

The following code sample illustrates setting this property in a script:

```
…
'Specify the zone you want to work with
set zone = cims.GetZone("zap.org/Program Data/Acme/Zones/default")
'Change the name of the “default” zone to “Pilot deployment”
zone.Name = "Pilot deployment"
zone.Commit()
…
```

NextAvailableGID

Returns or sets the next available value for the group identifier (GID) in the zone.

Syntax

```
int NextAvailableGID {get; set;}
```

Property value

The numeric value of the next available GID for the zone.

Discussion

This method returns or sets the next available GID to be used as the default GID assignment for the next group given access to the zone. If you are setting this property as part of creating a new zone, use this value to define the starting GID value for all groups in the zone. In most cases, this value is incremented automatically each time a new group profile is created for the zone. If you are creating new groups programmatically, use this property to read the current value.

There are two versions of this property: one designed for COM-based programs (NextAvailableGID) that supports a 32-bit signed number for the GID and one designed for .NET-based programs (Unexpected Link Text) that allows a 64-bit signed number for the GID. You can use either property.

Example

The following code sample illustrates setting this property in a script:

```
...
'Set the container object for the zone
set objContainer = GetObject("LDAP://cn=Zones,cn=UNIX, dc=ajax,dc=org")
'Create a new zone named “Sample_Zone”
set objZone = cims.CreateZone(objContainer, “Sample_Zone”)
'Set the starting UID and GID for the new zone
objZone.nextAvailableUID = 10000
objZone.nextAvailableGID = 10000
...
```

NextAvailableUID

Returns or sets the next available value for the user identifier (UID) in the zone.

Syntax

```
int nextAvailableUID {get; set;}
```

Property value

The numeric value of the next available UID for the zone.

Discussion

This method returns or sets the next available UID to be used as the default UID assignment for the next user given access the zone. If you are setting this property as part of creating a new zone, use this value to define the starting UID for all users in the zone. In most cases, this value is incremented automatically each time a new user is enabled for the zone. If you are creating new users programmatically, you can use this property to read the current value.

There are two versions of this property: one designed for COM-based programs (nextAvailableUID) that supports a 32-bit signed number for the UID and one designed for .NET-based programs (Unexpected Link Text) that allows a 64-bit signed number for the UID. You can use either method.

Example

The following code sample illustrates setting this property in a script:

```
...
'Specify the zone you want to work with
set objZone = cdc.GetZone("ajax.org/UNIX/Zones/ea_central")
'Reset the next available UID for the zone
objZone.nextAvailableUID = 5000
zone.Commit()
...
```

NextGID

Gets or sets the next GID to be used when adding groups (64-bit for use with .NET).

Syntax

```
long NextGID {get; set;}
```

Property value

The GID for new groups.

Discussion

This method returns or sets the next available GID to be used as the default GID assignment for the next group given access to the zone. If you are setting this property as part of creating a new zone, use this value to define the starting GID value for all groups in the zone. In most cases, this value is incremented automatically each time a new group profile is created for the zone. If you are creating new groups programmatically, use this property to read the current value.

There are two versions of this property: one designed for COM-based programs (Unexpected Link Text) that supports a 32-bit signed number for the GID and one designed for .NET-based programs (NextGID) that allows a 64-bit signed number for the GID. You can use either method.

NextUID

Gets or sets the next UID to be used when adding users (64-bit for use with .NET).

Syntax

```
long NextUID {get; set;}
```

Property value

The UID for new users.

Discussion

This method returns or sets the next available UID to be used as the default UID assignment for the next user given access to the zone. If you are setting this property as part of creating a new zone, use this value to define the starting UID for all users in the zone. In most cases, this value is incremented automatically each time a new user is enabled for the zone. If you are creating new users programmatically, you can use this property to read the current value.

There are two versions of this property: one designed for COM-based programs (NextAvailableGID](nextavailablegid.md)) that supports a 32-bit signed number for the UID and one designed for .NET-based programs (NextUID) that allows a 64-bit signed number for the UID. You can use either method.

NISDomain

Gets or sets the NIS domain associated with the zone when the zone is determined to be a zone that uses the Microsoft Services for UNIX (SFU) schema extension or is configured to support agentless NIS client requests.

Syntax

```
string NISDomain {get; set;}
```

Property value

The Network Information Service (NIS) distinguished name for the zone.

Discussion

If the zone is a Services for UNIX (SFU) zone, this property should be the NIS domain defined in users' UNIX attributes. For agentless client requests, the zone associated with the computer acting as the NIS server is the NIS domain.

Exceptions

NISDomain throws an ApplicationException if no value is specified when setting this property. You must specify a value when using this property to set the NIS domain.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set zone = GetZoneByPath("LDAP://cn=test_lab,cn=Zones,cn=UNIX,dc=ajax,dc=org")
'If the zone uses the SFU schema, display its NIS domain
If zone.IsSFU then
wScript.Echo "NIS Domain: " & zone.NISDomain
end if
...
```

ReservedGID

Gets or sets the list of reserved group identifiers (GIDs) in the zone.

Syntax

```
string[ ] ReservedGID {get; set;}
```

Discussion

Reserved GIDs cannot be assigned when creating new groups. The `get` argument returns a string containing the range of GIDs not available. The `set` argument specifies a number range to be reserved.

This property requires a strongly-typed array. Because strongly-typed arrays are not supported in VBScript, you cannot use this property in scripts written with VBScript. To use this property, you must use a programming language that allows strongly-typed arrays.

Example

The following code sample illustrates using `ReservedUID` in a Visual Studio (C#) script:

```
...
IZone objZone = cims.CreateZone(objContainer, strZone);
// Set the starting UID and GID for the zone
objZone.NextAvailableUID = 10000;
objZone.NextAvailableGID = 10000;

// Set the reserved UIDs and GIDs for the zone
objZone.ReservedUID = new string[] {"0-300", "999"};
objZone.ReservedGID = new string[] {"0-300", "999"};
objZone.Commit();
...
```

ReservedUID

Gets or sets the list of reserved user identifiers (UIDs).

Syntax

```
string[ ] ReservedUID {get; set;}
```

Discussion

Reserved UIDs cannot be assigned when creating new users. The get argument returns a string containing the range of UIDs not available. The set argument specifies a number range to be reserved.

This property requires a strongly-typed array. Because strongly-typed arrays are not supported in VBScript, you cannot use this property in scripts written with VBScript. To use this property, you must use a programming language that allows strongly-typed arrays.

Example

The following code sample illustrates using ReservedUID in a Visual Studio (C#) script:

```
...
IZone objZone = cims.CreateZone(objContainer, strZone);
// Set the starting UID and GID for the zone
objZone.NextAvailableUID = 10000;
objZone.NextAvailableGID = 10000;

// Set the reserved UIDs and GIDs for the zone
objZone.ReservedUID = new string[] {"0-300", "999"};
objZone.ReservedGID = new string[] {"0-300", "999"};
objZone.Commit();
...
```

Schema

Gets the schema type of the zone object.

Syntax

```
ZoneSchema Schema {get;}
```

Property value

The schema type for the zone.

Discussion

The schema type defines how data for the zone should be stored in Active Directory and is based on the specific Active Directory schema you are using. Zones can be defined as:

- Standard Delinea zones
- Standard Delinea RFC 2307-compliant zones
- Delinea Services for UNIX (SFU) zones

The schema type provides an additional level of granularity corresponding the specific version of the Active Directory schema you are using and where specific zone properties and UNIX attributes are stored. The schema types currently defined for Centify zones are:

Unknown	-1	Schema unknown
Dynamic_Schema_1_0	0	Standard Delinea zone, version 1.x Uses the Delinea version 1.x and standard Active Directory schema data storage model. This zone type is for backward compatibility and otherwise no longer in use.
Dynamic_Schema_2_0	1	Standard Delinea zone, version 2.x and 3.x Uses the Delinea version 2.x and standard Active Directory schema data storage model. This zone type is for backward compatibility and otherwise no longer in use.
SFU_3_0	2	SFU zone, version 2.x and 3.x Uses a combination of the Delinea version 3.x and Microsoft Services for UNIX (SFU) 3.0 data storage model. This zone type can be used when Active Directory has the Microsoft Services for UNIX (SFU), version 3.x, schema extension installed. The standard UNIX properties are stored as defined by the Microsoft SFU 3.x schema, but associated with zones. This zone type is for backward compatibility if you have the Microsoft Services for UNIX (SFU) schema extension installed, and otherwise no longer in use.
SFU_4_0	3	SFU zone, version 4.x Uses a combination of the Delinea version 3.x and Microsoft Services for UNIX (SFU) 4.0 data storage model. This zone type can be used when Active Directory has the Microsoft Services for UNIX (SFU), version 4.0, schema extension installed. The standard UNIX properties are stored as defined by the Microsoft SFU 4.0 schema, but associated with zones. This zone type is for backward compatibility if you have the Microsoft Services for UNIX (SFU) schema extension installed, and otherwise no longer in use.
CDC_RFC_2307	5	Standard RFC 2307-compatible zone, version 3.x Uses the Active Directory RFC 2307-compliant schema data storage model.
Dynamic_Schema_3_0	6	Standard Delinea zone, version 3.x and 4.x Uses the Delinea version 4.x and Active Directory schema data storage model. **Note**: The only difference between the Dynamic_Schema_2_0 data storage model and the Dynamic_Schema_3_0 data storage model is the use of the managedBy attribute. This attribute is set in zones that use the Dynamic_Schema_2_0 schema. The managedBy attribute is not used in zones that use in the Dynamic_Schema_3_0 schema.
CDC_RFC_2307_2	7	Classic RFC 2307-compatible zone, version 4.x Uses the Active Directory RFC 2307-compliant schema data storage model. **Note**: The only difference between the CDC_RFC_2307 data storage model and the CDC_RFC_2307_2 data storage model is the use of the managedBy attribute. This attribute is set in zones that use the CDC_RFC_2307 schema. The managedBy attribute is not used in zones that use in the CDC_RFC_2307_2 schema.

Dynamic_Schema_5_0	8	Hierarchical zone, version 5.x Uses the Delinea version 5.x and standard Active Directory schema data storage model. **Note**: The difference between the Dynamic_Schema_5_0 data storage model and the CDC_RFC_2307_3 data storage model is that in the Dynamic_Schema_5_0 storage model, all Delinea data is stored as part of the zone. In the CDC_RFC_2307_3 storage model, user and group attributes are stored as part of the User and Group objects.
CDC_RFC_2307_3	9	Hierarchical RFC 2307-compatible zone, version 5.x
SFU_3_0_V5	10	Hierarchical SFU zone, version 5.x

If the zone is not in one of these formats, an exception is thrown. For more information about the difference between these different schema types and the corresponding zone types, see “Planning for data storage in Active Directory” in the *Planning and Deployment Guide*.

Exceptions

Schema throws an ApplicationException if the zone schema is not recognized.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set zone = GetZone("ajax.org/UNIX/Zones/test_lab")
'If the zone uses the SFU schema, display its domain
If zone.IsSFU = true
wScript.Echo zone.SFUDomain
end if
...
```

SFUDomain

Gets or sets the Active Directory domain associated with this zone when the zone is determined to be a zone that uses the Microsoft Services for UNIX (SFU) schema extension.

Syntax

```
string SFUDomain {get; set;}
```

Property value

The Active Directory domain for the zone.

Example

The following code sample illustrates using this method in a script:

```
...
'Specify the zone you want to work with
set zone = GetZoneByPath("LDAP://cn=test_lab,cn=Zones,cn=UNIX,dc=ajax,dc=org")
'If the zone uses the SFU schema, display its domain
If zone.IsSFU = true
wScript.Echo zone.SFUDomain
end if
...
```

UserAutoProvisioningEnabled

Indicates whether the zone has auto-provisioning of user profiles enabled.

Syntax

```
bool UserAutoProvisioningEnabled {get;}
```

Property value

Returns `true` if the zone has auto-provisioning enabled for user profiles.

Discussion

When automatic provisioning is enabled for users, the Zone Provisioning Agent can automatically provision new UNIX profiles for new Active Directory users. In addition to enabling auto-provisioning, you must specify a provisioning group to use as the source for provisioning data. For details about automatic provisioning of users and groups, see the *Planning and Deployment Guide*.

Version

Gets the version number of the data schema.

Syntax

```
int Version {get;}
```

Property value

The version number associated with the schema found.

Example

The following code sample illustrates using Version in a script:

```
...
'Specify the zone you want to work with
set zone = GetZoneByPath("LDAP://cn=test_lab/cn=Zones, cn=UNIX,dc=ajax,dc=org")

'Display the schema version number for the zone
wScript.Echo zone.Version
...
```

Delinea

HierarchicalZoneComputer

The HierarchicalZoneComputer class represents a computer joined to a hierarchical zone.

Syntax

public interface IHierarchicalZoneComputer : IComputer

Discussion

The HierarchicalZoneComputer class inherits many methods and properties from the Unexpected Link Text class, but adds support for partial profiles and inheritable roles. Under hierarchical zones, both identity (profile data) and access (authorization data) are inherited, such that a computer's effective identity or access are determined by all the profile data and all the access data at all levels of the hierarchy.

See Unexpected Link Text for a discussion of profile and access inheritance.

When you assign computer-level overrides for user, group, or computer role assignments, Delinea creates a *computer zone*, which is a special type of zone that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed as zones in Access Manager, but are referred to in the method and property descriptions where appropriate.

Methods

The HierarchicalZoneComputer class provides the following methods:

Unexpected Link Text	Adds a group to the computer.
Unexpected Link Text	Adds a computer-specific partial profile for a specified group.
Unexpected Link Text	Adds a computer-specific partial profile for a specified local group.
Unexpected Link Text	Adds a computer-specific partial profile for a specified user.
Unexpected Link Text	Adds an empty role assignment.
Unexpected Link Text	Adds a computer-specific partial profile for a specified user.
Unexpected Link Text	Commits changes to the group object to Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Creates a pending imported group in this computer.
Unexpected Link Text	Creates a pending imported user in this computer.
Unexpected Link Text	Deletes the computer profile from Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Deletes all computer-specific users and groups.
Unexpected Link Text	Deletes the computer zone object if it exists.
Unexpected Link Text	Returns a group given a role for the group.
Unexpected Link Text	Returns an enumeration of groups in the computer object.
Unexpected Link Text	Returns the Active Directory object for the computer. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Returns an enumeration of effective users under this computer zone.
Unexpected Link Text	Returns the UNIX group profile in this computer zone for the specified Active Directory group.

Unexpected Link Text	Returns the UNIX group profile in this computer zone for the Active Directory group specified by distinguished name.
Unexpected Link Text	Returns the UNIX group profile in this computer zone for the Active Directory group specified by group name.
Unexpected Link Text	Returns an enumeration of the UNIX groups in this computer zone.
Unexpected Link Text	Returns the group with the specified ID pending import.
Unexpected Link Text	Returns an enumeration of groups pending import to this computer zone.
Unexpected Link Text	Returns the user with the specified ID pending import.
Unexpected Link Text	Returns an enumeration of users pending import to this computer zone.
Unexpected Link Text	Returns the numeric identifier for the pending import group with the specified group name.

| method | Description | | Unexpected Link Text | Returns the local UNIX group profile for a specified group name in the zone. | | Unexpected Link Text | Returns a local group profile using the distinguished name (DN) of the profile. | | Unexpected Link Text | Returns the local group profile using the Group Identifier (GID). This method is exposed to the .COM interface. | | Unexpected Link Text | Returns a list of the local group profiles in the zone. | | Unexpected Link Text | Returns the local user profile using the specified user name. | | Unexpected Link Text | Returns the local user profile specified by the distinguished name (DN) of the profile. | | Unexpected Link Text | Returns the local user profile using the User Identifier (UID). This method is exposed to the .COM interface | | Unexpected Link Text | Returns a list of the local user profiles in the zone. | | Unexpected Link Text | Returns the numeric identifier for the pending import user with the specified user name. | | Unexpected Link Text | VBScript interface to access NSS variables. | | Unexpected Link Text | VBScript interface to obtain all NSS variable names. | | Unexpected Link Text | Returns the primary profile for the specified user. | | Unexpected Link Text | Returns the role assignment for the specified role and trustee. | | Unexpected Link Text | Returns the role assignment for the specified GUID. | | Unexpected Link Text | Returns the collection of role assignments in the computer. | | Unexpected Link Text | Returns the role assignment given to all Active Directory users who have a specified role. | | Unexpected Link Text | Returns the role assignment given to all UNIX users who have a specified role. | | Unexpected Link Text | Returns an enumeration of the secondary profiles for the specified user. | | Unexpected Link Text | Returns an enumeration of all the user profiles for the specified user. | | Unexpected Link Text | Returns an enumeration of all the user role assignments in this computer zone. | | Unexpected Link Text | Returns the UNIX user profile in this computer zone for the specified user. | | Unexpected Link Text | Returns the UNIX user profile in this computer zone for the user specified by distinguished name. | | Unexpected Link Text | Returns the UNIX user profile in this computer zone for the user specified by user name. | | Unexpected Link Text | Returns the UNIX user profile in this computer zone for the user specified by UID. | | Unexpected Link Text | Indicates whether the specified user has a profile in this computer zone. |

Properties

The HierarchicalZoneComputer class provides the following properties:

Unexpected Link Text	Gets the IADs interface of the zone object in Active Directory. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the LDAP path to the zone object. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the Active Directory client version number. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the canonical name of the computer object. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the LDAP path of the computer zone object.

Unexpected Link Text	Indicates whether the CIMs data associated with this object is orphaned by the current credentials. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether this computer is an orphan zone object.
Unexpected Link Text	Indicates whether the CIMS data associated with this object is readable with the current user credentials. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Indicates whether the CIMS data associated with this object is writable with the current user credentials. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the computer is enabled for JBoss. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the name of the computer object. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the map of profile variables.
Unexpected Link Text	Gets the LDAP path to the computer UNIX profile. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets the version of the data schema. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the computer is enabled for Tomcat. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the UNIX directory path that is used to substitute for % in user profiles.
Unexpected Link Text	Gets or sets the shell that is used to substitute for %{shell}in user profiles.
Unexpected Link Text	Gets the version number of the data schema. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the computer is enabled for WebLogic. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Determines whether the computer is enabled for WebSphere. (Inherited from Unexpected Link Text.)
Unexpected Link Text	Gets or sets the zone that this computer joins.
Unexpected Link Text	Gets the zone mode of the computer. (Inherited from Unexpected Link Text.)

AddAccessGroup

Adds a group to the computer.

Syntax

IMzRoleAssignment AddAccessGroup(DirectoryEntry groupDE)

IMzRoleAssignment AddAccessGroup(SearchResult groupSR)

IMzRoleAssignment AddAccessGroup(string groupDn)

IMzRoleAssignment AddAccessGroup(IAdsGroup groupIAds)

Parameters

Specify one of the following parameters when using this method.

groupDE	The directory entry for the group you want to add.
groupSr	The directory entry for a group specified as a search result.
groupDn	The group specified as a distinguished name.
groupIads	The IADs interface to the group.

Return value

The computer role assignment that includes the specified group (IMzRoleAssignment.TrusteeType==Group).

Discussion

The role assignment is not stored in Active Directory until you call the Unexpected Link Text method.

The AddAccessGroup(DirectoryEntry groupDE) and AddAccessGroup(SearchResult groupSr) methods are available only for .NET-based programs. Call Unexpected Link Text for VBScript.

Exceptions

AddAccessGroup may throw one of the following exceptions:

- ApplicationException if the specified parameter is not a group or the method cannot find the group.
- ArgumentNullException if you pass a null parameter.

AddGroupPartialProfile

Adds a computer-specific partial profile for the specified group to the computer.

Syntax

```
IHierarchicalGroup AddGroupPartialProfile(DirectoryEntry groupDE)
IHierarchicalGroup AddGroupPartialProfile(SearchResult groupSR)
IHierarchicalGroup AddGroupPartialProfile(string groupDn)
IHierarchicalGroup AddGroupPartialProfile(IAdsGroup groupIAds)
```

Parameters

Specify one of the following parameters when using this method.

groupDE	The directory entry for the group for which you want a partial profile.
groupSr	The directory entry for a group specified as a search result.
groupDn	The group specified as a distinguished name.
groupIads	The IADs interface to the group.

Return value

The hierarchical group object that represents the group profile.

Discussion

When you assign computer-level overrides for user, group, or computer role assignments, Delinea creates a *computer zone*, which is a special type of zone that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed as zones in Access Manager.

This method creates a computer zone and a new group profile with values set for the Cims and User properties. You can then add other properties to the profile.

The profile is not stored in Active Directory until you call the Unexpected Link Text method.

The AddGroupPartialProfile(DirectoryEntry groupDE) and AddGroupPartialProfile(SearchResult groupSr) methods are available only for .NET-based programs.

Exceptions

If you pass a null or empty parameter, AddGroupPartialProfile throws the exception ArgumentNullException.

Example

The HierarchicalZoneComputer.AddGroupPartialProfile method is used in the same way as the HierarchicalZone.AddGroupPartialProfile method. See Unexpected Link Text for an example.

AddLocalGroupPartialProfile

Adds a partial profile for the specified group to the zone.

Syntax

```
IHierarchicalUser AddlocalGroupPartialProfile(string groupName)
```

Parameters

Specify groupName; the name of the local group.

Return value

The hierarchical group object that represents the local group profile.

Exceptions

If you pass a null parameter, AddLocalGroupPartialProfile throws the exception ArgumentNullException.

AddLocalUserPartialProfile

Adds a partial profile for the specified user to the zone.

Syntax

```
IHierarchicalUser AddLocalUserPartialProfile(string userName)
```

Parameters

Specify `userName`; the user name of the local user.

Return value

The hierarchical user object that represents the local user profile.

Exceptions

If you pass a `null` parameter, `AddLocalUserPartialProfile` throws the exception `ArgumentNullException`.

AddRoleAssignment

Adds an empty role assignment to the computer.

Syntax

```
IRoleAssignment AddRoleAssignment()
```

Return value

An empty role assignment object. This role assignment is not stored in Active Directory until you call the RoleAssignment:[Commit](dev/windows-api/object-reference/computerrole/commit.md) method.

AddUserPartialProfile

Adds a computer-specific partial profile for the specified user to the computer.

Syntax

```
IHierarchicalUser AddUserPartialProfile(DirectoryEntry userDE)
IHierarchicalUser AddUserPartialProfile(SearchResult userSR)
IHierarchicalUser AddUserPartialProfile(string userDn)
IHierarchicalUser AddUserPartialProfile(IAdsUser userIAds)
```

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want a partial profile.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The hierarchical user object that represents the user profile.

Discussion

When you assign computer-level overrides for user, group, or computer role assignments, Delinea creates a *computer zone*, which is a special type of zone that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed as zones in Access Manager.

This method creates a computer zone and a new user profile with values set for the `Cims` and `User` properties. You can then add other properties to the profile.

The profile is not stored in Active Directory until you call the Unexpected Link Text method.

The `AddUserPartialProfile(DirectoryEntry userDE)` and `AddUserPartialProfile(SearchResult userSr)` methods are available only for .NET-based programs.

Exceptions

If you pass a `null` or empty parameter, `AddUserPartialProfile` throws the exception `ArgumentNullException`.

Example

The `HierarchicalZoneComputer.AddUserPartialProfile` method is used in the same way as the `HierarchicalZone.AddUserPartialProfile` method. See Unexpected Link Text for an example.

CreateImportPendingGroup

Creates a "pending import" group in this computer.

Syntax

```
IGroupInfo CreateImportPendingGroup (string source, DateTime timestamp)
```

Parameters

Specify the following parameters when using this method.

source	The location of the source data for the group to be imported.
timestamp	The date and time at which the data was retrieved.

Return value

The newly created pending import group object.

Discussion

Group profiles in a pending import group object needed to be mapped to Active Directory groups before they can be used. Groups in this state are normally imported from NIS domains or from text files and stored temporarily either in Active Directory or XML files until they are mapped to Active Directory accounts. For more information about importing and mapping groups, see the *Administrator's Guide for Linux and UNIX*.

CreateImportPendingUser

Creates a "pending import" user in this computer.

Syntax

```
IUserInfo CreateImportPendingUser(string source, DateTime timestamp)
```

Parameters

Specify the following parameters when using this method.

source	The location of the source data for the user to be imported.
timestamp	The date and time at which the data was retrieved.

Return value

The newly-created pending import user object.

Discussion

User profiles in a pending import user object need to be mapped to Active Directory groups before they can be used. Users in this state are normally imported from NIS domains or from text files and stored temporarily either in Active Directory or in XML files until they are mapped to Active Directory accounts. For more information about importing and mapping users, see the *Administrator's Guide for Linux and UNIX*.

DeleteAllProfiles

Deletes all computer-specific users and groups.

Syntax

```
void DeleteAllProfiles ()
```

Discussion

Deleting a computer (Unexpected Link Text) doesn't delete all the profiles associated with the computer. Use this method to delete computer-specific profiles after deleting the computer.

DeleteZone

Deletes the computer zone object.

Syntax

```
void DeleteZone ()
```

Discussion

When you assign computer-level overrides for user, group, or computer role assignments, Delinea creates a *computer zone*, which is a special type of zone that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed as zones in Access Manager.

This method deletes only the computer zone object (if it exists). Call the Unexpected Link Text method to delete the computer profile object.

GetAccessGroup

Gets a user group assigned to this computer given a specific role.

Syntax

```
IMzRoleAssignment GetAccessGroup(IRole role, DirectoryEntry group)
IMzRoleAssignment GetAccessGroup(IRole role, SearchResult groupSr)
IMzRoleAssignment GetAccessGroup(IRole role, string groupDn)
IMzRoleAssignment GetAccessGroup(IRole role, IADsGroup groupIAds)
```

Parameters

Specify the following parameter when using this method:

role	The role of the group.

Specify one of the following parameters when using this method.

group	The directory entry for the group.
groupSr	The directory entry for the group specified as a search result.
groupDn	The group specified as a distinguished name.
groupIads	The IADs interface to the group.

Return value

The computer role assignment that includes the specified group (IMzRoleAssignment.TrusteeType==Group).

Discussion

Any number of user groups can be assigned to a computer role and each of those groups can have more than one role. Use this method to get the computer role assignment for a specific group and role.

The GetAccessGroup(IRole role, DirectoryEntry groupDE) and GetAccessGroup(IRole role, SearchResult groupSr) methods are available only for .NET-based programs. Call Unexpected Link Text for VBScript.

Exceptions

GetAccessGroup may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null.
- ApplicationException if the parameter value is not a valid user; or if it failed to create a role assignment because it cannot find the user.

Example

The HierarchicalZoneComputer.GetAccessGroup method is used in the same way as the HierarchicalZone.GetAccessGroup method. See Unexpected Link Text for an example of using the HierarchicalZone.GetAccessGroup method in a script.

GetAccessGroups

Returns the computer roles assigned to this computer.

Syntax

```
IRoleAssignments GetAccessGroups()
```

Return value

The collection of computer roles. Enumerate this object to get all of the `IAzRoleAssignment` objects for this computer.

GetEffectiveUserUnixProfiles

Returns the collection of effective users under this computer zone.

Syntax

```
IUserUnixProfiles GetEffectiveUserUnixProfiles()
```

Return value

A collection of IHierarchicalUser objects representing all the user profiles under this computer zone, including those inherited from zones higher in the hierarchy.

GetGroupUnixProfile

Returns the hierarchical group profile for a specified Active Directory group in the computer zone.

Syntax

```
IHierarchicalGroup GetGroupUnixProfile(IGroup group)
```

Parameter

Specify the following parameter when using this method:

group	The group for which you want profile information.

Return value

The profile for the specified group, or `null` if none is found.

Discussion

This method uses the `Centrify.DirectControl.API.IGroup` group returned by a Unexpected Link Text or Unexpected Link Text call to retrieve the group profile.

Exceptions

`GetGroupUnixProfile` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.
- `NotSupportedException` if the computer zone schema is not supported.
- `ApplicationException` if there is more than one group with the specified `IGroup` value in the zone.

GetGroupUnixProfileByDN

Returns the UNIX profile for a group in this computer zone using the distinguished name (DN) of the profile.

Syntax

```
IHierarchicalGroup GetGroupUnixProfileByDN(string dn)
```

Parameter

Specify the following parameter when using this method:

dn	The distinguished name (DN) of the group profile.

Return value

The group profile with the distinguished name (DN) specified, or `null` if no matching group profile is found.

Discussion

The group profile is the service connection point associated with the Active Directory group object.

Exceptions

`GetGroupUnixProfileByDN` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.
- `NotSupportedException` if the computer zone schema is not supported.

GetGroupUnixProfileByName

Returns the hierarchical group profile for a group with the specified name in the computer zone.

Syntax

```
IHierarchicalGroup GetGroupUnixProfileByName(string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the UNIX group profile for which you want to retrieve information.

Return value

The profile for the specified group name, or `null` if no profile is found.

Discussion

The name you specify should be the UNIX group name for the group if it differs from the Active Directory name for the group.

Exceptions

`GetGroupUnixProfileByName` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null` or empty.
- `NotSupportedException` if the computer zone schema is not supported.
- `ApplicationException` if there is more than one group with the specified name in the zone.

GetGroupUnixProfiles

Returns the collection of UNIX group profiles that have been defined for the computer zone.

Syntax

```
IComputerGroupUnixProfiles GetGroupUnixProfiles()
```

Return value

Returns a collection of Unexpected Link Text objects.

GetImportPendingGroup

Returns a group pending import to the computer zone given the GUID.

Syntax

```
IGroupInfo GetImportPendingGroup(string id, bool storePendingAD, string storePendingFilePath)
```

Parameter

Specify the following parameters when using this method:

id	The GUID of the group that's pending import.
storePendingAD	Specify true if the group is being imported from Active Directory. Specify false if the group is being imported from an XML file.
storePendingFilePath	The file path of the XML file.

Return value

The IGroupInfo object for the specified group.

Discussion

This method takes the storePendingAD Boolean and the storePendingFilePath information, stores them in the group profile, then finds and returns the group pending import that has the specified GUID.

Group profiles that are pending import are normally imported from NIS domains or from text files and not yet mapped to Active Directory groups. For more information about importing and mapping groups, see the *Administrator's Guide for Linux and UNIX*.

GetImportPendingGroups

Returns the list of groups pending import to this computer zone.

Syntax

```
IGroupInfos GetImportPendingGroups()
```

Return value

The collection of group profiles pending import to this computer zone.

GetImportPendingUser

Returns an individual user pending import for this computer given the GUID.

Syntax

```
IUserInfo GetImportPendingUser(string id, bool storePendingAD, string storePendingFilePath)
```

Parameter

Specify the following parameters when using this method:

id	The GUID of the user that's pending import.
storePendingAD	Specify true if the user is being imported from Active Directory. Specify false if the user is being imported from an XML file.
storePendingFilePath	The file path of the XML file.

Return value

The IUserInfo object for the specified ID in the computer.

Discussion

This method takes the storePendingAD Boolean and the storePendingFilePath information, stores them in the user profile, then finds and returns the user pending import that has the specified GUID.

User profiles that are pending import are normally imported from NIS domains or from text files and not yet mapped to Active Directory groups. For more information about importing and mapping groups, see the *Administrator's Guide for Linux and UNIX*.

GetImportPendingUsers

Returns the collection of users pending import to this computer zone.

Syntax

```
IUserInfos GetImportPendingUsers()
```

Return value

The collection of user profiles pending import to this computer zone.

GetIPendingGroupID

Returns the numeric identifier of the pending import group.

Syntax

```
IGroupInfo GetPendingGroupID()
```

Return value

The pending import group specified by group name to the selected zone.

GetIPendingUserID

Returns the numeric identifier of the pending import user.

Syntax

```
IUserInfo GetPendingUserID()
```

Return value

The pending import user specified by the user name to the selected zone.

GetLocalGroupUnixProfile

Returns the UNIX group profile for a specified local group.

Syntax

```
IGroupUnixProfile GetLocalGroupUnixProfile(string groupName)
```

Parameter

Specify the following parameter when using this method:

`groupName	The name of the local group for which you want to retrieve profile information.

Return value

The Unexpected Link Text object for the specified local group name. If there is no group, `null` is returned.

Exceptions

`GetGroupUnixProfile` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.

GetLocalGroupUnixProfileByDN

Returns the Local UNIX profile for a group in the zone using the distinguished name (DN) of the profile.

Syntax

```
IGroupUnixProfile GetLocalGroupUnixProfileByDN(string dn)
```

Parameter

Specify the following parameters when using this method.

dn	The distinguished name (DN) of the local group profile.

Return value

The local group profile with the distinguished name (DN) matching the distinguished name specified, or `null` if no matching group profile is found.

GetLocalGroupUnixProfileByGid (Int32)

Returns the Local UNIX profile for a group in the zone using the group identifier (GID) of the profile. This method is exposed to the .COM interface.

Syntax

```
IGroupUnixProfile GetLocalGroupUnixProfileByGid(int gid)
```

Parameter

Specify the following parameters when using this method.

gid	The group identifier (GID) of the local group profile.

Return value

The local group profile with the specified group identifier (GID) or `null` if no matching group profile is found.

GetLocalGroupUnixProfiles

Get the list of local group profiles in the zone.

Syntax

```
IGroupUnixProfiles GetLocalGroupUnixProfiles()
```

Return value

Returns a collection of Unexpected Link Text objects. If there are no groups, `null` is returned.

GetLocalUserUnixProfile

Returns the UNIX user profile for a specified local group.

Syntax

```
IUserUnixProfile GetLocalUserUnixProfile(string userName)
```

Parameter

Specify the `userName` parameter when using this method.

Return value

Returns the local user profile with the specified user name. If there is no group, `null` is returned.

GetLocalUserUnixProfileByDN

Returns the local UNIX profile for a user in the zone using the distinguished name (DN) of the profile.

Syntax

```
IUserUnixProfile GetLocalUserUnixProfileByDN(string dn)
```

Parameter

Specify the following parameters when using this method.

dn	The distinguished name (DN) of the local user profile.

GetLocalUserUnixProfileByUid (Int32)

Returns the local UNIX profile for a user in the zone using the user identifier (GID) of the profile. This method is exposed to the .COM interface.

Syntax

```
IUserUnixProfile GetLocalUserUnixProfileByUid(int uid)
```

Parameter

Specify the following parameters when using this method.

uid	The user identifier (UID) of the local user profile.

Return value

The local user profile with the specified user identifier (UID) or `null` if no matching user profile is found.

GetLocalUserUnixProfiles

Get a list of local UNIX user profiles in the zone.

Syntax

```
IUserUnixProfiles GetLocalUserUnixProfiles()
```

Return value

Returns a collection of local user profiles in the zone. If there are no users, `null` is returned.

GetNssVariable

Returns the specified NSS environment variable; VBScript only.

Syntax

```
string GetNssVariable (string name)
```

Parameter

Specify the following parameter when using this method:

name	The name of the variable.

Return value

The value of the variable, or `null` if there is no NSS variable with the specified name.

GetNSSVariables

Returns the names of all NSS variables; VBScript only.

Syntax

```
IEnumerable GetNSSVariables()
```

Return value

Returns a collection of NSS variable names.

GetPrimaryUser

Returns the primary profile for the specified user.

Syntax

```
IHierarchicalUser GetPrimaryUser(DirectoryEntry userDE)
IHierarchicalUser GetPrimaryUser(SearchResult userSR)
IHierarchicalUser GetPrimaryUser(string userDn)
IHierarchicalUser GetPrimaryUser(IAdsUser userIAds)
```

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want the primary profile.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The hierarchical user object that represents the user profile.

Discussion

The primary profile is the profile at the highest level in the zone hierarchy where the user's profile is defined. All or part of the primary profile can be overridden by secondary profiles farther down in the hierarchy.

The GetPrimaryUser(DirectoryEntry userDE)andGetPrimaryUser(SearchResult userSr)` methods are available only for .NET-based programs.

Exceptions

`GetPrimaryUser` throws an `ArgumentNullException` if the specified parameter value is `null` or empty.

GetRoleAssignment

Returns a role assignment given a role and trustee.

Syntax

```
IRoleAssignment GetRoleAssignment (IRole role, string dn)
```

Parameter

Specify the following parameters when using this method.

role	The role for which you want the assignment.
dn	The distinguished name of the user or group to whom the role is assigned.

Return value

The role assignment, or `null` if no match is found.

Exceptions

`GetRoleAssignment` throws an `ArgumentNullException` if either specified parameter value is `null` or empty.

GetRoleAssignmentById

Returns a role assignment given an ID.

Syntax

```
IRoleAssignment GetRoleAssignment (Guid id)
```

Parameter

Specify the following parameter when using this method:

id	The GUID of the role assignment.

Return value

The role assignment, or `null` if no match is found.

Exceptions

`GetRoleAssignmentById` throws an `ArgumentNullException` if the specified parameter value is empty.

GetRoleAssigments

Returns all the role assignments in the computer.

Syntax

```
IRoleAssignments GetRoleAssignments()
```

Return value

The collection of role assignments in the computer.

GetRoleAssignmentToAllADUsers

Returns the role assignment given to all Active Directory users who have a specified role.

Syntax

```
IRoleAssignment GetRoleAssignmentToAllADUsers(IRole role)
```

Parameter

Specify the following parameter when using this method:

role	The user role for which you want the role assignment.

Return value

The role assignment for the specified role.

Exceptions

GetRoleAssignmentToAllADUsers throws an ArgumentNullException if the specified parameter value is null.

GetRoleAssignmentToAllUnixUsers

Returns the role assignment given to all UNIX users who have a specified role.

Syntax

```
IRoleAssignment GetRoleAssignmentToAllUnixUsers(IRole role)
```

Parameter

Specify the following parameter when using this method:

role	The user role for which you want the role assignment.

Return value

The role assignment for the specified role.

Discussion

This method returns the role assignment for all local UNIX users with the specified role.

Exceptions

GetRoleAssignmentToAllUnixUsers throws an ArgumentNullException if the specified parameter value is null.

GetSecondaryUsers

Returns the secondary profiles for the specified user.

Syntax

```
IUserUnixProfiles GetSecondaryUsers(DirectoryEntry userDE)
IUserUnixProfiles GetSecondaryUsers(SearchResult userSR)
IUserUnixProfiles GetSecondaryUsers(string userDn)
IUserUnixProfiles GetSecondaryUsers(IAdsUser userIAds)
```

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want the secondary profiles.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The collection of secondary user UNIX profiles.

Discussion

The primary profile is the profile at the highest level in the zone hierarchy where the user's profile is defined. All or part of the primary profile can be overridden by secondary profiles farther down in the hierarchy.

The `GetSecondaryUsers(DirectoryEntry userDE)` and `GetSecondaryUsers(SearchResult userSr)` methods are available only for .NET-based programs.

Exceptions

`GetSecondaryUsers` throws an `ArgumentNullException` if the specified parameter value is `null` or the user does not exist.

GetUserProfiles

Returns all the profiles for the specified user.

Syntax

```
IUserUnixProfiles GetUserProfiles(DirectoryEntry userDE)
IUserUnixProfiles GetUserProfiles(SearchResult userSR)
IUserUnixProfiles GetUserProfiles(string userDn)
IUserUnixProfiles GetUserProfiles(IAdsUser userIAds)
```

Parameters

Specify one of the following parameters when using this method.

userDE	The directory entry for the user for which you want the profiles.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.

Return value

The collection of user UNIX profiles.

Discussion

The GetUserProfiles(DirectoryEntry userDE) and GetUserProfiles(SearchResult userSr) methods are available only for .NET-based programs.

Exceptions

GetUserProfiles throws an ArgumentNullException if the specified parameter value is null or the user does not exist.

GetUserRoleAssignments

Returns all the user role assignments in the computer zone, or for a specific user in the computer zone.

Syntax

```
IRoleAssignments GetUserRoleAssignments()
IRoleAssignments GetUserRoleAssignments(DirectoryEntry userDE)
IRoleAssignments GetUserRoleAssignments(SearchResult userSR)
IRoleAssignments GetUserRoleAssignments(string userDn)
IRoleAssignments GetUserRoleAssignments(IAdsUser userIAds)
IRoleAssignments GetUserRoleAssignments(IUser user)
```

Parameters

Specify no parameters to return all the role assignments in the computer zone.

Specify one of the following parameters to return all the role assignments for a specific user:

userDE	The directory entry for the user for which you want the role assignments.
userSr	The directory entry for a user specified as a search result.
userDn	The user specified as a distinguished name.
userIads	The IADs interface to the user.
user	The user specified as a CIMS user object.

Return value

The collection of role assignments as `IRoleAssignment` objects.

Discussion

The `GetUserRoleAssignments(DirectoryEntry userDE)` and `GetUserRoleAssignments(SearchResult userSr)` methods are available only for .NET-based programs.

Exceptions

`GetUserRoleAssignments` throws an `ArgumentNullException` if the required parameter is `null` or empty.

GetUserUnixProfile

Returns the UNIX user profile for a specified Active Directory user in this computer zone.

Syntax

```
IHierarchicalUser GetUserUnixProfile(IUser user)
```

Parameter

Specify the following parameter when using this method:

user	The user object for Active Directory user.

Return value

The profile for the specified Active Directory user, or `null` if none could be found.

Discussion

This method uses the `Centrify.DirectControl.API.IUser` returned by a `GetUser` or `GetUserByPath` call to retrieve the user profile.

Exceptions

`GetUserUnixProfile` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.
- `NotSupportedException` if the computer zone schema is not supported.

GetUserUnixProfileByDN

Returns the UNIX profile for a user in this computer zone given the distinguished name (DN) of the profile.

Syntax

```
IHierarchicalUser GetUserUnixProfileByDN(string dn)
```

Parameter

Specify the following parameter when using this method:

dn	The distinguished name (DN) of the user profile.

Return value

The user profile with the distinguished name (DN) specified, or `null` if no matching user profile is found.

Discussion

The user profile is the service connection point associated with the Active Directory user object.

Exceptions

`GetUserUnixProfileByDN` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.
- `NotSupportedException` if the computer zone schema is not supported.

GetUserUnixProfileByName

Returns the UNIX profile for a user in this computer zone given the user name.

Syntax

```
IHierarchicalUser GetUserUnixProfileByName(string name)
```

Parameter

Specify the following parameter when using this method:

name	The user's UNIX login name.

Return value

The profile of the specified user, or null if none is found.

Exceptions

GetUserUnixProfileByName may throw one of the following exceptions:

- ArgumentNullException if the specified parameter value is null or empty.
- NotSupportedException if the computer zone schema is not supported.
- ApplicationException if there is more than one user with the specified name in the zone.

GetUserUnixProfileByUid

Returns the UNIX profile for a user in this computer zone given the user identifier (UID).

Syntax

```
IHierarchicalUser GetUserUnixProfileByUid(int uid)
IHierarchicalUser GetUserUnixProfileByUid(long uid)
```

Parameter

Specify the following parameter when using this method:

uid	The user identifier (UID) associated with the Active Directory user.

Return value

The user profile for the specified UID in the computer zone, or `null` if none is found.

Discussion

If there are multiple user profiles with the UID specified, this method returns only the first user profile found. To find all user profiles with a specific UID, use the Unexpected Link Text method to return the collection of profiles for a computer, then search the collection for the UID.

> **Note**: There are two versions of this method: one designed for COM-based programs that supports a 32-bit signed number for the uid argument and one designed for .NET-based programs that allows a 64-bit signed number for the uid argument. These methods are provided for backward compatibility with earlier versions of Delinea software. These methods are not applicable for version 4.0 or later.

Exceptions

`GetUserUnixProfileByUid` may throw one of the following exceptions:

- `ArgumentException` if you specify a negative UID.
- `NotSupportedException` if the computer zone schema is not supported.

GetUserUnixProfiles

Returns the list of UNIX user profiles in this computer zone.

Syntax

```
IComputerUserUnixProfiles GetUserUnixProfiles()
```

Return value

The collection of computer user UNIX profiles.

GroupUnixProfileExists

Indicates whether a UNIX profile exists for the specified group in this computer zone.

Syntax

```
bool GroupUnixProfileExists(IGroup group)
```

Parameter

Specify the following parameter when using this method:

group	The group for which you want to check whether a UNIX profile exists.

Return value

Returns `true` if a UNIX profile is found in this computer zone for the specified group, or `false` if no UNIX profile exists for the group in the computer zone.

Exceptions

`GetUserUnixProfileByUid` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.
- `NotSupportedException` if the computer zone schema is not supported.

LocalGroupUnixProfileExists

Checks whether a UNIX profile exists for the specified local group in the zone.

Syntax

```
bool LocalGroupUnixProfileExists(string groupName)
```

Parameter

Specify the following parameter when using this method:

groupName	The group name for which you want to check whether a UNIX profile exists.

Return value

Returns `true` if the local UNIX group profile is found in the zone, or `false` if no UNIX profile exists for the group in the zone.

Exceptions

`LocalGroupUnixProfileExists` may throw the following exception:

- `ArgumentNullException` if the specified parameter value is `null`.

LocalUserUnixProfileExists

Checks whether a local UNIX profile exists for the specified user in the zone.

Syntax

```
bool LocalUserUnixProfileExists(string userName)
```

Parameter

Specify the following parameter when using this method:

userName	The local user name for which you want to check whether a UNIX profile exists.

Return value

Returns `true` if a UNIX profile is found in the zone for the specified local user, or `false` if no UNIX profile exists for the user in the zone.

Exceptions

`UserUnixProfileExists` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.

SetNSSVariable

Sets the value of the specified NSS environment variable; VBScript only.

Syntax

```
string SetNssVariable (string name, string value)
```

Parameter

Specify the following parameters when using this method.

name	The name of the variable.
value	The value of the variable. Pass null to remove the variable.

UserUnixProfileExists

Indicates whether a UNIX profile exists for the specified user in this computer zone.

Syntax

```
bool UserUnixProfileExists(IUser user)
```

Parameter

Specify the following parameter when using this method:

user	The user name for which you want to check whether a UNIX profile exists.

Return value

Returns `true` if a UNIX profile is found for the specified user, or `false` if no UNIX profile exists for the user in the computer zone.

Exceptions

`UserUnixProfileExists` may throw one of the following exceptions:

- `ArgumentNullException` if the specified parameter value is `null`.
- `NotSupportedException` if the computer zone schema is not supported.

ComputerZoneADsPath

Gets the LDAP path of the computer zone object.

Syntax

```
string ComputerZoneADsPath {get;}
```

Property value

The LDAP path.

Discussion

When you assign computer-level overrides for user, group, or computer role assignments, Delinea creates a *computer zone*, which is a special type of zone that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed as zones in Access Manager.

If the computer zone does not contain any users, groups, or computer roles, this property returns `null` or `string.Empty`.

IsOrphanZone

Indicates whether this computer zone is an orphan zone.

Syntax

```
bool OrphanZone {get;}
```

Property value

Returns `true` if this computer zone is an orphan zone object.

Discussion

The computer zone is an orphan if it has no corresponding service connection point (SCP) and Active Directory computer object.

When you assign computer-level overrides for user, group, or computer role assignments, Delinea creates a *computer zone*, which is a special type of zone that contains the users, groups, and computer role assignments that are specific to only that one computer. Computer zones are not exposed as zones in Access Manager.

NssVariables

Gets all the NSS environment variables.

Syntax

```
IDictionary\<string, string\> NssVariables {get;}
```

Property value

A dictionary of key-value pairs that define all the profile variables.

Discussion

This property uses a 64-bit value for use in .NET modules. Use the GetNSSVariablesproperty for VBScript.

UserHomeDirectory

Gets or sets the UNIX directory path that is used to substitute for % in user profiles.

Syntax

```
string UserHomeDirectory {get; set;}
```

Property value

The UNIX directory path, or `null` to inherit the path from the parent zone.

UserShell

Gets or sets the shell that is used to substitute for % in user profiles.

Syntax

```
int UserDefaultGid {get; set;}
```

Property value

The user shell, or `null` to inherit the shell from the parent zone.

Zone

Determines the zone object for the zone to which the computer is currently joined.

Syntax

```
IHierarchicalZone Zone {get; set;}
```

Property value

The zone the computer account has joined.

Discussion

Each computer object can only be associated with one zone: the zone used to join the computer to its Active Directory domain.

Exceptions

Zone throws an `ApplicationException` if you try to set the zone to a type that is not hierarchical or is not supported or if the computer is already joined to a zone and you try set a new zone.

Timebox

A role specifies a collection of rights. A role object contains a field, timebox, that defines the hours and days of the week that a role is either enabled or disabled. Setting the timebox field in a role object defines when a role's rights are in effect.

You can read and set a role's timebox field using the Unexpected Link Text property. You can modify an existing timebox value one day or one hour at a time using the Unexpected Link Text and Unexpected Link Text methods.

To interpret a timebox value, or to set it directly, however, you must know the timebox value format. This appendix explains following formats:

- Hex string
- Hour mapping
- Day mapping

Hex string

The timebox value is a 42-character (21-byte) hexadecimal value stored as a string. When the hex value is converted to a binary value, its 168 bits each map to a single hour within the week. If a bit is set to 1, its corresponding hour is enabled for the role. If set to 0, its corresponding hour is disabled.

Hour mapping

Each day of the week takes three bytes (24 bits) to specify how its hours are enabled or disabled. The following tables show how the hours of a day are mapped to the bits within each of a day's three bytes.

For byte 0 of each day of the week, you can enable or disable the hours a role is available from midnight to 8:00 AM:

12-1 AM	0 (least-significant bit)
1-2 AM	1
2-3 AM	2
3-4 AM	3
4-5 AM	4
5-6 AM	5
6-7 AM	6
7-8 AM	7 (most-significant bit)

For byte 1 of each day of the week, you can enable or disable the hours a role is available from 8:00 AM to 4:00 PM:

8-9 AM	0 (least-significant bit)
9-10 AM	1
10-11 AM	2
11-12 AM	3
12-1 PM	4
1-2 PM	5

2-3 PM	6
3-4 PM	7 (most-significant bit)

For byte 2 of each day of the week, you can enable or disable the hours a role is available from 4:00 PM to midnight:

4-5 PM	0 (least-significant bit)
5-6 PM	1
6-7 PM	2
7-8 PM	3
8-9 PM	4
9-10 PM	5
10-11 PM	6
11-12 PM	7 (most-significant bit)

Day mapping

Each of the seven days in a week have three bytes within the 21-byte timebox value. These bytes are in chronological order from most-significant byte to least-significant byte. (Note that this is the opposite of chronological bit order within each byte, which is LSB to MSB.)

The starting point of a week is 4 PM on Saturday afternoon.

The table below shows how each day's three bytes (0-2) map to the timebox value's bytes, listed here in order from most-significant byte to least-significant byte.

Saturday, byte 2	20 (most-significant byte)
Sunday, byte 0	19
Sunday, byte 1	18
Sunday, byte 2	17
Monday, byte 0	16
Monday, byte 1	15
Monday, byte 2	14
Tuesday, byte 0	13
Tuesday, byte 1	12

Tuesday, byte 2	11
Wednesday, byte 0	10
Wednesday, byte 1	9
Wednesday, byte 2	8
Thursday, byte 0	7
Thursday, byte 1	6
Thursday, byte 2	5
Friday, byte 0	4
Friday, byte 1	3
Friday, byte 2	2
Saturday, byte 0	1
Saturday, byte 1	0 (least-significant byte)

Server Suite - All Release Notes

2022.1 Release

- Server Suite Release Notes
- Server Suite Agent Release Notes
- Server Suite Authentication and Privilege Elevation Release Notes
- Server Suite Auditing Release Notes
- Server Suite PuTTY Release Notes
- Server Suite Mac Release Notes

For a list of supported components for the current release, see Component Versions.

2022 Release

- Server Suite Release Notes
- Server Suite Agent Release Notes
- Server Suite Authentication and Privilege Elevation Release Notes
- Server Suite Auditing Release Notes
- Server Suite PuTTY Release Notes
- Server Suite Adbindproxy Release Notes
- Server Suite Mac Release Notes

You can find release notes and documentation related to previous releases at Previous Releases.

Delinea Kerberos Tools			
Tools 5.1.0	March 2013	March 2016	March 2018

Tools 4.x	February 2009	February 2012	February 2014
Tools 3.x	July 2006	July 2009	July 2011

Note:

- Deployment Manager, and Delinea Kerberos Tools, are discontinued and hence no more new releases are available. (Ref: CS-47626)
- DirectSecure was deprecated in release 2020. The last supported version of DirectSecure was version 5.4.2 (Release 2017.2). No new release of DirectSecure is available after the 5.4.2 (2017.2) version.

Server Suite 2022.1 Release Notes

The DelineaServer Suite (previously called Centrify Infrastructure Services, or Centrify Zero Trust Privilege Services) is an integrated family of directory-based authentication, privileged access, privileged elevation, audit & monitoring solutions that secure your cross-platform environment and strengthen regulatory compliance initiatives.

Server Suite includes the following components:

- Authentication Service secures your platforms using the same authentication and Group Policy services deployed for your Windows environment.
- Privilege Elevation Service centrally manages and enforces role-based entitlements for fine-grained control of user access and privileges on UNIX, Linux, and Windows systems.
- Audit & Monitoring Service delivers auditing, logging, and real-time monitoring of user activity on your Windows, UNIX, and Linux system.

This integrated solution helps you improve IT efficiency, strengthen regulatory compliance initiatives, and centrally secure your heterogeneous computing environment.

This release notes cover information specifically about Authentication Service, Privilege Elevation Service, and Audit & Monitoring Service.

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement

This release usually includes packages for Windows, UNIX, and Linux operating system environments.

The files for this release are organized onto two media, each available in ISO and zip form:

Server Suite for 64-bit Windows

- main folder

This is the main folder containing information pertinent to this release.

- The readme.txt file provides a summary of where to find files in a plain text format.
- Copyright.txt and Acknowledgements.txt provide copyright information and legal notices for third party and open-source software used in Delinea Server Suite.
- Delinea-end-user-license-agreement.txt provides the text of the license agreement displayed during installation.
- autorun.inf controls the autorun program, autorun.exe, on Windows computers.

The following are sub-folders that are organized to provide you access to different software components in the Delinea Server Suite.

- Agent folder

  This folder contains the installer packages for installing Server Suite Agent for Windows on Windows computers.

- Common folder

  This folder contains the installer packages for common components necessary for all Delinea products on Windows computers.

- DirectAudit folder

  This folder contains the installer packages for Delinea Audit & Monitoring Service on Windows computers.

- DirectManage folder

  This folder contains the installer packages for Delinea Authentication Service and Delinea Privilege Elevation Service on Windows computers.

- LicensingService Folder

This folder contains the installer packages for Delinea Licensing Service utilities on Windows computers.

- Resources Folder

  This folder contains resources for internal use for the media. It can be safely ignored.

Server Suite Agents for UNIX/Linux

This image contains a zipped bundle of files for Server Suite agent on each supported UNIX, or Linux platform and an adcheck utility for each supported platform.

You may find the appropriate bundle for an OS platform based on the following table:

delinea-server-suite-<release number>-aix7.1-ppc.tgz	IBM AIX, IBM VIOS
delinea-server-suite-<release number>-cos-x86_64.tgz	Flatcar, RHCOS
delinea-server-suite-<release number>-deb9-arm64.tgz	Ubuntu
delinea-server-suite-<release number>-deb9-ppc64el.tgz	Ubuntu
delinea-server-suite-<release number>-deb9-x86_64.tgz	Debian, Ubuntu
delinea-server-suite-<release number>-hp11.31-ia64.tgz	HPUX
delinea-server-suite-<release number>-hp11.31-pa.tgz	HPUX
delinea-directcontrol-<release number>-mac10.15.tgz	MAC (Intel, M1)
delinea-server-suite-<release number>-rhel6-ppc64.tgz	RHEL
delinea-server-suite-<release number>-rhel6-x86_64.tgz	Amazon Linux, CentOS, Fedora, Oracle Linux, RHEL, AlmaLinux, Rocky Linux
delinea-server-suite-<release number>-rhel7-aarch64.tgz	Amazon Linux, CentOS, Oracle Linux, RHEL
delinea-server-suite-<release number>-rhel7-ppc64le.tgz	RHEL
delinea-server-suite-<release number>-sol10-sparc.tgz	Oracle Solaris
delinea-server-suite-<release number>-sol10-x86.tgz	Oracle Solaris
delinea-server-suite-<release number>-sol11-i386.tgz	Oracle Solaris (IPS package)
delinea-server-suite-<release number>-sol11-sparc.tgz	Oracle Solaris (IPS package)
delinea-server-suite-<release number>-suse12-aarch64.tgz	SUSE
delinea-server-suite-<release number>-suse12-ppc64le.tgz	SUSE
delinea-server-suite-<release number>-suse12-x86_64.tgz	SUSE

Notes:

- The OS version number specified in the bundle name indicates the minimum OS version that it supports.
- You should also choose the appropriate bundle for the specific architecture as indicated in the bundle name.
- Inside each bundle, it contains packages of associated products supported on that platform. The naming convention follows the above bundle names except that the prefix of a package reflects the product it serves. The following are the possible package prefixes and the corresponding product

names:

CentrifyDA	Delinea DirectAudit package
CentrifyDC	Delinea DirectControl package
CentrifyDC-cifsidmap	Delinea for CIFS ID mapping package
CentrifyDC-curl	Required component of Delinea DirectControl package
CentrifyDC-ldapproxy	Delinea OpenLDAP Proxy package
CentrifyDC-nis	Delinea Network Information Service and Delinea NIS Server package
CentrifyDC-openldap	Required component of Delinea DirectControl package
CentrifyDC-openssh	Delinea OpenSSH package
CentrifyDC-openssl	Required component of Delinea DirectControl package

- Before installation, please review the *Upgrade and Compatibility Guide* and run the adcheck utility to make sure the environment is ready, especially if you are using native package manager to install.

Go to Supported Versions.

Newly Added Supported Platforms

- RHEL 9
- RHEL 8.6
- Ubuntu 22.04

Supported UNIX/Linux Platforms

AlmaLinux 8.5	x86_64	Yes	Yes	Yes	
Alpine Linux 3.13, 3.14	X86_64	No	Yes	Yes	
Amazon Linux 2 LTS	aarch64	No	Yes	Yes	
Amazon Linux 2 LTS	x86_64	No	Yes	Yes	
CentOS 7.4-7.9, 8.0-8.5	aarch64	No	Yes	Yes	
CentOS 6.0-6.10, 7.0-7.9, 8.0-8.5	x86_64	Yes	Yes	Yes	
Debian 9.0-9.13, 10.0-10.11, 11	x86_64	Yes	Yes	Yes	
Flatcar	x86_64	No	Yes	Yes	

HP-UX 11.31 (Trusted and Untrusted)	Itanium	No	Yes	Yes	
HP-UX 11.31 (Trusted and Untrusted)	PA-RISC	No	Yes	Yes	
IBM AIX 7.1 TL1+, 7.2	ppc	No	Yes	Yes	Note 4
IBM Virtual I/O Server 3.x	ppc	No	Yes	Yes	
MacOS 11.0-11.6, 12	M1	No	Yes	No	Note 3
MacOS 10.15, 11.0-11.6, 12	x86_64	No	Yes	No	Note 3
Oracle Linux 7.4-7.9, 8.0-8.5	aarch64	No	Yes	Yes	
Oracle Linux 6.0-6.10, 7.0-7.9, 8.0-8.5	x86_64	Yes	Yes	Yes	
Oracle Solaris 10 u8+, 11.0-11.4	SPARC	No	Yes	Yes	Note 2
Oracle Solaris 10 u8+, 11.0-11.4	x86_64	No	Yes	Yes	Note 2
Red Hat Enterprise Linux 7.4-7.9, 8.0-8.6, 9	aarch64	No	Yes	Yes	
Red Hat Enterprise Linux 6.0-6.10, 7.0-7.9	ppc64	Yes	Yes	Yes	
Red Hat Enterprise Linux 7.1-7.9, 8.0-8.6, 9	ppc64le	Yes	Yes	Yes	
Red Hat Enterprise Linux 8.0	S390	No	Yes	No	
Red Hat Enterprise Linux 6.0-6.10, 7.0-7.9, 8.0-8.6, 9	x86_64	Yes	Yes	Yes	
Red Hat Enterprise Linux CoreOS (RHCOS)	x86_64	Yes	Yes	Yes	Note 1
Red Hat Fedora Linux 35	x86_64	Yes	Yes	Yes	
Rocky Linux 8.5	x86_64	Yes	Yes	Yes	
SUSE Enterprise Linux 12 SP3+, 15	aarch64	No	Yes	Yes	
SUSE Enterprise Linux 12 SP3+, 15	ppc64le	Yes	Yes	Yes	
SUSE Enterprise Linux 12 SP4	S390	No	Yes	Yes	
SUSE Enterprise Linux 12 SP3+, 15	x86_64	Yes	Yes	Yes	
Ubuntu Linux 18.04, 20.4, 22.04	arm64	No	Yes	Yes	
Ubuntu Linux 18.04, 20.4, 22.04	ppc64el	Yes	Yes	Yes	
Ubuntu Linux 18.04, 20.4, 22.04	x86_64	Yes	Yes	Yes	

Note 1: Please refer to the *Planning and Deployment Guide* for features supported on this platform.

Note 2: Starting with Release 2020, we require the OS patch level update 8 or above on Solaris 10.

Note 3: Delinea OpenSSH is not supported on this platform.

Note 4: Starting with Release 2021.1, we require the TL1 or above on AIX 7.1.

Additional Information

You should follow the OS vendors' recommendation to update the necessary patches. Here are the minimum patch requirements for the specific UNIX platforms (Ref: CS-45562):

1. HPUX 11.31
    1. PHNE_40225 - Cumulative Console and BSD Pty Patch (it is required for DirectAudit package)
2. Solaris 10 x86_64
    1. 119255-66
    2. 127128-11
    3. 141445-09
    4. 142910-17
3. Solaris 10 SPARC
    1. 119254-66
    2. 120011-14
    3. 127127-11
    4. 142909-17

Supported Windows Platforms

The following 64-bit Windows platforms are supported on Delinea Server Suite (Ref: CS-49379):

- Windows 10 LTSB/LTSC (Note 1)
- Windows 11 LTSB/LTSC
- Windows Server 2012
- Windows Server 2012R2
- Windows Server 2016
- Windows Server 2019 LTSC
- Windows Server 2022 LTSC
- Windows Server 2012 Core (Note 2)
- Windows Server 2012 Minimum Server Interface (Note 2)
- Windows Server 2012R2 Core (Note 2)
- Windows Server 2012R2 Minimum Server Interface (Note 2)

Note:

1. We support Windows 10 Long Term Servicing Channel (LTSC), or previously called Long Term Servicing Branch (LTSB), editions based on Microsoft's lifecycle fact sheet https://docs.microsoft.com/en-us/lifecycle/faq/windows and https://docs.microsoft.com/en-us/windows/release-health/release-information
2. Only the Privilege Elevation Service component of Server Suite Agent for Windows supports these platforms (Core and Minimum Server Interface)
3. Support for all 32-bit Windows platform was terminated in 2015 (Server Suite 2015.1)

Also note that Server Suite require specific versions of .NET to work. Please refer to the following table for the requirement (Ref: CS-49381):

Server Suite 2022.1	August 2022	4.8	--*
Server Suite 2022	April 2022	4.8	--*
Server Suite 2021.1	December 2021	4.8	--*
Server Suite 2021	July 2021	4.8	--*
Infrastructure Services 2020.1	December 2020	4.6.2	--*
Infrastructure Services 2020	September 2020	4.6.2	--*

Infrastructure Services 19.9	December 2019	4.6.2	--*
Infrastructure Services 19.6	August 2019	4.6.2	--*
Infrastructure Services 18.11	December 2018	4.6.2	4.6.2
Infrastructure Services 18.8	August 2018	4.6.2	4.6.2
Infrastructure Services 2018	April 2018	4.6.2	4.6.2
Infrastructure Services 2017.3	December 2017	4.5.2	4.5.2
Infrastructure Services 2017.2	September 2017	4.5.2	4.5.2
Server Suite 2017.1	May 2017	4.5	4.5.2
Server Suite 2017	February 2017	4.5	4.5.2
Server Suite 2016.1	May 2016	4.5	4.5.2
Server Suite 2016	December 2016	4.5	4.5.2

Note: We no longer bundle .NET in our installation media any more starting Release 19.6. (Ref: CS-47940)

This is the last release to support the following operating system platforms:

- macOS
- HP-UX 11.31 (PA-RISC)

Delinea has established product security policies documented at our support page. You may also find the details of all the published security advisories there.

For component specific security fixes in this release, you may find them in the corresponding component release-notes.html files. Please refer to Section 7 for a description of individual release notes.

See Component Version Table.

- For Access Manager, DirectControl agent and Delinea OpenSSH, see the Authentication Service and Privilege Elevation Service Release Notes.
- For Audit Manager and DirectAudit agent, see the Audit & Monitoring Service Release Notes.
- For Agent for Windows, see the Agent for Windows Release Notes.
- For Server Suite PuTTY, see the Server Suite PuTTY Release Notes

  Also, see Product Lifecycle Versions for product versions.

You can get all the supported releases from the download center in Delinea support web site.

- All the ISO, ZIP, and TGZ files are associated with the MD5 checksum.
- All RPM and DEB packages as well as YUM and APT repositories are also protected by the GPG signature. You can find the GPG public key in the download center.

Component specific bug fixes in this release can be found in the corresponding component release-notes.html files. Please refer to Release Notes for Server Suite Components for a description of individual release notes.

Component specific known issues/limitations can be found in the corresponding component release notes files. Please refer to Release Notes for Server Suite Components for a description of individual release notes.

For the most up to date list of known issues, please login to the Customer Support Portal at https://www.delinea.com/support and refer to Knowledge Base articles for any known issues with the release.

In addition to the documentation provided with this package, you can find the answers to common questions and information about any general or platform-specific known limitations as well as tips and suggestions from the Delinea Knowledge Base.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

- 2022.1 Auth/PE Release Notes
- 2022 Auth/PE Release Notes

About this Release

Authentication Service and Privilege Elevation Service, part of the product category Delinea Server Suite (previously called Centrify Infrastructure Services or Centrify Zero Trust Privilege Services), centralize authentication and privileged user access across disparate systems and applications by extending Active Directory-based authentication, enabling use of Windows Group Policy and Single-Sign-On. With Delinea Server Suite, enterprises can easily migrate and manage complex UNIX, Linux, and Windows systems, rapidly consolidate identities into the directory, organize granular access and simplify administration. Delinea Authentication Service, through Delinea's patented Zone technology, allows organizations to easily establish global UNIX identities, centrally manage exceptions on Legacy systems, separate identity from access management and delegate administration. Delinea's non-intrusive and organized approach to identity and access management results in stronger security, improved compliance and reduced operational costs.

The Upgrade Guide describes the correct order to perform updates such that all packages continue to perform correctly once upgraded.

The product-related release notes and documents are available online at https://docs.delinea.com/.

Feature Changes in this Release

For a list of the supported platforms by this release, refer to the "Supported Platforms" section in the Server Suite Release Notes.

For a list of platforms that Delinea will remove support in upcoming releases, refer to the 'Notice of Termination Support' section in the Server Suite Release Notes).

- Implemented a new feature to gather statistic information for NSS requests. See Configuration Parameters for details.
- Implemented a new feature to write info and warning logs when the time spent on a complete NSS request exceeds the configured threshold value. See Configuration Parameters for details.

General

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement

Security Fix

Server Suite DirectControl Agent for

- Added support for a systemd environment file under the /etc/default directory. (Ref: 394029)
- If the domain controller has installed Windows updates dated November 9, 2021 or later and set the new registry value "PacRequestorEnforcement" as "2", resetting passwords via Kerberos would fail. As a result, DirectControl adjoin, adkeytab, and adpasswd command line utilities would fail to reset accounts' password. Microsoft has confirmed this issue, please see the Known issues section of this article: https://prod.support.services.microsoft.com/en-us/topic/kb5008380-authentication-updates-cve-2021-42287-9dafac11-e0d0-4cb8-959a-143bd0201041 (Ref:430402)

  This release has a solution to bypass that issue.

DirectControl Command Line Utilities

Configuration Parameters

New Parameters

New Parameters for DirectControl

- pam.homedir.update.ownership: false This parameter specifies whether or not to update the home directory ownership when the user logs in. The default is false. (Ref: 430517)
- adclient.nss.statistic.interval: 30m This parameter specifies the statistic interval for adclient to gather NSS query statistics information. The default is 30

minutes. (Ref: 433831)

Added the following Server Suite configuration items for the NSS module:

Below are the global settings for all categories of NSS requests (in milliseconds): nss.watch.slow.lookup.info.threshold: -1 nss.watch.slow.lookup.warn.threshold: -1

Below are the per-category settings, append "user" or "group" suffix, which can override global settings. "user" category indicates these NSS calls: getpwnam* getpwuid* getgrouplist "group" category indicates these NSS calls: getgrnam* getgrgid*

nss.watch.slow.lookup.info.threshold.user: -1 nss.watch.slow.lookup.warn.threshold.user: -1 nss.watch.slow.lookup.info.threshold.group: -1 nss.watch.slow.lookup.warn.threshold.group: -1

Added the following Server Suite configuration items for adclient: Below are the global settings for all categories of NSS requests (in milliseconds): adclient.watch.slow.lookup.info.threshold: -1 adclient.watch.slow.lookup.warn.threshold: -1

Below are the per-category settings, append "user" or "group" suffix, which can override global settings. "user" category indicates these NSS calls: getpwnam* getpwuid* getgrouplist "group" category indicates these NSS calls: getgrnam* getgrgid*

adclient.watch.slow.lookup.info.threshold.user: -1 adclient.watch.slow.lookup.warn.threshold.user: -1 adclient.watch.slow.lookup.info.threshold.group: -1 adclient.watch.slow.lookup.warn.threshold.group: -1

New Parameters for OpenLDAP Proxy

- Added the support of bypassing caches for specified categories with the following new parameters in slapd.conf:
  - ldapproxy.bypass.adclientcache: set this parameter to specify some categories (separating with comma; "*" means all searches) to enable this feature.
  - ldapproxy.bypass.slapdcache: set this parameter in the /etc/centrifydc/openldap/ldapproxy.slapd.conf file to specify some categories (separating with comma; "*" means all searches) to enable this feature.
    Note: USER and GROUP categories always use caches.

Modified Parameters

Audit Trail Events

Server Suite Access Manager

Server Suite Access Module for PowerShell

Server Suite Group Policy Management

Server Suite Licensing Service

Server Suite OpenLDAP Proxy

Server Suite OpenSSH

Server Suite OpenSSL

Server Suite Report Services

- You can now specify registry keys to be created during the Report Services silent installation so you don't need to go back after it's installed to specify additional config parameters. (Ref:430713)

Server Suite Smart Card

- Added Smart Card Support for Rocky Linux. (Ref:433531)
- Added Smart Card Support for Alma Linux. (Ref:433532)

Server Suite Windows Installer

Server Suite Windows SDK

Server Suite Zone Provisioning Agent

Fixed Issues in this Release

General

- We have fixed the memory allocation issues related to Microsoft KB: KB5014697 (Win 11) / KB5014692 (Win10) / KB5014699 (Win2019) / KB5014702 (Win2016) KB updates. (Ref:441208)

Security Fixes

- Fixed the high severity CVE-2022-37434 of zlib with the official patch. (Ref:454508)
- OpenSSL was upgraded from 3.0.1. to 3.0.5 (Ref: 444612)
- Centrify cURL was upgraded based on cURL v7.84.0.(Ref:442043)
- Upgraded zlib to 1.2.12.(Ref:430916)

Server Suite DirectControl Agent for

- The obsolete group policy script TestFipsMode.pl has been removed from the CentrifyDC package. (Ref: 427705)
- Fixed an issue where single sign-on could fail when using the KCM kerberos credential cache. (Ref: 430385)
- Fixed an issue where dzdo may crash on Debian if audit is disabled in a kernel parameter. (Ref: 442864)
- Fixed an issue where adjoin didn't write Kerberos keytab entries of the computer userPrincipalName. (Ref: 442592)
- Fixed an issue where some groups may have lost members when 'adclient.local.group.merge' was true. (Ref: 431082)
- Fixed an issue where centrifydc.log was empty after log rotation on RHEL 8 (Ref: 429155)
- Fixed a race condition issue that would sometimes crash processes performing NSS user lookups. (Ref:443314)
- Fixed an issue where the user needed to add '+' at the end of /etc/passwd manually to resolve the AD user while NSS compatability mode was enabled. (Ref:441847)
- Fixed an issue where user lookup by NTLM name would fail when the adclient.included.domains setting was in place.(Ref:422590)

DirectControl Command Line Utilities

DirectControl Installation

Audit Trail Events

Server Suite Access Manager

- Fixed an issue where Access Manager showed an unknown OS type for AlmaLinux, Rocky Linux, Red Hat Enterprise Linux CoreOS, and Flatcar Container Linux. (Ref: 431687)
- Fixed an issue in Access Manager where users couldn't change the license container in the zone's properties dialog box. (Ref: 433612)
- Fixed an issue with the Access Manager analyzer where it showed incorrect orphaned role assignments. (Ref: 431820)

Server Suite Access Module for PowerShell

Server Suite ADEdit

- Fixed an issue where the adedit command 'create_assignment' couldn't create role assignments for the same user but with different start/end time. (Ref:422588)

Server Suite Group Policy Management

Server Suite Licensing Service

Server Suite NIS

Server Suite OpenLDAP Proxy

- Fixed an issue where the ldapproxy in-memory cache couldn't work with sizelimit. (Ref:445830)
- Fixed an issue where ldapproxy replied with two searchResultDone packets for one paged search.(Ref:442434)
- Fixed an issue where ldapproxy returned "no such object" when searching for an rfc2307nismap container. (Ref:441860)

Server Suite OpenSSH

Server Suite Report Services

- Fixed an issue where Report Services ended prematurely because of a null exception. (Ref: 430704)

Server Suite Smart Card

Server Suite Windows Installer

Server Suite Windows SDK

Server Suite Zone Provisioning Agent

Fixes in Release 2022.1 Component Update

Fixed several critical security fixes by upgrading 'Centrify OpenSSL' to 3.0.7. (Ref: 469895)

Fixed issues related to CVE-2022-42915 by upgrading cURL to 7.86.0. (Ref: 469896)

Known Issues

The following sections describe common limitations or known issues associated with this Authentication Service and Privilege Elevation Service release.

For the most up to date list of known issues, please login to the Customer Support Portal at https://www.delinea.com/support and refer to Knowledge Base articles for any known issues with the release.

Server Suite DirectControl Agent for

- Known Issues with Multi-Factor Authentication (MFA)

  If MFA is enabled but the parameter "adclient.legacyzone.mfa.required.groups" is set to a non-existent group, all AD users will be required for MFA. The workaround is to remove any non-existent groups from the parameter. (Ref: CS-39591b)

- Known Issues with AIX

  On AIX, upgrading DirectControl agent from 5.0.2 or older versions in disconnected mode may cause unexpected behavior. The centrifydc service may be down after upgrade. It's recommended not to upgrade DirectControl agent in disconnected mode. (Ref: CS-30494a)

  Some versions of AIX cannot handle username longer than eight characters. As a preventive measure, we have added a new test case in the adcheck command to check if the parameter LOGIN_NAME_MAX is set to 9. If yes, adcheck will show a warning so that users can be aware of it. (Ref: CS-30789a)

- Known issues with Fedora 19 and above (Ref: CS-31549a, CS-31730a)

  There are several potential issues on Fedora 19 and above:

  1. The adcheck command will fail if the machine does not have Perl installed.
  2. Group Policy will not be fully functional unless Text/ParseWords.pm is installed.

- Known issues with RedHat

When logging into a RedHat system using an Active Directory user that has the same name as a local user, the system will not warn the user of the conflict, which will result in unpredictable login behavior. The workaround is to remove the conflict or login with a different AD user. (Ref: CS-28940a, CS-28941a)

  - Known issues with rsh / rlogin (Ref: IN-90001)
  - When using rsh or rlogin to access a computer that has DirectControl agent installed, and where the user is required to change their password, users are prompted to change their password twice. Users may use the same password each time they are prompted, and the password is successfully changed.

- Known issues with compatibility

  Using DirectControl 4.x agents with Access Manager 5.x (Ref: IN-90001)

  - DirectControl 4.x agents can join classic zones created by Access Manager 5.x. It will ostensibly be able to join a DirectControl 4.x agent to a hierarchical zone as well, but this causes failure later as such behavior is undefined.

  Default zone not used in DirectControl 5.x (Ref: IN-90001)

  - In DirectControl 4.x, and earlier, there was a concept of the default zone. When Access Manager was installed, a special zone could be created as the default zone. If no zone was specified when joining a domain with adjoin, the default zone would be used.
  - This concept has been removed from DirectControl 5.0.0 and later as it is no longer relevant with hierarchical zones. In zoned mode, a zone must now always be specified.
  - A zone called "default" may be created, and default zones created in earlier versions of Access Manager may be used, but the name must be explicitly used.

Smart Card

- Release 18.8 includes an update to Coolkey to support Giesecke & Devrient 144k, Gemalto DLGX4-A 144, and HID Crescendo 144K FIPS cards. However, this has caused known issues that may cause CAC cards to only work sporadically. A workaround for CAC cards is to wait for it to prompt for PIN and Welcome, without removing the card, and then try again. (Ref: CC-58013a)
- There is a Red Hat Linux desktop selection issue found in RHEL 7 with smart card login. When login with smart card, if both GNOME and KDE desktops are installed, user can only log into GNOME desktop even though "KDE Plasma Workspace" option is selected. (Ref: CS-35125a)
- On RHEL 5.10 and 5.11, if "Smart Card Support" is enabled and a smartcard is inserted on the login screen, a PIN prompt may not show up until you hit the "Enter" key. The workaround is to replace libsoftokn3.so with the old one on RHEL 5.9, which is a shared object file in NSS package. (Ref: CS-35038a)
- On RHEL 5.10 and 5.11, if "Smart Card Support" is enabled and "Card Removal Action" is configured as "Lock", the screen will be locked several seconds after login with smart card. The workaround is to replace libsoftokn3.so with the old one on RHEL 5.9, which is a shared object file in NSS package. (Ref: CS-33871a)
- When a SmartCard user attempts to login on Red Hat 6.0 with a password that has expired, the authentication error message may not mention that authentication has failed due to an expired password. (Ref: CS-28305a)
- On RedHat, any SmartCard user will get a PIN prompt even if he's not zoned, even though the login attempt will ultimately fail. This is a divergence from Mac behavior - On Mac, if a SmartCard user is not zoned, Mac doesn't even prompt the user for PIN. (Ref: CS-33175c)
- If a SmartCard user's Active Directory password expires while in disconnected mode, the user may still be able to log into their machine using their expired password. This is not a usual case, as secure SmartCard AD environments usually do not allow both PIN and Password logins while using a Smart Card. (Ref: CS-28926a)
- To login successfully in disconnected mode (Ref: CS-29111a):
  - For a password user:
    - A password user must log in successfully once in connected mode prior to logging in using disconnected mode. (This is consistent with other DirectControl agent for *NIX behavior)
  - For a SmartCard user:
    - The above is not true of SmartCard login. Given a properly configured RedHat system with valid certificate trust chain and CRL set up, a SmartCard user may successfully login using disconnected mode even without prior successful logins in connected mode.
    - If certificate trust chain is not configured properly on the RedHat system, the SmartCard user's login attempt will fail.
    - If the SmartCard user's login certificate has been revoked, and the RedHat system has a valid CRL that includes this certificate, then the system will reject the user.

- After upgrading from DirectControl version 5.0.4 to version 5.1, a Smartcard user may not be able to login successfully. The workaround is to run the following CLI commands:

  sudo rm /etc/pam_pkcs11/cacerts/*

  sudo rm /etc/pam_pkcs11/crls/*

  sudo rm /var/centrify/net/certs/*

  then run adgpupdate. (Ref: CS-30025c)

- When CRL check is set via Group Policy and attempting to authenticate via Smartcard, authentication may fail. The workaround is to wait until the Group Policy Update interval has occurred and try again or to force an immediate Group Policy update by running the CLI command adgpupdate. (Ref: CS-30090c)

- After upgrading from DirectControl agent Version 5.0.4 to version 5.1.1, a SmartCard user may not be able to authenticate successfully. The workaround is to perform the following CLI command sequence:

```
sctool -d
sctool -e
sudo rm /etc/pam_pkcs11/cacerts/*
sudo rm /etc/pam_pkcs11/crls/*
sudo rm /var/centrify/net/certs/*"
adgpupdate
```

and then re-login using the SmartCard and PIN. (Ref: CS-30353c)

- A name-mapping user can unlock screen with password even though the previous login was with PIN. (Ref: CS-31364b)
- Need to input PIN twice to login using CAC card with PIN on RedHat. It will fail on the first input but succeed on the second one. (Ref: CS-30551c)
- Running "sctool –D" with normal user will provide wrong CRL check result. The work-around is to run it as root. (Ref: CS-31357b)
- Screen saver shows password not PIN prompt (Ref: CS-31559a)

Most smart card users can log on with a smart card and PIN only and cannot authenticate with a username and password. However, it is possible to configure users for both smart card/PIN and username/password authentication. Generally, this set up works seamlessly: the user either enters a username and password at the log on prompt, or inserts a smart card and enters a PIN at the prompt.

However, for multi-user cards, it can be problematic when the screen locks and the card is in the reader. When a user attempts to unlock the screen, the system prompts for a password, not for a PIN, although the PIN is required because the card is in the reader. If the user is not aware that the card is still in the reader and enters his password multiple times, the card will lock once the limit for incorrect entries is reached.

On RHEL 7, an authenticated Active Directory user via smart card cannot login again if the smart card is removed. This is due to a bug in RHEL 7, https://bugzilla.redhat.com/show_bug.cgi?id=1238342. This problem does not happen on RHEL6. (Ref: CSSSUP-6914c)

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

About this Release

Authentication Service and Privilege Elevation Service, part of the product category Delinea Server Suite (previously called Centrify Infrastructure Services or Centrify Zero Trust Privilege Services), centralize authentication and privileged user access across disparate systems and applications by extending Active Directory-based authentication, enabling use of Windows Group Policy and Single-Sign-On. With Delinea Server Suite, enterprises can easily migrate and manage complex UNIX, Linux, and Windows systems, rapidly consolidate identities into the directory, organize granular access and simplify administration. Delinea Authentication Service, through Delinea's patented Zone technology, allows organizations to easily establish global UNIX identities, centrally manage exceptions on Legacy systems, separate identity from access management and delegate administration. Delinea's non-intrusive and organized approach to identity and access management results in stronger security, improved compliance and reduced operational costs.

The Upgrade Guide describes the correct order to perform updates such that all packages continue to perform correctly once upgraded.

The product related release notes and documents are available online at https://docs.delinea.com/.

Delinea software is protected by U.S. Patents 7,591,005; 8,024,360; 8,321,523; 9,015,103; 9,112,846; 9,197,670; 9,378,391 and 9,442,962. (Ref: CS-44575)

Feature Changes in this Release

For a list of the supported platforms by this release, refer to the "Supported Platforms" section in the Server Suite Release Notes.

For a list of platforms that Delinea will remove support in upcoming releases, refer to the 'Notice of Termination Support' section in the Server Suite Release Notes.

General

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement

Security Fix

Server Suite DirectControl Agent for

NSS and adquery now supports NTLM name lookup for users from one-way trusted forests.

Enhanced the Domain Controller failover algorithm so that now the default behavior is that the UNIX Agent (adclient) will try to pick up Domain Controllers based on weighted random selection and re-establish LDAP bindings every 12 hours if adclient.binding.refresh.force is true.

DirectControl Command Line Utilities

Delinea cURL is upgraded based on cURL v7.75.0 instead of v7.70.0.

Configuration Parameters

New Parameters

The new parameters are:

- smartcard.pkcs11.module (replaces rhel.smartcard.pkcs11.module)
- smartcard.login.force (replaces rhel.smartcard.login.force)
- dzdo.timestamp_type

Modified Parameters

The following configuration parameters are deprecated (but are still supported for backward compatibility) :

- rhel.smartcard.pkcs11.module
- rhel.smartcard.login.force

Audit Trail Events

Server Suite Access Manager

Server Suite Access Module for PowerShell

Server Suite Group Policy Management

Server Suite Licensing Service

Server Suite OpenLDAP Proxy

Server Suite OpenSSH

DirectControl Openssh was upgraded based on openssh-8.8p1.

Server Suite OpenSSL

OpenSSL was upgraded from 3.0.0 to 3.0.1 with the CVE-2022-0778 patch applied.

Server Suite Report Services

You can now set gMSA as a service account through Report Service Silent Configuration.

Server Suite Smart Card

Added Smart Card Support for Ubuntu 21.10.

Server Suite Windows Installer

Server Suite Windows SDK

Server Suite Zone Provisioning Agent

Fixed Issues in this Release

General

Fix an issue where newly provisioned zone users were not listed as their parent zone groups' members. This issue occurred with AD users that were already added to the corresponding AD groups but were newly provisioned in the zone.

Fixed an issue where the user could not do an MFA log in with RADIUS MFA authentication.

Fixed an issue where the pass-through feature didn't work when a user tried to log in using MFA ssh.

Security Fix

Server Suite DirectControl Agent for

Fixed adclient so that it respects what is set in the "adclient.group.ignore.blocked.domain.member" configuration parameter so that adclient ignores groups from intentionally blocked domains when checking computer role groups.

Fixed an issue where the UNIX Agent (adclient) or CLIs produced the "No credentials found with supported encryption types" Kerberos error message after some customers changed the "adclient.krb5.permitted.encryption.types" and "adclient.krb5.tkt.encryption.types" settings.

Fixed an issue where, in some situations, the kset.altupn and krb5.conf settings were not updated as expected.

Fixed an issue where the NSS user lookup fails sometimes to find an zone user when the configuration "nss.user.group.prefer.cache: true" is in place and the corresponding AD user account is from another forest.

Fixed a library conflict between OpenSSL and DB2 server on AIX. This fixed a problem with using the DirectControl DB2 GSSAPI Kerberos plugin (Single Sign On) on AIX.

DirectControl Command Line Utilities

Fixed an issue where dzdo could not login using single sign-on to a remote host to run a command.

Fixed some issues in the CAPI cache, which is used by the DirectControl add-on packages (such as the adbindproxy and DB2 plugins), smart card support and macOS. Note that the CAPI cache is disabled by default prior to DirectControl version 5.8.1.

Fixed an issue where ssh SSO login failed when working with gssproxy.

DirectControl Installation

Fixed a problem where some services may not be registered after installing the packages on Solaris 10.

Audit Trail Events

Server Suite Access Manager

Server Suite Access Module for PowerShell

Server Suite Group Policy Management

Server Suite Licensing Service

Server Suite NIS

Fixed an issue with the NIS daemon loading snapshot files. You can now make the NIS daemon load all the snapshot files into memory. Doing this can be more efficient to respond ypGetAll, but it will also have a bigger memory footprint. Please contact support if you want to use this feature.

Fixed an issue where adnisd sometimes would get incomplete group NIS maps.

Server Suite OpenLDAP Proxy

Server Suite OpenSSH

Enhanced the GSSAPIKexAlgorithms to support more algorithms. Now DirectControl Openssh supports the following 7 algorithms:

- "gss-group1-sha1-"
- "gss-group14-sha1-"
- "gss-group14-sha256-"
- "gss-group16-sha512-"
- "gss-gex-sha1-"
- "gss-nistp256-sha256-"
- "gss-curve25519-sha256-"

Fixed an issue where the DirectControl Openssh systemd service file is not installed on SuSE15 SP3.

Fixed an issue where the DirectControl Openssh match block set in group policies were lost in sshd_config.

Server Suite Report Services

Server Suite Smart Card

Fixed an issue with Citrix VDA smartcard authentication on Debian or Ubuntu systems where some customers are using 3rd-party pkcs11 libraries.

Server Suite Windows Installer

Server Suite Windows SDK

Server Suite Zone Provisioning Agent

Fixes in Release 2022 Component Update

Fixed several critical security fixes by upgrading 'Centrify OpenSSL' to 3.0.7. (Ref: 469890)

Fixed issues related to CVE-2022-42915 by upgrading cURL to 7.86.0. (Ref: 469891)

Fixed an issue where if you were using Release 2021 (5.8.0) or earlier and you upgraded to the Release 2022 (5.9.0) GA, you might have encountered a cache upgrade issue. The issue caused login failures for offline upgrades and had a negative impact on *NIX agent performance for large Active Directory environments. If you're planning to upgrade, we highly recommend that you use this updated version. You know you have the updated version when you run `adinfo -v` and you get CentrifyDC 5.9.0-159.

Applied the patches of CVE-2022-1292, CVE-2022-1473, CVE-2022-1434 and CVE-2022-1343 to Centrify OpenSSL.

If the domain controller has installed Windows updates dated November 9, 2021 or later and set the new registry value "PacRequestorEnforcement" as "2", resetting passwords by way of Kerberos would fail. As a result, DirectControl adjoin, adkeytab and adpasswd command line utilities would fail to reset the accounts' password. Microsoft has confirmed this issue, please see the Known issues section of this article. This release has a solution to bypass that issue.

Known Issues

The following sections describe common limitations or known issues associated with this Authentication Service and Privilege Elevation Service release.

For the most up to date list of known issues, please login to the Customer Support Portal at https://www.delinea.com/support and refer to Knowledge Base articles for any known issues with the release.

Server Suite DirectControl Agent for

- Known Issues with Multi-Factor Authentication (MFA)

  If MFA is enabled but the parameter "adclient.legacyzone.mfa.required.groups" is set to a non-existent group, all AD users will be required for MFA. The workaround is to remove any non-existent groups from the parameter. (Ref: CS-39591b)

- Known Issues with AIX

  On AIX, upgrading DirectControl agent from 5.0.2 or older versions in disconnected mode may cause unexpected behavior. The centrifydc service may be down after upgrade. It's recommended not to upgrade DirectControl agent in disconnected mode. (Ref: CS-30494a)

  Some versions of AIX cannot handle username longer than eight characters. As a preventive measure, we have added a new test case in the adcheck command to check if the parameter LOGIN_NAME_MAX is set to 9. If yes, adcheck will show a warning so that users can be aware of it. (Ref: CS-30789a)

- Known issues with Fedora 19 and above (Ref: CS-31549a, CS-31730a)

  There are several potential issues on Fedora 19 and above:

  1. The adcheck command will fail if the machine does not have Perl installed.
  2. Group Policy will not be fully functional unless Text/ParseWords.pm is installed.

- Known issues with RedHat

  When logging into a RedHat system using an Active Directory user that has the same name as a local user, the system will not warn the user of the conflict, which will result in unpredictable login behavior. The workaround is to remove the conflict or login with a different AD user. (Ref: CS-28940a, CS-28941a)

  - Known issues with rsh / rlogin (Ref: IN-90001)
  - When using rsh or rlogin to access a computer that has DirectControl agent installed, and where the user is required to change their password, users are prompted to change their password twice. Users may use the same password each time they are prompted, and the password is successfully changed.

- Known issues with compatibility

  Using DirectControl 4.x agents with Access Manager 5.x (Ref: IN-90001)

- DirectControl 4.x agents can join classic zones created by Access Manager 5.x. It will ostensibly be able to join a DirectControl 4.x agent to a hierarchical zone as well, but this causes failure later as such behavior is undefined.

Default zone not used in DirectControl 5.x (Ref: IN-90001)

- In DirectControl 4.x, and earlier, there was a concept of the default zone. When Access Manager was installed, a special zone could be created as the default zone. If no zone was specified when joining a domain with adjoin, the default zone would be used.
- This concept has been removed from DirectControl 5.0.0 and later as it is no longer relevant with hierarchical zones. In zoned mode, a zone must now always be specified.
- A zone called "default" may be created, and default zones created in earlier versions of Access Manager may be used, but the name must be explicitly used.

Smart Card

- Release 18.8 includes an update to Coolkey to support Giesecke & Devrient 144k, Gemalto DLGX4-A 144, and HID Crescendo 144K FIPS cards. However, this has caused known issues that may cause CAC cards to only work sporadically. A workaround for CAC cards is to wait for it to prompt for PIN and Welcome, without removing the card, and then try again. (Ref: CC-58013a)
- There is a Red Hat Linux desktop selection issue found in RHEL 7 with smart card login. When login with smart card, if both GNOME and KDE desktops are installed, user can only log into GNOME desktop even though "KDE Plasma Workspace" option is selected. (Ref: CS-35125a)
- On RHEL 5.10 and 5.11, if "Smart Card Support" is enabled and a smartcard is inserted on the login screen, a PIN prompt may not show up until you hit the "Enter" key. The workaround is to replace libsoftokn3.so with the old one on RHEL 5.9, which is a shared object file in NSS package. (Ref: CS-35038a)
- On RHEL 5.10 and 5.11, if "Smart Card Support" is enabled and "Card Removal Action" is configured as "Lock", the screen will be locked several seconds after login with smart card. The workaround is to replace libsoftokn3.so with the old one on RHEL 5.9, which is a shared object file in NSS package. (Ref: CS-33871a)
- When a SmartCard user attempts to login on Red Hat 6.0 with a password that has expired, the authentication error message may not mention that authentication has failed due to an expired password. (Ref: CS-28305a)
- On RedHat, any SmartCard user will get a PIN prompt even if he's not zoned, even though the login attempt will ultimately fail. This is a divergence from Mac behavior - On Mac, if a SmartCard user is not zoned, Mac doesn't even prompt the user for PIN. (Ref: CS-33175c)
- If a SmartCard user's Active Directory password expires while in disconnected mode, the user may still be able to log into their machine using their expired password. This is not a usual case, as secure SmartCard AD environments usually do not allow both PIN and Password logins while using a Smart Card. (Ref: CS-28926a)
- To login successfully in disconnected mode (Ref: CS-29111a):
  - For a password user:
    - A password user must log in successfully once in connected mode prior to logging in using disconnected mode. (This is consistent with other DirectControl agent for *NIX behavior)
  - For a SmartCard user:
    - The above is not true of SmartCard login. Given a properly configured RedHat system with valid certificate trust chain and CRL set up, a SmartCard user may successfully login using disconnected mode even without prior successful logins in connected mode.
    - If certificate trust chain is not configured properly on the RedHat system, the SmartCard user's login attempt will fail.
    - If the SmartCard user's login certificate has been revoked, and the RedHat system has a valid CRL that includes this certificate, then the system will reject the user.
- After upgrading from DirectControl version 5.0.4 to version 5.1, a Smartcard user may not be able to login successfully. The workaround is to run the following CLI commands:

  sudo rm /etc/pam_pkcs11/cacerts/*

  sudo rm /etc/pam_pkcs11/crls/*

  sudo rm /var/centrify/net/certs/*

  then run adgpupdate. (Ref: CS-30025c)
- When CRL check is set via Group Policy and attempting to authenticate via Smartcard, authentication may fail. The workaround is to wait until the

Group Policy Update interval has occurred and try again or to force an immediate Group Policy update by running the CLI command adgpupdate. (Ref: CS-30090c)

- After upgrading from DirectControl agent Version 5.0.4 to version 5.1.1, a SmartCard user may not be able to authenticate successfully. The workaround is to perform the following CLI command sequence:

```
sctool -d
sctool -e
sudo rm /etc/pam_pkcs11/cacerts/*
sudo rm /etc/pam_pkcs11/crls/*
sudo rm /var/centrify/net/certs/*"
adgpupdate
```

and then re-login using the SmartCard and PIN. (Ref: CS-30353c)

- A name-mapping user can unlock screen with password even though the previous login was with PIN. (Ref: CS-31364b)
- Need to input PIN twice to login using CAC card with PIN on RedHat. It will fail on the first input but succeed on the second one. (Ref: CS-30551c)
- Running "sctool –D" with normal user will provide wrong CRL check result. The work-around is to run it as root. (Ref: CS-31357b)
- Screen saver shows password not PIN prompt (Ref: CS-31559a)

Most smart card users can log on with a smart card and PIN only and cannot authenticate with a username and password. However, it is possible to configure users for both smart card/PIN and username/password authentication. Generally, this set up works seamlessly: the user either enters a username and password at the log on prompt, or inserts a smart card and enters a PIN at the prompt.

However, for multi-user cards, it can be problematic when the screen locks and the card is in the reader. When a user attempts to unlock the screen, the system prompts for a password, not for a PIN, although the PIN is required because the card is in the reader. If the user is not aware that the card is still in the reader and enters his password multiple times, the card will lock once the limit for incorrect entries is reached.

On RHEL 7, an authenticated Active Directory user via smart card cannot login again if the smart card is removed. This is due to a bug in RHEL 7, https://bugzilla.redhat.com/show_bug.cgi?id=1238342. This problem does not happen on RHEL6. (Ref: CSSSUP-6914c)

- 2022.1 Windows Agent Release Notes
- 2022 Windows Agent Release Notes

For the list of the supported platforms by this release, refer to the "Supported Platforms" section in the Server Suite release notes.

For the platforms to be removed support in coming releases, refer to the "Notice of Termination Support" section in the Server Suite release notes.

About Server Suite Agent for Windows

The Server Suite Agent for Windows package contains software to support auditing, access control, and privilege management on Windows computers. Audit and Access features must be installed together but their services can be enabled separately on the Windows computers you want to manage.

For auditing, the Server Suite Agent for Windows requires the Auditing & Monitoring Service feature set, which is available in Server Suite. Auditing & Monitoring Service enables detailed auditing of user activity on a wide range of UNIX, Linux and Windows computers. With Auditing & Monitoring Service, you can perform immediate, in-depth troubleshooting by replaying user activity that may have contributed to system failures, spot suspicious activity by monitoring current user sessions, and improve regulatory compliance and accountability by capturing and storing detailed information about the applications used and the commands executed. If you enable auditing, the Server Suite Agent for Windows records user activity on the Windows computer when it is installed.

For access control and privilege management, the Server Suite Agent for Windows requires the Authentication Service and Privilege Elevation Service feature sets, which are available in Server Suite. With Authentication Service and Privilege Elevation Service, you can configure and manage role-based access controls for Windows servers. The Server Suite Agent for Windows extends the access control and privilege management features available for Linux and UNIX computers, so that you can use a single console to manage multiple platforms. You can deploy the Server Suite Agent for Windows in a Windows-only environment or as part of a mixed environment that includes Windows, Linux, and UNIX computers.

The Server Suite Agent for Windows provides both privilege elevation and auditing functionalities, and for more information about the auditing feature, refer to the Delinea Auditing & Monitoring Service Release Notes for more detailed information.

You can obtain information about previous releases from the Delinea Support Portal, in the Documentation & Application Notes page.

Feature Changes

Security Fixes

General Changes

Fixed Issues

We have fixed the memory allocation issues related to Microsoft KB: KB5014697 (Win 11) / KB5014692 (Win10) / KB5014699 (Win2019) / KB5014702 (Win2016) KB updates.

Known Issues

Installation and Uninstallation

- Upgrading from the beta build to this version may result in offline MFA mode if there are multiple authentication servers registered in your AD forest. To resolve this, uninstall the beta build first and then install this new version. (Ref: CS-41915)
- Upgrading Windows while the Agent is installed will result in a failure of the Windows upgrade. The workaround is to uninstall the agent before performing the upgrade or perform a fresh Windows install without keeping existing applications and settings. (Ref: CS-42200)
- Currently the MFA login feature is not supported on Windows Server 2016 "Server Core" systems. This feature component will not be installed on Windows Server 2016 "Server Core" systems. (Ref: CS-42192, CS-42527)
- The Delinea Common Component should be the last Delinea Server Suite component uninstalled. If the component is uninstalled before other component, it must be reinstalled by the uninstall process to complete its task. (Ref: 36226a)
- If you intend to install the software on the desktop with elevated privilege, you should not check the “Run with UAC restrictions” option when creating the desktop. (Ref: 39725b)
- When you double-click on the Server Suite Agent for Windows msi and select the “repair” option, the existing files are replaced irrespective of their

version number, even when they are identical. As a result, a prompt to restart the system is displayed as files that were in use were replaced. However, if you use the Easy Installer to do the repair and a file on the disk has the same version as the file that is part of the installer package, the installed file will not be replaced. Therefore, there will not be any prompt to restart the system. (Ref: 26561a)

- When the Server Suite Agent for Windows is either installed or uninstalled and the prompt for a machine restart is deferred using the "restart later" option or ignored, other components of DirectManage may display errors due to an incomplete installation. A restart is mandatory if requested after install or uninstall operation. (Ref: 36307a)
- Users may notice a few "Side by side" configuration errors in the Event Viewer after installing the Server Suite Agent for Windows, if Microsoft KB945140 related components have been installed on the local machine previously. These errors will go away after you restart the computer and have no functional effect. (Ref: 35302a)
- If you uninstall the Server Suite Agent for Windows while the DirectAudit Agent Control Panel is open, files needed by the uninstall process may be blocked. You should close the DirectAudit Agent Control Panel for a successful conclusion to the uninstall process. (Ref: 25753a)
- If you have installed the Access feature of Server Suite Agent for Windows from Server Suite 2013 and are trying to upgrade the component to the latest version, you may see the following error during the installation process, "Service 'DirectAuthorize Agent' could not be installed. Verify that you have sufficient privileges to install system services." If you see this error message, it typically indicates that the existing service is taking longer time to stop and hence the new service is not getting installed. When you see this error, wait for some time (typically 30 seconds) and click on Retry button on the error message box. (Ref: 47270a)
- Server Suite Agent for Windows and its installer are built on .NET. Therefore, .NET is always installed as a pre-requisite before the agent is installed. If .NET is removed from the system later, Server Suite Agent for Windows will not run properly. User will also experience problem when trying to remove Server Suite Agent for Windows from the system. To properly uninstall Server Suite Agent for Windows, please make sure Server Suite Agent for Windows is uninstalled before .NET. (Ref: 39051a)
- The list of rescue users is stored in different places in Suite 2013.3 (or previous releases) and Suite 2014 and this list is not automatically migrated to its new location when upgrading from Suite 2013.3 or a previous release to Suite 2014. Because of this, it's highly recommended that Server Suite Agent for Windows should not be upgraded in disconnected mode (i.e. when the system cannot connect to the Active Directory). If a system is upgraded in disconnected mode, the list of rescue users will be lost and only local administrators will be able to login to the system after reboot. (Ref: 57622a)
- If you install Access feature of Server Suite Agent for Windows without installing the Audit feature, the registry key value for HKEY_LOCAL_MACHINE\SOFTWARE\Centrify\AuditTrail\AuditTrailTargets is set to zero as expected, which means the audit trail is not sent to DirectAudit Audit Store database. However, if you try to change the installed features list of Server Suite Agent for Windows and add the Audit feature later, the change process does not automatically set the AuditTrailTargets value to the expected new value of 1, which means to send audit trail data to DirectAudit Audit Store database. This is a known issue and workaround is to set this value manually to 1 after the installer finishes the process of adding new feature. (Ref: 59353b)
- If you have installed the Access feature of Server Suite Agent for Windows from earlier version and then upgraded the component to the latest version while the Agent for Windows is not currently connected to any Active Directory domain controller, only users who have been assigned a role with rescue rights will be able to log on to the computer until the connection to Active Directory is restored. (Ref: 58858b)

Configuration

- In a cross-forest environment, forest A user cannot enroll a device joined to forest B when forest A does not have a connector. (Ref: CS-44805)
- When a machine that has MFA for Windows login enabled is reconfigured to connect to a different forest, the previous setting for the authentication server may no longer be valid. However, if there are Group Policy login settings applied to the machine in the new forest, the new settings will be enabled when the Group Policy Editor refreshes. (Ref: CS-41928)
- In Windows 2016 and Win10, during the login process, selecting SMS or using other mechanisms like Security Question/Phone call/Password/Email/Mobile for MFA and clicking the "Commit" button will be intermittently unresponsive. (Ref: CS-41699)
- It can take a long time for users in offline mode to be re-prompted for their passcode.

  In the event that the Agent cannot connect to the Delinea Authentication Server, and a user is required to enter an offline passcode, it can take up to several minutes for the agent to re-prompt for the passcode if the user enters it incorrectly. If the user tries to cancel login by pressing "back" or by switching the user, the login screen may become unresponsive. This time lag between an incorrect passcode and the re-prompt can also occur when a user incorrectly enters their offline passcode for privilege elevation. (Ref: CS-41302)
- Administrator should always leave the zone before joining the computer to a different domain. Otherwise, DirectAuthorize may not function correctly after the computer is joined to a different domain. (Ref: 54278b)

- In some large environment with multiple domain controllers, it may take up to one minute for the new zone setting in Server Suite Agent Configuration to take effect. (Ref: 58128b)
- If one of the Global Catalog servers is unavailable, user may not be able to configure the zone for Server Suite Agent for Windows. (Ref: 58621b)
- Microsoft normally automatically distributes and installs root certificates to the Windows system from trusted Certificate Authorities (CA) and users are seamlessly able to use a secure connection by trusting a certificate chain issued from the trusted CA. However, this mechanism may fail if the system is in a disconnected environment where access to Windows Update is blocked or this feature of automatic root certificate installation is disabled. Without updates on the certificate trust list (CTL), the default CTLs on the system may not be adequate for secure connections of Delinea multi-factor authentication especially for older versions of Windows. To ensure the success of Delinea multi-factor authentication, user may need manually distribute and install the latest CTLs and the required root certificate to systems in a disconnected environment. See Delinea KB-6724 for further information. (Ref: CS-39703)

Environment

- On Windows 10 and Win2K16 machines with Delinea Privilege Elevation Service, following will occur (Ref: CS-43883):

• Pop up an error dialog several seconds after clicking "Open file location" in the context menu of a shortcut on the start menu. Explorer windows will display correctly.

• No responses to the following actions

• Clicking "Open file location" in the context menu of a shortcut on desktop

• Clicking "Open file location" in the context menu of a shortcut on the Delinea Start menu in the Privileged Desktop

• Slow response to "OK", "Cancel" in the shortcut property page after "Open file location" in the general tab is clicked. The dialog will close after several seconds.

- On some Windows 10 machines, the smart card login option may not be displayed if another credential method has been recently used. To display the smart card login option, remove and insert a smart card into the reader. This will cause the login screen to reload and will display the smart card login option. (Ref: CS-41282)
- Server Suite Agent for Windows requires you to patch to at least build 10.0.14393 on Windows 10 and Windows Server 2016 to use MFA features. (Ref: CS-41387)
- Selective two-way external trusts are not supported. Both Windows machines and Server Suite zones are required to be in the same forest or different forests with a two-way forest trust established. (Ref: 40713b, 44644b, 44647b, 44657b, 40643b, 40650b, 45341b, 45372b)
- Environment with no Global Catalog is not supported. (Ref: 46577a)
- DirectAuthorize for Windows requires machine time to be synchronized with domain controller. VMware virtual machine has a known issue that its time may not be synchronized with domain controller. This problem occurs more often on an overloaded virtual machine host. If the system clocks on the local Windows computer and the domain controller are not synchronized, DirectAuthorize for Windows does not allow any domain users to login. You can try the following KB from VMware to fix the time synchronization issue. http://kb.vmware.com/selfservice/microsites/search.do?language=en_US&cmd=displayKC&externalId=1189 (Ref: 47795b)

RunAsRole

- If you use the “RunAsRole.exe /wait” command to run a Python script, the input/output cannot be redirected for versions of Python below 3.0.0. (Ref: 45061a)
- Run As Role menu is not available on the start screen in Windows 8 or Windows 2012 or later because Microsoft doesn’t support any custom context menu on the start screen. User has to go to the Windows desktop in order to launch an application using Run As Role context menu. (Ref: 35487a)
- On Windows 8, Windows 8.1, Windows Server 2012 and Windows Server 2012 R2, use “Run as role” with Local Administrators group privilege on Control Panel does not have sufficient permission to add printers if the printer drivers are not pre-installed on the computer. The workaround is to define a role run as a user with Local Administrator privilege or with a group as a member of Local Administrators group. (Ref: 68826a)
- The “Run as role” for Windows Media Player is not recommended. Please use privilege desktop instead. (Ref: 55615a)
- When running “RunAsRole.exe /wait sc.exe” with no argument provided to sc.exe, sc.exe will prompt

Would you like to see help for the QUERY and QUERYEX commands? [y I n]:

Typing 'y' or 'n' doesn't do anything because the input cannot be successfully redirected to sc.exe. (Ref: 47016b)

- It is not recommended to change zone via Run As Role since the role that is in use may no longer be available once after leaving from the previous zone during the change zone process. (Ref: 58043a)

Desktop with Elevated Privileges

- In desktop with elevated privilege a mouse left click does not work for SysTray Icons that involve opening the WinRT(or new Window) UI. The Systray icons affect are Time, Volume Control, or any third party icons on Windows 10/2016. (Ref: CS-39454)
- Server Manager cannot be started on multiple desktops at the same time. The bug exists on Windows 2012R2, 2016. (Ref: CS-42060)
- On a desktop with elevated privileges on Windows 8, 10 & 2016, the search for files or folders will be intermittently disabled from the Start menu ("Start" menu > "Search" > "For Files or Folders..."). (Ref: CS-42066)
- On a desktop with elevated privileges, if you open the Task Manager and select "*File > New* Task" to run an application without selecting the "Create this task with administrative privileges" option, the application will be launched on the default desktop. This issue occurs when User Account Control (UAC) is enabled. (Ref: 32169a)
- If the sAMAccountName attribute of an Active Directory account is changed while the old account name is still cached on the computer, you may see the following error message when creating a new desktop or using "Run as role" with a right configured to run as the modified user account:

  "Failed to open new desktop. Right xxx references bad user account."

  The workaround is to restart the computer. (Ref: 35124a)
- On a desktop with elevated privileges, if you use "Control Panel > Programs > Programs and Features" to uninstall a program, you may see the following warning message and cannot uninstall the software.

  "The system administrator has set policies to prevent this installation."

  This issue happens when User Account Control (UAC) is enabled and when "Run with UAC restrictions" is selected when creating the new desktop. (Ref: 33384a)
- When you open the Start menu "Help and Support" item on a desktop with elevated privileges, the Windows Help and Support is launched on the default desktop. Switch to the default desktop to view the information. (Ref: 32147a)
- If you shut down, restart, or log off from a desktop with elevated privileges, all running applications are terminated forcibly without being prompted to save any open documents. (Ref: 40749a)
- You cannot launch Windows Security Options using "Start menu -> Windows Security" on a privilege desktop with elevated privileges when using a remote desktop connection. You must switch back to the default desktop to continue. (Ref: 45995b)
- Installation of IE9 on desktops with elevated privileges may cause the privileged desktop to become unusable. Use "RunAsRole" for installation of IE9 instead. (Ref: 44930a)
- You cannot use the Start menu option "Switch User" while you are using a role-based, privileged desktop. To use the "Switch User" shortcut, change from the privileged desktop to your default Windows desktop. From the default desktop, you can then select Start > Switch User to log on as a different user. (Ref: 39011b)
- On a DirectAuthorize desktop using a role with local administrator privilege, the Stand By option in the shutdown menu does not work. This is a known issue and will be addressed in future release. (Ref: 58280a)
- VMWare registers to run VMwareUser.exe on the guest operating system to enable user to copy and paste text between the guest and managed host operating systems. Creating multiple desktops with different user accounts causes multiple VMwareUser.exe are run in different user accounts in the same logon session. VMwareUSer.exe cannot support this scenario and therefore an error message is displayed on the default desktop which blocks all the UI operation on the new desktop. To workaround this problem, user can disable the VMWare user program on the guest machine by deleting the registry value name "VMware User Process" from HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run. (Ref: 49268a)
- On a privileged desktop on Windows 8, Windows 8.1, Windows 2012 and Windows 2012 R2, you may not be able to access the VMware shared folder. (Ref: 40686c)

- Windows logo key keyboard shortcuts are not supported on privileged desktop. Depends on the key and operation system, the shortcut could either have no effect or its effect is applied to the default desktop instead. (Ref: 47588b)
- A Start menu on privileged desktop on Windows 8, Windows 8.1, Windows 2012 and Windows 2012 R2, to make up for a limitation of Windows 8, Windows 8.1, Windows 2012 and Windows 2012 R2. In addition, navigating to a Modern Start screen to use Modern-style apps from a privileged desktop is not possible from either the charm bar or using a Windows. Note: you must switch back to the default desktop in order to go to Modern Start screen. (Ref: 41245c)
- The Challenge Pass-Through Duration setting is currently not supported for Server Suite Windows multi-factor authentication. The Challenge Pass-Through Duration setting does not require a user, who has successfully met a multi-factor authentication challenge, to re-authenticate through mfa to use an mfa-required right or role if that user chooses the same challenge mechanism when prompted within the duration specified in the setting. (Ref: CS-39432)

Roles and Rights

- No 'Require multi-factor authentication' system right for the predefined 'Windows Login' role. To define this system right for MFA, use the pre-defined Require MFA for logon role, or create a new custom role. (Ref: CS-40888)
- Windows Network Access rights do not take effect on a Linux or UNIX machines. If you select a role to start a program or create a desktop that contains a Network Access right, you can only use that role to access Windows computers. The Windows computers you access over the network must be joined to a zone that honors the selected role. The selected role cannot be used to access any Linux or UNIX server computers on the network. (Ref: 32980a)
- To elevate privileges to the “Run as” account specified in a Windows right, the “run as” account must have local logon rights. If you have explicitly disallowed this right, you may receive an error such as “the user has not been granted the requested logon type at this computer” when attempting to use the right. (Ref: 34266a)
- If your computer network is spread out geographically, there may be failures in NETBIOS name translation. If a NETBIOS name is used, Active Directory attempts to resolve the NETBIOS name based on the domain controller that the user belongs to, which in a multi-segment network might fail. Therefore, Network Access rights might not work as expected if the remote server is located using NETBIOS name. You may need to consult your network administrator to work around this issue. (Ref: 39087a)
- File hash matching criteria in the Application right is not supported for a file larger than 500MB. This is to make sure DirectAuthorize does not spend too much CPU and memory resources to calculate the file hash. User trying to import a file with the size larger than 500MB will see an empty value for the file hash field. (Ref: 56778a)
- For a small set of applications, enabled matching criterion: “Product Name”, “Product version”, “Company”, “File Version” or “File Description” of a Windows Application Right may fail to match after upgrading agent under the following conditions: Any value for the enabled matching criteria is defined by either import from a process or file * The matching criteria is defined by 5.1.3 or 5.2.0 DirectManage Access Manager since the number of affected application is expected to be relatively low, proactively updating the defined matching criteria of Windows Application Right is not necessary. (Ref: 60053a)
- Smart card users can continue to use their own smart card to logon, but there will be no Server Suite MFA features applied to smart card users. (Ref: CS-41539)

Compatibility with 3rd Party Products

- MFA may be skipped when connecting through XenDesktop because the Citrix Credential Provider may be used instead of the Delinea Credential Provider. The workaround is to disable the Citrix Credential Provider through the Group Policy "Centrify Settings\Windows Settings\MFA Settings\Specify the credential providers to exclude from the logon screen." (Ref: CS-46744)
- VirtualDesktop is not compatible with Server Suite Agent for Windows. Users should use the Delinea system tray applet to create virtual desktop instead. (Ref: 44641b)
- Attempting to launch SCOM Operation Console on privileged desktops will fail if there is an existing instance on other desktops and a new SCOM Operation Console will be started on the desktop with the existing instance. The workaround is to close all existing instances before starting a new SCOM Operation Console. (Ref: CS-43790)
- The startup path for “SharePoint 2010 Management Shell” and “Exchange Management Shell” may set to C:\Windows instead of user home directory if it is launched via RunAsRole.exe or from a desktop with elevated privilege. (Ref: 38814b, 46943b)
- On a desktop with elevated privileges, if you install McAfee Security Scan products and click “View Readme”, the Readme.html is shown on the default desktop. Similar issues may happen with other third party programs. The alternate way to view the Readme.html on the desktop of a managed computer

is to open the Readme.html file directly. (Ref: 34642a)

- Attempting to enable Kerberos authentication for Oracle databases will fail. This issue is being brought to the attention of Oracle Support for a resolution in upcoming releases. (Ref: 33835b)
- The Microsoft Snipping Tool utility has a bug that prevents it from running on a desktop with elevated privileges. (Ref: 31931a)
- Some applications do not use the process token to check the group membership. They check the user's group membership on its own. Therefore, any Windows rights configured to use a privileged group will not take effect in these applications. The workaround is to use a privileged user account instead of a privileged group. Here is the list of known application with this issue:

  1. vCenter Server 5.1
  2. SQL Server
  3. Exchange 2010 or above
  4. SCOM 2007

  (Ref: 45318a, 45218a, 43779a, 38016a)
- Privilege elevation using Windows Rights for Internet Explorer (IE) 7 is not supported. (Ref: 33425a)
- Privilege elevation using Windows rights for "Remote Desktop" is not supported. (Ref: 45222b)
- Privilege elevation using Windows rights for taskmgr.exe, explorer.exe, and cmd.exe are not recommended. A user granted privileges with Windows rights is implicitly granted to run any executable under the same privilege. (Ref: 45861a, 40525a)
- Users may notice an error and cannot install ActivClient after installing Server Suite Agent for Windows. During the installation of ActivClient, it attempts to change the local security setting. However, there is a known issue for Server Suite Agent for Windows of blocking the local security setting (Ref: 63609b). Therefore, users may not be able to install ActivClient successfully after installing Server Suite Agent for Windows. We suggest installing ActivClient before installing Server Suite Agent for Windows. If Server Suite Agent for Windows has been installed, please uninstall it and follow the installation sequence suggested. This issue happens on Windows 8.1 and Windows 2012 R2 only. (Ref: 76016b)
- McAfee Virus scan may block the Server Suite Agent for Windows from registering the LSA packages while joining the system to a zone. The zone join operation now detects the same and shows a warning to the user. (Ref: CS-48893)

Application Manager

- Application Manager does not support Server Core edition of Windows. (Ref: CS-40656)
- Application Manager may not be able to generate Audit Trail event for the uninstall, change or repair operations which require reboot. (Ref: CS-45641)

Network Manager

- Network Manager does not support Server Core edition of Windows. (Ref: CS-42675)

Endpoint Enrollment

- When a Windows machine is enrolled by a user as a personal device and subsequently that user is disabled, after upgrading the product, there is no way to let another user to enroll a personal device for that machine. The workaround is to remove the service "Identity Services Platform" in Agent Configuration and add that service again. (Ref: CS-44514)

Server Suite Agent for Windows

- Auditing status is incorrectly displayed on Authorization Center and the desktop notification message when the following Group Policies are enabled:
  - Audited user list
  - Non-audited user list

  (Ref: CS-46321)
- Server Suite Agent for Windows installation may prematurely end on systems that have Citrix Virtual Delivery Agent version 7.9 or higher installed. Please refer to the Delinea Knowledge Base for possible workarounds to deploy Server Suite Agent for Windows on systems affected by this issue. (Ref: CS-46288)

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

For the list of the supported platforms by this release, refer to the "Supported Platforms" section in the Server Suite release notes.

For the platforms to be removed support in coming releases, refer to the "Notice of Termination Support" section in the Server Suite release notes.

About Server Suite Agent for Windows

The Server Suite Agent for Windows package contains software to support auditing, access control, and privilege management on Windows computers. Audit and Access features must be installed together but their services can be enabled separately on the Windows computers you want to manage.

For auditing, the Server Suite Agent for Windows requires the Auditing & Monitoring Service feature set, which is available in Server Suite. Auditing & Monitoring Service enables detailed auditing of user activity on a wide range of UNIX, Linux and Windows computers. With Auditing & Monitoring Service, you can perform immediate, in-depth troubleshooting by replaying user activity that may have contributed to system failures, spot suspicious activity by monitoring current user sessions, and improve regulatory compliance and accountability by capturing and storing detailed information about the applications used and the commands executed. If you enable auditing, the Server Suite Agent for Windows records user activity on the Windows computer when it is installed.

For access control and privilege management, the Server Suite Agent for Windows requires the Authentication Service and Privilege Elevation Service feature sets, which are available in Server Suite. With Authentication Service and Privilege Elevation Service, you can configure and manage role-based access controls for Windows servers. The Server Suite Agent for Windows extends the access control and privilege management features available for Linux and UNIX computers, so that you can use a single console to manage multiple platforms. You can deploy the Server Suite Agent for Windows in a Windows-only environment or as part of a mixed environment that includes Windows, Linux, and UNIX computers.

The Server Suite Agent for Windows provides both privilege elevation and auditing functionalities, and for more information about the auditing feature, refer to the Delinea Auditing & Monitoring Service Release Notes for more detailed information.

You can obtain information about previous releases from the Delinea Support Portal, in the Documentation & Application Notes page.

Delinea software is protected by U.S. Patents 7,591,005; 8,024,360; 8,321,523; 9,015,103; 9,112,846; 9,197,670; 9,378,391 and 9,442,962. (Ref: CS-44575)

Feature Changes

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement

Security Fixes

General Changes

Fixed Issues

Fixed Issues in the 2022 Component Update

We have fixed the memory allocation issues related to Microsoft KB: KB5014697 (Win 11) / KB5014692 (Win10) / KB5014699 (Win2019) / KB5014702 (Win2016) KB updates.

Known Issues

Installation and Uninstallation

- Upgrading from the beta build to this version may result in offline MFA mode if there are multiple authentication servers registered in your AD forest. To resolve this, uninstall the beta build first and then install this new version. (Ref: CS-41915)
- Upgrading Windows while the Agent is installed will result in a failure of the Windows upgrade. The workaround is to uninstall the agent before performing the upgrade or perform a fresh Windows install without keeping existing applications and settings. (Ref: CS-42200)
- Currently the MFA login feature is not supported on Windows Server 2016 "Server Core" systems. This feature component will not be installed on Windows Server 2016 "Server Core" systems. (Ref: CS-42192, CS-42527)

- The Delinea Common Component should be the last Delinea Server Suite component uninstalled. If the component is uninstalled before other component, it must be reinstalled by the uninstall process to complete its task. (Ref: 36226a)
- If you intend to install the software on the desktop with elevated privilege, you should not check the "Run with UAC restrictions" option when creating the desktop. (Ref: 39725b)
- When you double-click on the Server Suite Agent for Windows msi and select the "repair" option, the existing files are replaced irrespective of their version number, even when they are identical. As a result, a prompt to restart the system is displayed as files that were in use were replaced. However, if you use the Easy Installer to do the repair and a file on the disk has the same version as the file that is part of the installer package, the installed file will not be replaced. Therefore, there will not be any prompt to restart the system. (Ref: 26561a)
- When the Server Suite Agent for Windows is either installed or uninstalled and the prompt for a machine restart is deferred using the "restart later" option or ignored, other components of DirectManage may display errors due to an incomplete installation. A restart is mandatory if requested after install or uninstall operation. (Ref: 36307a)
- Users may notice a few "Side by side" configuration errors in the Event Viewer after installing the Server Suite Agent for Windows, if Microsoft KB945140 related components have been installed on the local machine previously. These errors will go away after you restart the computer and have no functional effect. (Ref: 35302a)
- If you uninstall the Server Suite Agent for Windows while the DirectAudit Agent Control Panel is open, files needed by the uninstall process may be blocked. You should close the DirectAudit Agent Control Panel for a successful conclusion to the uninstall process. (Ref: 25753a)
- If you have installed the Access feature of Server Suite Agent for Windows from Server Suite 2013 and are trying to upgrade the component to the latest version, you may see the following error during the installation process, "Service 'DirectAuthorize Agent' could not be installed. Verify that you have sufficient privileges to install system services." If you see this error message, it typically indicates that the existing service is taking longer time to stop and hence the new service is not getting installed. When you see this error, wait for some time (typically 30 seconds) and click on Retry button on the error message box. (Ref: 47270a)
- Server Suite Agent for Windows and its installer are built on .NET. Therefore, .NET is always installed as a pre-requisite before the agent is installed. If .NET is removed from the system later, Server Suite Agent for Windows will not run properly. User will also experience problem when trying to remove Server Suite Agent for Windows from the system. To properly uninstall Server Suite Agent for Windows, please make sure Server Suite Agent for Windows is uninstalled before .NET. (Ref: 39051a)
- The list of rescue users is stored in different places in Suite 2013.3 (or previous releases) and Suite 2014 and this list is not automatically migrated to its new location when upgrading from Suite 2013.3 or a previous release to Suite 2014. Because of this, it's highly recommended that Server Suite Agent for Windows should not be upgraded in disconnected mode (i.e. when the system cannot connect to the Active Directory). If a system is upgraded in disconnected mode, the list of rescue users will be lost and only local administrators will be able to login to the system after reboot. (Ref: 57622a)
- If you install Access feature of Server Suite Agent for Windows without installing the Audit feature, the registry key value for HKEY_LOCAL_MACHINE\SOFTWARE\Centrify\AuditTrail\AuditTrailTargets is set to zero as expected, which means the audit trail is not sent to DirectAudit Audit Store database. However, if you try to change the installed features list of Server Suite Agent for Windows and add the Audit feature later, the change process does not automatically set the AuditTrailTargets value to the expected new value of 1, which means to send audit trail data to DirectAudit Audit Store database. This is a known issue and workaround is to set this value manually to 1 after the installer finishes the process of adding new feature. (Ref: 59353b)
- If you have installed the Access feature of Server Suite Agent for Windows from earlier version and then upgraded the component to the latest version while the Agent for Windows is not currently connected to any Active Directory domain controller, only users who have been assigned a role with rescue rights will be able to log on to the computer until the connection to Active Directory is restored. (Ref: 58858b)

Configuration

- In a cross-forest environment, forest A user cannot enroll a device joined to forest B when forest A does not have a connector. (Ref: CS-44805)
- When a machine that has MFA for Windows login enabled is reconfigured to connect to a different forest, the previous setting for the authentication server may no longer be valid. However, if there are Group Policy login settings applied to the machine in the new forest, the new settings will be enabled when the Group Policy Editor refreshes. (Ref: CS-41928)
- In Windows 2016 and Win10, during the login process, selecting SMS or using other mechanisms like Security Question/Phone call/Password/Email/Mobile for MFA and clicking the "Commit" button will be intermittently unresponsive. (Ref: CS-41699)
- It can take a long time for users in offline mode to be re-prompted for their passcode.

In the event that the Agent cannot connect to the Delinea Authentication Server, and a user is required to enter an offline passcode, it can take up to several minutes for the agent to re-prompt for the passcode if the user enters it incorrectly. If the user tries to cancel login by pressing "back" or by switching the user, the login screen may become unresponsive. This time lag between an incorrect passcode and the re-prompt can also occur when a user incorrectly enters their offline passcode for privilege elevation. (Ref: CS-41302)

- Administrator should always leave the zone before joining the computer to a different domain. Otherwise, DirectAuthorize may not function correctly after the computer is joined to a different domain. (Ref: 54278b)
- In some large environment with multiple domain controllers, it may take up to one minute for the new zone setting in Server Suite Agent Configuration to take effect. (Ref: 58128b)
- If one of the Global Catalog servers is unavailable, user may not be able to configure the zone for Server Suite Agent for Windows. (Ref: 58621b)
- Microsoft normally automatically distributes and installs root certificates to the Windows system from trusted Certificate Authorities (CA) and users are seamlessly able to use a secure connection by trusting a certificate chain issued from the trusted CA. However, this mechanism may fail if the system is in a disconnected environment where access to Windows Update is blocked or this feature of automatic root certificate installation is disabled. Without updates on the certificate trust list (CTL), the default CTLs on the system may not be adequate for secure connections of Delinea multi-factor authentication especially for older versions of Windows. To ensure the success of Delinea multi-factor authentication, user may need manually distribute and install the latest CTLs and the required root certificate to systems in a disconnected environment. See Delinea KB-6724 for further information. (Ref: CS-39703)

Environment

- On Windows 10 and Win2K16 machines with Delinea Privilege Elevation Service, following will occur (Ref: CS-43883):

• Pop up an error dialog several seconds after clicking "Open file location" in the context menu of a shortcut on the start menu. Explorer windows will display correctly.

• No responses to the following actions

• Clicking "Open file location" in the context menu of a shortcut on desktop

• Clicking "Open file location" in the context menu of a shortcut on the Delinea Start menu in the Privileged Desktop

• Slow response to "OK", "Cancel" in the shortcut property page after "Open file location" in the general tab is clicked. The dialog will close after several seconds.

- On some Windows 10 machines, the smart card login option may not be displayed if another credential method has been recently used. To display the smart card login option, remove and insert a smart card into the reader. This will cause the login screen to reload and will display the smart card login option. (Ref: CS-41282)
- Server Suite Agent for Windows requires you to patch to at least build 10.0.14393 on Windows 10 and Windows Server 2016 to use MFA features. (Ref: CS-41387)
- Selective two-way external trusts are not supported. Both Windows machines and Server Suite zones are required to be in the same forest or different forests with a two-way forest trust established. (Ref: 40713b, 44644b, 44647b, 44657b, 40643b, 40650b, 45341b, 45372b)
- Environment with no Global Catalog is not supported. (Ref: 46577a)
- DirectAuthorize for Windows requires machine time to be synchronized with domain controller. VMware virtual machine has a known issue that its time may not be synchronized with domain controller. This problem occurs more often on an overloaded virtual machine host. If the system clocks on the local Windows computer and the domain controller are not synchronized, DirectAuthorize for Windows does not allow any domain users to login. You can try the following KB from VMware to fix the time synchronization issue. http://kb.vmware.com/selfservice/microsites/search.do?language=en_US&cmd=displayKC&externalId=1189 (Ref: 47795b)

RunAsRole

- If you use the “RunAsRole.exe /wait” command to run a Python script, the input/output cannot be redirected for versions of Python below 3.0.0. (Ref: 45061a)
- Run As Role menu is not available on the start screen in Windows 8 or Windows 2012 or later because Microsoft doesn’t support any custom context menu on the start screen. User has to go to the Windows desktop in order to launch an application using Run As Role context menu. (Ref: 35487a)

- On Windows 8, Windows 8.1, Windows Server 2012 and Windows Server 2012 R2, use "Run as role" with Local Administrators group privilege on Control Panel does not have sufficient permission to add printers if the printer drivers are not pre-installed on the computer. The workaround is to define a role run as a user with Local Administrator privilege or with a group as a member of Local Administrators group. (Ref: 68826a)
- The "Run as role" for Windows Media Player is not recommended. Please use privilege desktop instead. (Ref: 55615a)
- When running "RunAsRole.exe /wait sc.exe" with no argument provided to sc.exe, sc.exe will prompt

  Would you like to see help for the QUERY and QUERYEX commands? [y | n]:

  Typing 'y' or 'n' doesn't do anything because the input cannot be successfully redirected to sc.exe. (Ref: 47016b)
- It is not recommended to change zone via Run As Role since the role that is in use may no longer be available once after leaving from the previous zone during the change zone process. (Ref: 58043a)

Desktop with Elevated Privileges

- In desktop with elevated privilege a mouse left click does not work for SysTray Icons that involve opening the WinRT(or new Window) UI. The Systray icons affect are Time, Volume Control, or any third party icons on Windows 10/2016. (Ref: CS-39454)
- Server Manager cannot be started on multiple desktops at the same time. The bug exists on Windows 2012R2, 2016. (Ref: CS-42060)
- On a desktop with elevated privileges on Windows 8, 10 & 2016, the search for files or folders will be intermittently disabled from the Start menu ("Start" menu > "Search" > "For Files or Folders..."). (Ref: CS-42066)
- On a desktop with elevated privileges, if you open the Task Manager and select "*File > New* Task" to run an application without selecting the "Create this task with administrative privileges" option, the application will be launched on the default desktop. This issue occurs when User Account Control (UAC) is enabled. (Ref: 32169a)
- If the sAMAccountName attribute of an Active Directory account is changed while the old account name is still cached on the computer, you may see the following error message when creating a new desktop or using "Run as role" with a right configured to run as the modified user account:

  "Failed to open new desktop. Right xxx references bad user account."

  The workaround is to restart the computer. (Ref: 35124a)
- On a desktop with elevated privileges, if you use "Control Panel > Programs > Programs and Features" to uninstall a program, you may see the following warning message and cannot uninstall the software.

  "The system administrator has set policies to prevent this installation."

  This issue happens when User Account Control (UAC) is enabled and when "Run with UAC restrictions" is selected when creating the new desktop. (Ref: 33384a)
- When you open the Start menu "Help and Support" item on a desktop with elevated privileges, the Windows Help and Support is launched on the default desktop. Switch to the default desktop to view the information. (Ref: 32147a)
- If you shut down, restart, or log off from a desktop with elevated privileges, all running applications are terminated forcibly without being prompted to save any open documents. (Ref: 40749a)
- You cannot launch Windows Security Options using "Start menu -> Windows Security" on a privilege desktop with elevated privileges when using a remote desktop connection. You must switch back to the default desktop to continue. (Ref: 45995b)
- Installation of IE9 on desktops with elevated privileges may cause the privileged desktop to become unusable. Use "RunAsRole" for installation of IE9 instead. (Ref: 44930a)
- You cannot use the Start menu option "Switch User" while you are using a role-based, privileged desktop. To use the "Switch User" shortcut, change from the privileged desktop to your default Windows desktop. From the default desktop, you can then select Start > Switch User to log on as a different user. (Ref: 39011b)
- On a DirectAuthorize desktop using a role with local administrator privilege, the Stand By option in the shutdown menu does not work. This is a known issue and will be addressed in future release. (Ref: 58280a)
- VMWare registers to run VMwareUser.exe on the guest operating system to enable user to copy and paste text between the guest and managed host

operating systems. Creating multiple desktops with different user accounts causes multiple VMwareUser.exe are run in different user accounts in the same logon session. VMwareUSer.exe cannot support this scenario and therefore an error message is displayed on the default desktop which blocks all the UI operation on the new desktop. To workaround this problem, user can disable the VMWare user program on the guest machine by deleting the registry value name "VMware User Process" from HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Run. (Ref: 49268a)

- On a privileged desktop on Windows 8, Windows 8.1, Windows 2012 and Windows 2012 R2, you may not be able to access the VMware shared folder. (Ref: 40686c)
- Windows logo key keyboard shortcuts are not supported on privileged desktop. Depends on the key and operation system, the shortcut could either have no effect or its effect is applied to the default desktop instead. (Ref: 47588b)
- A Start menu on privileged desktop on Windows 8, Windows 8.1, Windows 2012 and Windows 2012 R2, to make up for a limitation of Windows 8, Windows 8.1, Windows 2012 and Windows 2012 R2. In addition, navigating to a Modern Start screen to use Modern-style apps from a privileged desktop is not possible from either the charm bar or using a Windows. Note: you must switch back to the default desktop in order to go to Modern Start screen. (Ref: 41245c)
- The Challenge Pass-Through Duration setting is currently not supported for Server Suite Windows multi-factor authentication. The Challenge Pass-Through Duration setting does not require a user, who has successfully met a multi-factor authentication challenge, to re-authenticate through mfa to use an mfa-required right or role if that user chooses the same challenge mechanism when prompted within the duration specified in the setting. (Ref: CS-39432)

Roles and Rights

- No 'Require multi-factor authentication' system right for the predefined 'Windows Login' role. To define this system right for MFA, use the pre-defined Require MFA for logon role, or create a new custom role. (Ref: CS-40888)
- Windows Network Access rights do not take effect on a Linux or UNIX machines. If you select a role to start a program or create a desktop that contains a Network Access right, you can only use that role to access Windows computers. The Windows computers you access over the network must be joined to a zone that honors the selected role. The selected role cannot be used to access any Linux or UNIX server computers on the network. (Ref: 32980a)
- To elevate privileges to the "Run as" account specified in a Windows right, the "run as" account must have local logon rights. If you have explicitly disallowed this right, you may receive an error such as "the user has not been granted the requested logon type at this computer" when attempting to use the right. (Ref: 34266a)
- If your computer network is spread out geographically, there may be failures in NETBIOS name translation. If a NETBIOS name is used, Active Directory attempts to resolve the NETBIOS name based on the domain controller that the user belongs to, which in a multi-segment network might fail. Therefore, Network Access rights might not work as expected if the remote server is located using NETBIOS name. You may need to consult your network administrator to work around this issue. (Ref: 39087a)
- File hash matching criteria in the Application right is not supported for a file larger than 500MB. This is to make sure DirectAuthorize does not spend too much CPU and memory resources to calculate the file hash. User trying to import a file with the size larger than 500MB will see an empty value for the file hash field. (Ref: 56778a)
- For a small set of applications, enabled matching criterion: "Product Name", "Product version", "Company", "File Version" or "File Description" of a Windows Application Right may fail to match after upgrading agent under the following conditions: Any value for the enabled matching criteria is defined by either import from a process or file * The matching criteria is defined by 5.1.3 or 5.2.0 DirectManage Access Manager since the number of affected application is expected to be relatively low, proactively updating the defined matching criteria of Windows Application Right is not necessary. (Ref: 60053a)
- Smart card users can continue to use their own smart card to logon, but there will be no Server Suite MFA features applied to smart card users. (Ref: CS-41539)

Compatibility with 3rd Party Products

- MFA may be skipped when connecting through XenDesktop because the Citrix Credential Provider may be used instead of the Delinea Credential Provider. The workaround is to disable the Citrix Credential Provider through the Group Policy "Centrify Settings\Windows Settings\MFA Settings\Specify the credential providers to exclude from the logon screen." (Ref: CS-46744)
- VirtualDesktop is not compatible with Server Suite Agent for Windows. Users should use the Delinea system tray applet to create virtual desktop instead. (Ref: 44641b)
- Attempting to launch SCOM Operation Console on privileged desktops will fail if there is an existing instance on other desktops and a new SCOM

Operation Console will be started on the desktop with the existing instance. The workaround is to close all existing instances before starting a new SCOM Operation Console. (Ref: CS-43790)

- The startup path for "SharePoint 2010 Management Shell" and "Exchange Management Shell" may set to C:\Windows instead of user home directory if it is launched via RunAsRole.exe or from a desktop with elevated privilege. (Ref: 38814b, 46943b)
- On a desktop with elevated privileges, if you install McAfee Security Scan products and click "View Readme", the Readme.html is shown on the default desktop. Similar issues may happen with other third party programs. The alternate way to view the Readme.html on the desktop of a managed computer is to open the Readme.html file directly. (Ref: 34642a)
- Attempting to enable Kerberos authentication for Oracle databases will fail. This issue is being brought to the attention of Oracle Support for a resolution in upcoming releases. (Ref: 33835b)
- The Microsoft Snipping Tool utility has a bug that prevents it from running on a desktop with elevated privileges. (Ref: 31931a)
- Some applications do not use the process token to check the group membership. They check the user's group membership on its own. Therefore, any Windows rights configured to use a privileged group will not take effect in these applications. The workaround is to use a privileged user account instead of a privileged group. Here is the list of known application with this issue:

  1. vCenter Server 5.1
  2. SQL Server
  3. Exchange 2010 or above
  4. SCOM 2007

  (Ref: 45318a, 45218a, 43779a, 38016a)
- Privilege elevation using Windows Rights for Internet Explorer (IE) 7 is not supported. (Ref: 33425a)
- Privilege elevation using Windows rights for "Remote Desktop" is not supported. (Ref: 45222b)
- Privilege elevation using Windows rights for taskmgr.exe, explorer.exe, and cmd.exe are not recommended. A user granted privileges with Windows rights is implicitly granted to run any executable under the same privilege. (Ref: 45861a, 40525a)
- Users may notice an error and cannot install ActivClient after installing Server Suite Agent for Windows. During the installation of ActivClient, it attempts to change the local security setting. However, there is a known issue for Server Suite Agent for Windows of blocking the local security setting (Ref: 63609b). Therefore, users may not be able to install ActivClient successfully after installing Server Suite Agent for Windows. We suggest installing ActivClient before installing Server Suite Agent for Windows. If Server Suite Agent for Windows has been installed, please uninstall it and follow the installation sequence suggested. This issue happens on Windows 8.1 and Windows 2012 R2 only. (Ref: 76016b)
- McAfee Virus scan may block the Server Suite Agent for Windows from registering the LSA packages while joining the system to a zone. The zone join operation now detects the same and shows a warning to the user. (Ref: CS-48893)

Application Manager

- Application Manager does not support Server Core edition of Windows. (Ref: CS-40656)
- Application Manager may not be able to generate Audit Trail event for the uninstall, change or repair operations which require reboot. (Ref: CS-45641)

Network Manager

- Network Manager does not support Server Core edition of Windows. (Ref: CS-42675)

Endpoint Enrollment

- When a Windows machine is enrolled by a user as a personal device and subsequently that user is disabled, after upgrading the product, there is no way to let another user to enroll a personal device for that machine. The workaround is to remove the service "Identity Services Platform" in Agent Configuration and add that service again. (Ref: CS-44514)

Server Suite Agent for Windows

- Auditing status is incorrectly displayed on Authorization Center and the desktop notification message when the following Group Policies are enabled:
  - Audited user list

- Non-audited user list

(Ref: CS-46321)

- Server Suite Agent for Windows installation may prematurely end on systems that have Citrix Virtual Delivery Agent version 7.9 or higher installed. Please refer to the Delinea Knowledge Base for possible workarounds to deploy Server Suite Agent for Windows on systems affected by this issue. (Ref: CS-46288)

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

- 2022.1 Auditing Release Notes
- 2022 Auditing Release Notes

About Server Suite Auditing & Monitoring Service

Delinea Server Suite is a product category that includes the following product offerings:

- Privileged Access Service
- Authentication Service
- Privilege Elevation Service
- Auditing & Monitoring Service

The DirectControl Agent provides services for the Authentication Service and Privilege Elevation Service contained in the CentrifyDC packages. The DirectAudit Agent provides services for Auditing & Monitoring Service contained in the CentrifyDA packages.

The Auditing & Monitoring Service is a key component of Server Suite. It enables detailed auditing of user activity on a wide range of UNIX, Linux, and Windows computers. With this service, you can perform immediate, in-depth troubleshooting by replaying user activity that may have contributed to system failures, spot suspicious activity by monitoring current user sessions, improve regulatory compliance, and ensure accountability by capturing and storing detailed information about the applications used and the commands executed. If you enable auditing, the Server Suite Agent for Windows records user activity on the Windows computer when it is installed. Auditing & Monitoring Service supports auditing of many different UNIX, Linux, and Windows operating systems.

In Unix and Linux agents, DirectControl Agent is a pre-requisite for the Auditing & Monitoring service.

This release note updates information available in the DirectAudit Administrator's Guide and describes known issues. You can obtain information about previous releases from the Delinea Support Portal, in the Product Documentation page.

Feature Changes in Auditing & Monitoring Service 5.9.1 (Release 2022.1)

General

Compatibility

- With the Server Suite Agent for Windows version 19.6 and later, the Audit and Monitoring Service uses a different compression library to compress the video data being sent from the agent to the collector. As a result, this agent and all future versions of agents are *not* compatible with audit collector versions 18.11 or earlier.

  IMPORTANT: You will lose video data if you deploy the newer agents in an environment with 18.11 or older collectors.___ Audit trail events and indexed events lists are not affected in this situation.

Because of this incompatibility and risk of data loss, you MUST upgrade all of your collectors to the 19.6 or higher version BEFORE you upgrade the agents to Release 2021.1.

As a reminder, before you upgrade the collectors you must first upgrade the database schema. So, to summarize, here's the order in which you upgrade the audit components:

1. Upgrade the database.
2. Upgrade the collectors.
3. Upgrade the agents.

- The minimum DirectControl Agent for *NIX version required by this version of the service is 5.9.0 (Release 2022)

Audit Module for PowerShell

- A new '-Limit' parameter was added to the 'Audit Module for Powershell' command 'Get-CdaAuditEvent'. The '-Limit' parameter is used to specify the number of database entries to return in the results. The '-Limit' parameter is an optional parameter. If the parameter is not specified the command will return 65,536 entries which is the same number of entries this command returned before the change. (Ref:430373)

Audit Management Server

Audit Module for PowerShell

Audit Management Server

Known Issues

The following sections describe known issues, suggestions, and limitations associated with the Audit and Monitoring Service.

General

For the most up-to-date list of known issues, refer to the knowledge base articles in the Delinea Support Portal.

- Starting in Release 2016, only ADMX format for group policies will be installed and ADM format will no longer be provided. (Ref: CS-6821)
- Starting in Release 2016, Server Suite will no longer be adding new features to the DirectManage Audit SDK component. It is recommended that all existing users of this component start using the Audit Module for PowerShell component, which is the intended replacement of the SDK. (Ref: CS-6713)
- From Release 2017.1 onward, DirectAudit no longer supports Version 1 Audit Store databases. You will no longer be able to attach Version 1 databases to an existing DirectAudit installation. To view data from version 1.x databases, please install a DirectAudit Auditor Console 1.x and attach the database. (Ref: CS-41219)

Windows Install / Upgrade / Uninstall

- If a DirectManage Audit installation has been configured with multiple Audit Management Servers and some of the servers are running on an older version, the Audit Manager may not list these older servers because the new servers list supersedes the older ones. (Ref: CS-40818)
- When upgrading DirectAudit in Windows, you should use the autorun program to perform the upgrade. The autorun program automatically upgrades other Delinea components such as Delinea Licensing Report. If you upgrade DirectAudit components individually using the Microsoft Installer (msi) and then attempt to use the autorun program to uninstall all components, autorun will only be able to uninstall the Delinea Licensing Report that were upgraded to the latest version. You can remove any remaining components manually using the Add/Remove Programs and Features Control Panel. (Ref: 46293a)
- If you run setup.exe with all DirectAudit components selected for installation on a single computer, the operation is known as the "Easy Install." Although this is the default for new installations, using the "Easy Install" option requires you to have local administrator privileges.
- If you uninstall the collector component on a computer that is not joined to the domain, you will see the following messages during an uninstall operation:

The specified domain either does not exist or could not be contacted.

(Exception from HRESULT: 0x8007054B)

Despite the alert message, the collector is successfully uninstalled when you click OK.

Collector

- In the Collector Configuration wizard, if the account credentials you give for the SQL Server do not match an existing account on the SQL Server, and you have the rights to create SQL Server accounts, the credentials you give will be used to automatically create a new SQL Server account.

Audit Analyzer and Session Player

- Release 2017.3 has introduced a new version of dzdo and PAM authentication audit trail events. However, these events cannot be captured by older version of database/Collector or reported by older versions of DirectAudit Audit Analyzer console or FindSessions utility or PowerShell cmdlets. To rectify this issue, you need to upgrade the DirectAudit backend components (such as Audit Manager console, Audit Analyzer console, Collector, and Audit Store databases) to Release 2017.3 or later version. Contact Delinea support if you are unable to upgrade the DirectAudit backend components so that DirectAudit database patching scripts can be provided to you based on your current version. (Ref: CS-44654)
- When detaching and re-attaching an Audit Store database from an Audit Store, Delinea recommends refreshing the query results for all open queries in Audit Analyzer console prior to replaying a session from that database. Failure to do so may result into a database error. (Ref: CS-42125)
- If the active audit store database spans two SQL databases, the Audit Analyzer will show UNIX sessions as "Disconnected" until some data is received from those sessions. Once data has been received, the session state will change to "In Progress."
- If an audited Windows session is using multiple monitors in extended mode in DirectAudit 3.2.2 or earlier, it cannot be exported as WMV files. In DirectAudit 3.2.3 or later, it will be trimmed to 2048x2048 pixels before it is saved and can be exported as in WMV file in 2048x2048 resolution. (Ref: 27003a, 75163, CS-6450, CS-3265).
- When Server Suite Agent for Windows machine's system color depth is changed during an audited session, the playback of the session may not be displayed properly. (Ref: 36818c)

- Entering specific keywords in the “Application” Event list column will not filter based on the keywords as expected. For example, entering the search term "c" will locate the string "Windows Explorer". This is because application characteristics are stored in the database as a set of related attributes as follows: "Explorer.EXE | Microsoft® Windows® Operating System | Windows Explorer | Microsoft Corporation | 6.1.7600.16385" A match with any of the Windows Explorer attributes will yield “Windows Explorer". This issue will be addressed in an upcoming release. (Ref: 39645b)
- In Audit Analyzer, you can specify double-quote enclosed strings in the query that searches for “Unix Commands and Outputs” attribute. However, if a double-quote character is inside the double-quote enclosed string, the query result is undefined. (Ref: CS-39348)
- If a DirectAudit Installation is configured to not capture video data, parameters of the UNIX command are also not captured. Therefore, the query using "Parameters of Commands and Applications” as the criteria does not work under this configuration. This is a known issue and will be addressed in future release. (Ref: 55741b)
- If you open Audit Analyzer and right click on any child node of predefined queries such as "All, Grouped by User", "All, Grouped by Machine" or "All, Grouped by Audit Store" in the left pane, the context menu is displayed and it shows a menu item named "Properties". This context menu item, when clicked, does not open any dialog box because it is not a valid action for the selected child node. This menu item will be removed in the future release. (Ref: 48681b)
- By default, Audit Analyzer uses MSS2 codec to export audited sessions to a WMV (Windows Media Video) file. The MSS2 codec has a known issue which results in fuzzy video when an audited Windows session is exported as WMV file and opened in Windows Movie Maker 2012. From DirectAudit 3.2.0 onward, you can specify your own codec to export an audited session to a WMV file. Please refer to KB-4029 for additional information. (Ref: 56021a)

Audit Manager

- User and group criteria should not be combined in an Audit Role or it may result into inconsistent results, the workaround is for users to use two different audit roles (one for groups, another for users) if they want to mix users and groups in audit role assignment. (Ref: CS-38968)
- When creating an AuditRole with "ClientName" Audit Manager's Role Properties / Criteria will display an empty value rather than "ClientName = <IP address>" (Ref: CS-41803)
- If you assign DirectAudit permissions to a Domain Local group, which is not in the current domain in the Audit Manager Installation Property Security tab, and a user belonging to that group runs Audit Analyzer and tries to connect to the DirectAudit Installation, Audit Analyzer will display the warning “You do not have permission to connect to the SQL server.” A workaround is to grant permission to a Global or Universal group instead. (Ref: 25546c)

Server Suite DirectAudit Agent for

General

- Delinea recommends customers use the session auditing capability of DirectAudit to ensure the complete login session is audited vs. auditing individual commands. When the administrator configures Direct Audit to audit a specific command, Direct Audit moves the original command executable to a different location and replaces it by a symbolic link to the Direct Audit shell. It is possible for a user to find out the new location of the executable and runs that command directly to bypass auditing. Whereas the likelihood of this happening is very minute, Delinea recommends session auditing be turned on to avoid the chance of this happening.

- If a user is logged in to AIX and HP-UX via a GUI, for example Xmanager, a terminal opened in the GUI will not be audited. To workaround this issue, set the centrifyda.conf parameter 'dash.allinvoked' to true. (Ref: 66330, CS-5876)

- Obfuscation of session data has the following limitation: If the information is sent to stdout not as a whole, but piece by piece, the information will not be obfuscated. Example: A user wants to obfuscate a pattern "1234-5678". However, "1234-" is shown first and "5678" is shown 1 second later, this pattern will not be obfuscated. Since the stdout buffer in the audit shell is 4KB, the obfuscation string is at most 4KB long. Note: this applies to stdout only. (80462a)

- Auditing init during startup on UNIX is not possible. The init command used during the boot process should not be audited using per-command auditing. If you attempt to audit init, your operating system will not reboot properly.

- You cannot start a GUI session if you are logged in via an interactive session. Running startx or starting a GUI session from an interactive session results in the following message:

  X: user not authorized to run the X server, aborting.

  Workaround:

  - Run "sudo dpkg-reconfigure x11-common"

  - When you are prompted for users allowed to start the X server, choose "anybody" (the default is "console users only").

  The GUI session or X server should start normally. (Ref: 25036a)

- To audit the GUI terminal emulators, GUI login managers have to be fully reinitialized after auditing is enabled. On Linux, "init 3 && init 5" will start the reinitialization. (Stopping the X server only, or pressing ctrl+alt+backspace in Gnome, will not start the reinitialization.)
- When a local user and an Active Directory user use the same UNIX user name, the user name will default to the name of the Active Directory user. If the local user name is intended, setting the pam.allow.override parameter in /etc/centrifydc/centrifydc.conf will help. After this setting, the user name implies the Active Directory user; and <username>@localhost will imply the local user.

  DirectAudit 3.0 or later understands the "@localhost" syntax. DirectControl Agent will respond to <username>@localhost if the user name is set in pam.allow.override.

  If you upgrade from DirectAudit 2.0, disable DirectAudit so that the new DirectAudit mechanism for hooking shells can be installed: Run 'dacontrol –d -a' to disable auditing, then restart the upgrade.

  DirectAudit maintains a cache of user information for performance reasons. This cache interferes with Unix commands that manipulate the local user database (passwd file). These commands include useradd, userdel and usermod. From DirectAudit 3.2.0 onwards, DirectAudit will not access its local cache to fully support the following commands: useradd, userdel, adduser, usermod, mkuser, rmuser, chuser

  Please contact support if your operating system platform has other programs that directly access the local passwd file. (Ref: 56259a)
- If session auditing is enabled, all local user logins are processed by DirectAudit to determine whether the session should be audited. This may block login if domain controllers are not responsive and/or DirectControl Agent is not running. Two new parameters are introduced in /etc/centrifyda/centrifyda.conf:

  - user.ignore: specifies a list of local users that DirectAudit does not use Active Directory to determine audit level. By default, the list is /etc/centrifydc/user.ignore (the same one that DirectControl uses), which includes some important accounts like root, bin, daemon, etc.

  - user.ignore.audit.level - specifies the audit level for the local users specified in the user.ignore list. The supported values are 0 (audit if possible) and 1 (audit not requested/required). Default is 0 (audit if possible). Note that "audit required" is not a reasonable choice, as this user needs to login all the time; and "audit required" may block login if DirectAudit does not function correctly. (Ref: 55599a, 57946a, 56935a, 58251a)
- The /usr/share/centrifydc/bin/centrifyda script should be used to start/stop DirectAudit service in all *nix platforms. However, systemd is not fully supported in /usr/share/centrifydc/bin/centrifyda. For platforms that use systemd by default (such as SUSE Linux Enterprise 12/SUSE Linux Desktop 12), users need to set the environment variable SYSTEMD_NO_WRAP to 1 before calling the /usr/share/centrifydc/bin/centrifyda. Operations such as killing a daemon, running dad (DirectAudit daemon) directly, or running dastop command, could lead to issues in daemon managers in some *nix platforms. For example, SMF of Solaris, SRC of AIX and systemd of Fedora 20, may record incorrect running status of the daemon; and may fail to start daemon. (Ref: 57653a, 71211a)
- Disable auditing before upgrade

  If you upgrade from DirectAudit 2.0, please run "dacontrol -d -a" to disable DirectAudit before upgrade. Both the installer shell script, install-da.sh, and the native package manager will detect if auditing is enabled and abort if so.

  If you are using the native package manager to upgrade and youattempt to upgrade while auditing is enabled, you may find that,after the package manager aborts, the DirectAudit installation isshown as broken. This may be ignored. Simply disable auditing,upgrade and then re-enable auditing and the package will beshown as committed.

RedHat Linux

- Due to a limitation of some implementations of audispd (audit dispatcher daemon provided by the operating system), DirectAudit advanced monitoring feature may not work if “dacontrol –n/-m” was run multiple times and over the limit specified in the parameter max_restarts in /etc/audisp/audispd.conf (default 10). If you enable the DirectAudit Advanced monitoring feature and it does not generate the audit trail events as expected, you can run dainfo to check on the status of advanced monitoring feature. If the program /usr/share/centrifydc/bin/dadispatcher is not running, dainfo will show “DirectAudit advanced monitoring status” as “not running”. In this case, you need to restart the system audit daemon using the command “service auditd restart”. This will re-activate the advanced monitoring feature. (Ref: CS-41267)
- The characters ('%', '#', '>' and '$') are used by DirectAudit to recognize UNIX commands. They should not be used in role names and as part of trouble-tickets; otherwise they will be recognized as part of a UNIX command. (Ref: 51687a)
- DirectAudit advanced monitoring features may not work with early versions of RedHat 5 due to different system configurations. The earliest version that Delinea tested is RedHat 5.6. Please contact Delinea Support if you need support in versions earlier than RedHat 5.6. (Ref: CS-43042)
- The advanced monitoring feature in RedHat 5 version only supports selinux mode set to 'disabled' or 'permissive', 'enforcing' is not supported due to incompatible selinux policies. Moreover, advanced monitoring feature may not work with earlier versions of RedHat 5 releases due to different system configurations. Please contact Delinea support if you need support in versions earlier than RedHat 5.6. (Ref: CS-43024)

Debian Linux

- To install the Delinea DirectAudit package on a computer with the Debian operating environment, you must use the dpkg --install or dpkg -i option. You cannot use the dpkg --update or dpkg -u options to install or update the Delinea DirectAudit package. If you need to update the Delinea DirectAudit package, you need to first delete the old package using the dpkg --purge or dpkg -P option then install the new package with the dpkg --install or dpkg -i option.

  > **Note**: Do not use the dpkg --remove or dpkg -r command to remove Delinea DirectAudit. Using the --remove option prevents the DirectAudit configuration file, /etc/centrifyda/centrifyda.conf, from being created properly when you reinstall the package.

Solaris

- Delinea recommends that you install the appropriate recommended patch bundles for the version of Sun Solaris you are using before installing Delinea DirectAudit.

  The patch installation will skip any individual patches that don't apply to your system, and you can use Sun's patch management system to ensure your computers get the latest security fixes.

  To help you identify any required patches for your environment, Delinea supplies the pca patch checker in all Solaris Delinea Server Suite packages. Install.sh will prompt you to check the patch level of your environment during installation.

  To check for Sun recommended patches with the pca patch checker you should have the wget package installed. This package may be obtained from:

  http://ftp.wayne.edu/sun_freeware/

  And source code may be obtained from:

  http://www.gnu.org/software/wget/

  For more information about downloading and installing patches, see the Sun Web site.

  The minimum patches required for Delinea DirectAudit are provided below for reference purposes. In some cases these patches may be obsoleted or incorporated into other patches, so the patch numbers on your Solaris machines may be different. The authoritative source on patch compatibility is Sun; their Web site will allow you to follow patch histories to ensure any later patches you are using are compatible with the ones required by DirectAudit.

  For Solaris 10: 119254-65 120011-14 127127-11 138263-03

- Please contact technical support if you are using sparse zone(s) and like to do one of the following:
  - Change session auditing status from disabled to enabled during upgrade.
  - Enable session auditing in a global zone and want to disable session auditing in sparse zone(s) when using the same global zone. (Ref: 76572, 80616b)

- The following commands, located in /usr/bin, might be implemented as ksh programs or scripts:

  alias bg cd

  command fc fg

  getopts hash jobs

  kill read test

  type ulimit umask

  unalias wait

  To identify commands implemented as ksh scripts, run the following script:

  #!/bin/ksh -p

  cmd=`basename $0`

```
$cmd "$@"
```

The commands that are implemented internally by ksh should not be audited.

- On a system using SMF (Service Management Facility), such as Solaris 10, the DirectAudit daemon might not start up after an upgrade from DirectAudit 1.x. This does not affect a fresh installation. To bring the daemon up, run these commands:
  - svcadm disable centrifyda
  - svcadm enable centrifyda
  - Run 'svcs' and find 'centrifyda' to confirm the daemon is online.

AIX

- Some versions of AIX sshd do not function reliably with Delinea products. When possible, Delinea recommends using sshd included in Delinea openSSH on AIX platforms. (Ref: CS-7098)
- Local AIX users cannot be audited when they log in via built-in ssh, due to a change in AIX 7.0 ML1. Customers are advised to install Delinea OpenSSH if auditing of ssh login by local users is required (Ref: 33299a).
- Change in AIX root user behavior: By default, all releases starting with Release 2014 (DirectAudit 3.2.0) DO NOT modify the root stanza in AIX for new installations. One side effect is that root user login WILL NOT be audited. If your environment requires session auditing of root user login, you need to do the followings:
  a. Set up a DirectAuthorize role that has the audit level of "audit required" or "audit if possible"; and assign this role to root.
  b. Set the parameter adclient.autoedit.user.root to TRUE in /etc/centrifydc/centrifydc.conf.
  c. If DirectAudit session auditing is not enabled, enable DirectAudit session auditing using the command "dacontrol -e".
  d. Restart adclient (Ref: 56239a, 56604a)
- For AIX customers who upgrade from prior versions of Release 2014 (DirectAudit 3.2.0), there is NO change in behavior. The parameter adclient.autoedit.user.root is set to true in /etc/centrifydc/centrifydc.conf. The root user will still be audited. (Ref: 56235)

HPUX

You can install this package by copying it to a HP-UX computer and running install.sh, the installer, or by running the following commands, where <release> is the version of the DirectAudit package you are installing:

```
gzip -d centrifyda-<release>-hp11.31-ia64.depot.gz

swinstall -s /path/centrifyda-<release>-hp11.31-ia64.depot \

-x allow_incompatible=true
```

- You must specify the full path to the Delinea DirectAudit depot file and set the allow_incompatible option to true to install successfully.
- The installation script checks your environment for the minimum patch levels required. If you have more recent patches installed, however, you may see an error message. To install, re-run the installation command with the following additional command line option:

  ```
  -x enforce_scripts=false
  ```

Database

- When adding an Audit Store database to a SQL Server Availability Group with the multi subnet failover feature, the SQL Server that hosts the management database must be SQL Server 2012 or above. In addition, when upgrading an existing DirectAudit installation to use the SQL Server Availability Group feature, Delinea recommends upgrading Collectors, Audit Management Server service, Audit Manager consoles and Audit Analyzer consoles to the latest version to benefit from this feature. (Ref: CS-39872)
- In previous versions of DirectAudit, it was possible to specify the location of the database file. In DirectAudit 2.0.0 and later this capability is not provided in the Audit Store Database Wizard. However, you can still specify the full text file location, database file location, or transaction log file location by choosing "View SQL Scripts" and modifying the relevant database location manually in the script.
- If the default memory setting for SQL Server is more than the actual memory in the system a memory error may occur. For more information see:

http://social.msdn.microsoft.com/Forums/en-US/sqldatabaseengine/thread/74a94f06-adf5-4059-bb92-57a99def37bd/

SQL Server 2008 R2 full text search categorizes certain words as stop words by default and ignores them for searches. Some stop words are common UNIX commands such as like, which, do, and while. For more details about stop words and how to configure, please refer to http://technet.microsoft.com/en-us/library/ms142551.aspx

- The collector monitors the active Audit Store database to check if it is running low on disk space. If an active Audit Store the database is on a disk with volume mount point, the collector may give a false alarm. In such cases, it is recommended to disable the detection by setting the following registry key with the type of DWORD to 0 on all your collector machines. (Ref: 53389a)

  HKLM\Software\Centrify\DirectAudit\Collector\AuditStoreDiskSpaceLowThreshold

- Collector only detects AuditStore disk space low against a configurable threshold if the SQL Server version is 2008 R2 SP1 (10.50.2500.0) and above. The threshold can be configured at Collector machine Registry: HKLM\Software\Centrify\DirectAudit\Collector\AuditStoreDiskSpaceLowThreshold DWORD in MB, not configured, default to 1024 MB. If free disk space is less than the threshold, Collector state is changed to "AuditStore database disk space is low", and stops accepting audit data from Agent(s).

Audit Management Server

- To configure the audit management server to point to an installation, the user who is running the Audit Management Server Configuration Wizard must have the "Manage SQL Logins" permission on the management database of the installation. For example, if you are configuring an audit management server in an external forest with a one-way trust, be sure that the installation supports Windows and SQL Server authentication and the account you are using is from the internal forest and has the "Manage SQL Logins" permission on the management database. (Ref: 46989a)

FindSession Tools

- For per-command auditing of dzdo command, when a ticket is entered, the role and ticket are associated with the audited session. For such sessions, the FindSessions tool's export of type UnixCommand, UnixInput, or UnixInputOutput based on the role and/or ticket criteria will have the exported command, STDIN, or STDIN and STDOUT marked with role and ticket. When per session auditing is enabled, the exported data will not have role and ticket information. (Ref: 53936a)

- When per-command auditing is enabled for dzdo command, and role and trouble ticket capturing is also configured, FindSessions.exe run with /export=UnixCommand option will not show the role and trouble ticket information in the exported file for the dzdo command itself, if the dzdo command executed is "dzdo su –" or "dzdo –i". However, all the command executed within that dzdo session will have correct role and trouble ticket information. (Ref: 51787a)

Server Suite Agent for Windows

- When a user disconnects and then later reconnects to an existing user session from a switch user operation, a successful logon audit trail message will not be logged after the user has reconnected to the session though authentication. This does not apply when the user is performing lock and unlock operations or the logon method is different from the previous login (remote vs. console logon). (Ref: CS-41453)

- In the DirectAudit Agent for Windows control panel, the setting "Maximum size of the offline data file" indicates the minimum amount of disk space (in percentage) that must be available/free in the spool volume in order to continue auditing users (especially when the DirectAudit Agent cannot send audit data to collector). The DirectAudit Agent makes its best attempt to pause auditing when the specified amount of disk space is no longer available and in certain cases may continue to write to spool volume for a few minutes before eventually pausing the auditing activity. (78072, CS-6718)

- The optional video capture feature requires both the Collector and the DirectAudit Agent to use 2013.2 or later. If any of collectors or agents are running an older version, video data may still be recorded even though you have turned it off in Release 2013 Update 2 Audit Manager. (Ref: 44064a)

- If Server Suite Agent for Windows is auditing a Windows 8 or Windows 2012 system, the Indexed Event List of the corresponding audited session will not show any events for the applications that are using the Metro User Interface. The Metro UI is not supported. (Ref: 56556b)

- Upon making changes to Group Policy "Centrify Audit Trail Setting" > "Centrify Common Setting" > "Send audit trail to log file", it would require reboot of the client computer (agent) for this setting to be effective despite the Group Policy has already been refreshed on the client computer. (Ref: 73368b)

- The offline data location (and subdirectories below it) is expected to be a location dedicated to spooling, for example c:\spool. If the offline data location is changed, all files in the old location (including subdirectories and their contents) are moved to the new location. This may cause problems if the old location was not exclusively for spooling use. For example, choosing c:\ as the original spool location and d:\spool as the new location would cause all files on the c:\ drive to be copied to d:\spool. (Ref: 26592a)

- Some events related to the login script are not listed in the indexed events list. The login script cannot be audited for an initial few seconds because the

DirectAudit software has not completed its setup. (Ref: 26286a)

- Some events related to the login script are not listed in the indexed events list. The login script cannot be audited for an initial few seconds because the Server Suite Agent for Windows software has not completed its setup. (Ref: 26286a)

Delinea Audit Module for PowerShell

- Audit Module for PowerShell may take a long time to start because of the publisher's certificate verification. To resolve the problem, disable the "Check for publisher's certificate revocation" option in System Control Panel\Internet Options\Advanced\Security. (Ref: 72499)
- After installing Audit Module for PowerShell in a RDP session, PowerShell complains module "Delinea.DirectAudit.PowerShell" cannot be loaded. This is because the installation package needs to modify system environment variables to let PowerShell know where to load the module. This operation needed to be done in a "Console Session" if installation is done via RDP. To resolve this problem, logout and re-login or run RDP with the "admin" option as "mstsc /admin" or "mstsc /console". (Ref: 72500a)

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

About Server Suite Auditing & Monitoring Service

Delinea Server Suite is a product category that includes the following product offerings:

- Privileged Access Service
- Authentication Service
- Privilege Elevation Service
- Auditing & Monitoring Service

The DirectControl Agent provides services for the Authentication Service and Privilege Elevation Service contained in the CentrifyDC packages. The DirectAudit Agent provides services for Auditing & Monitoring Service contained in the CentrifyDA packages.

The Auditing & Monitoring Service is a key component of Server Suite. It enables detailed auditing of user activity on a wide range of UNIX, Linux, and Windows computers. With this service, you can perform immediate, in-depth troubleshooting by replaying user activity that may have contributed to system failures, spot suspicious activity by monitoring current user sessions, improve regulatory compliance, and ensure accountability by capturing and storing detailed information about the applications used and the commands executed. If you enable auditing, the Server Suite Agent for Windows records user activity on the Windows computer when it is installed. Auditing & Monitoring Service supports auditing of many different UNIX, Linux, and Windows operating systems.

In Unix and Linux agents, DirectControl Agent is a pre-requisite for the Auditing & Monitoring service.

Starting in Release 2016, only ADMX format for group policies will be installed and ADM format will no longer be provided. (Ref: CS-6821)

Starting in Release 2016, Server Suite will no longer be adding new features to the DirectManage Audit SDK component. It is recommended that all existing users of this component start using the Audit Module for PowerShell component, which is the intended replacement of the SDK. (Ref: CS-6713)

From Release 2017.1 onward, DirectAudit no longer supports Version 1 Audit Store databases. You will no longer be able to attach Version 1 databases to an existing DirectAudit installation. To view data from version 1.x databases, please install a DirectAudit Auditor Console 1.x and attach the database. (Ref: CS-41219)

This release note updates information available in the DirectAudit Administrator's Guide and describes known issues. You can obtain information about previous releases from the Delinea Support Portal, in the Product Documentation page.

Delinea software is protected by U.S. Patents 7,591,005; 8,024,360; 8,321,523; 9,015,103; 9,112,846; 9,197,670; 9,378,391 and 9,442,962. (Ref: CS-44575)

Feature Changes in Auditing & Monitoring Service 5.9.0 (Release 2022)

General

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement

Compatibility

- With the Server Suite Agent for Windows version 19.6 and later, the Audit and Monitoring Service uses a different compression library to compress the video data being sent from the agent to the collector. As a result, this agent and all future versions of agents are *not* compatible with audit collector versions 18.11 or earlier.

  IMPORTANT: You will lose video data if you deploy the newer agents in an environment with 18.11 or older collectors.___ Audit trail events and indexed events lists are not affected in this situation.

Because of this incompatibility and risk of data loss, you MUST upgrade all of your collectors to the 19.6 or higher version BEFORE you upgrade the agents to Release 2021.1.

As a reminder, before you upgrade the collectors you must first upgrade the database schema. So, to summarize, here's the order in which you upgrade the audit components:

1. Upgrade the database.
2. Upgrade the collectors.
3. Upgrade the agents.

- The minimum DirectControl Agent for *NIX version required by this version of the service is 5.9.0 (Release 2022)

For the platforms to be removed support in coming releases, refer to the "Notice of Termination Support" section in the Server Suite release notes.

Bugs Fixed in this Release

General

Windows Install / Upgrade / Uninstall

Audit Collector

Fixed an issue where commands longer than 255 characters were truncated. You can now set a new Registry value HKLM\SOFTWARE\Centrify\DirectAudit\Collector\StdinBuffSize so that large commands can be logged. The default value is 255.

Audit Analyzer and Session Player

Audit Manager

DirectAudit Agent for

Fixed an issue where the third-party program might crash in DirectAudit NSS/LAM module when session auditing is enabled.

FindSessions Tool

Server Suite Agent for Windows

Audit Module for PowerShell

Audit Management Server

Known Issues

The following sections describe known issues, suggestions, and limitations associated with the Audit and Monitoring Service.

General

For the most up-to-date list of known issues, refer to the knowledge base articles in the Delinea Support Portal.

Windows Install / Upgrade / Uninstall

- If a DirectManage Audit installation has been configured with multiple Audit Management Servers and some of the servers are running on an older version, the Audit Manager may not list these older servers because the new servers list supersedes the older ones. (Ref: CS-40818)
- When upgrading DirectAudit in Windows, you should use the autorun program to perform the upgrade. The autorun program automatically upgrades other Delinea components such as Delinea Licensing Report. If you upgrade DirectAudit components individually using the Microsoft Installer (msi) and then attempt to use the autorun program to uninstall all components, autorun will only be able to uninstall the Delinea Licensing Report that were upgraded to the latest version. You can remove any remaining components manually using the Add/Remove Programs and Features Control Panel. (Ref: 46293a)
- If you run setup.exe with all DirectAudit components selected for installation on a single computer, the operation is known as the "Easy Install." Although this is the default for new installations, using the "Easy Install" option requires you to have local administrator privileges.
- If you uninstall the collector component on a computer that is not joined to the domain, you will see the following messages during an uninstall operation:

The specified domain either does not exist or could not be contacted.

(Exception from HRESULT: 0x8007054B)

Despite the alert message, the collector is successfully uninstalled when you click OK.

Collector

- In the Collector Configuration wizard, if the account credentials you give for the SQL Server do not match an existing account on the SQL Server, and you have the rights to create SQL Server accounts, the credentials you give will be used to automatically create a new SQL Server account.

Audit Analyzer and Session Player

- Release 2017.3 has introduced a new version of dzdo and PAM authentication audit trail events. However, these events cannot be captured by older version of database/Collector or reported by older versions of DirectAudit Audit Analyzer console or FindSessions utility or PowerShell cmdlets. To rectify this issue, you need to upgrade the DirectAudit backend components (such as Audit Manager console, Audit Analyzer console, Collector, and Audit Store databases) to Release 2017.3 or later version. Contact Delinea support if you are unable to upgrade the DirectAudit backend components so that DirectAudit database patching scripts can be provided to you based on your current version. (Ref: CS-44654)
- When detaching and re-attaching an Audit Store database from an Audit Store, Delinea recommends refreshing the query results for all open queries in Audit Analyzer console prior to replaying a session from that database. Failure to do so may result into a database error. (Ref: CS-42125)
- If the active audit store database spans two SQL databases, the Audit Analyzer will show UNIX sessions as "Disconnected" until some data is received from those sessions. Once data has been received, the session state will change to "In Progress."

- If an audited Windows session is using multiple monitors in extended mode in DirectAudit 3.2.2 or earlier, it cannot be exported as WMV files. In DirectAudit 3.2.3 or later, it will be trimmed to 2048x2048 pixels before it is saved and can be exported as in WMV file in 2048x2048 resolution. (Ref: 27003a, 75163, CS-6450, CS-3265).
- When Server Suite Agent for Windows machine's system color depth is changed during an audited session, the playback of the session may not be displayed properly. (Ref: 36818c)
- Entering specific keywords in the "Application" Event list column will not filter based on the keywords as expected. For example, entering the search term "c" will locate the string "Windows Explorer". This is because application characteristics are stored in the database as a set of related attributes as follows: "Explorer.EXE | Microsoft® Windows® Operating System | Windows Explorer | Microsoft Corporation | 6.1.7600.16385" A match with any of the Windows Explorer attributes will yield "Windows Explorer". This issue will be addressed in an upcoming release. (Ref: 39645b)
- In Audit Analyzer, you can specify double-quote enclosed strings in the query that searches for "Unix Commands and Outputs" attribute. However, if a double-quote character is inside the double-quote enclosed string, the query result is undefined. (Ref: CS-39348)
- If a DirectAudit Installation is configured to not capture video data, parameters of the UNIX command are also not captured. Therefore, the query using "Parameters of Commands and Applications" as the criteria does not work under this configuration. This is a known issue and will be addressed in future release. (Ref: 55741b)
- If you open Audit Analyzer and right click on any child node of predefined queries such as "All, Grouped by User", "All, Grouped by Machine" or "All, Grouped by Audit Store" in the left pane, the context menu is displayed and it shows a menu item named "Properties". This context menu item, when clicked, does not open any dialog box because it is not a valid action for the selected child node. This menu item will be removed in the future release. (Ref: 48681b)
- By default, Audit Analyzer uses MSS2 codec to export audited sessions to a WMV (Windows Media Video) file. The MSS2 codec has a known issue which results in fuzzy video when an audited Windows session is exported as WMV file and opened in Windows Movie Maker 2012. From DirectAudit 3.2.0 onward, you can specify your own codec to export an audited session to a WMV file. Please refer to KB-4029 for additional information. (Ref: 56021a)

Audit Manager

- User and group criteria should not be combined in an Audit Role or it may result into inconsistent results, the workaround is for users to use two different audit roles (one for groups, another for users) if they want to mix users and groups in audit role assignment. (Ref: CS-38968)
- When creating an AuditRole with "ClientName" Audit Manager's Role Properties / Criteria will display an empty value rather than "ClientName = <IP address>" (Ref: CS-41803)
- If you assign DirectAudit permissions to a Domain Local group, which is not in the current domain in the Audit Manager Installation Property Security tab, and a user belonging to that group runs Audit Analyzer and tries to connect to the DirectAudit Installation, Audit Analyzer will display the warning "You do not have permission to connect to the SQL server." A workaround is to grant permission to a Global or Universal group instead. (Ref: 25546c)

Server Suite DirectAudit Agent for

General

- Delinea recommends customers use the session auditing capability of DirectAudit to ensure the complete login session is audited vs. auditing individual commands. When the administrator configures Direct Audit to audit a specific command, Direct Audit moves the original command executable to a different location and replaces it by a symbolic link to the Direct Audit shell. It is possible for a user to find out the new location of the executable and runs that command directly to bypass auditing. Whereas the likelihood of this happening is very minute, Delinea recommends session auditing be turned on to avoid the chance of this happening.

- If a user is logged in to AIX and HP-UX via a GUI, for example Xmanager, a terminal opened in the GUI will not be audited. To workaround this issue, set the centrifyda.conf parameter 'dash.allinvoked' to true. (Ref: 66330, CS-5876)

- Obfuscation of session data has the following limitation: If the information is sent to stdout not as a whole, but piece by piece, the information will not be obfuscated. Example: A user wants to obfuscate a pattern "1234-5678". However, "1234-" is shown first and "5678" is shown 1 second later, this pattern will not be obfuscated. Since the stdout buffer in the audit shell is 4KB, the obfuscation string is at most 4KB long. Note: this applies to stdout only. (80462a)

- Auditing init during startup on UNIX is not possible. The init command used during the boot process should not be audited using per-command auditing. If you attempt to audit init, your operating system will not reboot properly.

- You cannot start a GUI session if you are logged in via an interactive session. Running startx or starting a GUI session from an interactive session results in the following message:

  X: user not authorized to run the X server, aborting.

  Workaround:

- Run "sudo dpkg-reconfigure x11-common"

- When you are prompted for users allowed to start the X server, choose "anybody" (the default is "console users only").

The GUI session or X server should start normally. (Ref: 25036a)

- To audit the GUI terminal emulators, GUI login managers have to be fully reinitialized after auditing is enabled. On Linux, "init 3 && init 5" will start the reinitialization. (Stopping the X server only, or pressing ctrl+alt+backspace in Gnome, will not start the reinitialization.)
- When a local user and an Active Directory user use the same UNIX user name, the user name will default to the name of the Active Directory user. If the local user name is intended, setting the pam.allow.override parameter in /etc/centrifydc/centrifydc.conf will help. After this setting, the user name implies the Active Directory user; and <username>@localhost will imply the local user.

  DirectAudit 3.0 or later understands the "@localhost" syntax. DirectControl Agent will respond to <username>@localhost if the user name is set in pam.allow.override.

  If you upgrade from DirectAudit 2.0, disable DirectAudit so that the new DirectAudit mechanism for hooking shells can be installed: Run 'dacontrol –d -a' to disable auditing, then restart the upgrade.

  DirectAudit maintains a cache of user information for performance reasons. This cache interferes with Unix commands that manipulate the local user database (passwd file). These commands include useradd, userdel and usermod. From DirectAudit 3.2.0 onwards, DirectAudit will not access its local cache to fully support the following commands: useradd, userdel, adduser, usermod, mkuser, rmuser, chuser

  Please contact support if your operating system platform has other programs that directly access the local passwd file. (Ref: 56259a)
- If session auditing is enabled, all local user logins are processed by DirectAudit to determine whether the session should be audited. This may block login if domain controllers are not responsive and/or DirectControl Agent is not running. Two new parameters are introduced in /etc/centrifyda/centrifyda.conf:

  - user.ignore: specifies a list of local users that DirectAudit does not use Active Directory to determine audit level. By default, the list is /etc/centrifydc/user.ignore (the same one that DirectControl uses), which includes some important accounts like root, bin, daemon, etc.

  - user.ignore.audit.level - specifies the audit level for the local users specified in the user.ignore list. The supported values are 0 (audit if possible) and 1 (audit not requested/required). Default is 0 (audit if possible). Note that "audit required" is not a reasonable choice, as this user needs to login all the time; and "audit required" may block login if DirectAudit does not function correctly. (Ref: 55599a, 57946a, 56935a, 58251a)
- The /usr/share/centrifydc/bin/centrifyda script should be used to start/stop DirectAudit service in all *nix platforms. However, systemd is not fully supported in /usr/share/centrifydc/bin/centrifyda. For platforms that use systemd by default (such as SUSE Linux Enterprise 12/SUSE Linux Desktop 12), users need to set the environment variable SYSTEMD_NO_WRAP to 1 before calling the /usr/share/centrifydc/bin/centrifyda. Operations such as killing a daemon, running dad (DirectAudit daemon) directly, or running dastop command, could lead to issues in daemon managers in some *nix platforms. For example, SMF of Solaris, SRC of AIX and systemd of Fedora 20, may record incorrect running status of the daemon; and may fail to start daemon. (Ref: 57653a, 71211a)
- Disable auditing before upgrade

  If you upgrade from DirectAudit 2.0, please run "dacontrol -d -a" to disable DirectAudit before upgrade. Both the installer shell script, install-da.sh, and the native package manager will detect if auditing is enabled and abort if so.

  If you are using the native package manager to upgrade and youattempt to upgrade while auditing is enabled, you may find that,after the package manager aborts, the DirectAudit installation isshown as broken. This may be ignored. Simply disable auditing,upgrade and then re-enable auditing and the package will beshown as committed.

RedHat Linux

- Due to a limitation of some implementations of audispd (audit dispatcher daemon provided by the operating system), DirectAudit advanced monitoring feature may not work if “dacontrol –n/-m” was run multiple times and over the limit specified in the parameter max_restarts in /etc/audisp/audispd.conf (default 10). If you enable the DirectAudit Advanced monitoring feature and it does not generate the audit trail events as expected, you can run dainfo to check on the status of advanced monitoring feature. If the program /usr/share/centrifydc/bin/dadispatcher is not running, dainfo will show “DirectAudit advanced monitoring status” as “not running”. In this case, you need to restart the system audit daemon using the command “service auditd restart”. This will re-activate the advanced monitoring feature. (Ref: CS-41267)
- The characters ('%', '#', '>' and '$') are used by DirectAudit to recognize UNIX commands. They should not be used in role names and as part of trouble-tickets; otherwise they will be recognized as part of a UNIX command. (Ref: 51687a)

- DirectAudit advanced monitoring features may not work with early versions of RedHat 5 due to different system configurations. The earliest version that Delinea tested is RedHat 5.6. Please contact Delinea Support if you need support in versions earlier than RedHat 5.6. (Ref: CS-43042)
- The advanced monitoring feature in RedHat 5 version only supports selinux mode set to 'disabled' or 'permissive', 'enforcing' is not supported due to incompatible selinux policies. Moreover, advanced monitoring feature may not work with earlier versions of RedHat 5 releases due to different system configurations. Please contact Delinea support if you need support in versions earlier than RedHat 5.6. (Ref: CS-43024)

Debian Linux

- To install the Delinea DirectAudit package on a computer with the Debian operating environment, you must use the dpkg --install or dpkg -i option. You cannot use the dpkg --update or dpkg -u options to install or update the Delinea DirectAudit package. If you need to update the Delinea DirectAudit package, you need to first delete the old package using the dpkg --purge or dpkg -P option then install the new package with the dpkg --install or dpkg -i option.

  > **Note**: Do not use the dpkg --remove or dpkg -r command to remove Delinea DirectAudit. Using the --remove option prevents the DirectAudit configuration file, /etc/centrifyda/centrifyda.conf, from being created properly when you reinstall the package.

Solaris

- Delinea recommends that you install the appropriate recommended patch bundles for the version of Sun Solaris you are using before installing Delinea DirectAudit.

  The patch installation will skip any individual patches that don't apply to your system, and you can use Sun's patch management system to ensure your computers get the latest security fixes.

  To help you identify any required patches for your environment, Delinea supplies the pca patch checker in all Solaris Delinea Server Suite packages. Install.sh will prompt you to check the patch level of your environment during installation.

  To check for Sun recommended patches with the pca patch checker you should have the wget package installed. This package may be obtained from:

  http://ftp.wayne.edu/sun_freeware/

  And source code may be obtained from:

  http://www.gnu.org/software/wget/

  For more information about downloading and installing patches, see the Sun Web site.

  The minimum patches required for Delinea DirectAudit are provided below for reference purposes. In some cases these patches may be obsoleted or incorporated into other patches, so the patch numbers on your Solaris machines may be different. The authoritative source on patch compatibility is Sun; their Web site will allow you to follow patch histories to ensure any later patches you are using are compatible with the ones required by DirectAudit.

  For Solaris 10: 119254-65 120011-14 127127-11 138263-03

- Please contact technical support if you are using sparse zone(s) and like to do one of the following:
  - Change session auditing status from disabled to enabled during upgrade.
  - Enable session auditing in a global zone and want to disable session auditing in sparse zone(s) when using the same global zone. (Ref: 76572, 80616b)
- The following commands, located in /usr/bin, might be implemented as ksh programs or scripts:

  alias bg cd

  command fc fg

  getopts hash jobs

  kill read test

  type ulimit umask

  unalias wait

To identify commands implemented as ksh scripts, run the following script:

```
#!/bin/ksh -p

cmd=`basename $0`

$cmd "$@"
```

The commands that are implemented internally by ksh should not be audited.

- On a system using SMF (Service Management Facility), such as Solaris 10, the DirectAudit daemon might not start up after an upgrade from DirectAudit 1.x. This does not affect a fresh installation. To bring the daemon up, run these commands:
  - svcadm disable centrifyda
  - svcadm enable centrifyda
  - Run 'svcs' and find 'centrifyda' to confirm the daemon is online.

AIX

- Some versions of AIX sshd do not function reliably with Delinea products. When possible, Delinea recommends using sshd included in Delinea openSSH on AIX platforms. (Ref: CS-7098)
- Local AIX users cannot be audited when they log in via built-in ssh, due to a change in AIX 7.0 ML1. Customers are advised to install Delinea OpenSSH if auditing of ssh login by local users is required (Ref: 33299a).
- Change in AIX root user behavior: By default, all releases starting with Release 2014 (DirectAudit 3.2.0) DO NOT modify the root stanza in AIX for new installations. One side effect is that root user login WILL NOT be audited. If your environment requires session auditing of root user login, you need to do the followings:
  a. Set up a DirectAuthorize role that has the audit level of "audit required" or "audit if possible"; and assign this role to root.
  b. Set the parameter adclient.autoedit.user.root to TRUE in /etc/centrifydc/centrifydc.conf.
  c. If DirectAudit session auditing is not enabled, enable DirectAudit session auditing using the command "dacontrol -e".
  d. Restart adclient (Ref: 56239a, 56604a)
- For AIX customers who upgrade from prior versions of Release 2014 (DirectAudit 3.2.0), there is NO change in behavior. The parameter adclient.autoedit.user.root is set to true in /etc/centrifydc/centrifydc.conf. The root user will still be audited. (Ref: 56235)

HPUX

You can install this package by copying it to a HP-UX computer and running install.sh, the installer, or by running the following commands, where <release> is the version of the DirectAudit package you are installing:

```
gzip -d centrifyda-<release>-hp11.31-ia64.depot.gz

swinstall -s /path/centrifyda-<release>-hp11.31-ia64.depot \

-x allow_incompatible=true
```

- You must specify the full path to the Delinea DirectAudit depot file and set the allow_incompatible option to true to install successfully.
- The installation script checks your environment for the minimum patch levels required. If you have more recent patches installed, however, you may see an error message. To install, re-run the installation command with the following additional command line option:

  ```
  -x enforce_scripts=false
  ```

Database

- When adding an Audit Store database to a SQL Server Availability Group with the multi subnet failover feature, the SQL Server that hosts the management database must be SQL Server 2012 or above. In addition, when upgrading an existing DirectAudit installation to use the SQL Server Availability Group feature, Delinea recommends upgrading Collectors, Audit Management Server service, Audit Manager consoles and Audit Analyzer consoles to the latest version to benefit from this feature. (Ref: CS-39872)

- In previous versions of DirectAudit, it was possible to specify the location of the database file. In DirectAudit 2.0.0 and later this capability is not provided in the Audit Store Database Wizard. However, you can still specify the full text file location, database file location, or transaction log file location by choosing "View SQL Scripts" and modifying the relevant database location manually in the script.
- If the default memory setting for SQL Server is more than the actual memory in the system a memory error may occur. For more information see:

  http://social.msdn.microsoft.com/Forums/en-US/sqldatabaseengine/thread/74a94f06-adf5-4059-bb92-57a99def37bd/

  SQL Server 2008 R2 full text search categorizes certain words as stop words by default and ignores them for searches. Some stop words are common UNIX commands such as like, which, do, and while. For more details about stop words and how to configure, please refer to http://technet.microsoft.com/en-us/library/ms142551.aspx
- The collector monitors the active Audit Store database to check if it is running low on disk space. If an active Audit Store the database is on a disk with volume mount point, the collector may give a false alarm. In such cases, it is recommended to disable the detection by setting the following registry key with the type of DWORD to 0 on all your collector machines. (Ref: 53389a)

  HKLM\Software\Centrify\DirectAudit\Collector\AuditStoreDiskSpaceLowThreshold
- Collector only detects AuditStore disk space low against a configurable threshold if the SQL Server version is 2008 R2 SP1 (10.50.2500.0) and above. The threshold can be configured at Collector machine Registry: HKLM\Software\Centrify\DirectAudit\Collector\AuditStoreDiskSpaceLowThreshold DWORD in MB, not configured, default to 1024 MB. If free disk space is less than the threshold, Collector state is changed to "AuditStore database disk space is low", and stops accepting audit data from Agent(s).

Audit Management Server

- To configure the audit management server to point to an installation, the user who is running the Audit Management Server Configuration Wizard must have the "Manage SQL Logins" permission on the management database of the installation. For example, if you are configuring an audit management server in an external forest with a one-way trust, be sure that the installation supports Windows and SQL Server authentication and the account you are using is from the internal forest and has the "Manage SQL Logins" permission on the management database. (Ref: 46989a)

FindSession Tools

- For per-command auditing of dzdo command, when a ticket is entered, the role and ticket are associated with the audited session. For such sessions, the FindSessions tool's export of type UnixCommand, UnixInput, or UnixInputOutput based on the role and/or ticket criteria will have the exported command, STDIN, or STDIN and STDOUT marked with role and ticket. When per session auditing is enabled, the exported data will not have role and ticket information. (Ref: 53936a)
- When per-command auditing is enabled for dzdo command, and role and trouble ticket capturing is also configured, FindSessions.exe run with /export=UnixCommand option will not show the role and trouble ticket information in the exported file for the dzdo command itself, if the dzdo command executed is "dzdo su –" or "dzdo –i". However, all the command executed within that dzdo session will have correct role and trouble ticket information. (Ref: 51787a)

Server Suite Agent for Windows

- When a user disconnects and then later reconnects to an existing user session from a switch user operation, a successful logon audit trail message will not be logged after the user has reconnected to the session though authentication. This does not apply when the user is performing lock and unlock operations or the logon method is different from the previous login (remote vs. console logon). (Ref: CS-41453)
- In the DirectAudit Agent for Windows control panel, the setting "Maximum size of the offline data file" indicates the minimum amount of disk space (in percentage) that must be available/free in the spool volume in order to continue auditing users (especially when the DirectAudit Agent cannot send audit data to collector). The DirectAudit Agent makes its best attempt to pause auditing when the specified amount of disk space is no longer available and in certain cases may continue to write to spool volume for a few minutes before eventually pausing the auditing activity. (78072, CS-6718)
- The optional video capture feature requires both the Collector and the DirectAudit Agent to use 2013.2 or later. If any of collectors or agents are running an older version, video data may still be recorded even though you have turned it off in Release 2013 Update 2 Audit Manager. (Ref: 44064a)
- If Server Suite Agent for Windows is auditing a Windows 8 or Windows 2012 system, the Indexed Event List of the corresponding audited session will not show any events for the applications that are using the Metro User Interface. The Metro UI is not supported. (Ref: 56556b)
- Upon making changes to Group Policy "Centrify Audit Trail Setting" > "Centrify Common Setting" > "Send audit trail to log file", it would require reboot of the client computer (agent) for this setting to be effective despite the Group Policy has already been refreshed on the client computer. (Ref: 73368b)

- The offline data location (and subdirectories below it) is expected to be a location dedicated to spooling, for example c:\spool. If the offline data location is changed, all files in the old location (including subdirectories and their contents) are moved to the new location. This may cause problems if the old location was not exclusively for spooling use. For example, choosing c:\ as the original spool location and d:\spool as the new location would cause all files on the c:\ drive to be copied to d:\spool. (Ref: 26592a)
- Some events related to the login script are not listed in the indexed events list. The login script cannot be audited for an initial few seconds because the DirectAudit software has not completed its setup. (Ref: 26286a)
- Some events related to the login script are not listed in the indexed events list. The login script cannot be audited for an initial few seconds because the Server Suite Agent for Windows software has not completed its setup. (Ref: 26286a)

Delinea Audit Module for PowerShell

- Audit Module for PowerShell may take a long time to start because of the publisher's certificate verification. To resolve the problem, disable the "Check for publisher's certificate revocation" option in System Control Panel\Internet Options\Advanced\Security. (Ref: 72499)
- After installing Audit Module for PowerShell in a RDP session, PowerShell complains module "Delinea.DirectAudit.PowerShell" cannot be loaded. This is because the installation package needs to modify system environment variables to let PowerShell know where to load the module. This operation needed to be done in a "Console Session" if installation is done via RDP. To resolve this problem, logout and re-login or run RDP with the "admin" option as "mstsc /admin" or "mstsc /console". (Ref: 72500a)

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

Server Suite 2022 Release Notes

The Delinea Server Suite (previously called Centrify Infrastructure Services, or Centrify Zero Trust Privilege Services) is an integrated family of directory-based authentication, privileged access, privileged elevation, audit & monitoring solutions that secure your cross-platform environment and strengthen regulatory compliance initiatives.

Server Suite includes the following components:

- Authentication Service secures your platforms using the same authentication and Group Policy services deployed for your Windows environment.
- Privilege Elevation Service centrally manages and enforces role-based entitlements for fine-grained control of user access and privileges on UNIX, Linux, and Windows systems.
- Audit & Monitoring Service delivers auditing, logging, and real-time monitoring of user activity on your Windows, UNIX, and Linux system.

This integrated solution helps you improve IT efficiency, strengthen regulatory compliance initiatives, and centrally secure your heterogeneous computing environment.

This release notes cover information specifically about Authentication Service, Privilege Elevation Service, and Audit & Monitoring Service.

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement

This release usually includes packages for Windows, UNIX, and Linux operating system environments.

The files for this release are organized onto two media, each available in ISO and zip form:

Server Suite for 64-bit Windows

- main folder

This is the main folder containing information pertinent to this release.

- The readme.txt file provides a summary of where to find files in a plain text format.
- Copyright.txt and Acknowledgements.txt provide copyright information and legal notices for third party and open-source software used in Delinea Server Suite.
- Delinea-end-user-license-agreement.txt provides the text of the license agreement displayed during installation.
- autorun.inf controls the autorun program, autorun.exe, on Windows computers.

The following are sub-folders that are organized to provide you access to different software components in the Delinea Server Suite.

- Agent folder

  This folder contains the installer packages for installing Server Suite Agent for Windows on Windows computers.

- Common folder

  This folder contains the installer packages for common components necessary for all Delinea products on Windows computers.

- DirectAudit folder

  This folder contains the installer packages for Delinea Audit & Monitoring Service on Windows computers.

- DirectManage folder

  This folder contains the installer packages for Delinea Authentication Service and Delinea Privilege Elevation Service on Windows computers.

- LicensingService Folder

This folder contains the installer packages for Delinea Licensing Service utilities on Windows computers.

- Resources Folder

  This folder contains resources for internal use for the media. It can be safely ignored.

Server Suite Agents for UNIX/Linux

This image contains a zipped bundle of files for Server Suite agent on each supported UNIX, or Linux platform and an adcheck utility for each supported platform.

You may find the appropriate bundle for an OS platform based on the following table:

delinea-server-suite-<release number>-aix7.1-ppc.tgz	IBM AIX, IBM VIOS
delinea-server-suite-<release number>-cos-x86_64.tgz	Flatcar, RHCOS
delinea-server-suite-<release number>-deb9-arm64.tgz	Ubuntu
delinea-server-suite-<release number>-deb9-ppc64el.tgz	Ubuntu
delinea-server-suite-<release number>-deb9-x86_64.tgz	Debian, Ubuntu
delinea-server-suite-<release number>-hp11.31-ia64.tgz	HPUX
delinea-server-suite-<release number>-hp11.31-pa.tgz	HPUX
delinea-directcontrol-<release number>-mac10.15.tgz	MAC (Intel, M1)
delinea-server-suite-<release number>-rhel6-ppc64.tgz	RHEL
delinea-server-suite-<release number>-rhel6-x86_64.tgz	Amazon Linux, CentOS, Fedora, Oracle Linux, RHEL, AlmaLinux, Rocky Linux
delinea-server-suite-<release number>-rhel7-aarch64.tgz	Amazon Linux, CentOS, Oracle Linux, RHEL
delinea-server-suite-<release number>-rhel7-ppc64le.tgz	RHEL
delinea-server-suite-<release number>-sol10-sparc.tgz	Oracle Solaris
delinea-server-suite-<release number>-sol10-x86.tgz	Oracle Solaris
delinea-server-suite-<release number>-sol11-i386.tgz	Oracle Solaris (IPS package)
delinea-server-suite-<release number>-sol11-sparc.tgz	Oracle Solaris (IPS package)
delinea-server-suite-<release number>-suse12-aarch64.tgz	SUSE
delinea-server-suite-<release number>-suse12-ppc64le.tgz	SUSE
delinea-server-suite-<release number>-suse12-x86_64.tgz	SUSE

Notes:

- The OS version number specified in the bundle name indicates the minimum OS version that it supports.
- You should also choose the appropriate bundle for the specific architecture as indicated in the bundle name.
- Inside each bundle, it contains packages of associated products supported on that platform. The naming convention follows the above bundle names except that the prefix of a package reflects the product it serves. The following are the possible package prefixes and the corresponding product

names:

CentrifyDA	Delinea DirectAudit package
CentrifyDC	Delinea DirectControl package
CentrifyDC-cifsidmap	Delinea for CIFS ID mapping package
CentrifyDC-curl	Required component of Delinea DirectControl package
CentrifyDC-ldapproxy	Delinea OpenLDAP Proxy package
CentrifyDC-nis	Delinea Network Information Service and Delinea NIS Server package
CentrifyDC-openldap	Required component of Delinea DirectControl package
CentrifyDC-openssh	Delinea OpenSSH package
CentrifyDC-openssl	Required component of Delinea DirectControl package

- Before installation, please review the *Upgrade and Compatibility Guide* and run the adcheck utility to make sure the environment is ready, especially if you are using native package manager to install.

Go to Supported Versions.

Newly Added Supported Platforms

Support is added for the following operating system platforms in this release:

- AlmaLinux 8.5
- Flatcar
- Red Hat Enterprise Linux CoreOS (RHCOS)
- Rocky Linux 8.5

Supported UNIX/Linux Platforms

AlmaLinux 8.5	x86_64	Yes	Yes	Yes	
Alpine Linux 3.13, 3.14	X86_64	No	Yes	Yes	
Amazon Linux 2 LTS	aarch64	No	Yes	Yes	
Amazon Linux 2 LTS	x86_64	No	Yes	Yes	
CentOS 7.4-7.9, 8.0-8.5	aarch64	No	Yes	Yes	
CentOS 6.0-6.10, 7.0-7.9, 8.0-8.5	x86_64	Yes	Yes	Yes	
Debian 9.0-9.13, 10.0-10.11, 11	x86_64	Yes	Yes	Yes	

Flatcar	x86_64	No	Yes	Yes

Note 1: Please refer to the Unexpected Link Text for features supported on this platform.

Note 2: Starting with Release 2020, we require the OS patch level update 8 or above on Solaris 10.

Note 3: Delinea OpenSSH is not supported on this platform.

Note 4: Starting with Release 2021.1, we require the TL1 or above on AIX 7.1.

Additional Information

You should follow the OS vendors' recommendation to update the necessary patches. Here are the minimum patch requirements for the specific UNIX platforms (Ref: CS-45562):

1. HPUX 11.31
    1. PHNE_40225 - Cumulative Console and BSD Pty Patch (it is required for DirectAudit package)
2. Solaris 10 x86_64
    1. 119255-66
    2. 127128-11
    3. 141445-09
    4. 142910-17
3. Solaris 10 SPARC
    1. 119254-66
    2. 120011-14
    3. 127127-11
    4. 142909-17

Supported Windows Platforms

The following 64-bit Windows platforms are supported on Delinea Server Suite (Ref: CS-49379):

- Windows 10 LTSB/LTSC (Note 1)
- Windows 11 LTSB/LTSC
- Windows Server 2012
- Windows Server 2012R2
- Windows Server 2016
- Windows Server 2019 LTSC
- Windows Server 2022 LTSC
- Windows Server 2012 Core (Note 2)
- Windows Server 2012 Minimum Server Interface (Note 2)
- Windows Server 2012R2 Core (Note 2)
- Windows Server 2012R2 Minimum Server Interface (Note 2)

Note:

1. We support Windows 10 Long Term Servicing Channel (LTSC), or previously called Long Term Servicing Branch (LTSB), editions based on Microsoft's lifecycle fact sheet https://docs.microsoft.com/en-us/lifecycle/faq/windows and https://docs.microsoft.com/en-us/windows/release-health/release-information
2. Only the Privilege Elevation Service component of Server Suite Agent for Windows supports these platforms (Core and Minimum Server Interface)
3. Support for all 32-bit Windows platform was terminated in 2015 (Server Suite 2015.1)

   Also note that Server Suite require specific versions of .NET to work. Please refer to the following table for the requirement (Ref: CS-49381):

Server Suite 2022	April 2022	4.8	--*
Server Suite 2021.1	December 2021	4.8	--*
Server Suite 2021	July 2021	4.8	--*
Infrastructure Services 2020.1	December 2020	4.6.2	--*

Infrastructure Services 2020	September 2020	4.6.2	--*
Infrastructure Services 19.9	December 2019	4.6.2	--*
Infrastructure Services 19.6	August 2019	4.6.2	--*
Infrastructure Services 18.11	December 2018	4.6.2	4.6.2
Infrastructure Services 18.8	August 2018	4.6.2	4.6.2
Infrastructure Services 2018	April 2018	4.6.2	4.6.2
Infrastructure Services 2017.3	December 2017	4.5.2	4.5.2
Infrastructure Services 2017.2	September 2017	4.5.2	4.5.2
Server Suite 2017.1	May 2017	4.5	4.5.2
Server Suite 2017	February 2017	4.5	4.5.2
Server Suite 2016.1	May 2016	4.5	4.5.2
Server Suite 2016	December 2016	4.5	4.5.2

Note: We no longer bundle .NET in our installation media any more starting Release 19.6. (Ref: CS-47940)

This is the last release to support the following operating system platforms:

- Ubuntu 21.04, 21.10
- Fedora 34

Delinea has established product security policies documented in this web page. You may also find the details of all the published security advisories there.

For component specific security fixes in this release, you may find them in the corresponding component release-notes.html files. Please refer to Section 7 for a description of individual release notes.

See Component Version Table.

- For Access Manager, DirectControl agent and Delinea OpenSSH, see the Authentication Service and Privilege Elevation Service Release Notes.
- For Audit Manager and DirectAudit agent, see the Audit & Monitoring Service Release Notes.
- For Agent for Windows, see the Agent for Windows Release Notes.
- For Server Suite PuTTY, see the Server Suite PuTTY Release Notes

You can get all the supported releases from the download center in Delinea support web site.

- All the ISO, ZIP, and TGZ files are associated with the MD5 checksum.
- All RPM and DEB packages as well as YUM and APT repositories are also protected by the GPG signature. You can find the GPG public key in the

download center.

Component specific bug fixes in this release can be found in the corresponding component release notes files. Please refer to Release Notes for Server Suite Components for a description of individual release notes.

Component specific known issues/limitations can be found in the corresponding component release notes files. Please refer to Release Notes for Server Suite Components for a description of individual release notes.

For the most up to date list of known issues, please login to the Customer Support Portal at https://www.delinea.com/support and refer to Knowledge Base articles for any known issues with the release.

In addition to the documentation provided with this package, you can find the answers to common questions and information about any general or platform-specific known limitations as well as tips and suggestions from the Delinea Knowledge Base.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

This section lists the recent release notes for Server Suite for Mac.

- Release 2022
- 2020 Release Notes -- Adbindproxy (Samba)

DirectControl for Samba is a proxy agent package that seamlessly integrates the Server Suite Agent for *NIX with open source Samba (referred to as stock Samba in this document), enabling the two products to share Active Directory user and group membership and to agree upon Unix identity attributes for Active Directory users. It is a proxy that passes identity management requests from Samba to the Server Suite Agent for *NIX.

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement.

The DirectControl for Samba bundle package contains the following resources:

- DirectControl for Samba software package

  (for example, CentrifyDC-adbindproxy-<version#>-<OS>.<architecture>.rpm, or similar platform specific package file)

The DirectControl for Samba bundle package is available on the following OS/platforms in this release:

- IBM AIX on PPC
- Oracle Solaris on SPARC
- Oracle Solaris on x86_64
- Ubuntu on x86_64
- Red Hat Enterprise Linux on PPC
- Red Hat Enterprise Linux on PPC64LE
- Red Hat Enterprise Linux on x86_64
- SUSE Linux Enterprise Server on x86_64

  This DirectControl for Samba release supports stock Samba version 4.14 to 4.16. You are strongly advised to apply the latest security patches from Samba first before deploying DirectControl for Samba.

  For the OS versions that a DirectControl for Samba bundle package supports, please refer to the supported OS versions of the matching DirectControl Agent for *NIX package of the corresponding Server Suite release. Similarly, DirectControl for Samba also follows DirectControl Agent for *NIX's schedule for End-of-Support platforms and hence please refer to the announcements there.

No new features in this release.

The following sections describe common known issues or limitations associated with this DirectControl for Samba release.

- Limitations with stock Samba

  In previous releases of DirectControl for Samba, we modified the following in stock Samba for interoperability. Using stock Samba instead of Centrify Samba, you may see related issues.

  - Default Kerberos keytab location, KEYTAB_DEFAULT, from /etc/krb5.keytab to /etc/krb5/krb5.keytab on Solaris (SAMBA-890).

- Default Kerberos cache location, CCNAME, from /tmp/krb5cc_% to /var/krb5/security/creds/krb5cc_%" on AIX (SAMBA-892).

- Limitations with RHEL 7.2 PPC (SAMBA-965)

  If you are using 64bit Samba on a RHEL 7.2 PPC machine, you may have problem with adclient failed to use the 64bit tdb library come with 64 bit Samba. The symptom can be shown in the error message while trying to access samba server - "session setup failed: NT_STATUS_CANT_ACCESS_DOMAIN_INFO".

  You need to install a 32bit tdb library, such as libtdb-1.3.6-2.el7.ppc.rpm in rhel-server-7.2-ppc64-dvd.iso, for adclient to work with, and you need to tell adclient where to get this library by adding a parameter "samba.libtdb.path: /usr/lib/libtdb.so.1" into centrifydc.conf, assuming the path to libtdb is /usr/lib/libtdb.so.1.

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

This section lists the recent release notes for Server Suite for Mac.

- Server Suite for Mac 2022.1
- Server Suite for Mac 2022

You can find release notes and documentation related to previous releases at Previous Releases.

Server Suite for Mac provides Active Directory-based authentication, single sign-on, and group policy support for the macOS platform.

Server Suite for Mac is a part of Delinea software and is protected by U.S. Patents 7,591,005; 8,024,360; 8,321,523; 9,015,103; 9,112,846; 9,197,670; 9,378,391 and 9,442,962.

What's Included in this Release

- CentrifyDC-5.9.0-mac10.15.dmg: A Mac disk image for macOS 12.x, 11.x, and 10.15 containing the following:
  - AD Check.app: Graphical application to perform environment checks before installing Server Suite on macOS 12.x, 11.x, and 10.15
  - CentrifyDC-5.9.0-x86_64.pkg: Graphical installer of Server Suite for Macs (valid on both Intel and Apple Silicon) on macOS 12.x, 11.x, and 10.15

Supported Platforms and System Requirements

The Server Suite for Mac in the applicable package can be installed on the following versions of the macOS operating system:

- macOS 12.x on both Intel and Apple Silicon
- macOS 11.x on both Intel and Apple Silicon
- macOS 10.15.x on Intel

Installing on macOS 12 Monterey

If you are running the current release of Server Suite, you MUST UPGRADE Server Suite BEFORE upgrading your Mac to macOS 12 Monterey.

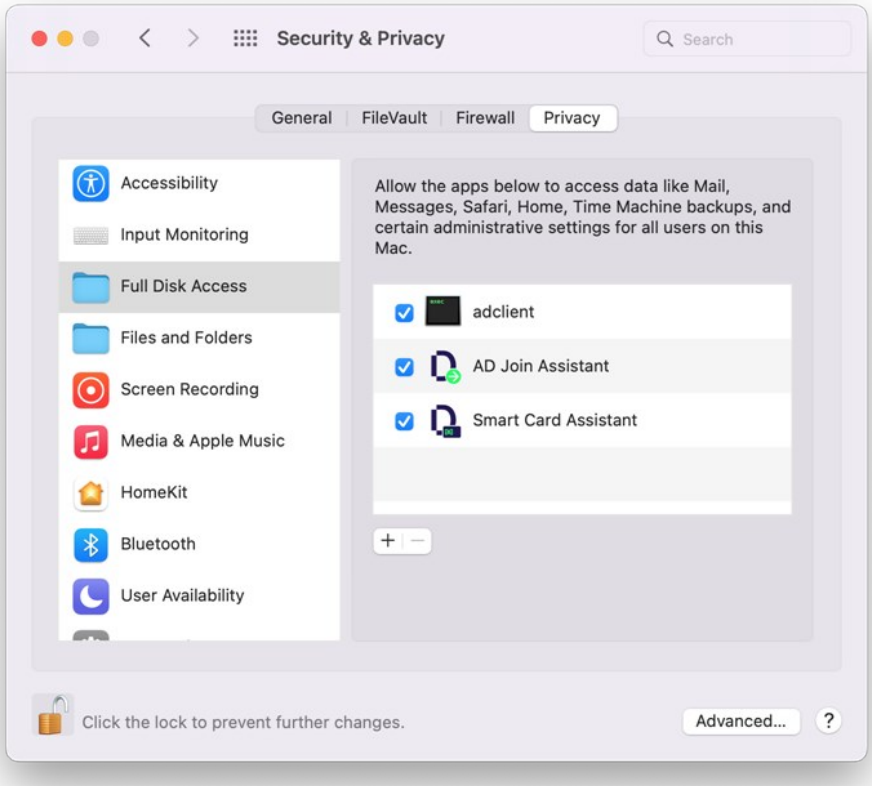
Follow these steps:

1. Download the Server Suite package for macOS.
2. Upgrade Server Suite for macOS using the package you downloaded.
3. Upgrade to macOS 12.

Setting Full Disk Access for the DirectControl Agent

Due to a limitation of macOS 11.x and macOS 12.x, "Full Disk Access" is required for the DirectControl Agent for Mac. You can configure this yourself if you're an administrator on the computer, or you can set it by way of your MDM (Mobile Device Management) provider.

1. To configure full disk access as an administrator:
    1. Log in to the Mac as an admin user.
    2. Open **System Preferences**.
    3. Click **Security & Privacy**.
    4. Click **Privacy**.
    5. Click the **Lock** button to input password or use TouchID to unlock.
    6. Scroll down a little bit on the left list, find and select **Full Disk Access**.
    7. Click the **Plus** button.
    8. Press and hold these three keys together: shift + command + G.
    9. Input the path /usr/local/sbin/adclient and click **GO**, then click **Open** to add it.
    10. Repeat step 7 and 8, then input the path /Applications/Utilities/Centrify/AD Join Assistant.app and click **GO**, then click **Open** to add it.
    11. Repeat step 7 and 8, then input the path /Applications/Utilities/Centrify/Smart Card Assistant.app and click **GO**, then click **Open** to add it.
    12. Click the **Lock** button again to lock.



2. Configure full disk access through your MDM provider. Contact your MDM provider for more information.

   Your MDM provider will need the following information:

```
% codesign -dv /usr/local/sbin/adclient
Executable=/usr/local/sbin/adclient
Identifier=adclient
...
% codesign -dr - /usr/local/sbin/adclient
Executable=/usr/local/sbin/adclient
designated => identifier adclient and anchor apple generic and certificate 1[field.1.2.840.113635.100.6.2.6] /* exists */ and certificate leaf[field.1.2.840.113635.100.6.1.13] /* exists */ and certificate leaf[subject.OU] = "64CT837G5Z"

% codesign -dv /Applications/Utilities/Centrify/AD\ Join\ Assistant.app
Executable=/Applications/Utilities/Centrify/AD Join Assistant.app/Contents/MacOS/AD Join Assistant
Identifier=com.centrify.cdc.centrifyjoinassistant
...
% codesign -dr - /Applications/Utilities/Centrify/AD\ Join\ Assistant.app

Executable=/Applications/Utilities/Centrify/AD Join Assistant.app/Contents/MacOS/AD Join Assistant
designated => identifier "com.centrify.cdc.centrifyjoinassistant" and anchor apple generic and certificate 1[field.1.2.840.113635.100.6.2.   6] /* exists */ and certificate leaf[field.1.2.840.113635.100.6.1.13] /* exists */ and certificate leaf[subject.OU] = "64CT837G5Z"

% codesign -dv /Applications/Utilities/Centrify/Smart\ Card\ Assistant.app
Executable=/Applications/Utilities/Centrify/Smart Card Assistant.app/Contents/MacOS/SCTool
Identifier=com.centrify.cdc.smartcardassistant
...
% codesign -dr - /Applications/Utilities/Centrify/Smart\ Card\ Assistant.app
Executable=/Applications/Utilities/Centrify/Smart Card Assistant.app/Contents/MacOS/SCTool
designated => identifier "com.centrify.cdc.smartcardassistant" and anchor apple generic and certificate 1[field.1.2.840.113635.100.6.2.   6] /* exists */ and certificate leaf[field.1.2.840.113635.100.6.1.13] /* exists */ and certificate leaf[subject.OU] = "64CT837G5Z"
```

Feature Changes and Notable Fixes in this Release

- The application "Centrify Join Assistant" is now called the "AD Join Assistant".

Known macOS Issues

- As of macOS Big Sur, Apple no longer permits to silently install configuration profiles. It affects the following group policies and they will not work on macOS Big Sur:
    1. Group policy "Install MobileConfig Profiles"
    2. Group policy "Enable Profile Custom Settings"
    3. Group policy "Require password to wake this computer from sleep or screen saver"
    4. Group policy "Enable Machine Ethernet Profile"
    5. Group policy "Enable Machine Wi-Fi Profile"
    6. Group policy "Enable User Ethernet Profile"
    7. Group policy "Enable User Wi-Fi Profile"
- When upgrading Mac from macOS 10.14 or lower to macOS 10.15 or higher, you must install the new agent version. You don't need to leave the domain or uninstall the old CentrifyDC agent.
- A network user doesn't work on macOS 10.15 and higher. We suggest using a mobile user or a general Active Directory user instead.
- When a mobile user logs in for the first time on macOS Big Sur and higher, in some cases they cannot set up Touch ID with their fingerprints. They just need to re-login in order for Touch ID to work.

Apple Support has provided the following resolutions:

* [Reset the SMC of Mac](https://support.apple.com/en-us/HT201295)
* [Reset NVRAM or PRAM on Mac](https://support.apple.com/en-us/HT204063)

Notice of Termination of Support

Server Suite has discontinued support for Mac OS 10.14.x, 10.13.x, 10.12.x, and 10.11.x starting with this 2022 release of Server Suite for Mac.

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

Server Suite for Mac provides Active Directory-based authentication, single sign-on, and group policy support for the macOS platform.

Server Suite for Mac is a part of Delinea software and is protected by U.S. Patents 7,591,005; 8,024,360; 8,321,523; 9,015,103; 9,112,846; 9,197,670; 9,378,391 and 9,442,962.

What's Included in this Release

- CentrifyDC-5.9.1-mac10.15.dmg: A macOS disk image for macOS 13.x, 12.x, 11.x, and 10.15 that contains contains the following:
  - AD Check.app: A graphical application to perform environment checks before installing Server Suite on macOS 13.x, 12.x, 11.x, and 10.15
  - CentrifyDC-5.9.1.pkg: A graphical installer of Server Suite for Mac (valid on both Intel and Apple Silicon) on macOS 13.x, 12.x, 11.x, and 10.15

Supported Platforms and System Requirements

The Server Suite for Mac in the applicable package can be installed on the following versions of the macOS operating system:

- macOS 13.x on both Intel and Apple Silicon
- macOS 12.x on both Intel and Apple Silicon
- macOS 11.x on both Intel and Apple Silicon
- macOS 10.15.x on Intel

Installing on macOS 13 Ventura

If you are running the current release of Server Suite, you MUST UPGRADE Server Suite BEFORE upgrading your Mac to OS 13 Ventura.

Follow these steps:

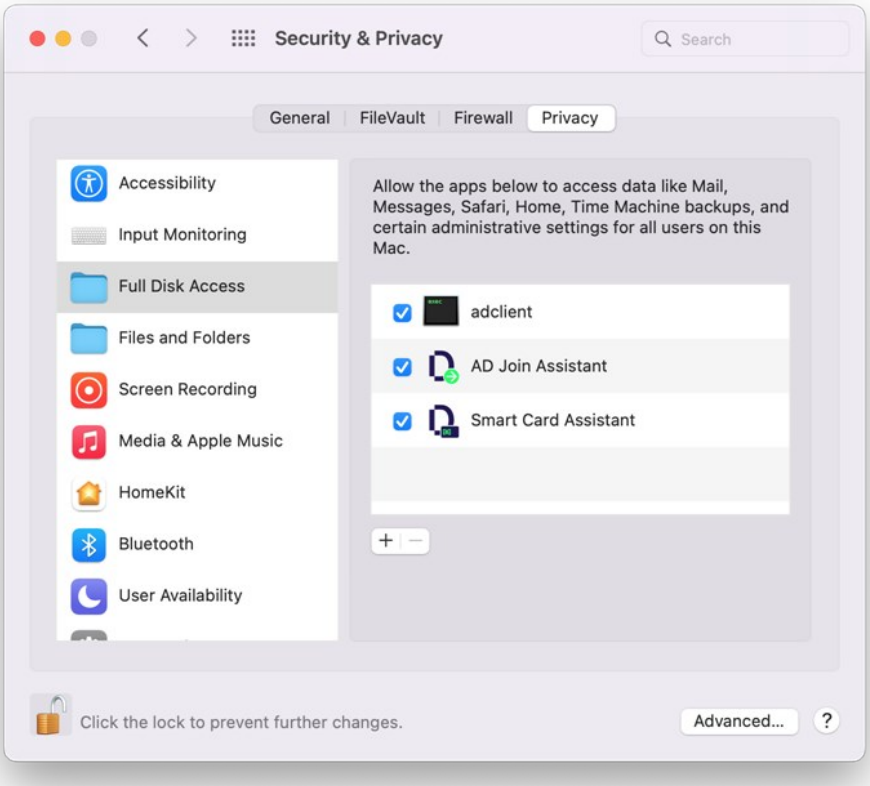
1. Download the Server Suite package for macOS.
2. Upgrade Server Suite for macOS using the package you downloaded.
3. Upgrade to macOS 13.

Setting Full Disk Access for the DirectControl Agent

Due to a limitation of macOS 11.x, macOS 12.x, and macOS 13.x, "Full Disk Access" is required for the DirectControl Agent for Mac. You can configure this yourself if you're an administrator on the computer, or you can set it by way of your MDM (Mobile Device Management) provider.

1. To configure full disk access as an administrator:
    1. Log in to the Mac as an admin user.
    2. Open **System Preferences**.
    3. Click **Security & Privacy**.
    4. Click **Privacy**.
    5. Click the **Lock** button to input password or use TouchID to unlock.
    6. Scroll down a little bit on the left list, find and select **Full Disk Access**.
    7. Click the **Plus** button.
    8. Press and hold these three keys together: shift + command + G.
    9. Input the path /usr/local/sbin/adclient and click **GO**, then click **Open** to add it.
    10. Repeat step 7 and 8, then input the path /Applications/Utilities/Centrify/AD Join Assistant.app and click **GO**, then click **Open** to add it.
    11. Repeat step 7 and 8, then input the path /Applications/Utilities/Centrify/Smart Card Assistant.app and click **GO**, then click **Open** to add it.

12. Click the **Lock** button again to lock.



2. Configure full disk access through your MDM provider. Contact your MDM provider for more information.

   Your MDM provider will need the following information:

```
% codesign -dv /usr/local/sbin/adclient
Executable=/usr/local/sbin/adclient
Identifier=adclient
...
% codesign -dr - /usr/local/sbin/adclient
Executable=/usr/local/sbin/adclient
designated => identifier adclient and anchor apple generic and certificate 1[field.1.2.840.113635.100.6.2.6] /* exists */ and certificate leaf[field.1.2.840.113635.100.6.1.13] /* exists */ and
certificate leaf[subject.OU] = "64CT837G5Z"

% codesign -dv /Applications/Utilities/Centrify/AD\ Join\ Assistant.app
Executable=/Applications/Utilities/Centrify/AD Join Assistant.app/Contents/MacOS/AD Join Assistant
Identifier=com.centrify.cdc.centrifyjoinassistant
...
% codesign -dr - /Applications/Utilities/Centrify/AD\ Join\ Assistant.app

Executable=/Applications/Utilities/Centrify/AD Join Assistant.app/Contents/MacOS/AD Join Assistant

```

Feature Changes and Notable Fixes in this Release (Release 2022.1 Component Update)

- This release supports macOS 13 "Ventura". (Ref: 486761)
- DirectControl now natively supports Apple Silicon. Rosetta 2 is no longer needed. (Ref: 486761)

Known macOS Issues

- As of macOS Big Sur, Apple no longer permits to silently install configuration profiles. It affects the following group policies and they will not work on macOS Big Sur:
    1. Group policy "Install MobileConfig Profiles"
    2. Group policy "Enable Profile Custom Settings"
    3. Group policy "Require password to wake this computer from sleep or screen saver"
    4. Group policy "Enable Machine Ethernet Profile"
    5. Group policy "Enable Machine Wi-Fi Profile"
    6. Group policy "Enable User Ethernet Profile"
    7. Group policy "Enable User Wi-Fi Profile"
- When upgrading Mac from macOS 10.14 or lower to macOS 10.15 or higher, you must install the new agent version. You don't need to leave the domain or uninstall the old CentrifyDC agent.
- A network user doesn't work on macOS 10.15 and higher. We suggest using a mobile user or a general Active Directory user instead.
- When a mobile user logs in for the first time on macOS Big Sur and higher, in some cases they cannot set up Touch ID with their fingerprints. They just need to re-login in order for Touch ID to work.

Apple Support has provided the following resolutions:

* [Reset the SMC of Mac](https://support.apple.com/en-us/HT201295)
* [Reset NVRAM or PRAM on Mac](https://support.apple.com/en-us/HT204063)

Notice of Termination of Support

Server Suite has discontinued support for Mac OS 10.14.x, 10.13.x, 10.12.x, and 10.11.x starting with the 2022 release of Server Suite for Mac.

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.

The Delinea Resources web site provides access to a wide range of information including analyst report, best practice brief, case study, datasheet, ebook, white papers, etc., that may help you optimize your use of Delinea products. For more information, see the Delinea Resources web site.

You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone. To contact Delinea Support or to get help with installing or using this software, send email to support@delinea.com or call 1-202-991-0540. For information about purchasing or evaluating Delinea products, send email to info@delinea.com.

This section lists the recent release notes for Server Suite PuTTY.

About this Release

PuTTY is a popular open-source client on Windows and UNIX-based computers that provides access to remote machines using well-known network protocols such as Telnet, SSH, rlogin and raw TCP. However, it does not support Kerberos authentication.

Delinea has enhanced PuTTY so that user authentication can be accomplished using Kerberos before establishing a remote connection. The Delinea-enhanced version of PuTTY takes advantage of the Kerberos environment that the Delinea DirectControl agent sets up automatically on managed UNIX and Linux computers. By using the Delinea PuTTY client to access Delinea-managed computer, you gain the benefits of centralized authentication and password policy enforcement using a secure and well-established authentication infrastructure.

Delinea PuTTY is currently integrated with open-source PuTTY version 0.75.

The Delinea Server Suite and PuTTY release notes and documents are available online at https://docs.delinea.com/.

Feature Changes

Server Suite and its component services have been changed to use the new Delinea name and logo.

For more information about Delinea, see Delinea Announcement

Fixed Issues

Known Issues

- puttytel does not support Kerberos authentication.
- If you specify Alternate Kerberos credentials on the SSH > Kerberos properties page, you will always be prompted for a password. This will happen even if you choose to remember the password when first prompted for it.

Additional Information and Support

In addition to the documentation provided with this package, see the Delinea Knowledge Base for answers to common questions and other information (including any general or platform-specific known limitations), tips, or suggestions. You can also contact Delinea Support directly with your questions through the Delinea Web site, by email, or by telephone.
