5. Select all or a subset of pending import users or groups, right-click, then click **Check status**.
    - For pending import groups, a potential match is an Active Directory group with a common name or sAMAccountName that is the same as the pending import group name.
    - For pending import users, a potential match is an Active Directory user with a common name that is the same as the pending import user's GECOS field, or sAMAccountName that is the same as the UNIX user name.

      If there is a match, Access Manager displays that group or user as the default Active Directory candidate and the status as **Ready to import**.

      If Access Manager can't identify a potential match in Active Directory or there are other issues, the status for the pending import group or user describes the issue encountered.

Mapping UNIX profiles to Active Directory accounts

After you check the status of pending import groups or users, you can map the pending import group or user to an Active Directory group or user. The actions you can take depend on the object you select and its current state. For example, if you select a pending group, you can choose to:

- Accept the default Active Directory candidate for the selected group if a candidate is identified.
- Create a new Active Directory group and attach the selected UNIX group profile to it.
- Extend an existing Active Directory group to include the selected UNIX group profile.
- Merge the members of the selected UNIX group with an existing UNIX group in Active Directory.
- Delete the selected UNIX group.
- View and modify the properties of the selected UNIX group.

Accepting the Active Directory candidate

If Access Manager finds a potential match for the pending import group or user in Active Directory, it displays the matching candidate in the details pane. You can accept the suggested candidate by right-clicking the pending import group or user, then selecting **Accept**. After you accept the Active Directory candidate for a pending group or user, the group or user is removed from the Pending Import list.

If all of the pending import group members have an Active Directory candidate associated with them, they are added as members of the Active Directory group. However, the group will remain in the Pending Import list until all of its members are successfully mapped to Active Directory users or removed as members.

Creating a new Active Directory account

If Access Manager did not find a potential match in Active Directory, you must determine whether the pending import group or user should be mapped to an existing Active Directory account or requires a new Active Directory account. If the pending group or user requires a new Active Directory account, right-click the pending group or user, then select the **Create new** option to open the wizard for creating a new Active Directory group or a new Active Directory user.

Follow the prompts displayed in the wizard to provide the additional information needed to create the group or user account.

Adding a profile to an existing Active Directory account

If Access Manager did not find a potential match in Active Directory but an appropriate Active Directory account exists, you must map the pending import group or user to the appropriate Active Directory group or user. If the pending import profile should be added to an existing Active Directory group or user, right-click the pending group or user, then select the **Extend existing** option to open the wizard for adding a UNIX profile to an existing Active Directory group or existing Active Directory user.

Merging pending group members into an existing group

If Access Manager did not find a potential match for a Pending Import group in Active Directory, you might want to merge the members of the Pending Import

group into a group that already has a UNIX profile in the zone. If you want to add the members of a selected pending import group to an existing group profile, right-click the pending import group, then select the **Merge into existing Unix group** option to open the wizard for merging the membership of a pending import group with the membership of an existing UNIX group.

Deleting a UNIX profile for a pending group or user

If there are no suitable candidates to map a pending import group or user, you might want to remove a pending group or user from the Pending Import list. If you want to delete a pending import group or user, you can do so by right-clicking the pending import group or user, then selecting the **Delete** option.

Viewing or modifying properties for a pending group or user

If there are conflicts between a pending import profile and information in Active Directory, you might need to modify the properties associated with the pending import profile before you can take any other action. If you want to view or modify the properties for a pending import group or user, right-click the pending import group or user, then select **Properties**.

If you select a pending group, the properties include the UNIX profile, the time of the import, the file location the information was imported from, the members of the group, and the status of the group.

If you select a pending user, the properties include the UNIX profile, the time of the import, the file location the information was imported from, and the status of the user.

Resolving errors and conflicts

In some cases, you might encounter errors (Error) that must be resolved before a pending import user or group can be migrated into Active Directory. For example, pending import groups cannot be imported if the group profile has any of the following problems:

- The group's GID is negative.
- There is another UNIX group with the same GID already defined in the zone.
- There is a UNIX group with the same group name already defined in the zone.
- The matching Active Directory candidate already has a UNIX profile in the zone.

Similarly, pending import users cannot be imported if the user profile has any of the following problems:

- The user's UID is negative.
- The user's primary group GID is negative.
- There is a UNIX user with the same user name already defined in the zone.

In most cases, you must resolve these issues by modifying the properties for the pending import profile. For example, assume you are importing a passwd file that includes the UNIX user account pierre with the UID 1001, but there is already an UNIX profile in the zone with the UNIX name pierre and UID of 500. After you check the status, the Pending Import list of users will indicate there is an error.

To resolve a conflict like this, you might select the pending import user, right-click, then select **Properties** to change the UNIX user name from pierre to another name, such as pierre2. You should keep in mind, however, that conflicts like this might require investigation to determine the appropriate course of action. For example, if you are attempting to import the UNIX profile for the user pierre and there's a conflict, you need to determine whether pierre with the UID of 1001 is the same person as pierre with a UID of 500 and where each UID is applicable. If both profiles are for one person accessing different computers, you might simply need to define a computer-level override on the specific computer where the UID of 1001 is required. If the pending import user actually refers to a different person, you might have to map the profile to a different Active Directory account or move the computer to a different zone.

Resolving warnings

In addition to the errors that prevent users or groups from being imported, there are several conditions that generate a warning (Warning). Warnings indicate potential problems that you should try to resolve. After you check the status for pending import groups and users, the most common warning is "No matching Active Directory candidate is found." To continue, you must identify or create an Active Directory account for the pending import profile.

If you make changes to a pending import user or group to correct problems, you should click **Check status** after the change to check for any additional issues that might need to be resolved.

Overriding and modifying user properties

If you are using hierarchical zones, user profile information is inherited from parent zones into any child zones you define. You can override the inherited profile attributes at any time to create a new user profile in a specific child zone or on individual computers, if needed. Overriding profile attributes enables you to migrate legacy local accounts without modifying any existing account information or file and directory ownership.

You can also modify either the user profile or the Active Directory user account properties for any user at any time using the tool of your choice. For example, you can use Access Manager, the Access Module for Windows PowerShell, ADEdit, Active Directory Users and Computers, or the Centrify Windows API to modify the zone profile or Active Directory properties for a selected user.

To override a profile attribute in a user profile:

1. Open Access Manager.
2. Expand Zones and any parent or child zones required to select the zone name in which you want to override a profile attribute.

   For example, if you want to override the default login shell in the child zone that only AIX computers join, you might expand Child Zones to view and select the IBM AIX Only zone.

   If you want to override a profile attribute for a specific computer, expand Computers to select the computer name on which you want to override the profile attribute. For example, if you want to override the default numeric identifier for a user on the AIX computer aix6v0.ajax.org, you might expand the IBM AIX Only child zone and the Computers node to view and select the aix6v0.ajax.org computer.
3. Expand UNIX Data for the zone or computer, then select Users.
4. Select the user, right-click, then select **Zone Profile**.

   The profile displays the attributes inherited from the parent zone or currently set.
5. Select an attribute and provide the override value.

   For example, select **Shell** and type /usr/bin/ksh to give the selected user profilea different default login shell—one appropriate for an AIX computer—in the selected zone or on the selected computer.
6. Click **OK** to save the profile change.

Overriding and Modifying Group Properties

If you are using hierarchical zones, group profile information is inherited from parent zones into any child zones you define. You can override the inherited profile attributes at any time to create a new group profile in a specific child zone or on individual computers, if needed.

You can also modify either the group profile or the Active Directory group properties for any group at any time using the tool of your choice. For example, you can use Access Manager, the Access Module for Windows PowerShell, ADEdit, Active Directory Users and Computers, or the Centrify Windows API to modify the zone profile or Active Directory properties for a selected group.

Adding Users or Groups from a Trusted Forest

In most cases, when you create a profile for a user or group in a zone, the Active Directory account already exists in the local Active Directory forest. You can, however, also add profiles for remote users and groups to a zone without adding them to the local forest. If you have established a one-way or two-way trust relationship with a remote or external Active Directory forest, you can add users and groups from that forest to a selected Centrify zone.

You add remote or external users and groups to the zone in the same way you add profiles for local Active Directory users and groups except that you must select the remote forest or domain before searching for the user or group account. For example, at Step 4 of the procedure To create a group profile for an Active Directory group using Access Manager, click **Browse** to select a trusted external forest or a specific domain in the trusted forest.

If you have defined a one-way or two-way trust between a local forest (wonder.land) and a remote forest (w2k3r2.dev), you can select the remote forest in the Browse for container dialog box to add groups from that forest (w2k3r2.dev) to the currently selected zone.

Add groups from the forest

If you use attribute variables to define any part of the user profile, keep in mind that the Centrify Agent cannot directly read any of the attributes for a user from a one-way trusted forest. The agent can retrieve the userPrincipalName and sAMAccountName from the zone profile for the user. However, the agent cannot retrieve other user attributes. If the agent cannot resolve a variable in the user profile, the agent leaves the attribute value undefined. For example, if you use the displayName variable to define the GECOS attribute, that attribute will be undefined for all users from an external forest with a one-way trust.

Identifying users from remote forests

You can identify the Active Directory users who have been added from a remote or external forest by checking the icon displayed in the Access Manager console. If a user is added from a remote or external forest, the user name displays the following icon:

Remote or external forest

Valid login names for users from a remote forest

If you add users from an external forest to a zone, you should be aware that those users can only log on or be identified using the following information:

- A valid UNIX profile name that has a complete set of profile attributes.
- The full Active Directory user name including the user's external forest domain name.

When users are defined in a local forest, they can be located in Active Directory by their UNIX profile name, their userPrincipalName, or their sAMAccountName in the form of their user logon name alone or in the format of domainname\username, so any of these login name formats can be used to access user information or to log on to a Centrify-managed computer.

To identify a user from a trusted external forest, however, you must use either the user's UNIX profile name for the zone or the user's sAMAccountName followed by the user's external domain name in the form of sAMAccountName@domainname. Using the UNIX profile name or the sAMAccountName@domainname ensures the name is unique when there are cross-forest trust relationships. For example, if an Active Directory user from a trusted external forest (sierra.org) has the Active Directory logon name of sofia.perez and a UNIX profile name of sofiapz, the user can be identified using:

- sofia.perez@sierra.org
- sofiapz

You cannot use sierra\sofia.perez or sofia.perez without the domain to retrieve information or authenticate from a remote forest. In addition, the userPrincipalName (username@domainname) for any user might be different from the sAMAccountName@domainname. For example, if you use alternate UPN suffixes, the domain name used in the userPrincipalName might be different from the domain name that uniquely identifies the user. Similarly, a user's logon name (sAMAccountName) might be different from the user name used in the userPrincipalName. For example, if the Active Directory user sofia.perez@sierra.org has a user logon name of SIERRA\perez.s, that user would be found as perez.s@sierra.org.

Adding Multiple Profiles for a User to a Zone

It is possible for a single Active Directory user to have more than one UNIX profile defined in a zone. If you attempt to add a new UNIX profile for an Active Directory account that already has a UNIX profile in the current zone, Access Manager displays a warning but allows you to continue.

If an Active Directory user has more than one UNIX profile in a zone, however, the user should log on to computers in the zone with the UNIX profile name he wants to use. Logging on with the Active Directory user login name—the user's sAMAccountName attribute—might prevent the user from accessing some files because the account has multiple UNIX profiles and UIDs associated with it. In most cases, users can log on with their Active Directory account name if you have created parent and child hierarchical zones that address conflicting profile attributes. However, if you are using classic zones or hierarchical zones that don't address the need for multiple UNIX profiles, users might encounter file ownership issues.

Enabling and Disabling Users in Classic Zones

If you have added user profiles to classic zones, you can enable or disable their UNIX profiles in those zones at any time. Enabling and disabling a UNIX profile is not applicable in hierarchical zones.

To enable or disable the UNIX profile for multiple users in a classic zone, select all of the user names to enable or disable using the CTRL or SHIFT keys, right-click, then click **Enable UNIX Account** or **Disable UNIX Account**.

Forcing Replication for Read-Only Domain Controllers

If the Active Directory forest includes read-only domain controllers, you should force replications when adding or modifying users and groups in a zone. Forcing replication ensures that the new information is available right away.

To force replication after updating a zone:

1. Click Start > Administrative Tools > Active Directory Sites and Services.
2. Expand Sites, then select the Active Directory site that contains the connection over which you want to replicate directory information.

   For example, select **Default-First-Site-Name**.
3. Expand **Servers**, then select the read-only domain controller for which you want to force replication.
4. Click **NTDS Settings**.
5. In the details pane, right-click the connection over which you want to replicate directory information, then click **Replicate Now**.

If you choose not to force replication, the changes made to the zone will not take effect until replication is complete for the forest.

Using Configuration Parameters and Group Policies

You can use local configuration parameters or applied group policies to manage many operations for users and groups on Linux and UNIX computers. For example, you can use configuration parameters or group policies to bypass Active Directory authentication for specific users or to allow some users or groups to be approved for prevalidation. For more information about working with group policies, see the *Group Policy Guide*. For more information about setting parameters in the Centrify configuration file, see the *Configuration and Tuning Reference Guide*.

Enabling and configuring local account management

The local account management features described earlier in this guide require that local account management be enabled and configured.

Several configuration parameters and group policies let you control whether local account management is enabled in your environment, and how local account management is configured after it is enabled.

Local account management is disabled by default unless you are upgrading from a release in which local account management was enabled.

Follow these guidelines to determine whether you need to enable local account management:

- If you perform a fresh installation of Server Suite, the **Enable Local Account Management Feature** group policy is set to **Disabled**, and the adclient.local.account.manage configuration parameter on each local (agent-managed) computer is set to false. To use the local account management features described in this guide, you must manually enable local account management by setting the **Enable Local Account Management Feature** group policy to **Enabled**, or by setting the adclient.local.account.manage configuration parameter to true.

  See the following sections, "Group Policies" and "Configuration Parameters," for more information.

- If you are upgrading from a previous release, you can check the **Enable Local Account Management Feature** group policy setting to enable or disable local account management.

The following information is a summary of how various parameters and group policies affect local account management enablement and configuration. For more details about these parameters and group policies, see the *Configuration and Tuning Reference Guide* and the *Group Policy Guide*.

Group Policies

- **Enable Local Account Management Feature**: Use this group policy to control whether local accounts are managed by the UNIX agent and Access Manager. This group policy is disabled by default, unless you are upgrading from a previous release in which local account management was enabled.

  This group policy is located in Computer Configuration > Centrify Settings > DirectControl Settings > Local Account Management.

  This group policy controls the adclient.local.account.manage configuration parameter.

- **Notification Command Line:** Use this group policy to define a command to process changes to local account profiles after the agent synchronizes local user and group profiles with profiles defined in Access Manager.

This group policy is located in Computer Configuration > Centrify Settings > DirectControl Settings > Local Account Management.

This group policy controls the adclient.local.account.notification.cli configuration parameter.

- **Set refresh interval for access control cache**: Use this group policy to specify how often etc/group and etc/passwd are updated on UNIX and Linux computers, based on the local group and local user settings that you configure in Access Manager. This group policy also controls how often the authorization store cache is updated.

  This group policy is located in Computer Configuration > Centrify Settings > DirectControl Settings > Network and Cache Settings.

  This group policy controls the adclient.refresh.interval.dz configuration parameter.

Configuration Parameters

The following configuration parameters are located in the /etc/centrifydc/centrifydc.conf configuration file.

- **adclient.local.account.manage**: Use this parameter to control whether local account management is enabled on an individual computer. This parameter has a value of false by default, unless you are upgrading from a previous release in which local account management was enabled.

- **adclient.local.account.notification.cli**: Use this parameter to define a command to process changes to local account profiles after the agent

synchronizes local user and group profiles with profiles defined in Access Manager.

- **adclient.local.account.notification.cli.arg.length.max**: Use this parameter to specify the maximum argument length for the command that you define in the adclient.local.account.notification.cli parameter.
- **adclient.refresh.interval.dz**: Use this parameter to specify how often etc/group and etc/passwd are updated on an individual computer based on the local group and local user settings that you configure in Access Manager. This parameter also controls how often the authorization store cache is updated.

Authorizing Basic Access

This chapter describes the basic principles of authorization and how to grant access to Centrify-managed computers using the default predefined rights and role definitions for Linux and UNIX computers. You should review the information in this chapter before creating custom role-based access rights and role definitions.

Delinea

Basic concepts of Access Rights and Roles

To log on and use Centrify-managed computers, Active Directory users must have a complete UNIX profile and be assigned to at least one role that grants them access. Both the profile and the role assignment can be explicitly defined for the zone or for an individual computer, or inherited from a parent zone.

You can use Access Manager to centrally manage what users can do on computers that have the Centrify Agent installed. For example, you can control who can log on or connect remotely for each computer in a zone through the definition of rights and the assignment of roles. A **right** represents a specific operation that a user is allowed to perform. A **role** is a collection of rights that can be defined in a parent or child zone and assigned to Active Directory users and groups.

The most basic rights are the predefined **system rights** that determine whether a user can log on locally with a password, log on remotely without a password, and run commands in a standard shell or in a restricted shell. The most common settings for these system rights are defined by default in the UNIX Login role so that you can grant users access to Centrifymanaged computers by simply assigning the predefined UNIX Login role and without defining any custom roles or creating any additional access rights.

System Rights Authorize Access in Role Definitions

System rights are always associated with a role definition, whether it is a predefined role such as the UNIX Login role or a custom role you create. You can enable or disable specific system rights in any role definition, but you cannot add, modify, or delete the rights themselves. For Linux and UNIX computers, you can select the following system rights for any role:

- **Password login and non password (SSO) login are allowed**: Specifies that a user is allowed to log on interactively using a password or without a password using a single sign-on token.
- **Non password (SSO) login is allowed**: Specifies that a user is allowed to log on using a single sign-on token.
- **Account disabled in AD can be used by sudo, cron, etc.**: Specifies that an account that is disabled in Active Directory is allowed to access the computer. This right is intended to allow service accounts that run without a password to perform operations.
- **Login with non-Restricted Shell**: Controls whether a user gets a standard shell or is forced into a restricted shell. Users must be assigned at least one role with this right to have access to a standard shell environment. A restricted shell only allows a user to execute explicitly defined commands.

In addition to the platform-specific system rights, there is a system right that allows users to bypass auditing or role restrictions to log on when there are problems on a computer. By selecting the **Rescue rights** option you can allow users in a particular role to log on in situations when all users would normally be locked out. For example, if authentication, authorization information, or auditing is required but not available, most users are prevented from logging on. You can use the rescue rights option to allow selected administrators to access the computer and fix the issues that are preventing other users from logging on.

Note: If you do not explicitly set the **Allow users assigned to this role to log on if problems with authentication, authorization or auditing services prevent logon access** rescue right option for any users, only the local root account will have rescue rights. The root account is always allowed to log on by default.

Access Rights Defined in the UNIX Login Role

The predefined UNIX Login role is configured by default to allow users to log on locally with a password, connect remotely to a computer without being prompted for a password, and access the standard shell environment. The UNIX Login role is also configured to allow users to access all PAM-enabled applications in their environment. The UNIX Login role grants access to PAM-enabled applications through a predefined loginall PAM access right.

For most users and organizations, the default settings in the UNIX Login role make the user experience consistent before and after deploying the Centrify Agent and joining an Active Directory domain. Users can log on and use the shell environment and applications in the same way they did before the deployment of the Centrify Agent.

The predefined UNIX Login role and predefined loginall PAM access right are available by default in every zone. Depending on your requirements and policies, you can assign the UNIX Login role to all Active Directory users or to specific Active Directory users and groups. You can also choose whether to assign the UNIX Login role in parent or child zones to control where different groups of users can log on to Linux and UNIX computers.

Users must have both a complete identity profile and at least one role assignment that grants access before they can log on to any Centrify-managed computer. If you don't use the UNIX Login role, you must create at least one custom role definition that provides similar functionality.

Default Access Rights and Roles

In addition to the predefined UNIX Login role that grants basic access to Centrify-managed computers during deployment, there are other predefined access rights and role definitions that are available by default in every zone. These other predefined rights and role definitions provide specialized access rights for specific scenarios that are common in Linux and UNIX environments.

Default PAM access rights

For Linux and UNIX computers, the following predefined PAM access rights are available:

- login-all grants access to all PAM-enabled applications by specifying the asterisk (*) wild card for the application name. This right is included in the predefined UNIX Login role. You can add this right to any custom role to grant access to all PAM applications, such as login, ftp, ssh, telnet, and many others, without specifying them individually.
- ssh grants access to secure shell sessions on Debian and Ubuntu 6 and 7 computers. By default, this access right grants users access to all secure shell applications and operations.
- sshd grants access to secure shell sessions on all Linux and UNIX computers except Debian and Ubuntu 6 and 7 computers. By default, this access right grants users access to all secure shell applications and operations.

Default secure shell (SSH) access rights

Secure shell (SSH) access rights enable you to limit what users who are granted the PAM ssh or sshd right can do. These rights have no effect without the PAM ssh or sshd right. In addition, the default secure shell rights are only applicable for the Centrify-compiled version of OpenSSH.

For Linux and UNIX computers, the following predefined secure shell access rights are available:

- dzssh-all grants access to all secure shell services.
- dzssh-direct-tcpip allows local and dynamic port forwarding (ssh-L, ssh -D).
- dzssh-exec allows command execution.
- dzssh-scp allows secure copy (scp) operations.
- dzssh-sftp allows secure file transfer (sftp) operations.
- dzssh-shell allows secure terminal (tty/pty) connections.
- dzssh-Subsystem allows an external subsystem except sftp subsystem which has its own right.
- dzssh-tcpip-forward allows remote port forwarding (ssh -R).
- dzssh-tunnel allows tunnel device forwarding.
- dzssh-X11-forwarding allows X11 forwarding.

Predefined role definitions

In addition to the predefined UNIX Login role, there are several predefined role definitions that are available by default in every zone. For Linux and UNIX computers, the following predefined role definitions are available:

- listed makes a user profile visible in a zone but does not grant any type of access rights, PAM rights, or command rights. This is a specialized role that can be used when a user profile must exist for computers in a zone, but no local or remote access should be granted. For example, if a user owning files on a computer in a zone should no longer have access to the computers in the zone, you can assign the listed role so that the files continue to have an owner, but the user has no effective logon rights in the zone.
- local listed makes a local user profile visible in a zone but does not grant any type of access rights. This is a specialized role that can be used when a user profile must exist for computers in a zone, but no user access should be granted. For example, if a user owning files on a computer in a zone should no longer have access to the computers in the zone, you can assign the listed role so that the files continue to have an owner, but the user still has no effective rights in the zone.
- require MFA for login forces two-step authentication for access. This role does not grant access to any PAM applications but can be used in

combination with the UNIX Login role to require users who are assigned to both roles to provide more than one form of authentication. You can also use this role with custom roles that grant access to specific applications if you want to require multi-factor authentication for those applications. You should note that using this predefined role definition requires additional configuration outside of Access Manager. For more information about what is required to support multi-factor authentication, see Requiring multi-factor authentication to log on.

- Rescue - always permit login enables users to log on to computers if there are problems with the authentication, authorization, or auditing service that are preventing other users from logging on. For example, if auditing is required on a computer and the auditing service is not available, only users assigned to a role with the “rescue” system right will be able to log on.
- scp grants secure copy (scp) access rights.
- sftp grants secure file transfer (sftp) access rights.

Identifying the Scope for Role Definitions

The rights from multiple role assignments accumulate, which provides great flexibility and granularity in how you define and assign rights and roles. For example, you can use the UNIX Login role to control basic access, and define a second role that grants the rights to execute a set of privileged commands, so that a user assigned to both roles could log on, but only execute a few specific commands with elevated privileged. By separating rights into separate role definitions, not every role requires PAM applications or system rights, as long as a user is assigned a role that has those rights.

Because access rights are additive, however, it is important to consider where you define and assign roles to control who has administrative privileges on which computers. For example, it might seem reasonable to assign the predefined UNIX Login role to all Active Directory users. Doing so, however, could grant broad permission to log on to Linux or UNIX computers to which you want to restrict access. If you assign that role in a parent zone, it is inherited along with any additional rights granted in child zones.

In most cases, it is appropriate to define roles in parent zones, but assign roles carefully in child zones to avoid granting access rights on computers that host administrative applications or sensitive information.

Assigning the UNIX Login Role

The predefined UNIX Login role allows Active Directory users to log on to Centrify managed computers using any PAMenabled application—such as login, ssh, or ftp—with a default shell and permission to execute the same set of commands available to any standard UNIX user account. By default, the UNIX Login role is configured to take effect immediately and never expire. By default, the UNIX Login role is also configured to audit user activity if the auditing service is running on a computer users access.

The default settings are appropriate for most Linux and UNIX users in most organizations. However, you can change any of the default settings in either a parent or a child zone, if needed.

What to do before assigning the UNIX Login role

You can assign the UNIX Login role to all Active Directory users, to specific Active Directory users, or to specific Active Directory groups. Because the UNIX Login role is a predefined role, you cannot assign any local users to the role.

Before you assign the role, you should decide whether you want to assign and inherit the role from a parent zone or make the assignment in a specific child zone. You should also decide whether you want to specify optional start and end times for some role assignments.

Rights required for this task

The following table describes the minimum rights that must be granted for users to successfully manage role assignments in a zone:

Authorization	On the **Object** tab, select **Allow** for the following: List contents Read all properties Create all child objects Delete all child objects On the **Properties** tab, select **Allow** for the following: Write msDS-AzApplicationData	This object only
	On the **Properties** tab, select **Allow** for the following: Write displayName Write msDS-AzApplicationData Write msDS-TasksForAzRole Write msDS-MembersForAzRole	The msDS-AzRole object
AzRoleObjectContainer	On the **Object** tab, select **Allow** for the following: List contents Read all properties Create msDS-AzRole objects Delete msDS-AzRole objects	The msDS-AzApplication object and all child objects
	On the **Properties** tab, select **Allow** for the following: Write displayName Write msDS-AzApplicationData Write msDS-TasksForAzRole Write msDS-MembersForAzRole	The msDS-AzRole object
	On the **Properties** tab, select **Allow** for the following: Write msDS-AzApplicationData	The msDS-AzAdminManager object
AzOpObjectContainer	On the **Object** tab, select **Allow** for the following: Read all properties Create msDS-AzOperation objects Delete msDS-AzOperation objects Create msDS-AzRole objects Delete msDS-AzRole objects	This object only
	On the **Properties** tab, select **Allow** for the following properties: Write displayName Write msDS-AzApplicationData Write msDS-TasksForAzRole Write msDS-MembersForAzRole	The msDS-AzRole object
	On the **Properties** tab, select **Allow** for the following: Read name Read Name Write msDS-AzApplicationData Write name Write description	The msDS-AzOperation object

Who should perform this task

A UNIX administrator who manages one or more zones most often performs this task, depending on your organization's policies.

How often you should perform this task

In most organizations, you assign the UNIX Login role to target groups of users at a time during deployment and as needed, thereafter.

Steps for completing this task

The following instructions illustrate how to assign the UNIX Login role using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To assign users and groups to the UNIX Login role in a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to make role assignments.
3. Expand Authorization.
4. Select Role Assignments, right-click, then click **Assign Role**.
5. Select the UNIX Login role definition from the list of roles, then click **OK**.

   By default, the role is set to start immediately and never expire. You can set a **Start time**, **End time**, or both start and end times for the role assignment. For example, if the role assignment applies to a contractor who will be hired for a specific period of time and you want to automatically disable the role after they finish the job and leave the organization, you can specify the start and end times when you assign the role.
6. Select whether the role assignment applies to all Active Directory accounts or specific accounts.

   If you want to automatically assign the role to every user added to the Active Directory forest or trusted forests, you can select **All Active Directory accounts** for convenience. This option is similar to selecting the "Authenticated Users" or "Everyone" system groups. For example, if you want to assign all Active Directory users the UNIX Login role by default, you can select this option. Only users who also have a complete UNIX profile will be able to log on to the UNIX computers joined to the domain.

   If you are assigning the role to specific accounts, click **Add AD Account** to search for and select the Active Directory groups or users to assign to the role, then click **OK**.
7. Click **OK** to complete the role assignment.

What to do next

Verify Active Directory users or group members assigned the UNIX Login role can log on to Centrify-managed computers in the zone where you have made the role assignment.

Where you can find additional information

If you want to learn more about working with rights, roles, and role assignments, see the following topics for additional information:

- Defining rights to use commands
- Defining rights to use PAM applications
- Using secure shell session-based rights
- Creating and assigning custom role definitions

Performing Role Assignment on Multiple Computers

To simplify the process of assigning Active Directory users or groups to a role, you can perform a bulk role assignment. With a bulk role assignment, you can assign a role to multiple Active Directory users and groups on multiple computers at the same time. For example, if you have two groups of Oracle administrators and three computers where the members of those groups need access to their OracleAdmin role, you can select those two groups and those three computers to be assigned the OracleAdmin role in the same process. You can also specify optional start and end times for the role assignment and have those settings apply for all of the users, groups, and computers you have selected for bulk assignment.

To assign a role to multiple users and groups on multiple computers

1. Open Access Manager.
2. Expand **Zones** and the individual parent or child zones required to select the zone name where you want to make a bulk role assignment.
3. Right-click, then select **Assign Roles to Computers**.
4. Type the user and group names you want to be included in the role assignment, then click **OK**.

   You can specify multiple names separated by a semi-colon (;). You can also search for user and group names by typing part of the name and clicking Check Names or by clicking Advanced and entering search criteria. If multiple users or groups match the search criteria, select the appropriate users and groups, then click **OK**.
5. Type the computer names you want to be included in the role assignment, then click **OK**.

   You can specify multiple names separated by a semi-colon (;). You can also search for the computer names by typing part of the name and clicking Check Names or by clicking Advanced and entering search criteria. If multiple computers match the search criteria, select the appropriate computers, then click **OK**.
6. Select a role for the list of roles available, then click **OK**.
7. Review the role assignment start and end time and the user and group accounts that are being assigned the role, then click **OK**.

   You can make changes to the start and end times if you want those changes applied for all of the users, groups, and computers that are part of this bulk role assignment.

After you click OK, the selected users and groups are then automatically assigned the selected role on the selected computers.

Viewing Rights and Roles

Access Manager allows you to view the status and effective rights for any Active Directory user or local user in a zone, whether they have been assigned a role or not. You can view detailed information about the rights and role assignments for users by using **Show Effective UNIX User Rights**. If a user is not assigned a role or does not have a complete user profile, be certain to select the **Show omitted users** option, otherwise, information will not be shown for the user.

> **Note:** Local users are defined in Access Manager in the zone and are saved in /etc/passwd on each computer in each zone where the profile is defined. Local users that you define in the zone do not need to be Active Directory users. For more information about local users, including information that is required for a user profile to be complete, see Creating user profiles.

To view rights for an individual user in Access Manager

1. Open Access Manager.
2. Expand **Zones** and the individual parent or child zones required to select the zone name where you want to view rights and other account details.
3. Right-click, then select **Show Effective UNIX User Rights**.
4. Select a computer or click Browse if you want to limit the information included to a specific computer.
5. Select **Show AD users** and **Show local users** as necessary, depending on which users you want to view. One or both of these choices might already be selected, depending on the location from which you originally selected **Show Effective UNIX User** rights.
6. Select **Show omitted users** to include users who have an incomplete profile or do not have a role assignment in the list of UNIX users.

   User information is displayed as shown in the following example. Key points about the information displayed are as follows:

   - Users with incomplete profiles are displayed in red (if **Show omitted users** is selected).
   - Local users are not required to have an AD name, resulting in a displayed **AD Name** value of N/A.
   - AD users are not required to have a UNIX profile, resulting in a displayed **Profile State** value of N/A.
   - For more information about the differences between AD users and local users, as well as details about profile states for local users, see Creating, modifying, and deleting user profiles for local users.

     Creating, modifying, and deleting user profiles
7. Select a user to see more detailed information about the user's profile, role assignments, and rights in the selected zone or on a specific computer:
   - Click **Zone Profile** to review the UNIX profile defined for a user and where the profile attributes are defined. If a user has an incomplete profile, you can click the **Zone Profile** tab to see which profile attributes are missing.
   - Click **Role Assignments** to review a user's role assignments. The Object Assigned column indicates whether the role is explicitly assigned to the user (user@domain) or to a group the user is a member of (group@domain). The Location of Assignment column indicates the zone or computer role in which the assignment was made. Information for the Start Time, End Time, or both columns is only displayed if a role assignment has time constraints.
   - Click **PAM Accesses** to review the PAM application access rights for the user in the selected zone or on a specific computer, including the role to which the right belongs.
   - Click **Commands** to review the command access rights for the user in the selected zone or on a specific computer, including the role to which the right belongs.
   - Click **SSH Rights** to review the secure shell rights for the user in the selected zone or on a specific computer, including the role to which the right belongs.
8. Click **Close** when you are finished reviewing user rights in a zone or on particular computers.

Checking rights and roles with the dzinfo program

You can also view rights and roles for specific users or the current user by running the dzinfo command-line program on Centrifymanaged computers. If you want to use the dzinfo program to view roles and rights for other users, however, you must have root permission.

You can run dzinfo without any arguments to see your own rights and role assignments. The command displays detailed information about the your role assignments, the availability for each role assignments, your effective rights, the current audit level, and the specific PAM access, command, and secure shell rights you have been granted.

To see more detailed information, such as the days and times a role is available, you can use the --verbose option. For example, to see detailed information, you could type the following command:

dzinfo --verbose

To view roles and rights for a specific user:

1. Log on or switch to root on a managed computer.
2. Run the dzinfo command for a specific user with the username in the command line.

   dzinfo username

   For example, to see details about the rights and roles assigned to the user sonya, you could type the following command:

   dzinfo sonya

If rights and role assignments have been configured for the specified user, the command displays detailed information about the user's role assignments, the availability of those role assignments, the user's effective rights, the audit level in effect, and the specific rights that have been granted.

You can also use the dzinfo program to test whether a user has the right to run specific commands. For more information about using dzinfo and the dzinfo command line options, see the dzinfo man page.

Changing the Audit Level for Role Definitions

By default, all role definitions—including predefined role definitions—are set to "Audit if possible" as the audit level. With this setting, user activity is audited if the auditing service is installed and enabled on a managed computer. If the auditing service is not installed or not running on a given computer, this setting has no effect. Users can log on and use the access rights that are defined for their role assignment without having their activity audited.

In most cases, the default "Audit if possible" setting is appropriate because it doesn't block user access if you are not deploying the auditing infrastructure but will automatically capture user activity if you are deploying auditing. In some cases, however, you might want to change the audit level. You can modify the audit level for any role definition to specify whether users must be audited in order to log on.

To change the audit level for a role definition:

1. Open Access Manager.
2. Expand **Zones** and the individual parent or child zones required to select the zone name where you want to change the audit level.
3. Expand Authorization and Role Definitions.
4. Select a role definition, right-click, then select **Properties**.
5. Click the **Audit** tab.
6. Select the appropriate audit level to use for the role definition.
    - Select **Audit not requested/required** if you are not interested in auditing session activity for users in the role.
    - Select **Audit if possible** if you want to audit user activity on computers running the Centrify auditing service. If you select this option and the auditing service is not installed or not currently available, users assigned to the role are allowed to log on without having their activity audited. This option is selected by default for new roles.
    - Select **Audit required** if you want to audit all session activity for users assigned to the role. If you select this option and the auditing service is not installed or not currently available, users assigned to this role are not allowed to log on.

      If auditing is required for users in a role, you should also define a role with rescue rights to allow selected administrators to log on and correct problems when other users are locked out. For more information about creating a role with rescue rights, see Creating a role definition with rescue rights.
7. Click **OK** to save the role definition.

Delinea

Requiring Multi-Factor Authentication to Log On

You can configure multi-factor authentication for users logging on to Centrify-managed computers to improve the security of physical or virtual data centers. You can assign the predefined require MFA for login role in combination with the UNIX Login role to require users who are assigned to both roles to provide more than one form of authentication. You can also create custom role definitions with the **Require multifactor authentication for login** system right. Before setting this system right, however, you should be aware the multifactor authentication for Centrify-managed computers relies on the infrastructure provided by the Centrify Identity Platform.

As a preview, here are the steps involved to enable multi-factor authentication for Centrifymanaged computers in hierarchical zones:

- Register for Privileged Access Service.
- Install and configure at least one **connector** for communication with Privileged Access Service.
- Verify the users who are required to provide more than one form of authentication have valid **Active Directory accounts** that are active in Privileged Access Service.
- Add or select the **authentication profiles** that specify the types of authentication challenges to support.
- Create a role with the appropriate **computer members and administrative rights** for multifactor authentication.
- Verify the **identity platform instance URL** you want to use if you have access to more than one instance.

After you have completed the preliminary steps, you can assign users the predefined require MFA for login role or a custom role with the **Require multi-factor authentication for login** system right to require two-step authentication when logging on using PAM applications. These preliminary steps are also required if you want to create command rights that require two-step authentication when executing commands using elevated privileges (dzdo) or in restricted shell (dzsh) environments.

The preliminary steps are also required to support multi-factor authentication in classic zone and Auto Zone. However, the implementation is slightly different than in hierarchical zones, so some of the steps differ depending on the type of zone where you want to use multi-factor authentication.

For more information, see the Preparing to use multi-factor authentication

Defining Rights to Use Commands

As discussed in Basic concepts of access rights and roles, access rights allow users to perform specific operations. You define the most basic rights—such as the right to log on or connect remotely—when you define roles. However, you can use more granular command access rights to tightly control who has access to individual command-line programs. This chapter describes how to define access rights that allow users to execute command-line programs on Centrify-managed computers.

Controlling Access to Commands

In a standard UNIX shell environment, an ordinary user account can execute a large number of common command-line programs without any special privileges, and one or more administrative accounts, such as root, are required to execute commands that perform privileged operations. If ordinary users need to execute any of the commands requiring administrative privileges, they might have to switch to an administrative account that requires them to know the password for a privileged users or been granted access by configuration settings in a sudoers file.

For Centrify-managed Linux and UNIX computers, however, you can define command access rights to tightly control the specific commands users can execute. You can also refine those rights to only allow specific arguments to be used or to require an executable to be located in a specific directory.

There are no predefined rights for commands. Therefore, only the specific command access rights you define will be available for you to add to roles. You should keep in mind that any command rights you define are specific to the zone where you configure them, but can be used in any child zones of that zone.

What Command Rights Provide

Command access rights identify the specific commands that can be executed on a Linux or UNIX computer by a user assigned the role to which the rights are added. Command rights also specify whether the commands defined in the right are executed under the user's own account or using another user account.

There are two primary reasons for defining command rights:

- To **grant access** to specific commands that must be executed with elevated privileges
- To **restrict access** to only allow specific commands to be executed.

Granting access using command rights

The most common reason for defining a command right is to grant access to commands that perform privileged operations. For example, you might want to grant users additional privileges to execute specific commands in a standard shell environment that they are not otherwise allowed to execute with the default rights associated with their account.

With this type of command right, most commands are executed in the default shell environment with ordinary user privileges. When users assigned to a role with this type of command right want to use their elevated privileges, they invoke the command they have been granted access to using the dzdo command. This type of command right is similar to configuring privileges in a sudoers file, then invoking a command using sudo.

This type of command right is appropriate for UNIX users who have a standard shell environment and only need elevated rights to perform specific tasks.

Restricting access using command rights

It is less common, but also possible to define a command right to restrict access. For example, you might want to create a role that provides strictly controlled access to an explicitly defined subset of shell commands. This type of command right creates a customized restricted environment shell (dzsh) where only explicitly defined commands can be executed. This type of command right is similar to configuring a "whitelist" of allowed command and is appropriate for users who only need access to a limited set of commands to perform their job.

Controlling the Shell Environment for Commands

You can define command rights to control who has permission to run specific commands in a zone. When you define individual command rights, you can also specify whether the commands can be executed in a non-restricted shell environment, a restricted shell environment, or both. After you define the command right, you can then add it to an appropriate role definition. It is then the role definition to which you add the command right that controls whether users can use the command in a standard, unrestricted shell environment or in a restricted shell environment.

If the role definition allows a non-restricted shell environment—like the UNIX Login role—the command right provides functionality similar to the UNIX sudo command except that it uses the role settings and the zone authorization store rather than through a sudoers configuration file.

If the role definition does not allow access to a non-restricted shell environment, the command right can only be used in a restricted shell environment and users assigned to the role can only execute the specific commands explicitly defined in command right.

Defining Rights to Run Privileged Commands

The most common reason for creating a command right is to allow users to execute commands that require privileges not granted to a standard UNIX user account. For example, you might want to grant some users permission to run Centrify command-line programs that require root privileges to better manage their own computers.

Defining command rights that grant elevated privileges is similar to granting access to privileged commands using the sudoers configuration file and the sudo program.

Steps for completing this task

The following instructions illustrate how to define a command right to execute a command with elevated privileges. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To define a command right for privileged access

1. Open Access Manager.
2. Expand **Zones** and the individual parent or child zones required to select the zone name where you want to define a command right.
3. Expand Authorization and UNIX Right Definitions, then select Commands.
4. Right-click, then click **New Command**.
5. On the General tab, type a short descriptive name for the command right, and optionally, a more detailed description for the command right.

   The privileged command name is required and must not be more than 63 characters in length or contain any special characters, such as asterisks (*), slashes (\ /), question marks (?), or quotation marks (").
6. Type the command you want to add.

   The Command field is required and should include any parameters or options, if needed. You can also use wild cards or a regular expression to specify commands matching a particular pattern.
7. Select the type of pattern matching to use for the "Command" and "Specific path" fields.
   - Select **Glob expressions** to use glob pattern matching syntax for wild cards.
   - Select **Regular expressions** to use extended regular expression pattern matching.

     For more information about pattern matching, see Selecting the pattern matching syntax.
8. Select an appropriate path for matching the command on the different operating environments you support.
   - Select **Standard user path** to use the local operating system's common set of user directories to find the command.
   - Select **Standard system path** to use the directories the root user would normally get on the local operating environment to find the command.
   - Select **System search path** if you want to search for the command in a predefined set of locations. The search locations are defined using the dzdo.search_path configuration parameter. If you select **System search path** and the dzdo.search_path parameter is not defined, the current user's path is used to search for the command.
   - Select **Specific path** if you want to define a custom set of locations for finding the command specified. If you select this option, you can specify one or more paths, separated by a colon.

     If you are specifying a path, the path must start with a forward slash (/) unless you are matching all paths (*). For example, if the command you specify is ls and you set the path to *, the ls command from any path is allowed.

     If you set both the "Command" field and the "Specific path" field to match all strings (*), any command from any path is allowed.
9. Specify an integer that determines the priority of the command — the lower the number, the higher the priority.

   If there are multiple commands that match the pattern you specified for the "Command" field, the priority determines which command has higher

priority.

10. Click the **Run As** tab, then select **Can be used by dzdo** to allow the command to be added to a role for privileged execution.
11. Select the user or group accounts that can be used to execute the command.
    - Select **Any User** if any standard user account can be used to execute the command with dzdo.
    - Select **One of the following users, uids, groups or gids** if you want to specify one or more user or groups that can be used to execute the command with dzdo.

      In most cases, the local root account is the appropriate account to use because it allows ordinary users to execute the specified command using root account privileges. However, you can click **Add** to add other users, groups, or service accounts that can be used to execute the command. Use the format #UID for UID values, %group for group names, or %#GID for GID values.

      The account used to execute commands can be an Active Directory user with a UNIX profile in the zone or a local UNIX user account. However, the account used to log on and invokes the command using dzdo must be associated with an Active Directory account.

      Optionally, you can specify the primary groups can be used when executing the command using dzdo:
    - Select **Any Group** if any group can be used as the primary group when executing the command with dzdo.
    - Select **One of the following groups**, then click **Add** if you want to specify the groups that can be used as the primary group when executing this command with dzdo.

      You can also configure commands to be executed using dzdo in a restricted shell environment. For this example, however, the command right is only used in a nonrestricted shell environment.
12. Click **OK** to save the new command right.

    In most cases, you can use the default settings for environment variables and execution attributes.
    - If you want to keep, remove, or add environment variables for command execution, see Customizing environment variables for command execution.
    - If you want customize any of the execution attributes, see Customizing command execution attributes.

Creating a role to run commands with elevated privileges

On most Linux and UNIX computers, you can identify commands that require elevated permissions, who can run those commands, and where different users or groups can run the commands using a sudoers configuration file. Users who have been granted the appropriate permissions can run privileged commands by invoking the sudo command.

Centrify provides similar functionality, but the commands are configured by defining command rights, adding the rights to the appropriate roles, and assigning the roles to different users and groups. Users who have been assigned the appropriate roles can then run privileged commands by invoking the dzdo command.

If users are assigned the predefined UNIX Login role, they have access to all of the standard command-line programs that are available to ordinary UNIX users. You can create a separate role for commands that run using root or another privileged user account. Alternatively, you can combine command rights and system rights in a custom role definition or by adding the command rights to the default UNIX Login role.

Command rights that allow users to execute commands with elevated privileges should only be added to roles with the **Login with Non-Restricted Shell** system right.

Users must execute command rights that grant elevated privileges using the dzdo command. If you selected the **Re-authenticate current user** option as an execution attribute when defining a command right, users must also provide the password for their own account, their own password and one or more other forms of authentication, or the types of authentication determined by the authentication profile configured in Privileged Access Service, which might or might not involve providing a password.

If you selected the **Re-authenticate using the target user's password** option as an execution attribute when defining a command right, users must also provide the password for the account used to execute the command.

To create a role that can execute commands with elevated privileges, do the following:

- Create command rights for the privileged commands users are allowed to run.
- Create a new role definition and set the System Rights for the role to allow password login, nonpassword login, or both, and select the **Login with Non-Restricted Shell** option, then click **OK** to save the role definition.
- Right-click the role, select **Add Right**, then select login-all or a specific PAM access right and the privileges command rights users are allowed to run, then click **OK** to save the changes to the role definition.

For more information about creating, assigning, and testing custom role definitions, see Customizing command execution attributes.

Defining a Restricted Shell Command Right

You can also use command rights to strictly control which commands certain users can execute. In a restricted shell environment, users can only execute the specific commands and command-line options that are explicitly allowed. For example, you might want to grant some users permission to run a specific Centrify command-line program, such as adinfo, without allowing them to run any other command-line programs on some computers.

Users who are assigned to a role with the restricted shell environment are not be able to run any other commands, including informational commands such ls, ps, and whoami, unless you explicitly include them in the command right. You are not required to explicitly add basic navigational commands, such as cd and pwd, to the command right.

What the restricted shell provides

For Linux and UNIX computers, Centrify provides a customized Bourne shell, dzsh, to serve as the restricted shell environment. The dzsh restricted shell supports environment variables, job control, command history, and the specific command rights you define. For example, you can use the up-arrow key in the dzsh shell to recall previously-entered commands. You can also set a limit to the command history available by adding HISTSIZE=n to the $HOME/.dzshrc file.

For most operations, working in the dzsh shell is similar to working in an unrestricted shell except that the command set available is limited to the command rights you add to the environment.

Limitations of the restricted shell

The restricted shell environment does not enforce rights for commands that run outside of the shell. For example, if users run a graphical desktop manager, they can run commands and applications that are launched from menu selections in the graphical user interface.

In addition, the command rights defined for the dzsh shell do not prevent users from running built-in shell commands, accessing the file system, or seeing process or system information. For example, even in a restricted shell environment with no rights to run any commands, users in a dzsh shell could get a process listing using the following script:

```
for i in /proc/[0-9]*;
do read PROC < $i/cmdline;
echo $PROC;
done
```

Because the shell scripting environment allows the operations, users can effectively access information that the commands defined for the restricted shell environment do not allow.

Securing the restricted shell environment

There are many ways sophisticated users can get around limitations placed on a restricted shell environment. For example, most text editors, such as vi and emacs, allow shell escapes. Giving users permission to run programs that allow shell escapes in a restricted shell enables them to open a new unrestricted shell environment with none of the restrictions placed on them in their defined environment, Similarly, giving users access to commands that set or modify local time and date settings might allow users to avoid time constraints for running commands or the expiration date and time for specific role assignments.

In some cases, even individual command line options might provide users with the means to run commands not defined in their restricted shell environment. For example, defining a command right that allows users to run the tar command with the usecompressprogram program_name option allows user to run the specified program_name even though the program_name is not an allowed command in their restricted shell environment.

In choosing the commands to allow in a restricted shell, therefore, you should carefully consider ways to plug potential security holes the commands might introduce or whether there are alternative commands that provide the same functionality more securely. For example, if you need to give a user access to an editor, such as vi or vim, you could restrict the ability to execute nested commands to prevent users from opening a new shell from within the editor. Alternatively, you could add the rvi command to the restricted environment instead of vi or vim because rvi doesn't allow the user to open a new shell.

For more information about setting attributes that control command executions, see Customizing command execution attributes.

Steps for completing this task

The following instructions illustrate how to define a command right for use in a restricted shell using Access Manager. For more information about any step, see Defining rights to run privileged commands. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To define a command right for restricted shell access

1. Open Access Manager.
2. Expand **Zones** and the individual parent or child zones required to select the zone name where you want to define a command right.
3. Expand Authorization and UNIX Right Definitions, then select Commands.
4. Right-click, then click **New Command**.
5. Type a short descriptive name for the command right, and optionally, a more detailed description for the command right.
6. Type the command you want to add.
7. Select the type of pattern matching to use for the "Command" and "Specific path" fields.
8. Select an appropriate path for matching the command on the different operating environments you support.
9. Specify an integer that determines the priority of the command—the lower the number, the higher the priority.
10. Click the **Restricted Shell** tab, then select **Can be used in a restricted role** to allow the command to be added to a role that runs in a restricted shell environment.
11. Select whether commands are executed using the user's logon account or using a specific the user name or UID.

    If you want to configure commands to be executed using dzdo in a restricted shell environment, you can click the Run As tab to specify a user or group for command execution.
12. Click **OK** to save the new command right.

    In most cases, you can use the default settings for environment variables and execution attributes.

    - If you want to keep, remove, or add environment variables for command execution, see Customizing environment variables for command execution.
    - If you want customize any of the execution attributes, see Customizing command execution attributes.

Creating a role to run commands in a restricted shell

For Linux and UNIX computers, Centrify provides a customized Bourne shell, dzsh, to serve as a restricted shell environment. The dzsh restricted shell supports environment variables, job control, command history, and the command access rights you define.

To create a role that runs a restricted shell, do the following:

- Create command rights for the restricted shell commands users are allowed to run.
- Create a new role definition and set the System Rights for the role to allow password login, nonpassword login, or both, and verify that the **Login with Non-Restricted Shell** option is not selected, then click **OK** to save the role definition.
- Right-click the role, select **Add Right**, then select login-all or a specific PAM access right and the restricted shell command rights users are allowed to run, then click **OK** to save the changes to the role definition.

For more information about creating, assigning, and testing custom role definitions, see Customizing command execution attributes.

Selecting the Pattern Matching Syntax

When you define a command right, you can specify whether you want to use glob pattern matching syntax or extended regular expression syntax to match the strings specified for the “Command” and “Specific path” fields.

Customizing Environment Variables for Command Execution

You can customize the environment variables used during command execution in both the non-restricted and restricted shell environments. For example, if a command is executed using a specific user or service account that requires environment variables that are not defined for the user invoking a command, you can define those environment variables as part of the command right definition.

If you want to configure the environment variables to use for a command right, click the **Environment** tab. You can then select one of the following options:

- Reset environment variables
- Remove unsafe environment variables
- Add environment variables

Resetting environment variables

Select **Reset environment variables** if you want to define the list of environment variables to set when the user runs the command. Note that only the environment variables you explicitly specify are retained and those environment variables will replace the default set of environment variables, rather than append the default set of environment variables. You can use Access Manager or dzdo.env_* configuration parameters in the centrifydc.conf file to control the list of environment variables to use when executing commands. For example, you can set the dzdo.env_keep configuration parameter in the centrifydc.conf file to keep a specific set of environment variables like this:

dzdo.env_keep: VAR

With this setting, only the VAR environment variable is defined for the list of environment variables to keep. All other environment variables, including the default list of user environment variables—such as PATH and KRB5CCNAME—are removed.

If you select this option, click **Edit** to specify the environment variables to retain from the user's environment in a comma-separated list. Click **Add**, type the environment variable name, then click **OK** for each environment variable you want to retain.

Removing environment variables

Select **Remove unsafe environment variables** if you want to remove a specific set of unsafe environment variables when the user runs the command. The list of unsafe environment variables is defined by the dzdo.env_delete configuration parameter in the centrifydc.conf file. Note that only the environment variables you explicitly specify are removed.

If you select this option, click **Edit** to specify the environment variables to remove from the user's environment in a comma-separated list. Click **Add**, type the environment variable name, then click **OK** for each environment variable you want to remove.

Adding environment variables

Select **Add environment variables** to define new environment variables to add when the user runs the command. Enter variables in a comma-separated list in the form name=value, or click **Edit** then **Add** to add new variables and values. You can add new variables regardless of which of the other options you select.

Customizing Command Execution Attributes

You can modify the default command execution attributes that are used when commands run in either the non-restricted shell or in a restricted shell environment. In most cases, changes are rarely required for commands that run in a non-restricted shell. It is more common to change the execution attributes for commands that run in restricted shell environments. For example, you can use the execution attributes to control whether an allowed command can invoke a nested command. In a restricted shell environment, you might want to prevent a command from invoking nested commands to reduce the chance that users can run commands not explicitly defined for their environment.

If you want to set any execution attributes for a command right, click the **Attributes** tab. You can then select different options to control different aspects of command execution.

Requiring re-authentication to run commands

After successful authentication during the login process, you can control whether running a command in a restricted shell or using elevated privileges requires re-authentication or not. If you want to require re-authentication, select the authentication rules to apply. When defining the rights for executing commands, you can select from the following authentication options:

- No re-authentication required

  Select this option to allow users to run the command without any additional authentication.

- Re-authenticate current user

  Select this option to require the user to be re-authenticated before running the command using their own credentials. If you select this option, you can also specify whether reauthentication requires the user to provide their password, requires their password and another form of authentication, or requires multi-factor authentication as determined by the authentication profile configured in Privileged Access Service, which might or might not involve providing a password.

  If you select both **Use password** and **Require multi-factor authentication for login,** users are prompted to type their password and provide another form of authentication before the command is executed. If you have configured the authentication profile to accept more than one type of authentication challenge, users are prompted to select the authentication method to continue.

- Re-authenticate using the target user's password.

  Select this option to require the user to be re-authenticated before running the command using the target run-as user's credentials.

Preserving group membership

When defining command rights, you should consider whether keeping a user's existing group membership would provide benefits for command execution or could be exploited to perform unauthorized operations.Select **Preserve group membership** if you want to retain the logged-on user's group membership while executing commands.

Allowing nested commands

When defining command rights, you should consider whether allowing the execution of nested commands could be exploited to perform unauthorized operations. Select **Allow nested command execution** if you want to allow a command to invoke another program or open a new shell. To enhance the security of a restricted shell environment, you should deselect this option to prevent an allowed command to be used to run another program or open an unrestricted shell.

Preventing unsafe path navigation

When defining command rights, you should consider whether the command or any of the allowed command arguments could be exploited to perform unauthorized operations. One way command arguments can be exploited is to allow navigation up the path hierarchy. To prevent command arguments from allowing unsafe navigation up a path hierarchy, you can select the **Prevent navigation up a path hierarchy**. For example, if a command right allows a user to execute a command such as vi /etc/httpd/conf/* without this option, the right could be exploited by specifying a command argument that navigates up a path hierarchy to perform an unauthorized operation. In this case, the right might be used to edit any file as the root user by specifying a relative path as a command-line argument.

vi /etc/httpd/conf/../../shadowpass

You can avoid this potential security risk by disabling upward path navigation for command arguments, if needed. Note that this setting is only supported in

hierarchical zones and is only applicable for glob command rights.

Setting the umask value

Set the **Umask value** by selecting the read (R), write (W), and execute (X) permissions for the owner, group, and other users if you want to change the permission settings for executing a command.

Setting SELinux role-based access control

Configure the **SELinux Setting** for dzdo Security Enhanced Linux (SELinux) role-based access control (RBAC). By enabling the SELinux role and SELinux type fields, privileged commands can be specified with the default role and type for creating SELinux context in execution. These settings can be overridden using the '-r'/'-t' command-line options respectively. To enable this setting, click the **SELinux Setting** button and enable SELinux role and SELinux type, then enter string values in the corresponding text fields. Settings are saved in the attribute of the msDS-AzOperation command object.

Note: These settings are currently supported only on the RHEL systems and effective only on system with SELinux enabled and joined to a hierarchical zone.

Setting the command digest

You can use Digest Settings to specify SHA-2 digests so that sudo can verify the binary's checksum (SHA-2) before sudo executes the binary. The supported digest (hash) types are as follows:

- SHA224
- SHA256
- SHA384
- SHA512

Select a digest type, and then enter a checksum. You can specify multiple digests for a command.

Note that setting a command digest is only supported in the explicit path matches against the command right, and only supported in the hierarchical zone.

Testing Command Rights

After command rights have been defined, added to role definitions, and assigned, you can use dzinfo --test "command" to check whether you have permission to execute a specific command. You can use the dzinfo username --test "command" command to check whether a specified user has permission to run a specified command. If you want to use the dzinfo program to view command rights for other users, however, you must have root permission.

To check for command rights, you must enter the complete path to the command and enclose the command in single or double quotes. For example, to test whether the user, qa1 has a command right that allows execution of the id command as root, you could run the following command on a Linux or UNIX computer:

[user1@rh5]# dzinfo qa1 --test "/bin/id"

Depending on the role definition and the user's role assignment, the command might display information similar to this:

Testing: User = qa1 command = /bin/id

User qa1 can run the command as 'root' via dzdo, authentication will not be required, noexec mode is off

Using Command Rights in a Standard Shell

After command rights have been defined, added to role definitions, and assigned, users can execute privileged commands in a standard shell environment by invoking the dzdo command then typing the command to execute, including any command-line options they are allowed to use.

For example, assume you have defines a command right for shutdown -r that enables users to execute the command as the root user. If you add that right to a role definition—such as the UNIX Login role—that allows users to log on using a standard shell environment, users assigned to that role can execute the command by typing the following:

```
dzdo shutdown -r
```

Using Command Rights in a Restricted Shell Environment

After command rights have been defined, added to role definitions, and assigned, users can execute commands in a restricted shell environment by typing the command, including any command-line options they are allowed to use.

For example, assume you have defines a command right for shutdown -r that enables users to execute the command as the root user. If you add that right to a role definition that forces users into a restricted shell environment, users assigned to that role can execute the command by typing the following:

shutdown -r

Users can only execute the specific command rights that have been added to the role within the restricted shell environment.

Running unauthorized commands

When users are assigned to roles that require a restricted shell environment, the dzsh shell provides the subset of commands the user is allowed to run and automatically runs each allowed command as the user the command is configured to run as. If the user attempts to run a command he is not authorized to use in his current role, the shell displays a warning. For example, if the user is not authorized to run the uname command in the dzsh shell, the following message is displayed:

$ uname
uname: command not allowed

Setting or changing the active role

Users who are only assigned to one or more restricted shell environments roles are only allowed to run commands within the dzsh shell. Within the restricted shell, a user can only be in one active role at a time to prevent ambiguity about the commands the user can run or the user account that should be used to execute those commands.

For example, if the user carol is assigned to the lab_staff restricted shell environment role that specifies the tar command should run as root and to the temps restricted shell environment role that specifies the tar command should run as tmp_admin, she needs to specify which role she is using to run the tar commands under the proper account.

Within the restricted shell, users can switch between available roles, as needed, using the built-in role command. If a user has been assigned to the backup_ops role and the dev_managers role, he can run the role command to specify which role should be active so that only commands from that role apply. For example, to switch from the backup_ops role to the dev_managers role:

$ role dev_managers
Role changed to: dev_managers

For more information about using the role option in a restricted shell, see the man page for dzsh.

Viewing available roles

The dzinfo command enables users to view information about the roles they have available and what they are allowed to do within their different roles. You may want to add this command to all of your restricted environment roles to allow users to check their definitions and availability within the authentication and privilege elevation restricted environment shell.

For more information about using the dzinfo command, see the man page for dzinfo.

Using a graphical desktop manager in a restricted environment

In some operating environments, users who are placed into a restricted environment may not be able to log on using a graphical user interface desktop manager unless they are explicitly given permission to run the desktop manager or related commands within the dzsh restricted environment. For example, on Red Hat Linux, users must be allowed to run /usr/bin/dbus-launch to log on using KDE or Gnome desktop manager.

To allow restricted environment users to log on using KDE or Gnome on Red Hat, you must add dbus-launch to the list of allowed commands for the restricted environment user's role. If you want to prevent restricted environment users from logging on using the graphical user interface, you can restrict their access to specific PAM-enabled applications such as ssh.

Defining rights to use PAM applications

As discussed in Basic concepts of access rights and roles, access rights allow users to perform specific operations. You define the most basic rights—such as the right to log on or connect remotely—when you define roles. To use the rights associated with a role, however, you must be able to authenticate your identity through a pluggable authentication module (PAM) application, such as login or ssh. This chapter describes how to define PAM application rights that authorize users to log on or access services on Centrify-managed computers.

How applications determine access rights

Most of the programs you run on Linux and UNIX computers are configured to use a pluggable authentication module (PAM) to control access. For example, the login, secure shell (ssh), and file transfer (ftp) services are all PAM-enabled programs. These programs check the local PAM configuration to determine whether a user is allowed to use the requested service.

When you install the Centrify Agent and join a domain, you replace the default PAM authentication service with a PAM service that looks for the users and groups to allow or deny access to in Active Directory. Because the PAM service is the first “gatekeeper” to access on most computers, users must have at least one PAM access right to log on at all.

Default PAM access rights

By default, Access Manager creates three predefined PAM access rights in every parent and child zone:

login-all	All PAM applications on a computer joined to the domain. Adding the login_all PAM access right allows users to log on and use any PAM-enabled application. The right uses the wild card (*) character to match all PAM application names and is included by default in the predefined UNIX Login role.
ssh	Secure shell sessions on Debian and Ubuntu 6 and 7. Adding the ssh PAM access right allows users to log on remotely using secure shell connections on Debian and Ubuntu computers joined to the domain.
sshd	Secure shell sessions on all Linux and UNIX computers except Debian and Ubuntu 6 and 7. Adding the sshd PAM access right allows users to log on remotely using secure shell connections on all other distributions of Linux and UNIX computers joined to the domain.

Adding Specific PAM Access Rights

PAM access rights control who can access specific PAM-enabled applications in the zone where they are created and any child zones of that zone. You can add as many **PAM Access** rights as you need to identify the specific PAM-enabled applications users can access. For example, you can add PAM access rights to control who can use file transfer protocol (ftp) services on specific computers.

If you want to grant rights to specific PAM applications, however, you must know the appropriate application name on the specific computers you support. For example, if you want to allow Active Directory users to log on and use a default shell, you might create a PAM access right for the login program and for a graphical desktop manager such as gdm.

What to do before creating a new access right

Before creating a new PAM access right, you should review the operating system of the computers in the zone where you plan to create the new right. The application name might be different on computers with different operating systems. If you are creating separate rights for individual PAM applications, keep in mind that users must have at least one PAM access right or they will not be able to log on to any computers.

Rights required for this task

You can create new PAM access rights if you have been delegated the "Manage roles and rights" administrative task in the Zone Delegation Wizard. If you have not been delegated this task, your user account must be a domain user with the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-OpObjectContainer This object is listed under a globally unique identifier (GUID) for the Authorization object.	On the **Object** tab, select **Allow** to apply the following permissions to this object: Create msDS-AzOperation objects Click the **Properties** tab, then select **Allow** for the following properties: Read objectClass

Who should perform this task

In most cases, a UNIX administrator or a delegated zone administrator familiar with PAM applications and the operating system of the managed computers performs this task, depending on your organization's policies.

How often you should perform this task

It is common to add new PAM access rights over time as the need arises and as you develop more granular control over the specific rights different users should be granted.

Steps for completing this task

The following instructions illustrate how to add a PAM access right using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To define a PAM access right using Access Manager:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that will contain the new PAM access right.
3. Expand Authorization, then expand **UNIX Right Definitions**.
4. Select PAM Access, right-click, then click **Add PAM Access Right**.
5. Type a name for the access right.

   The name of the access right can be the same as the PAM application name, or any name that is easily identifiable.

6. Type the name of the PAM-enabled application for which you want to create an access right.

   You can use wildcards to perform pattern matching for the application name. For example, you can specify *ftp* to match all PAM-enabled applications containing the string ftp, such as vsftpd, ftpd, and ftp.

   The Application Name field supports glob pattern matching syntax. For example, the name can contain a question mark (?) to represent any single character, an asterisk (*) to represent any string, including an empty string, or an expression enclosed by brackets ([. . .]). For more detailed information about using wildcard patterns and glob syntax, see the glob man page.

   You should note that application names vary depending on the local operating system where the application is accessed. For example, the following table lists several common PAM-enabled applications and the appropriate application name to use on different platforms.

telnet	Common Linux platforms, such as Red Hat, Debian, SuSE, Centos, and Ubuntu, HP-UX, and Irix	login
	Sun Solaris	telnet
	VMware ESX, Oracle Linux, Scientific Linux	remote
ftp	Common Linux platforms, such as Red Hat, Oracle Linux, and Scientific Linux, and VMware ESX	vsftpd
	Some Linux platforms, such as Debian, Centos, and Ubuntu, Sun Solaris, HP-UX, Irix	ftp
graphical desktop	Common Linux platforms, such as Red Hat, Debian, Oracle Linux, Centos, Scientific Linux, and Ubuntu	gdm
	Sun Solaris and HP-UX	dtlogin
	SuSE and Irix	xdm
ssh	Most platforms	sshd
	Debain and Ubuntu	ssh

1. Type an optional description of the access right.
2. Click **OK** to save the PAM access right.

What to do next

After you define a new PAM access right, you might want to create a new role definition and add this right to it in the current zone or in a child zone. You must add the right to a role to test its operation.

Modifying an existing PAM access right

After you have created and tested a new PAM access right, you might want to modify the right name and description, or the pattern used to match the application name. For example, if you add computers with a different operating system to the zone where the PAM access right is defined, you might have to modify the application name to use wild card characters.

To modify a PAM access right using Access Manager:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the PAM access right.
3. Expand Authorization, UNIX Right Definitions, and **PAM Access**.
4. Select the PAM access right to modify, right-click, then click **Properties**.
5. Change the right name, application name, or description for the access right, then click **OK**.

Copying a PAM access right

You should keep in mind that PAM access rights are specific to the zone where you create them. They can be added to any roles you define for the zone or to roles defined in any child zone of the zone. After you define PAM access rights in a zone, however, you can also copy and paste or drag and drop the rights from one zone to another, as needed.

To copy a PAM access right using Access Manager:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the PAM access right.
3. Expand Authorization, UNIX Right Definitions, and **PAM Access**.
4. Select the PAM access right to copy, right-click, then click **Copy**.
5. Navigate to the PAM Access node in the new zone, right-click, then click **Paste**.

Deleting a PAM access right

If you are no longer using a specific PAM access right in any roles, you might want to delete the right. For example, if you create new rights for testing purposes and found some of them were not appropriate or failed to work as expected, you might want to delete the rights you aren't going to use.

To delete a PAM access right using Access Manager:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the PAM access right.
3. Expand Authorization, UNIX Right Definitions, and **PAM Access**.
4. Select the PAM access right to delete, right-click, then click **Delete**.

Renaming a PAM access right

If you only need to change the name of a PAM access right, you can rename the right at any time without modifying the description or the pattern used to match the application name.

To rename a PAM access right using Access Manager:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the PAM access right.
3. Expand Authorization, UNIX Right Definitions, and **PAM Access**.
4. Select the PAM access right to rename, right-click, then click **Rename** and type a new name for the access right.

Using PAM-enabled applications

The default UNIX Login role includes the predefined login-all PAM access right to enable users to log on and access any PAM-enabled application. If you define specific PAM access rights, users who are assigned a role with that right can only access the specifically authorized PAM-enabled applications. For example, users who are assigned to a role that includes the right to access FTP (ftpd) can connect to the FTP server by typing a command similar to the following:

ftp ginger.ajax.org

Requiring multi-factor authentication for PAM applications

If you select the "Multi-factor authentication required" system right in a role definition, the PAM applications you add to the role will require users to select a secondary form of authentication to log on successfully. You define the forms of authentication available and presented to the user in the authentication profile you have configured using the administrative portal for the Centrify Platform. For example, you might configure an authentication profile that require users to answer a phone call, click a link in an email message, or respond to a text message.

Note that some applications do not support multi-factor authentication and users might be denied access to applications that they would otherwise be able to use. For example, if a specific version of an application that you want to use only supports a single layer of authentication—such as a password challenge—users would be prevented from logging on and using the service even if they are assigned to a role with the predefined login-all PAM application right.

If you want to grant access to applications that only support one layer of authentication in roles where you are generally using the "Multi-factor authentication required" system right, you must add those applications to the list of applications for which you want to skip multifactor authentication. You can update the list of applications for which to skip multifactor authentication by enabling and modifying the "Specify programs for which multi-factor authentication is ignored" group policy or setting the pam.mfa.program.ignore configuration parameter in the centrifydc.conf file.

Before assigning roles with multi-factor authentication required to users, you should test access to all of the applications you expect users to access to verify they won't be unexpectedly denied access simply because multi-factor authentication isn't supported. Because the applications that don't support multi-factor authentication will depend on the platforms and the versions of the applications you plan to support, testing in your own environment is the only way to determine which applications to add to the pam.mfa.program.ignore configuration parameter.

The most common applications that are known to only support a single password challenge and response for authentication are ignored for multi-factor authentication by default. For example, some versions of java and vsftpd do not support multi-factor authentication and are ignored by default.

Additionally, while some platforms support multi-factor authentication for all PAM applications, they may not allow you to require multi-factor authentication for GUI log in. For example, for users running AIX, Solaris, and HP-UX, multi-factor authentication for GUI login is not supported.

Options applied to the Centrify PAM module

The authentication service applies some options to the Centrify PAM module pam_centrifydc module. For example, in a RHEL system, you would see the following in the /etc/pam.d/system-auth file:

auth sufficient pam_centrifydc.so

auth requisite pam_centrifydc.so deny

account sufficient pam_centrifydc.so

account requisite pam_centrifydc.so deny

session required pam_centrifydc.so homedir

password sufficient pam_centrifydc.so try_first_pass

password requisite pam_centrifydc.so deny

In addition, you could see the following in the /etc/pam.d/su file:

auth sufficient pam_centrifydc.so enable_dzpamgate

For each management group, a set or stack of modules can be defined and used in turn. When an application calls the PAM library function (for example to authenticate), the PAM runtime will call each authentication function in each module— one at a time like cards from a stack. The order of calling is determined by the order in the configuration (service) file.

Be careful when changing the order in the stack; changing the order might have impact on the functionality considerably.

There are four types of PAM services:

- Authentication service modules
- Account management modules
- Session management modules

- Password management modules

There are four control flags:

- **Requisite**: The requisite flag is probably the strongest of the flags. If a module is flagged as requisite, and it fails (returns not-OK), PAM will return to the calling application instantly and report the failure.
- **Required**: The return code for a required module is stored. In the case of failure, execution is not stopped but continues to the next module. When the stack of modules has been executed, and at least one required module has failed, PAM will return failure to the calling application. Moreover, the failure is associated with the first failing module) The required control flag is useful in keeping unauthorized persons out of your computer, particularly since the other modules in the stack are applied as well.
- **Sufficient**: A sufficient module can actually be quite strong. The processing of the stack is stopped if a sufficient module returns OK, if no previous required module has failed. If there are required modules after the sufficient modules, these modules are not called.
- **Optional**: When a module is flagged as optional, a failure does not alter the execution of the stack as in the case of the requisite flag. Moreover, the return code is ignored, and neither failure nor success is taken into account.

The list of options that are applied to pam_centrifydc are as follows:

- Deny: When it gets to this line, it will just deny the request
- Try_first_pass, use_first_pass, get_first_pass: All three follow PAM standards.
- Try_first_pass: Use the password from the previous stacked authentication module, and prompt for a new password if the retrieved password is blank or incorrect.
- Use_first_pass: The default is to use the old password saved by a previous module, or if none, to ask for it. With use_first_pass it fails if there is no old password.
- Requisite: This is an HP platform only option. The effect is the same as HP "pam requisite"
- Unix_cred: This is Solaris only option to provide Solaris's pam_unix_cred
- Homedir: Create user home directory
- Enable_dzpamgate: This is a Centrify option to seal a potential pam security hole. In some systems, pam account module does not always gets called so the authorization checking in auth module is inserted with the enable_dzpamdate option.

In /etc/centrifydc/centrifydc.conf, the parameter equivalents are provided as:

pam_mkhomedir.so [umask=mode] [skel=skeldir]

pam.homedir.perms: 0700

pam.homeskel.dir: /etc/skel

To update the parameters, remove the # sign and change values as desired.

Using secure shell session-based rights

As discussed in Default secure shell (SSH) access rights, **Access Manager includes predefined secure shell rights that enable you to** identify the specific secure shell services that a user who has the PAM SSH access right can run. This chapter describes how to use the secure shell (ssh) session-based rights that control the operations specific users or groups can perform on Centrifymanaged computers.

Secure shell rights require Centrify OpenSSH

SSH has become the defacto standard for administrators and users to securely access remote UNIX systems. The combination of the latest versions of OpenSSH supporting Kerberized connections, along with the DirectControl Agent directly integrating the UNIX computer with Active Directory's Kerberos infrastructure, provides the administrator with the ideal environment for secured single sign-on. Users logging in from Windows computers can securely access remote UNIX computers using their Active Directory credentials to automatically log in to the UNIX computer.

While many UNIX systems might have an sshd server installed, most are older implementations of the sshd server that do not support Kerberos and newer versions might not have been compiled with support for Kerberos. The Centrify package contains OpenSSH compiled with support for Kerberos by dynamically linking to the Centrify Kerberos libraries to ensure that single sign-on works seamlessly as expected in an Active Directory environment.

This provides several advantages, including:

- The OpenSSH client and server are preconfigured to automatically support PAM and Kerberos.
- There is no need for DNS-to-realm mapping because DirectControl knows the relationship between hosts and their SPNs.
- There is no need for a .k5login file in the user's home directory since DirectControl can automatically map the UPN (User Principal Name) in the Kerberos ticket to the UNIX profile for the Active Directory username presented in the ticket.
- OpenSSH in combination with DirectControl accepts connections to any of the computer's valid hostnames, either fully qualified or not, because all combinations are registered with Active Directory. This further reduces the dependency on accurate DNS entries to enable Kerberos to operate properly.
- The installation process automatically updates the $PATH.

The Centrify version of OpenSSH is a separate package that can be installed with the Centrify Agent. Before you configure any specific secure shell rights to include in roles, verify that you have the Centrify OpenSSH package installed on your managed computers. The default secure shell rights are only applicable for the Centrify-compiled version of OpenSSH. If you did not select the OpenSSH package as part of a custom installation when you installed the agent, re-run the installation script to install the package before attempting to use secure shell rights.

Secure shell rights require PAM access rights

Before you configure any specific secure shell rights, you should also identify the PAM access right to use. The predefined PAM access right sshd—or ssh for Ubuntu computers—grants users permission to log on and use all secure shell services on Centrify-managed computers. You must grant the sshd, ssh, login-all, or a custom PAM access right before you can use any secure shell (SSH) rights to restrict access to specific services.

The SSH access rights only work in conjunction with the PAM access right that allows a user to log on using a secure shell session. If a user is not assigned to a role that grants the PAM access right to log on using a secure shell, SSH rights are ignored.

When a user attempts to log on using a secure shell session, adclient first verifies that at least one role in effect for the user has the PAM access right that allows him too log on using SSH. If a PAM access right is in effect, adclient checks to see which specific SSH rights the user has before allowing or denying the action the user is attempting.

Combining secure shell rights

You can add predefined SSH rights to any role that can be assigned to Active Directory users and can combine different rights for fine-grain control over the specific secure shell operations users are allowed to perform. For Linux and UNIX computers, only the following predefined secure shell session-based rights are available:

- dzssh-all grants access to all secure shell services.
- dzssh-direct-tcpip allows local and dynamic port forwarding (ssh-L, ssh -D).
- dzssh-exec allows command execution.
- dzssh-scp allows secure copy (scp) operations.
- dzssh-sftp allows secure file transfer (sftp) operations.
- dzssh-shell allows secure terminal (tty/pty) connections.
- dzssh-Subsystem allows an external subsystem except sftp subsystem which has its own right.
- dzssh-tcpip-forward allows remote port forwarding (ssh -R).
- dzssh-tunnel allows tunnel device forwarding.
- dzssh-X11-forwarding allows X11 forwarding.

When combining rights into role definitions, you should keep in mind that some secure shell operations require you to explicitly include the dzssh-exec right. For example, if you include the dzssh-scp right in a role definition, a user might attempt to execute an arbitrary program with a command line similar to following:

ssh troll@localhost scp -S/home/troll/script " -f "

Because this command line presents a potential security risk, the operation is not allowed. To prevent the dzssh-scp right from being used on its own to execute an arbitrary program on a remote computer, the -S command line option is only supported if you also include the dzssh-exec right in the role definition. Similarly, you must explicitly include the dzsshexec right in a role definition if you want to support using the dzssh-sftp right with the -S command line option. For security reasons, only the dzsshexec right allows the remote execution of a program on a target computer.

If the dzssh-exec right is not included in the role definition when it is required, users will see an “access denied” message.

You should note that you cannot add any secure shell rights to role definitions that allow local users. You can only include them in role definitions for Active Directory users.

Configuring secure shell settings

You can use Centrify group policies to manage several aspects of secure shell (ssh) authentication and operation. The Centrify group policies for secure shell are located in the **SSH Settings** folder after you add the centrify_unix_settings.xml administrative template to a Group Policy Object. When you enable and configure secure shell group policies, the changes are recorded in the secure shell configuration file, /etc/centrifydc/ssh/sshd_config, at the next group policy update interval. To have your changes take effect immediately, run the adgpupdate command.

Centrify puts all of the configuration files for secure shell operations in the /etc/centrifydc/ssh directory. Depending on your operating system, you might also have other ssh configuration files stored in the other locations. When users start a secure shell session and use their secure shell rights, the Centrify Agent first checks the /etc/centrifydc/ssh directory for configuration files, then looks for configuration file in the /usr/local/etc directory on AIX computers, and in /etc/ssh directory on most other Linux and UNIX computers.

At a minimum, you should enable the **Enable application rights** group policy in a Group Policy Object that applies to the site, domain, or organizational unit that contains Centrify-managed Linux and UNIX computers.

To configure the secure shell group policy for application rights

1. On a Windows computer, open the Group Policy Management console.
2. Select an appropriate Group Policy Object, right-click, then select Edit.

   You can select any Group Policy Object that applies to the site, domain, or organizational unit that contains Centrify-managed Linux and UNIX computers.
3. Expand Computer Configuration > Policies > Centrify Settings > SSH Settings and double-click **Enable application rights**.
4. Click Enable, then click OK.

   This setting adds the following parameter to the /etc/centrifydc/ssh/sshd_config file:

   ServiceAuthLocation /usr/share/centrifydc/libexec/dzsshchk

   This parameter sets the path to the dzsshchk command. The dzsshchk command verifies the access rights for users when they log in with SSH for all computers to which the group policy object applies.

You can also use secure shell group policies to control other configuration settings, such as the allowed and denied groups and users and authentication processing. For example, you can use the following group policies to configure operations for Centrify OpenSSH connections:

- **Add sshd_config properties** enables you configure secure shell properties defined in the sshd_config file by group policy. If you enable this group policy, you can add and edit properties as name-value pairs.
- **Allow challenge-response authentication** enables you use multi-factor authentication if you are using the secure shell package installed with the operating system. This group policy is not required if you are using the Centrify OpenSSH package for the agent.
- **Allow groups** specifies the list of groups whose members are allowed to log on through sshd.
- **Allow GSSAPI authentication** enables authentication either as the result of a successful key exchange, or through GSSAPI user authentication.
- **Allow GSSAPI key exchange** enables authentication using a key exchange based on GSSAPI.
- **Allow users** specifies the list of users who are allowed to log on through sshd.
- **Deny groups** specifies the list of groups whose members are not allowed to log on through sshd.
- **Deny users** specifies the list of users who are not allowed to log on through sshd.
- **Enable application rights** allows secure shell applications to grant secure shell rights.
- **Enable PAM authentication** to use PAM account and session handling.
- **Permit root login** specifies whether the root account can be used to log in using ssh.
- **Set banner path** specifies the path to a local file that is sent to a remote user requesting authentication.
- **Specify authorized keyfile** specifies the file that contains the public keys that can be used for user authentication.

- **Specify ciphers allowed for protocol version 2** enables you to add or delete ciphers allowed for single sign-on connections.
- **Specify client alive interval** specifies a timeout interval, in seconds, for requesting a response to client alive messages.
- **Specify log level** specifies the level of detail to record in the log file for messages from sshd.
- **Specify login grace period** specifies the time, in seconds, after which the server disconnects if a user has failed to log in.
- **Specify maximum client alive count** specifies the maximum number of client alive messages that may be sent by the secure shell daemon (sshd) without receiving a response from the client.

For more information about adding administrative templates for group policies to a Group Policy Object and how to configure and apply the group policies for secure shell, see the *Group Policy Guide*.

Configuring secure shell parameters

The following parameters apply to specific usage for SSH.

ServiceAuthLocation

Uncomment this line in sshd_config to enable the SSH application right feature. Refer to the pre-defined scp, sftp, and winscp for how to utilize this feature. Default is disable.

AuditSshCommandline

Set this parameter in sshd_config to yes if the command line options are displayed in the audit trail message. Default is no.

krb5ccUnique

Set this parameter to yes to specify when storing the Kerberos credentials cache. Centrify sshd generates a unique credential cache name for it. If this parameter is set to no, the old style credential cache name, krb5cc_<uid> or KCM:<uid>, is used.

SSOMFA

Set this parameter is yes to support Single Sign-On (SSO) with Multi- Factor Authentication (MFA). The MFA order is determined by the AuthenticationMethods keyword in sshd_config. This keyword works only when UsePAM is enabled and the Centrify keyword ServiceAuthLocation is set. Default is no.

Note: MFA is not supported for authentication using public key.

Creating and assigning custom role definitions

Access rights and role definitions are intended to give you maximum flexibility to grant or restrict access for the users and groups in your organization. This chapter describes how you can configure role-based access controls for Centrify-managed computers by adding custom access rights to custom role definitions and assigning those custom role definitions to users and groups. This chapter provides examples to illustrate how you can create and assign custom role definitions. The authorization scenarios you can support might be far more complex than the examples described in this guide.

Combining rights into role definitions

Rights can be combined in a variety of ways to accomplish different goals. In general, however, role definitions fall into one of these broad categories:

- Roles that grant access to one or more PAM applications and a standard UNIX shell.

  With this type of role, Active Directory users can log on using all or a specified PAM application, such as login or ftp, and execute commands that are commonly available to non-administrative users. This type of role can only be assigned to Active Directory users or groups.

- Roles that grant users additional privileges to execute administrative commands and perform administrative tasks they would not be able to perform with a standard user account.

  With this type of role, users can temporarily elevated their privileges to execute administrative commands by first invoking the dzdo command, which is similar to sudo. This type of role can be assigned to Active Directory users or to local users.

- Roles that provide access to a specific subset of shell commands in a customized restricted environment shell (dzsh).

  With this type of role, users can execute the commands explicitly defined for them in a restricted shell environment. This type of role can be assigned to Active Directory users or to local users.

In preparing role definitions for different groups of users, you should keep in mind that the rights from multiple role assignments accumulate. For example, you could use one role definition to control login rights, and another role definition to specify a set of privileged commands. By separating login rights from privileged access rights, not every role definition requires PAM application or UNIX system rights.

Creating a root-equivalent role definition

Most organizations require at least one root user role definition that is equivalent to specifying ALL:ALL in a sudoers file or giving users access to the root password on their computers. The purpose of this role definition is to allow selected users to execute privileged commands on a regular basis. The role definition allows them to execute commands without being given the root password or having privileges hard-coded in individual sudoers files on multiple computers.

Because this role definition enables system administrators to execute privileged commands without the root password, you can improve security for the organization and reduce the chance of an audit finding for access to the root password.

You can create this role definition in a parent zone or a child zone to control its scope. In most cases, you should only assign the role in a child zone or on an individual computers.

Define the right for running all commands

Rights and roles are defined at the zone level and inherited down the zone hierarchy. If you define a right in the top-level zone, it is available in all child zones. If you define a right in a child zone, it can be used in that zone and any of its child zones. Similarly, you can define roles in the top-level parent or any child zone, depending on where you want to make the role available. In this example, the right to run all commands as the root user is defined in a toplevel parent zone.

The following instructions illustrate how to define a right for running all commands using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To define a right for running all commands as root:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new command right.

   For this example, select the top-level parent zone so that this command right is available in all child zones.
3. Expand Authorization > UNIX Right Definitions.
4. Select Commands, right-click, then click **New Command**.
5. On the General tab, type a name for this command right and, optionally, a description for this right, then define the right to run all commands like this:
   - Type an asterisk (*) in the Command field to indicate all commands are allowed.
   - Select Specific path and type an asterisk (*) in the field to indicate that any path is allowed.
6. Click the Restricted Shell tab and deselect the **Can be used in a restricted role** option if you want to prevent this command from being used in a role that uses a restricted shell environment.
7. Click the Run As tab to verify the command can be used with dzdo and is set to run as root by default.
8. Click **OK** to use the default environment variable settings and command attributes.

   Alternatively, you can click the Environment and Attributes tabs if you want to view or set additional properties for this right definition.

Create a role definition for running all commands

After you have defined the right to allow a user to run any command with root privileges, you can create a role definition for that right. You must create a role definition somewhere in the zone hierarchy before you can assign users to the role.

To create a role definition with the right to run all commands as root:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the role definition.
3. Expand Authorization.
4. Select Role Definitions, right-click, then click **Add Role**.

5. Type a name and description for the new role, then click **OK**.

   For example, type a name such as root_equivalent and descriptive text such as Users with this role can run any command with root privileges.

   Optionally, you can select **Allow local accounts to be assigned to this role** if you want to assign both Active Directory users and local users to the role. This option is only available when you first create a role definition. You can also click **Available Times** if you want to limit when the role is available for use. By default, roles are available at all times.

   If you using the UNIX Login role to grant access to computers in the zone and want to use the default auditing level of **Audit if possible**, you can click **OK** then skip to Step 8.

6. If you are not assigning the UNIX Login role to grant access to computers, click the System Rights tab and select the following options:
   - Password login and non-password (SSO) login are allowed
   - Non-password (SSO) login is allowed
   - Login with non-Restricted Shell

     Note that you cannot set these system rights if you selected the option to allow local users to be assigned to this role.

7. If you don't want to use the default auditing level, click the Audit tab.
   - Select **Audit not requested/required** if you have the auditing service enabled but don't want to audit user activity when this role is used.
   - Select **Audit if possible** to audit user activity where you have the auditing service enabled.
   - Select **Audit required** to always audit user activity. If the auditing service is not available, users in this role are not allowed to log on.

8. Select the new role definition, right-click, then click **Add Right**.
9. Select the right you defined for running all commands as root, then click **OK**.

Assign an Active Directory group to the role

You should associate Centrify role definitions with Active Directory security groups so that you can manage them using the processes and procedures you have for managing Active Directory group membership. For example, create an Active Directory group named sanfrancisco_role_rootequivalent. You can then assign the new role definition to that group.

To assign the role definition to an Active Directory group:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to assign the role definition.
3. Expand Authorization.
4. Select Role Assignments, right-click, then click **Assign Role**.
5. Select the role definition you created for root-level access, such as root_equivalent, then click **OK**.
6. Click **Add AD Account** to search for and select the Active Directory security group you created for the role.
   - Select Group as the object to find.
   - Optionally, type all or part of the group name.
   - Click Find Now,

     Select the group you created for the role in the results, then click **OK**.

7. Click **OK** to complete the assignment.

Creating a role definition for a shared service account

The root-equivalent role definition provides centralized management for a limited number of administrators who have permission to execute all commands on selected computers. Another common reason for defining a role is to execute privileged commands associated with a service account. In many organizations, service account passwords are known by multiple users, making them a security risk. For example, all of the database administrators in the organization might know the password for an oracle service account, an account with permission to perform privileged database operations. Because the password is shared information, it presents a security risk and a potential audit finding that might have costly consequences.

Setting up a role definition for a service account involves creating a command right for switching to the service account user and defining a PAM access right for role.

Define the right for switching to a service account

The steps for defining a right for switching to the service account user are similar to defining the rights for the root-equivalent user, but the definition is more restrictive.

To define a right for switching to a service account:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new command right.
3. Expand Authorization > UNIX Right Definitions.
4. Select Commands, right-click, then click **New Command**.
5. On the General tab, type a name for this command right and, optionally, a description for this right, then define the right to switch to the service account.For example, if the service account is oracle:
    - Type su - oracle in the Command field.
    - Verify the Standard user path is selected.
6. Click the Restricted Shell tab, under Can be used in a restricted role, select **Specific user or uid**, then type root.
7. Click the Run As tab, deselect **Can be used by dzdo**.

    These settings specify that this right can only be used in a restricted shell environment and users can only run the commands that are explicitly allowed in the restricted role they are assigned. If this is the only right defined for a role, the only command users assigned to the role can run is su - oracle. For a role definition with this right to be effective, you would add command rights for the specific database operations users should be allowed to perform after switching to the oracle service account. For example, if the oracle service account is used to run a backup-all-dbs script, you would add a right to allow the execution of that script.
8. Click **OK** to use the default environment variable settings and command attributes.

    Alternatively, you can click the Environment and Attributes tabs if you want to view or set additional properties for this right definition.

Define a PAM access right to allow logging on

The default UNIX Login role allows users to log on using a password or without a password in an unrestricted environment. If you are creating a role for a service account, you can use PAM access rights to control the specific commands users can use to log in. To illustrate controlling how users log on, this example of a restricted role for the oracle service account only allows users to log on with ssh.

To define a PAM access right for a specific application:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new PAM access right.
3. Expand Authorization > UNIX Right Definitions.
4. Select PAM Access, right-click, then click **Add PAM Access Right**.
5. Type a name and, optionally, a description of the PAM application for which you are adding an access right.

For the Application field, type the platform-specific name for the PAM application as defined in the PAM configuration file or PAM directory. For example, type ssh or sshd. You can also use wildcards in this field to perform pattern matching for the application name.

6. Click **OK** to save the access right for this PAM-enabled application.

Create a restricted role definition for the service account

After you have defined the rights that allow a user to log on using a PAM-enabled application and run the su - command for a service account, you can create a role definition for these rights. You must create a role definition somewhere in the zone hierarchy before you can assign users to the role.

To create a restricted role definition for switching to a shared service account:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new role definition.
3. Expand Authorization.
4. Select Role Definitions, right-click, then click **Add Role**.
5. Type a name and description for the new role, then click **OK**.

   For example, type a name such as oracle_service and descriptive text such as Users with this role can start a secure shell session and switch to oracle.

   By default, this role is available at all times. You can click **Available Times** if you want to specify days of the week or select times of the day for making the role available.
6. Click the System Rights tab and select at least one option that allow users assigned to this role definition to log on, then click **OK**.

   In this example, users open a secure shell to switch to the service account so you might select **Non-password (SSO) login is allowed**.

   If a service account instead of a user account is used to log on, it might be mapped to a disabled Active Directory account. In this case, you might select the **Account disabled in AD can be used by sudo, cron etc** system right to ignore the disabled state and allow the service account to log on.
7. Select the new role definition, right-click, then click **Add Right**.
8. Select the rights you defined for running the switch user (su -) command and logging on with the PAM application ssh, then click **OK**.

Assign an Active Directory group to the role

You should associate Centrify role definitions with Active Directory security groups so that you can manage them using the processes and procedures you have for managing Active Directory group membership. For example, create an Active Directory group named sanfrancisco_role_oracle. You can then assign the new role definition to that group.

To assign the role definition to an Active Directory group:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to assign the role definition.
3. Expand Authorization.
4. Select Role Assignments, right-click, then click **Assign Role**.
5. Select the role definition you created for using secure shell and switching to the service account access, such as oracle_service, then click **OK**.
6. Click **Add AD Account** to search for and select the Active Directory security group you created for the role definition.
   - Select Group as the object to find.
   - Optionally, type all or part of the group name.
   - Click Find Now.

     Select the group you created for the role in the results, then click **OK**.

7. Click **OK** to complete the assignment.

Working in a restricted shell environment

When users who are assigned to this role want to open a secure shell session and switch to the oracle service account, they will be placed in a restricted shell environment. Within the restricted shell, they can only execute the commands you have added to the role definition until they exit the restricted shell session. In this example, the role definition only allows users to log on using ssh and execute one command, su - oracle. If those users are also assigned the UNIX Login role, they will have access to an unrestricted shell when they close the restricted shell session.

If you want users who access a shared service account to work exclusively within the restricted shell environment, you must remove the UNIX Login role assignment in the zone or on the computer where they should only have restricted shell access. Before removing the UNIX Login role assignment, however, you should consider the trade-off between improved operational security and audit compliance and reduced operational access. Depending on the rights you add to a role that runs in a restricted shell environment, the restricted shell can dramatically limit what users can do.

Testing access in a restricted shell

If you create a role definition for a shared service account that runs in a restricted shell environment, you should test it before migrating any users to it. You can use the dzinfo command with the --test option from a UNIX command prompt. For example, type dzinfo, the user name to test, the --test option, then the full path to the command to test:

dzinfo raejames --test "/usr/bin/su - oracle

You can also run the dzinfo command with the --roles option to see information about the rights defined for the current user or a specified user. For example, run the following command to check the roles and rights defined for the user raejames:

dzinfo raejames --roles

For more information about using this command, see the dzinfo man page.

What users see in a restricted shell environment

For users assigned to a role that runs in a restricted shell, logging on opens a dzsh shell. Within that shell users can only execute the commands you have explicitly defined for them. In this example scenario for a shared service account, typing su - oracle is the only allowed command. If the user types any other command, the shell reports that the command is not allowed.

Define a command that allows root access

The steps for defining a right for switching to the root user are similar to defining the right to run commands for the root-equivalent user, but Centrify recommends you create a separate right definition for this case.

To create the right to switch to the root user:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new command right.
3. Expand Authorization > UNIX Right Definitions.
4. Select Commands, right-click, then click **New Command**.
5. On the General tab, type a name, such as emergency_access, for this command right and, optionally, a description for this right, then define the right to switch to the root user:
    - Type the command for switching to the root user. For example, type su - root in the Command field.
    - Verify Standard user path is selected.
6. Click the Restricted Shell tab and verify **Can be used in a restricted role** and **User running the command are selected**.

    These options enable you to use this command right in combination with other rights in a role definition that requires a restricted shell environment.
7. Click the Run As tab and verify **Can be used by dzdo** and **Any user** are selected, then click **OK**.

    In most cases, you can leave the default settings for the other properties. If you want to make changes, click the Environment and Attributes tabs before saving the new command.

Create a role definition for temporarily running as root

After you have defined the right to switch to the root user, you can create a role definition for that right.

To create a role definition with the right to run the emergency_access command:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new role definition.
3. Expand Authorization.
4. Select Role Definitions, right-click, then click **Add Role**.
5. Type a name and description for the new role.

    For example, type a name such as emergency_access and descriptive text such as Users with this role can temporarily run commands with root privileges.
6. Click **Available Times** to specify days of the week or select times of the day for making the role definition available.

    For example, you might want to allow access only on Friday, Saturday, and Sunday and deny access the rest of the week. After you have set the days and times for the role definition to be available, click **OK**.
7. Click **OK** to save the role definition.
8. Select the new role definition, right-click, then click **Add Right**.
9. Select the emergency_access command you defined for switching to the root user, then click **OK**.

    To use this role, a user must be assigned to the UNIX Login role for the zone or a role definition that has at least one UNIX system right, such as Password login and nonpassword (SSO) login are allowed.

Assign the role as a computer-level override

In most cases, a role definition of this type is assigned to a specific computer rather than applied to all computers in a zone.

To make a role assignment on an individual computer:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the computer for which you want to define a computer-level role assignment.
3. Expand Computers, then select the specific computer on which you want to make a role assignment.
4. Select Role Assignments, right-click, then click **Assign Role**.
5. Select the role definition you created for temporary root access, such as emergency_access, then click **OK**.
6. Click **Add AD Account** to search for and select the Active Directory user who should have temporary root access:
    - Leave User as the object to find.
    - Optionally, type all or part of the use name.
    - Click Find Now.

      Select the user in the results, then click **OK**.
7. Deselect **Start immediately** and set a specific Start time for the role assignment.
8. Deselect **Never expire** and set a specific End time for the role assignment.
9. Click **OK**.

Verify the role assignment on the computer

You can run dzinfo --roles or dzinfo username --roles to see if the emergency_access role is available based on the start time for the role definition and the local time of the Linux or UNIX computer.

At the specified start time for the role assignment on the local computer, the user you assigned to the emergency_access role can type the following command:

dzdo su - root

The user is not prompted to provide the password and becomes the root user on the local computer until the specified role assignment end time. The one caveat to be aware of is that the user would continue to have root access after the specified end time if the shell session remains open continuously. If a user is still logged on after the time period has expired, you should check whether the user still requires root-level access. If the session has remained open but the user should no longer have root access, kill the session and log the user off.

Creating a role definition with specific privileges

The previous examples of role definitions granted broad privileges. You can also use role definitions grant or deny very specific rights. For example, you might want to deny access to a specific set of commands for a specific group of administrators who otherwise have broad access rights or to strictly limit exactly what commands users can execute. Depending on the requirements of your organization, you might configure these types of role definitions to be used in a restricted or unrestricted shell.

The steps for creating a role definition with specific privileges are similar to the steps for creating the other roles. In this example, rights are defined to prevent the execution of specific commands and combined with a right to grant access to all commands not explicitly listed.

Define command rights to prevent the use of commands

The steps for defining rights that deny access to specific commands are similar to the steps defining other rights, but require different syntax. In this example, you create a “blacklist” of commands users cannot execute.

To create the right to switch to the root user:

1. Open Access Manager.

2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new command right.
3. Expand Authorization > UNIX Right Definitions.
4. Select Commands, right-click, then click **New Command**.
5. On the General tab, type a name, such as No password resets, for this command right and, optionally, a description for this right, then define the right:
    - Type !passwd * in the Command field.
    - Verify Standard user path is selected.

    An exclamation point (!) at the start of a command disallows matching commands. Command rights that start with the exclamation point take precedence over others that don't.
6. Click the Restricted Shell tab and verify **Can be used in a restricted role** and **User running the command are selected**.

    These options enable you to use this command right in combination with other rights in a role definition that requires a restricted shell environment.
7. Click the Run As tab and verify **Can be used by dzdo** and **Any user** are selected, then click **OK**.

    In most cases, you can leave the default settings for the other properties. If you want to make changes, click the Environment and Attributes tabs before saving the new command.
8. Repeat Step 4 to Step 7 to create rights for the following specific commands:

    !groupadd *
    !useradd *
    !groupdel *
    !userdel *

Create a restricted shell role definition that uses the command rights

After you have defined all of the command rights that disallow specific commands, you can create one or more role definitions to use those rights. For example, you might create one role definition to run in an unrestricted shell that requires users to invoke dzdo to execute privileged commands and another role definition that runs in a restricted shell but does not require users to execute privileged commands using dzdo. The second role might be useful if you have existing scripts that would have to be modified if invoking dzdo is required.

To create a role definition for specific command rights:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new role definition.
3. Expand Authorization.
4. Select Role Definitions, right-click, then click **Add Role**.
5. Type a name and description for the new role.

    For example, type a name such as operators and descriptive text such as Users with this role can run privileged commands but not reset passwords, add or delete users and groups.
6. Click **System Rights** if you want this role definition to be used in a restricted shell environment as a replacement for the predefined UNIX Login role.

    To use this role, a user must be assigned to a role definition that has at least one login system right, such as Password login and nonpassword (SSO) login are allowed or Nonpassword (SSO) login is allowed.
7. Click **OK** to save the role definition.
8. Select the new role definition, right-click, then click **Add Right**.
9. Select all of the command right that disallow specific operations, the command right that grants access to all remaining commands, and a PAM access right, then click **OK**.

For example, you might add the following previously-defined command rights to this role definition:

No password resets
No user adds
No group adds
No user deletes
No group deletes
Root like access (* for all commands not explicitly disallowed)
PAM ssh/login allowed

This role definition allows members of the operators role to execute any command within a restricted shell environment except those explicitly disallowed, including privileged commands, without invoking dzdo first. You can assign the role definition to the appropriate Active Directory users or groups like the previous role definitions.

Create an unrestricted shell role definition that uses the command rights

The command rights were configured to allow execution in either a restricted shell environment or an unrestricted shell environment. In an unrestricted shell environment—for example, the default shell environment when users are assigned the UNIX Login role—commands that require administrative privileges must be executed by first invoking the dzdo command, which is similar to invoking commands with sudo.

You can control whether users are required to enter a password or another form of authentication when they execute privileged commands using dzdo by setting one of the **Re-authenticate** options on the Attributes tab when you create a command right. By default, no password is required. If you were adding a new command right that requires reauthentication, you would click the Attributes tab, then select **Re-authenticate current user** or **Re-authenticate using target user's password**. For more information about these options, see Requiring re-authentication to run commands.

In most cases, the default of no password is appropriate because the user has been previous authenticated before invoking dzdo to execute a privileged command and the **Reauthenticate using target user's password** option requires the user to know the privileged account password. For example, if select this option and the run-as user is root, the user must know the password for the root account.

The steps for creating the role definition that includes the previously-defined command right are the same for the unrestricted shell as for the restricted shell except that, at Step 6 in the topic Create a restricted role definition for the service account, in the System Rights tab you would also select the **Login with non-Restricted Shell** option if you are not using the UNIX Login role. You could add all of the same command rights to the role definition and grant the same privileges and exceptions.

The primary difference between the two role definitions would be how users execute their privileged commands.

In the restricted shell environment, users running the adflush command requiring administrative privileges:

dzsh $ adflush

In the unrestricted shell environment, users running the adflush command requiring administrative privileges:

[tulo@ajax]$ dzdo adflush

Creating a role definition with rescue rights

The Rescue rights option allows you to control which users should be able to log on if problems with authentication, the authorization cache, or the auditing service are preventing all other users from logging on. For example, if you have a computer with sensitive information, such as credit card numbers or intellectual property, you might require auditing for all users in the role with access that computer. If the auditing service is stopped or removed on that computer, no one would be able to log on and use the computer until auditing is restored. If you create a role with the Rescue rights option selected, only the users assigned to that role are able to log on and continue working until the problem that caused the lockout is found and fixed.

Users who are in a role granted access because they have rescue rights can still be audited through the system logging facility. However, their activity is not recorded in the audit store database if the auditing service is not available.

Creating a role definition that allows local users

Most role definitions are only applicable to Active Directory users and groups. In some cases, however, you might want to create a role definition that can be assigned to local users. For example, you might want to assign local users to a role that grants rescue rights to ensure a specific local account can log on if an Active Directory user is not available.

Role definitions that allow local users to be assigned cannot include PAM access rights or SSH rights, however, and therefore do not include any of the UNIX

system rights. You can use role definitions that allow local users to assign specific command rights to local and Active Directory users. You can also set the audit level for the role definitions that allow local users to be assigned.

If you select the option to allow local users, you can specify the local accounts when you assign the role by clicking **Add Local Account**, then typing the name of local UNIX or Windows accounts to assign to the role. The **Add Local Account** option is not displayed when assigning a role definition that does not allow local accounts.

Creating a role definition for secure shell rights

You can add SSH rights to any role definition as long as the role does not accept local users. Although SSH rights require the PAM ssh right, the role definition to which you add SSH rights does not require the PAM access right. As long as a user is assigned to a role that includes the PAM ssh right, you can add SSH rights to any other role definition to make the rights effective.

In addition to adding the rights to a role definition, you must set the ServiceAuthLocation parameter in the sshd_config configuration file to check for secure shell rights when users log on using a secure shell. In most cases, you should use the **Enable application rights** group policy to set this parameter for all Centrify-managed Linux and UNIX computers. This group policy sets the path to the dzsshchk command which verifies the specific applications rights for users when they log on.

Alternatively, you can manually set this parameter on an individual computer by editing the configuration file to include the following:

ServiceAuthLocation /usr/share/centrifydc/libexec/dzsshchk

Creating additional custom roles and role assignments

The previous sections described common role definitions that organizations implement to begin the process of migrating and removing locally defined privileged accounts. For most organizations, locallydefined accounts with privileged access present a security risk and are often identified as a compliance issue by auditors.

By creating role definitions similar to those described in this chapter, you can eliminate the need to share root and service account passwords while still providing privileged access to computers where it's needed. These additional roles are not required, however. You can choose to create them or create a completely different set of role definitions to suit your organization. For example, you might decide to create custom roles specifically tailored to the needs of database administrators, backup operators, and web application developers. Similarly, you might decide to create separate role definitions that are customized with AIX command rights for AIX administrators that are different from the command rights defined for Solaris administrators.

As with the common role definitions, additional custom role definitions can be created in the top-level parent zone and available throughout the zone hierarchy or in any child zone. They can also span all the computers in a zone or be assigned specifically to individual computers.

If you plan to create your own custom role definitions and role assignments, keep the following key points in mind:

- Rights associated with roles are cumulative. Users receive all of the rights in all of the roles they are assigned.
- Users must be assigned at least one role that allows an interactive login or Kerberos authentication to have any access to any computers. For existing users, this is accomplished by assigning the default UNIX Login role during the migration to Active Directory.
- Users must be given the Login with non-Restricted Shell system right to have access to a full shell. If they are in a role without this right, they can only execute the commands explicitly defined for their role.

  For users who have previously had full shell access, this limitation can be frustrating, unexpected, and unworkable. Before placing or moving users into a restricted role, be sure those users and managers throughout the organization are well-informed and wellprepared for the change and understand the business reasons for the change.

Adding custom attributes

You can add custom attributes to role definitions and role assignments. For example, you might want to use a custom attribute to reference a ticket number associated with a specific type of access request, role definition, or temporary role assignment. Custom attributes are optional and you can use them to capture any kind of information that is meaningful to your organization.

You can add custom attributes when defining or modifying a role, defining or modifying a computer role, or when modifying role assignment properties.

Exporting and importing rights and roles

You can export rights and role definitions from any zone if you want to save part or all of the information to a file. You can then import all or part of that information into a new zone and modify it, if needed. For example, you can choose to export all the rights you have defined in one zone but create a completely new set of role definitions for those rights in another zone. Exporting and importing provides a convenient way to copy and paste multiple rights and role definitions at one time.

Rights, roles, and role assignments are all inherited from parent to child zones, so there is no need to import or export any authorization information within a zone hierarchy. However, if you have multiple parent zones—for example, representing different geographical regions—you might want to use export and import to copy authorization information from one geographical region's zone to another.

Exporting authorization information

You can export multiple rights and role definitions to an .xml file that you can then use to import these definitions into another zone. You can also copy and paste or drag and drop individual rights and role definitions between zones.

To export rights and role definitions:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name from which you want to export authorization information.
3. Select the Authorization node, right-click, then click **Export Roles and Rights**.
4. Select the information you want to export, then click **Next**.

   For example, select **All** to export all of the rights and all role definitions. Selecting all or individual role definitions exports all of the rights included in those role definitions.
5. Click **Browse** to specify a location and file name for the export file, then click **Next**.
6. Review the information to be exported, then click **Finish**.

Importing authorization information

You can import multiple rights and role definitions that you have previously exported from a zone and saved to an .xml file. You can also copy and paste or drag and drop individual rights and role definitions between zones.

To import rights and role definitions

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name into which you want to import authorization information.
3. Select the Authorization node, right-click, then click **Import Roles and Rights**.
4. Click **Browse** to navigate to the file that contains the authorization information you want to import, then click **Next**.
5. Select the information you want to import, then click **Next**.
6. Review the information to be imported, then click **Finish**.

Updating rights, roles, and role assignments

When you make changes to rights, roles, or role assignments, these changes take effect on managed computers at the next cache update interval, as set by the adclient.cache.expires parameter or the "Set object expiration" group policy. The default update interval is 10 minutes. If you want changes to take place immediately, you can flush the cache on individual computers.

To flush the cache and update authorization changes:

1. Log on or switch to the root user on the managed computer.
2. Run the adflush command to clear the agent cache. For example:

   /usr/sbin/adflush

Reviewing the fundamentals of role definitions

As discussed in Basic concepts of access rights and roles, rights are fundamental to authorizing user access, you cannot assign rights directly to users. Instead, rights are combined into **role definitions** that reflect the needs of a specific job function, such as database administrator, or the ability to perform a particular task, such as start a web service or run commands that compress or extract files. It is up to you, as an administrator, to decide on the role definitions your organization needs and to assign those custom role definitions to the appropriate users and groups.

Basic access rights require Active Directory users to have a complete UNIX profile and at least one role assignment, for example by using the UNIX Login role, that is in effect in the zone to which a computer is joined. To move beyond basic access rights, you must define custom rights and custom role definitions, then add the specific rights to each role definition.

After you configure a role definition with rights, you can assign it to individual Active Directory users or to Active Directory groups, so that the role applies to all members of the group. By assigning role definitions to groups, you can manage ongoing role-based user access completely through Active Directory.

Working with computer roles

In previous chapters a *role definition* described a specific set of access rights for a user or group, including the period of time when those access rights were in effect. A *computer role* is an association that enables you to make the most of those role definitions. Role definitions grant specific access rights or enforce certain access restrictions. Computer roles enable you to associate role definitions with computers that share a similar function or have a common attribute. This chapter describes how you can configure and use computer roles to manage access rights for different sets of users.

How computer roles provide flexibility

Centrify-managed computers can only be joined to one zone at any time. This limitation makes it difficult to manage granular access rights at the zone level alone. Computer roles enable you to group computers that share a common function or attribute and associate the group of computers with a specific set of role assignments to users or groups. Individual computers can be members of any number of computer roles with different sets of users who have different access rights based on their role assignments.

Computer roles can have multiple role assignments

A computer role associates a group of computers with a set of role assignments. For example, you might have several computers that host Oracle database instances. Using a computer role, you can associate the group of computers that host an Oracle database with one role assignment that grants some users full administrative access. That same computer role can associate the same group of computers with a second role assignment that grants some users access to specific commands that must be run using the oracle account. That same computer role can also associate the same group of computers with a third role assignment that grants application users permission to log on using a secure shell session. As long as the set of computers remains the same, you can use the same computer role to grant different sets of users different access rights.

Managing access using multiple computer roles

Computer roles enable you to manage access rights using multiple filters. For example, you might have several computers that host Oracle database instances. Some of the computers that host an Oracle database might also belong to specific departments, such as the finance or engineering organizations. Some of the computers that host an Oracle database might run Red Hat Enterprise Linux while others have a Solaris operating system. You can use computer roles to grant different sets of access rights based on the criteria you want to use to group the computers. In this example, you might have one computer role for Oracle database servers and their database administrators, another computer role for users in the finance and engineering departments, and another computer role for IT staff who specialize in managing either Linux or Solaris computers.

Computer roles enable you to define access rights using any grouping criteria that makes sense for your organization. In this case, you might have one computer role linked with the Active Directory security group for all Oracle servers, a second computer role linked with the security group that only has computers that belong to the finance or engineering organization, and a third computer role linked with the security group for Linux or Solaris computers. If the set of computers grouped together changes, you should use a new computer role to grant different sets of users different access rights.

Planning to use computer roles

Because computer roles provide you with a great deal of flexibility for defining access rights, you might want to do some planning before you create new computer roles. For example, before you create a computer role you must know the criteria you want to use to group computers into one or more Active Directory security groups. You must also identify the users who will have a common set of access rights based on the computer grouping.

At a high-level, defining a computer role requires the following:

- Identify a unique Active Directory security group for each computer role.

  You should identify an attribute the computers in a particular group share, such as computers in the web farm, that host specific applications, or serve a specific department. You can create the group and add computers to it in Access Manager when you create the computer role, or before creating the computer role using Active Directory Users and Computers.

- Identify the sets of users that share common access rights and create Active Directory groups for them.

  You might want to define multiple sets of user-based roles. For example, a computer role for Oracle servers might require a “database users” group, a “database administrators” group, and a “backup operators” group.

- Identify the access rights and role definitions for each set of user-based roles.

  You might want to create specific rights, role definitions, and role assignments for different sets of users, or use existing roles. For example, the “database users” group might only require the predefined UNIX Login role definition, while the “database administrators” group might require access to privileged commands, and the “backup operators” groups might be only be allowed to run a specific set of commands in a restricted shell.

Creating a new computer role

A computer role is similar to a zone in that it defines a group of computers, a set of users, and specific access rights for a combination of computers and users. However, computer roles do not require a computer to be joined to the zone where the computer role is defined and a computer can be a member of multiple security groups and thus multiple computer roles.

Because computer role assignments define a relationship between a security group of computers, a set of rights in a role definition, and a security group of users, they control who can do what on specific computers. You can change the list of computers or the list of users dynamically simply by changing the security group membership.

What to do before creating a new computer role

Before you create computer roles, you must join a domain and zone. You should also decide on the criteria to use for grouping computers. Each computer might belong to several different security groups to used in different computer roles. Depending on your organization's policies for creating security groups, you might want to prepare one or more Active Directory security groups for Centrify-managed computers.

Rights required for this task

To create computer roles, your user account must be a domain user with the following permissions:

msDS-AzScope This object is listed under a globally unique identifier (GUID) for the Authorization object. For example: CN=cab186af-61a0-4d54-a0dd...	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read description Read msDS-AzScopeName Read msDS-AzApplicationData Write description Write msDS-AzScopeName Write msDS-AzApplicationData

Who should perform this task

A UNIX zone administrator or a Windows domain administrator who is responsible for adding and maintaining security groups performs this task, depending on your organization's policies.

How often you should perform this task

It is common to create new computer roles any time you identify new criteria for grouping computers and role assignments.

Steps for completing this task

The following instructions illustrate how to create a new computer role using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To create a new computer role using Access Manager

1. Open Access Manager.
2. Expand **Zones** and the individual parent or child zones required to select the zone name that will contain the new computer role.
3. Expand **Authorization to select Computer Roles**, right-click, then click **Create Computer Role**.
4. Type a name for the computer role and an optional description, then select either **<Create group>** to create a new Active Directory group for computers or **<...>** to search for an existing group of computers to use.

   For example, click **Create group** to create a new Active Directory security group named oracle_servers for the computers that host Oracle database instances. If creating a new group, you are prompted for the location, group name, and scope.
5. After you have selected or created an Active Directory security group, click **OK**, then click **OK** to save the new computer role.

   Note: If you're using classic zones, you cannot add cross-forest groups to roles at this time. All groups added to roles should be defined in the local forest. However, users from a trusted forest may be added to groups in the local forest and then added to a role, or they may be directly added to a role. (Ref: IN-90001)

Delinea

Adding computers to a computer role

After you create an Active Directory security group for computers and associate it with a computer role, you can add or remove computers simply by updating the group membership. For example, if you have a computer role for managing access to Oracle database servers and you deploy a new instance, you simply add the new server to the computer security group you created for Oracle servers. You can update the group membership using Active Directory Users and Computers, Access Manager, ADEdit, or another tool of your choice.

After you have specified the Active Directory security group you want associated with a computer role, the account membership is synchronized so you can use Access Manager or another program to make changes.

Steps for completing this task

The following instructions illustrate how to add computers to a computer role using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To add computers to the computer role using Access Manager

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the computer role to which you want to add computers.
3. Expand Authorization and Computer Roles, then expand the computer role to which you want to add computers.
4. Select Members, right-click, then select **Add Computer**.
5. Type all or part of a computer name, then click **Find Now** to search for the computer accounts to add.
6. Select one or more computers from the results, then click **OK** to automatically add computers to the Active Directory group associated with the computer role.

Adding role assignments to a computer role

For computer roles to be effective, you must create the access rights and role definitions for different sets of users. You can then assign the appropriate predefined or custom roles to different sets of users to grant or restrict their rights within the scope of the computer role. With proper role definitions and role assignments, you can manage access rights for computers completely through group membership. For example, after you have created the role definition for Oracle database administrators, you can add and remove group members to the group you created for Oracle administrators in Active Directory.

For information about creating access rights and role definitions, see the following:

- Defining rights to run privileged commands
- Defining a restricted shell command right
- Adding specific PAM access rights
- Combining secure shell rights
- Creating and assigning custom role definitions

After you have create the appropriate access rights and role definitions, you must assign those roles to the appropriate users and groups to complete the configuration of the computer role.

Steps for completing this task

The following instructions illustrate how to add role assignments to a computer role using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To associate user role assignments with a computer role using Access Manager

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the computer role to which you want to add role assignments.
3. Expand Authorization and Computer Roles, then expand the computer role to which you want to add role assignments.
4. Select Role Assignments, right-click, then select **Assign Role**.
5. Select the role definition that you want to add to the computer role, then click **OK**.
6. Click **Add AD Account** to search for and select an Active Directory user or security group to assign to the role.

   You can select User or Group as the object to find, type all or part of the user or group name, then click **Find Now**. For example, type "ora" to search for and select the "oracle_db_admins" Active Directory group then click **OK**.
7. Click **OK** to complete the role assignment for the selected user or group in the selected computer role.

Repeat these steps for each role definition you want to assign to users and groups in this computer role. For example, if you have an Active Directory "oracle_db_users" group that should be allowed to log on and run shell commands on the computers in the "oracle_servers" computer role, you would select the predefined UNIX Login role in Step 5 and assign that role definition for the computers in the "oracle_servers" computer role to the "oracle_db_users" group in Step 6.

Viewing and modifying a computer role

You can view information about computer roles by expanding Authorization and Computer Roles for a zone. However, computer roles are also closely linked to the Active Directory groups that define their scope and role assignments, so there are several different ways you might view or modify information about a computer role. For example, you might use Access Manager, Active Directory Users and Computers, or ADEdit commands, depending on what you are trying to do.

In Access Manager, you can expand a computer role, then select **Role Assignments** to see the users, groups, and role definitions that have been assigned on the computers that are members of the computer role. You can also expand a computer role, then select **Members** to see the computers to which the role assignments apply. To see the Active Directory group assigned to the computer role in Access Manager, select the computer role, right-click, then select **Properties**.

If you are using Active Directory Users and Computers, you can view the properties for the Active Directory group associated with the computer role and click the **Members** tab to see the computers assigned to the computer role.

If you want to add a computer to an existing computer role, you can simply add that computer to the Active Directory group associated with the computer role without making any changes in Access Manager. Similarly, if users join or leave your organization, you can simply add or remove those user accounts in the appropriate Active Directory groups that are associated with the computer role. For example, if you define the oracle_servers computer role to associate a specific set of computers with a role assignment that grants administrative rights to users in the Active Directory security group oracle_db_admins, you could simply add the user account for Frank.Smith to the Active Directory security group oracle_db_admins to give that user administrative access on the computers that are members of the oracle_servers computer role. You do not need to make any changes in Access Manager.

To modify the rights and role assignments for a computer role, you must use Access Manager or ADEdit commands.

Using computer roles

Deciding how best to use computer roles requires some planning and configuration that might not be part of your initial deployment plan. To make effective use of computer roles, you must also prepare appropriate role definitions for different sets of users. However, computer roles provide a powerful and flexible option for managing access to computers using your existing processes and procedures for managing Active Directory group membership.

After you create a computer role, it is easy to manage even as your organization changes and grows. For example, if another Oracle database server comes online, you add it to the computer group you created for Oracle database servers in Active Directory. If other DBAs join your organization, you add them to the Active Directory group you created for Oracle administrators. The computer role links the computer group to the role assignment and no additional updates are needed to accommodate these kinds of organizational changes. If you need to modify the access rights, you can change the role definition and have the changes apply to all members of the group.

Requiring multi-factor authentication using computer roles

Computer roles enable you to group and provide access to computers through role assignments. One strategy you might find useful is to use computer roles to control where multi-factor authentication should apply. For example, you might have several computers with highly sensitive material where you want to ensure all user access will require multifactor authentication. To accomplish this goal, you can configure a computer role, then add and remove computers with sensitive information to control whether multi-factor authentication is required.

To require multi-factor authentication based on a computer role

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that will contain the new computer role.
3. Expand Authorization to select Computer Roles, right-click, then click **Create Computer Role**.
4. Type the role name and, optionally, a role description, then select **<Create group>** for the Computer group to create a new Active Directory group for computers.

   For example, to create a new Active Directory security group for the computers with sensitive information, click **Browse** to select the Active Directory location for the new group. If you are using the default deployment structure, you would browse to a location similar to acme.pubs.org/Acme/Computer Roles then type a group name such as mfa_required_servers, select a scope, and click **OK**.
5. Click **OK** to save the new computer role.
6. Add the computers that require multi-factor authentication for access to the mfa_required_servers Active Directory security group.

   As you add computers to the Active Directory security group, the computers are listed as Members of the computer role.
7. Expand the computer role you creates in Step 4, select Role Assignments, right-click, then select **Assign Role**.

   For example, if you created a new computer role with the role name CR_MFA_required, expand that computer role name to select Role Assignments, right-click, then select **Assign Role**.
8. Select the predefined require MFA for login role definition, then click **OK**.
9. Select **All Active Directory accounts**, then click **OK**.

Working with managed computers

This chapter describes how to add Linux and UNIX computers to Active Directory domains, manage computer accounts and properties, perform common administrative tasks, and leave the domain.

Identifying who can add computers to the domain

Who can join computers to a domain depends on your organization's policies and those policies are enforced through Active Directory. In general, there are two common scenarios:

- Any authenticated domain user can add up to ten computers to the domain.

  This is the default behavior for Windows computers. Many organizations follow this policy, so that administrative access is not required to add computers to a domain.

- Only users with specific permissions can add computers to the domain.

  Some organization restrict who can add computers to the domain. For example, a user might have to be a member of the Domain Admins or Account Operators group to add computers to a domain.

The policy your organization follows for Windows also applies when you want to add Linux and UNIX computers to a domain. If any authenticated user can add a Windows computer to the domain, adding a Linux or UNIX computer does not require an administrative user name and password. If only administrative or delegated users are allowed to add computers to the domain, the user adding a Linux or UNIX computer must provide an administrative or delegated user name and password.

If you aren't sure whether an administrative account is required to join a domain, you can prepare computer account before attempting to join the domain, and allow the computer account itself to be used to join the domain. Performing this type of "selfservice" join simplifies the operation and allows the computer account to manage its own password without administrative intervention.

Preparing computer accounts before joining

If joining the domain is restricted to privileged users, or if you know that you will need to specify computerlevel overrides, you can prepare computer accounts in advance for the Linux and UNIX computers you want to add to the domain.

There are several advantages to preparing computer accounts before joining the domain. For example, preparing a computer account enables you to accomplish the following:

- Specify the user, group, or computer account with permission to join the computer to the domain.
- Define the organizational structure you want to use for computers in Active Directory.
- Delegate administrative tasks for managing the computer account.
- Specify the user or group with permission to manage computer-level overrides for the computer.

By preparing the computer account in advance, you can minimize the changes or configuration steps you might otherwise have to perform after joining the domain. For example, by identifying the account to use when a computer joins the domain you can ensure users can add their own workstations without being assigned any special rights. By selecting the appropriate organizational unit for the computer account ahead of time, you minimize the need to move the computer account after joining the domain.

To prepare a computer account using Access Manager:

1. Open Access Manager.
2. Expand Zones and any parent or child zones required to select the zone name to which you want to add the computer account.
3. Right-click, then click **Prepare UNIX Computer**.
4. Select the type of preparation you want to perform, then click **Next**.

   In most cases, you should select both options to ensure the appropriate user or group has the permissions required to join the domain and set computer-level overrides.
5. Choose whether to create a new computer object or select an existing computer object, then click **Next**.

   If the computer account exists, but you want to add a zone profile and delegate permission to join the domain and manage computer overrides for the computer, click **Browse** to search for and select the existing computer object. After selecting an existing computer account, click **Next** to continue to Step 7.
6. Type the computer name to use for the new computer account and specify a location for the computer account object in Active Directory, then click **Next**.
   - For **Computer name**, type the host name to use for the computer account in Active Directory.
   - For **Domain**. verify the domain name displayed is the appropriate domain for the computer account to join. Click **Browse** to navigate to a different Active Directory domain.
   - For **DNS name**, verify the DNS name for the computer account. You can modify the DNS name for the computer, if needed. For example, if computer names in DNS use a different suffix than the Active Directory domain, you might need to modify the default value displayed.
   - Select **Create the computer object in the container** to specify the parent container for the new computer account in Active Directory. In most cases, you should use the default parent container object. Click **Change** to navigate to a different container object for the computer account.
7. Select the **Allow this computer to join the domain using a read-only domain controller** option if you want the computer to join itself to the domain using a read-only domain controller and select the type of license to use, then click **Next**.

   If you click **Next** without selecting **Allow this computer to join the domain using a read-only domain controller**, the computer must join the domain by connecting to a writable domain controller.
8. Review the default list of service types and service principal names for the specified computer, then click **Next** to accept the default set of service principal names.

If you want to make changes to the default services or service principal names, you can do the following:

- Click **Add** to add a service type or add a new service name to an existing service type.
- Select a service principal name and click **Edit** to change the name.
- Select a service principal name and click **Remove** to delete the name.
- Click **Default SPN** to restore the default list of service principal names.

  If you are in an environment where multiple instances of the same SPN are possible, as a user with administrator privileges, use the -d or --forceDeleteObjWithDupSpn parameter with the adjoin command to ensure duplicate SPNs are removed.

9. Select whether to allow a specific user or group to join the computer to the domain or use the computer account and automatically-generate password to join the domain, then click **Next**.

   In most cases, select **Allow the computer to join itself to the zone** to allow the computer account to perform a "self-service" join. This option is selected by default because it allows you to automate the join operation so that a user name and password are not required.

   If you want a specific user, group, or computer account to be used to join the domain, select **Allow this user, group, or computer to join the computer to the zone** then click **Browse** to search for the user, group, or computer that you want to give permission to join the computer to the domain.

10. Select the user, group, or computer account with permission to set computer-level overrides, then click **Next.**

    By default, the permissions required to manage computer-level overrides are granted to members of the Domain Admins group. You can click **Browse** to search for and select another user, group, or computer account.

11. You can choose to skip permission delegation, if desired.

    If you select this option, the service does not set the security descriptor for the computer; you'll need to go in and set that attribute yourself. Some organizations prefer to set security descriptors manually. Security descriptors include security information such as the object owner, who has access rights to the object, and so forth.

12. Review your configuration settings, then click **Next**.

13. Review the confirmation of the operation performed, then click **Finish**.

    The computer account is created in Active Directory and a zone profile for the computer is added to Access Manager in the zone's Computers container. The user or group you have designated as the trustee can now join this computer to the domain using the adjoin selfserve command line option, and the group you designated for computerlevel overrides can add users and role assignments to the computer.

Delegating permissions when preparing a computer account

When you prepare a computer account, you have the option to grant a specific user, group, or computer account the administrative permissions required to perform two separate tasks:

- The permissions required to join the computer account to the domain.
- The permissions required to set and manage computer-level overrides

In most cases, you should select both options even if you want to grant different accounts the permissions required to perform each task.

However, it is possible to create a computer account and not delegate permission for computer-level overrides by deselecting the **Delegate permission for machine overrides** option. If you deselect this option, you are the only administrator who can set profile or role assignment overrides for the computer. No other user or group will be granted the permissions required to set or manage computer-level override for user profiles or role assignments.

Likewise, it is possible to delegate permissions for computer-level overrides without preparing the computer to join the domain by deselecting the **Prepare computer for adjoin** option. If you deselect this option, the computer icon appears in the zone, but the Active Directory computer object and service connection point are not created. The designated trustee can set computer-level override for user profiles or role assignments. No other user, group, or computer account will be specifically granted the permissions required to join the domain.

If any authenticated user can add computers to the domain, then any user with a valid domain account can join Linux and UNIX computers to the domain. If adding computers to a domain requires an administrative account, only the administrator who creates the computer account can join it to Active Directory.

For more information about who can add computers to a domain, see Identifying who can add computers to the domain.

Allowing password resets for computer accounts

If you use Access Manager and the Prepare UNIX Computer wizard to create a computer account before joining the domain, you can select the **Allow the computer to join itself to the zone** option to set the permissions required for a computer to manage its own account. If you use Active Directory Users and Computers to create a computer account, however, you need to manually modify the permissions for the account.

By default, most computer accounts do not have permission to reset their own account password. This prevents the delegation of administrative rights for the computer to the local computer account. If you want to give a computer account administrative rights in a zone, you need to modify the computer account to allow password resets. In addition, allowing a computer account to update its own properties enables Access Manager to display the agent version and maintain operating system information for the computer account.

Checking for the appropriate permissions

To check whether a computer account allows password resets, you can view the permission settings for the account.

To check and modify the permissions for a computer account:

1. Open Active Directory Users and Computers, expand the domain, and select Computers to find the computer account to which you want to assign administrative rights.
2. Select the computer account, right click, then select **AD Properties**.
3. Click the **Security** tab, scroll down the list of group or user names and select **SELF**.
4. In the list of Permissions for SELF, scroll to the **Reset Password** permission, click **Allow**, then click **OK**.
5. Select the computer account, right-click and select **Reset Account**, then click **Yes**. When the account is reset, click **OK**.

Assigning administrative rights to computer accounts

After you have checked the Active Directory permissions for a managed computer account and modified them, if necessary, you can assign zone administrative rights to the account through Access Manager.

To give administrative rights to the computer account:

1. Open the Access Manager console.
2. In the console tree, select **Zones**, and if necessary, **Child Zones**, then select and expand the zone in which you are interested.
3. Right-click, then click **Delegate Zone Control**.
4. Click **Add**, select **Computer** from the Find list, then click **Find Now**.
5. In the results, select **Domain Computers**, click **OK**, then click **Next**.
6. Click **Join computers to the zone** and optionally, **Remove computers from the zone**, then click **Next**.

   Note: {/b}In most cases, these are the only administrative tasks you should assign to the computer account. You can, however, give the account additional rights, if needed. For information about the permissions associated with each delegated task, see the *Planning and Deployment Guide*.
7. Click **Finish**.

Joining a domain

To begin authenticating users and authorizing access to Linux and UNIX computers and resources, you must first add the computers you want to manage to the appropriate Active Directory domains in one or more Active Directory forests. You can do this by running the adjoin command interactively or by using the adjoin command in a script. A successful join operation is what converts a Linux or UNIX computer into a **Centrify-managed computer**.

Connecting to the domain controller

To add a new computer to a domain, you must specify the domain you want to join. The adjoin program then locates an appropriate domain controller for the domain you specify and connects to Active Directory through that domain controller. By default, the domain controller to contact is determined by the Active Directory site topology. If the nearest domain controller in the site is not available, the agent attempts to connect to the next closest domain controller in the site. If no domain controller can be contacted or the connection takes too long to complete, the join operation fails.

If you don't want to agent to select a domain controller based on the site topology, you can specify a master domain controller on a zone-by-zone basis. If you specify a master domain controller, the agent will connect to the appropriate domain controller based on the zone you are joining.

What happens during the join operation

If the Centrify Agent can successfully connect to an Active Directory domain controller, it performs a series of key tasks to complete the join operation. For example, during the join operation, the adjoin program completes the following tasks:

- Starts the Centrify Agent for *NIX adclient process.
- Checks whether a computer account already exists for the local computer in Active Directory. It creates a new Active Directory computer account for the local computer, if needed.
- Sets the password on the Active Directory computer account to a randomly-generated password. The password is encrypted and stored locally on the UNIX host to ensure that only the Centrify Agent has control of the account.
- Updates the Kerberos service principal names used by the host computer, generating new a Kerberos configuration file and krb5.keytab entries, and generating new service keys for the host and http services.
- Synchronizes the local computer's time with Active Directory to ensure the timestamps for Kerberos tickets are accepted for authentication.

After joining a domain

By default, computers function exactly the same after joining the domain as they did before joining the domain. Local users can continue to log on and existing programs and applications can continue to work as they did before joining the domain. The primary difference after joining the domain is that you have more complete control over access to the computer and what Active Directory users who are granted access can do. You will also have more tools at your disposal for managing computer properties and operations. For example, after joining a domain, you can use any combination of the following tools:

- Access Manager
- Access Module for Windows PowerShell
- ADEdit command line programs and scripts
- Active Directory Users and Computers
- Group Policy Management console and Centrify group policies

You can use any of these tools to add Active Directory users to the appropriate zones, and to define and assign appropriate rights and roles for the users who need access to Linux and UNIX computers.

Joining a domain and zone with the adjoin command

In most cases, you add a computer to the domain by running the adjoin command directly on a local computer. You run this command once for each Linux or UNIX computer you want to add to a domain in the forest. Using the administrator or a designated user account, you can run the command interactively at the command line or include the command in a script to automate joining a domain.

Specifying the most common arguments

Whether you join the domain interactively from the command line or using a script, you must specify a few required arguments. You might also need to specify several additional arguments, such as a user name and password for an account with permission to join the domain, an alias for the computer in Active Directory, or the organizational unit in which to place the computer.

The most common format for the adjoin command is:

adjoin --user username --zone zonename domain

For example, the following command illustrates the most common format for the adjoin command:

adjoin --user shea@acme.com --zone LinuxDev sales.acme.com

This command connects to Active Directory as the user shea@acme.com to add the local computer to a previously-created zone called LinuxDev zone and to the sales.acme.com domain. In this example, the zone and domain name are required. The user name is not a required argument—if not specified the adjoin command would prompt for the Administrator account password. However, because the user shea is a member of the acme.com domain rather than the sales.acme.com domain, the user account must be specified in the user_name@domain_name format.

Because the password is not specified in the command line, the adjoin program prompts for the Active Directory password to authenticate the shea@acme.com account before connecting to Active Directory.

In most cases, you should avoid including the password for an account as part of the adjoin command line for security reasons. If you are using adjoin in a script, however, you must include the --password option or provide another mechanism for inputting a valid password. For more information about adjoin command line options and running adjoin commands, see the adjoin man page.

If the adclient process is able to connect to Active Directory and the join is successful, a confirmation message is displayed. By default, the join operation adds the new computer account to Active Directory in the domain_name/Computers container. If the connection to Active Directory fails, a warning message is displayed and the join operation fails.

Using the self-serve option for a previously-created computer account

If you have previously prepared a computer account in Active Directory as described in Preparing computer accounts before joining, you can use the selfserve (-S) option to join a domain without specifying a user name and password. For example, you can run a command similar to the following to join the domain:

adjoin --selfserve domain

For example:

adjoin --selfserve cendura.org

Note that you must specify the domain to join but not the zone—the computer is automatically joined to the zone in which the computer object was pre-created.

If you want to preserve service principal names (SPN) configured in the centrifydc.conf, use the adjoin command option -r spn or --useConf spn. This option only works in conjunction with the -S, --selfserve command.

Joining a domain in workstation mode

In most cases, zones are required if you are adding Linux and UNIX computers to Active Directory to address account migration and role-based access rights. However, it is possible to deploy without using zones to organize computers, rights, roles, and other information.

The workstation mode is intended for computers that function in the same way as Windows workstations where any valid user can log on to any computer that is joined to the domain. In general, workstations do not require you to manage identity attributes, such as UIDs and GIDs, or access-related attributes, such as the hours a user is allowed to log on. To mirror this behavior for Linux and UNIX computers, the workstation mode automatically creates a local user profile for users when they log on and does not apply any access rules unless you configured them for the user account in Active Directory.

Computers that join the domain using workstation mode are added to a single Auto Zone and are treated the same as Windows workstations, and are managed by Active Directory and group policy settings. You can use the workstation mode and Auto Zone for any computers that do not require profile management or role-based access controls. You can also have any combination of workstation computers that don't require profile management and access control and workstations and servers that do require profile management, access control, hierarchical zones. For more information, see Using workstation mode and Auto Zone.

To join a domain using workstation mode instead of zones, you can run a command similar to the following:

adjoin --workstation --user username domain

For example:

adjoin --workstation --user kai.rodriguez cendura.org

This command adds the local computer to a single Auto Zone. The Auto Zone requires no configuration and there are no properties, user profiles, or access rights to manage. All Active Directory users and groups in the forest, or in forests with a two-way trust, can access the computers in the Auto Zone.

Joining the domain using the computer account

On the computer to which you have given administrative rights, run the adjoin command and set the user name parameter to the computer name with a dollar sign ($) appended and the password to the computer name.

adjoin domain --zone zoneName --user computername$ --password computername

For example, if the computer name is valencia and the Active Directory domain is arcade.com, you would run a command similar to the following:

adjoin arcade.com --zone finance --user valencia$ --password valencia

Setting the password interval for managed computers

After joining a domain, the password for the managed computer account in Active Directory is automatically reset at a regular interval to ensure security. By default, the password for the computer account is updated with a new, randomlygenerated password every seven days. You can customize how frequently the password for the account is changed through the **Password change interval** group policy or by modifying the adclient.krb5.password.change.interval parameter in the configuration file, centrifydc.conf, on any managed computer.

Allowing a managed computer to authenticate NIS users

If you are using one or more managed computers as a NIS server to provide "agentless" authentication to NIS client requests or to publish NIS network maps, you can identify those computers in Access Manager by setting the **Allow this computer to authenticate NIS users** option on the computer's Centrify Profile. Setting this option adds the computer account to the zone_nis_servers Active Directory group. Additional configuration is required if you want a managed computer to respond to NIS client request.

This option is provided because using Centrify Network Information Service (adnisd) is more secure than using a legacy NIS server and can be useful to accommodate certain situations, such as a transition from NIS domains to Active Directory domains. However, continuing to use NIS client requests to retrieve network information is not a secure practice and might result in an audit finding in some organizations.

For more information about installing, configuring, and using the Centrify Network Information Service, see the *Network Information Service Administrator's Guide*.

Changing the zone for a managed computer

When you join a domain, you must join a specific zone unless you are using workstation mode and connecting through Auto Zone. Over time, you might want to migrate managed computer accounts from one zone to another. You can change the zone information for a computer at any time, if needed. You can change the zone for a computer by selecting a new parent or child zone in the computer properties or by cutting and pasting the computer object from one zone to another in Access Manager.

After you change the zone for a managed computer, you must restart the Centrify Agent for *NIX on that computer for the change to take effect. You are not required to run adleave or adjoin to complete the change. For example, after you have changed the zone for a computer log on to that computer and run the following command:

/etc/init.d/centrifydc restart

Alternatively, you can restart the managed computer to restart all services, including the Centrify Agent for *NIX. In most cases, however, restarting the agent is sufficient.

Note: If the computer has role assignments defined, you might be prevented from moving the computer until you remove the role assignments.

Changing domain information for a managed computer

Once a computer successfully joins a domain, you can remove it from a domain at any time by using the adleave command. You must also use the adleave command before you can join a new domain or make changes to the domain information for a computer, such as changing the computer name.

Leaving a domain

Leaving the domain before attempting to join a new domain or changing a computer name ensures that there will not be file conflicts or orphaned information that might prevent the join operation from completing.

You should note that leaving the domain removes all of the Centrify-specific information for the managed computer from Active Directory and reverts any computer settings that were changed by the adjoin command to their preadjoin condition. These changes include reverting PAM, NSS, and Kerberos configuration files to their pre-adjoin states and deleting the /etc/krb5.keytab file. Leaving the domain does not delete the Active Directory computer object itself.

Leaving the domain does not delete the Active Directory computer object itself. If you want to completely remove any record of the computer from Active Directory, you must delete the computer object using Active Directory Users and Computers.

Joining a different domain

After running the adleave command, re-run the adjoin command with the appropriate arguments to join a different Active Directory domain. For example:

adjoin --zone arcade.com --user gale.harris operations.acme.com

For more information about using the adjoin and adleave commands, see the adjoin or adleave man page.

Renaming a managed computer

If you need to rename a Linux or UNIX computer that is joined to a domain, you should first leave the domain, rename the computer, then rejoin the domain. Otherwise, you could have issues with the service connection point or service principal name for the computer.

Customizing configuration settings for a computer

You can configure many aspects of the environment for individual computers by applying a Group Policy Object to a site, domain, or organizational unit that includes managed computers and enabling Centrify-specific group policies. For example, you can use policies to customize PAM operations, the length of time to wait for connections between the Centrify Agent for *NIX and Active Directory, or how frequently to change the computer account password. For information about the group policies available and how to enable them, see the *Group Policy Guide*.

If you are not deploying Centrify group policies, you can also customize the configuration settings in any computer's local agent configuration file, centrifydc.conf. The comments within the file describe the most common settings. For more information about setting the parameters directly in the agent configuration file, see the *Configuration and Tuning Reference Guide*.

Enabling FIPS-compliant encryption

The Federal Information Processing Standard 140-2 (FIPS 140-2) describes US Federal government requirements that IT products should meet for sensitive, but unclassified use. The standard is published by the National Institute of Standards and Technology (NIST) and is required by all non-military agencies of the United States Government. This standard is also widely used by many other organizations outside of the government.

The standard defines the security requirements that must be satisfied by a cryptographic module used to secure unclassified information. There are four levels of security: from Level 1 (lowest) to Level 4 (highest). These levels are intended to cover the wide range of potential applications and environments in which cryptographic modules might be deployed. The security requirements cover areas related to the secure design and implementation of a cryptographic module.

The Centrify Agent can be configured to use FIPS-compliant encryption so that a managed computer can successfully join a domain that is FIPS 140-2, Level 1, compliant.

Verifying the Windows environment

Before you configure the Centrify Agent to use FIPS-compliant encryption, you should verify that the Active Directory domain meets the minimum requirements for FIPScompliance. For a Centrify-managed computer to join a FIPS 140-2 Active Directory domain, the Active Directory domain must meet the following basic requirements:

- The domain must be at domain functional level Windows Server 2008, or later.
- The forest must have a global catalog computer that is running at domain functional level Windows Server 2008, or later.
- The domain must have at least one Windows Server 2008 R2, or later, domain controller.
- Any trusted domains you plan to access must be at domain functional level Windows Server 2008, or later.

Although a managed computer can successfully join a domain that has trust relationships to domains at a lower functional level, it cannot access users in those trusted domains, for example, to add user profiles or roles to a zone.

Using group policy for FIPS compliance

If your Active Directory forest meets the minimum requirements and you have configured the Windows environment with the local or group "System cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing" security policy, you can make Centrifymanaged computers FIPS-compliant by enabling and applying the Centrify "Use FIPS compliant algorithms for encryption, hashing and signing" group policy. You should not use the equivalent Windows group policy to configure FIPScompliant communications for Linux and UNIX computers. The Centrify "Use FIPS compliant algorithms for encryption, hashing and signing" group policy is specifically designed to support Active Directory domains that are configured for FIPS 140-2 compliance.

The Centrify "Use FIPS compliant algorithms for encryption, hashing and signing" group policy is defined in a separate XML (centrifydc_fips.xml) or ADM (centrifydc_fips.adm) template file. The template file is included in the Centrify group policy extension. You must add one of these templates to a Group Policy Object to make a Centrify-managed computer FIPS-compliant mode. For information about adding template files and enabling group policies, see the Group Policy Guide. After you enable the policy, it takes effect at the next group policy update interval. To have the policy applied immediately, run the adgpdupdate command.

Using the XML template group policy

If you use the XML group policy template to enable FIPS mode, the policy verifies that each computer is joined to a domain at the domain functional level Windows Server 2008, or later. If a domain controller does *not* meet this minimum domain functional level, the policy issues a warning that allows you to skip enabling of FIPS mode for that computer.

The XML group policy template also verifies *all* computers to which the policy applies are running a supported operating system. On the computers that are running a supported operating system, the policy sets the fips.mode.enable configuration parameter to true and automatically stops and restarts the adclient process. After the restart, the computers where the policy was applied are FIPS-compliant.

If the computer is *not* running a supported platform, the XML policy leaves the fips.mode.enable configuration parameter set to false, and does not stop and restart adclient. The computer remains joined and the current encryption and hashing algorithms remain in force.

Modifying the agent configuration file

The Centrify "Use FIPS compliant algorithms for encryption, hashing and signing" group policy sets the fips.mode.enable parameter in the Centrify

configuration file to true. By default, this parameter is set to false until the group policy is applied and the computer is updated at the next group policy update interval. You can also manually modify this parameter setting directly in the agent configuration file (centrifydc.conf), then restart the adclient process to enable FIPS mode. In most cases, however, you should use the group policy to set the configuration parameter to enable FIPS mode rather than manually editing the fips.mode.enable parameter on individual computers.

Applying the group policy to a domain

In most cases, you should apply the "Use FIPS compliant algorithms for encryption, hashing and signing" group policy to a Windows Server 2008, or later, domain to enable FIPS mode. If the group policy is applied to the domain, then the computer will be enabled for FIPS mode automatically when it joins the domain.

Agent requirements for FIPS-compliant encryption

You can only configure FIPS mode for Centrify Agents, version 5.0.2, or later. In addition, FIPS mode is only supported on specific distributions of Linux and Mac OS X operating systems. For a complete and up-to-date list of the platforms that Centrify supports in FIPS mode, see the NIST validation entry for Centrify FIPS mode.

NTLM authentication

The Centrify Agent does not support NTLM authentication through SMB or SMB2 when configured to use FIPS-compliant encryption. FIPS mode only allows NTLM pass-through authentication over SChannel. Note that NTLM pass-through authentication requires a Windows Server 2008 R2, or later, domain controller.

Non-compliant operations

When configured to run in FIPS mode, the agent uses non-FIPS compliant *hash* and *key-hash* algorithms, as follows:

- MD4, MD5 and HMAC-MD5 are used to support NTLM passthrough authentication (including using NLTM for PAM authentication).
- MD4 is used to generate the managed computer password hash for use in setting up AES NetLogon Secure Channel. AES NetLogon Secure Channel is used for NTLM pass-through authentication as well as for updating operating system version attributes.
- MD5 is used to generate the UNIX password hash to verify against the MD5 password hash that is stored in the cache during disconnected mode login. (This is for backward compatibility support; this happens when you upgrade from a DirectControl version that does not support the SHA256 password hash.)

When configured to run in FIPS mode, the agent uses a non-FIPS compliant *encryption* algorithm, as follows:

- Non-FIPS compliant encryption will be used in encrypting secret information for internal communication through a UNIX domain socket.
- A non-FIPS compliant random number generator is used in generating the Initialization Vector used in the encryption.

Configuring the encryption types for trusted domains

Inter-realm keys for the AES256-CTS and AES128-CTS encryption types must be established between any trusted domains to enable Active Directory users from these domains to log on to the joined computer. You can use the ksetup utility, installed by default on the domain controller, to set up the inter-realm keys.

To configure the inter-realm keys

1. On the domain controller, open a Command Prompt window.
2. Type the following commands:

   C:\>ksetup.exe /SetEncTypeAttr trustedDomain AES256-CTS-HMAC-SHA1-96

   C:\>ksetup.exe /SetEncTypeAttr trustedDomain AES128-CTS-HMAC-SHA1-96

   Note: If you are using pre-validated Active Directory users, you must enable these users for Kerberos AES 128- and 256-bit encryption. You can do so by editing user accounts in Active Directory or by setting attributes for the users in ADSI Edit. For more information, see Enabling required encryption types for pre-validated users.

Manually granting write permissions for a computer account

If the domain that the managed computer is joining does not have at least one Windows Server 2008 R2 domain controller, you must manually grant write permission for the Operating System Version and msDS-supportedEncryptionTypes attributes to the computer account of the joined computer.

To grant write permission for required attributes to the computer account

1. Open Active Directory Users and Computers or ADSI Edit.
2. Expand the Computers container and select the computer that is joining the domain, right-click, then click **Properties**.
3. Click the Security tab, then click **Advanced**.
4. Click **Add**.
5. In the "Enter the object name to select" field, type SELF and click **OK**.
6. Click the Properties tab, select **This object only** from the Apply to list, then scroll down and click **Allow** for the following attributes:
    - Write msDS-supportedEncryptionTypes
    - Write Operating System Version
7. Click **OK** in each dialog box to close the dialog and save the new permissions.

Manually granting write permissions for a user account

If the domain that the managed computer is joining does not have at least one Windows Server 2008 R2 domain controller, you must manually grant write permission for the Operating System Version and msDS-supportedEncryptionTypes attributes to the user account used to join the computer to the domain.

1. Open Active Directory Users Computers or ADSI Edit.
2. Expand the Computers container and select the computer that is joining the domain, right-click, then click **Properties**.
3. Click the Security tab, then click **Advanced**.
4. Click **Add**.
5. In the "Enter the object name to select" field, type the name of the Active Directory user who will join the computer to the domain and click **OK**.
6. Click the Properties tab, select **This object only** from the Apply to list, then scroll down and click **Allow** for the following attributes:
    - Write msDS-supportedEncryptionType
    - Write Operating System Version attributes
7. Click **OK** in each dialog box to close the dialog and save the new permissions.

Enabling required encryption types for pre-validated users

If you are using pre-validated Active Directory users, you must enable Kerberos AES 128- and 256-bit encryption for these users. You can do so by editing the user accounts in Active Directory Users and Computers or by setting attributes for the users in ADSI Edit.

To enable encryption for pre-validated users by using Active Directory Users and Computers

1. On the domain controller, open Active Directory Users and Computers.
2. Navigate to the domain and select **Users**.
3. Select the pre-validated user, right-click, then click **Properties**.
4. Click the Account tab, then select the following Account options:
    - This account supports Kerberos AES 128 bit encryption.
    - This account supports Kerberos AES 256 bit encryption.

5. Click **OK** to save the updated account information.

To enable encryption for pre-validated users by using ADSI Edit

1. On the domain controller, open ADSI Edit.
2. Navigate to the domain and select **CN=Users**.
3. Select the user, right-click, then click **Properties**.
4. In the Attribute Editor tab, select the msDS-supportedEncryptionTypes attribute and select **Edit**.
5. Type 0X18 to set the hex value for the attribute and click **OK**.

   You should see that the value shows:

   0x18 = (AES128-CTS-HMAC-SHA1-96 | AES256-CTS-HMAC-SHA1-96)
6. Click **OK** to save the new setting.

How Centrify FIPS mode affects other encryption settings

If you enable FIPS mode, you cannot specify the Data Encryption Standard when joining the domain. The adjoin --des option is not supported. Only AES authentication is supported.

If you have specified multiple types of encryption for the computer by setting the adclient.krb5.permitted.encryption.types parameter in the centrifydc.conf configuration file, only aes256-cts and aes128-cts encryption type keys are generated and saved to the keytab file. However, if arcfour-hmac-md5 encryption is specified, the MD4Hash of the computer password is generated and saved to the keytab file.

In addition, depending on how your environment is configured, you can choose whether to remove any non-AES encryption keys for service principal names (SPNs) from the computer's keytab file by setting the adclient.krb5.clean.nonfips.enctypes parameter in the centrifydc.conf configuration file. If you set this parameter to true, adclient scans the keytab file and removes any non-AES encryption keys for SPNs during startup. This parameter is false by default.

Restarting the agent after enabling FIPS mode

If you use the ADM group policy template, which does not perform validation checks, or if you manually enable FIPS mode by setting the fips.mode.enable parameter in the agent configuration file, the adclient process will not start if the domain functional level is below Windows Server 2008.

If you attempt to start adclient and the domain functional level is below Windows Server 2008, you will see the following error message:

Cannot start adclient in FIPS Mode as machine is joined to domain with PreWindows 2008 Domain Functional Level!

To restart the agent, you must disable FIPS mode by setting the fips.mode.enable parameter to false or the "Use FIPS compliant algorithms for encryption, hashing and signing" group policy to Not configured. After disabling FIPS mode, you can continue working at your current domain functional level in non-FIPS mode by restarting the agent:

/usr/share/centrifydc/centrifydc restart

If you want to enable FIPS mode, leave the current domain, update your domain functional level, then join a Windows Server 2008, or later, domain.

Importing sudoers configuration files

If you are currently managing privileges on Linux and UNIX computers using multiple sudoers configuration files, you can import that information and convert it into rights and role definitions that can then be assigned to Active Directory users and groups, local users and groups, or both.

This chapter describes how to migrate all of your privilege management information from sudoers configuration files to Active Directory through Access Manager.

Identify the sudoers file on each computer

Most organizations use sudoers configuration files and the sudo program to manage privileges on Linux and UNIX computers. To read the sudoers file on each Linux or UNIX computer, you must have root-level permission. You can define a command right to grant this level of access to other users.

The default location for the sudoers configuration file is /etc/sudoers, and in general, this is the file to import from each computer. However, there are some exceptions:

- If sudo was compiled with the --sysconfdir option to specify a different location for sudoers file, you need to find the actual location. Run sudo -V to see the sudo configuration options, including the path to the sudoers file.
- If your environment has an automatic mechanism for distributing a single sudoers file to the entire network, you can use that one file and don't need to import multiple files.

Get the sudoers file from each computer

You can manually copy the sudoers file to a location on the Windows computer that has Access Manager installed. You should specify a file name that identifies the computer where the file was used. For example, you might include the local host name or a functional description, such as oracle_server_sudoers.txt or qa1_server_sudoers.txt.

Import the sudoers file

After you have copied the sudoers file to the computer where Access Manager is installed, you can import the sudoers file into a selected Centrify zone.

To import the sudoers file

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name into which you want to import the sudoers file.

   In most cases, if you have a sudoers file that covers multiple computers, you should import it into a parent zone so that it is available to multiple child zones. If the file is used on a single computer, you might select the specific child zone that contains that computer.
3. Right-click, then select **Import sudoers file.**
4. Click **Browse** and navigate to the location in which you copied the sudoers file, select the file, click **Open**, then click **Next**.
5. Review the contents of the file to verify you are ready to import, then click **Next**.

   If you have previously imported a sudoers file—for example, from a different computer—importing a new sudoers file overwrites the data from the previous import. If you have not yet converted the previous sudoers information to rights and rights in Access Manager, click **Cancel** to exit the wizard.

   For more information about convert the imported information to Centrify rights and roles, see Converting sudoers aliases and user specifications before importing an another sudoers file.
6. Review the parsing summary for errors or warnings to verify whether you are ready to import, then click **Next**.

   You can click **Details** to see the list of error and warnings, if applicable. From the list, you can select a specific error or warning, then click **Go To** to see the definition in the sudoers file. You can continue with the import if the list only displays warnings. If there are errors, you must fix them before continuing. Make note of any errors and warnings to fix, then click **Close** to close the Details list.

   If the file contains errors, or if you want to fix warnings before importing, click **Cancel** to exit the wizard. You can then open the sudoers file in a text editor to fix, delete, or comment out the lines in the file, then save it. After you have modified the file, you can rerun the Import Sudoers File wizard.
7. Click **Finish** to complete the import.

The import wizard creates a new node called Sudoers, which contains sub-nodes for the types of data contained in a sudoers file. For example, expand **Sudoers** to see the nodes for User Alias, Runas Alias, Host Alias, Command Alias, and User Specifications. If the Sudoers node is not visible, select Authorization, right-click, then click **Refresh**.

Some or all of the Sudoers sub-nodes might be empty depending on whether the sudoers file included definitions of that type. For example, if there are no user aliases defined in the sudoers file, the User Alias sub-node is displayed in Access Manager, but there are no entries under it.

You can now convert the sudoers data to rights, role definitions, and role assignments in the Centrify zone. If you intend to import more than one sudoers file into the same zone, you must convert the imported aliases and user specifications to rights, role definitions, and role assignments before importing another sudoers file.

Converting sudoers aliases and user specifications

Before you convert the sudoers file aliases and user specifications to rights, role definitions, and role assignments, be certain that you have imported all the users and groups specified in the sudoers file into Active Directory, and that you have added them to the zone in which you are imported the sudoers file. If there are users and groups without a profile in the zone when you attempt to convert the user specifications from the imported sudoers file into role assignments in Access Manager, the conversion will fail.

In addition, keep in mind that the role definitions and assignments you create from sudoers specifications do not contain any UNIX system rights or PAM access rights. You can assign those rights through other roles, such as the predefined UNIX Login role, or you can add system rights and PAM access rights to the role definitions after you create them from the sudoers specifications.

Within each item are objects for the sudoers definitions that were imported. For example, within User Alias are alias definitions, each one of which contains the user accounts defined for that alias.

Each type of information from the sudoers file converts to a different type of authorization information in the Centrify zone. You do not need to convert all of the imported aliases. You can simply ignore or delete aliases that are obsolete or no longer relevant.

Converting user aliases

On Linux and UNIX computers, a user alias in the sudoers file defines a set of users without creating a group. When you convert a user alias specification to be used in a zone, however, it becomes an Active Directory group. Assigning users to groups simplifies user management because if users change roles or leave the company, you can simply remove their group membership, without deleting their accounts, and effectively, they no longer have access to the roles assigned to members of the group.

You can create a new Active Directory group from the user alias you imported or map the imported alias to an existing Active Directory group.

To create a new Active Directory group from a user alias

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name into which you imported the sudoers file.
3. Expand Authorization and Sudoers, then select **User Alias**.
4. Select the alias name, right-click, then select **Create AD Group**.
5. Verify the container location, or click **Browse** to select a different container, then click **Next**.
6. Verify the group name, which defaults to the alias name, optionally, add a prefix or suffix, and select the scope for the group, then click **Next**.
7. Review the group and group membership information displayed, then click **Next**.

   If there are any warnings or errors displayed, you must fix the errors before continuing. If only warning are displayed, you can continue to create the group. For example, if the user alias has members that don't have a corresponding Active Directory account, you can continue creating the group.
8. Review information about the new Active Directory group, then click **Finish** to create the group.

To map a user alias to an existing group

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name into which you imported the sudoers file.
3. Expand Authorization and Sudoers, then select **User Alias**.
4. Select the alias name, right-click, and select **Map to AD Group**.
5. Select **Remove original AD group membership** or cancel the selection depending on whether you want to keep the current members of the group when adding the users from the alias definition.

   If you select this option, the wizard removes the existing members of the group when adding the new members. If you do not select this option, the wizard adds the new members to the existing members.
6. Click **Browse**, then enter search criteria to identify the group and click **Find Now**.

7. Select the name of the group and click **OK**.

   The wizard imports the users defined by the alias into the specified Active Directory group. It also issues a warning message that it can't import users who are defined by the alias but who are not defined in Active Directory.

Viewing run-as aliases

A run-as alias defines a group of one or more users who other users are able to run commands as. Select and double-click the alias name to expand it and see the users who are defined for it. You cannot directly import run-as aliases. However, if a user specification includes a run-as alias, you can view the run-as definition in the **Runas Alias** node, and import the commands defined in the specification. For more information about user specifications, see Converting user specifications.

Converting host aliases

Host alias definitions are popular in centralized sudoers files because they allow you to assign privileges to groups of computers rather than managing privileges on an individual computer and file basis. They convert naturally to computer roles, which also assign privileges to groups of computers.

When you convert a host alias to a computer role, the wizard creates a new computer role, creates an Active Directory group that contains the computers defined in the host alias, and adds these computers to the new computer role. Because the computer role group is an Active Directory group, the computers can span multiple zones and include computers that are joined to different zones. To complete the computer role definition, you must add the appropriate user role assignments, which specify what specific users and groups in different role definitions are allowed to do on the computers included in the computer role group.

To create a computer role from a host alias

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name into which you imported the sudoers file.
3. Expand Authorization and Sudoers, then select **Host Alias**.
4. Select the alias name, right-click, then select **Create Computer Role**.
5. Click **Next** to accept the location for the group of computers, or change the location, then click **Next**.
6. Verify or change the group name, optionally, add a prefix or suffix, and select the scope for the group, then click **Next**.
7. Review the group and group membership information displayed, then click **Next**.
8. Review information about the new Active Directory group for computers, then click **Finish** to create the group and the new computer role.

   If the computer accounts exist in Active Directory, the computers defined in the host alias are automatically added to the new Active Directory computer group and to the "Members" node of the new computer role.
9. Expand Authorization, Computer Roles, and the computer role name.
10. Select Role Assignments, right-click, and click **Assign Role**.
11. Select the role and click **OK**.
12. Click **Add AD Account**.
13. Select User or Group, enter search criteria, then click **Find Now** to search for and elect the user or group, then click **OK**.
14. Select the appropriate user or group from the result, then click **OK** to complete the user role assignment.

Viewing command aliases

You can select the Command Alias sub-node to view the command aliases that were imported from the sudoers file. You can't edit or delete the command aliases. The information is displayed for your reference. You can assign the command aliases listed role definitions, role groups, and computer roles when you convert the user specifications imported from the sudoers file.

Converting user specifications

In the sudoers file, user specifications make use of the alias definitions to assign commands and privileges to users. After you import the sudoers file, you can convert the user specifications into role assignments.

To convert user specifications to role definitions and role assignments

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name into which you imported the sudoers file.
3. Expand Authorization and Sudoers, then select **User Specifications**.
4. Select the name of a user specification, right-click, then select **Import**.
5. Review the list of commands to be created, then click **Next**.
6. Verify the name of the role definition name to be created, then click **Next**.

   By default, the role definition is named Role_n. You can change it after it is created.
7. If the user or group defined in the imported user specification is not found in the zone, the role assignment to be created is displayed and you can click **Next**, then click **Finish**.

   If the user or group defined in the imported user specification is not found in the zone, the role assignment will fail and the role displays an error (Error). Click **Cancel** to exit the wizard and add the user or group to Active Directory and the zone.

   Importing a user specification will fail if the user or group defined in the user specification is not found in the zone or if no computers are defined for the host alias in the user specification are found in the zone.
8. Rename the role definition by expanding Authorization and Role Definitions.
   - Select the new role definition, for example, Role_2.
   - Right-click, then select **Rename**
   - Type a new name for the role definition.

The role definitions you create from a sudoers specification do not contain the UNIX system rights or PAM access rights. You can assign these rights through a separate role assignment or by add the appropriate UNIX system rights and PAM access rights to the new role definitions.

Removing imported sudoers information

Once you have validated the conversion of imported sudoers file information, you can purge the sudoers information from Access Manager.

To purge sudoers information

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name into which you imported the sudoers file.
3. Expand Authorization, then select **Sudoers**.
4. Right-click, then select **Purge**.

   The Sudoers node and sub nodes are removed from Access Manager.

Mapping sudo to dzdo

To execute privileged commands users must type dzdo and the command name. If you want, you can map sudo to dzdo, which allows your users, who are accustomed to using sudo to execute their privileged commands, to continue to type sudo commandName. If the user has a role assignment that allow him to execute the command in an unrestricted shell, the command is executed using dzdo commandName. To map sudo to dzdo on computers in your organization, you can enable the "**Replace sudo by dzdo"** group policy for a site, domain, or organizational unit.

For more information about working with group policies, see the *Group Policy Guide*.

Using Centrify OpenLDAP proxy service

This section describes the Centrify OpenLDAP proxy service (centrifydc-ldapproxy) that you can use to map Active Directory users to UNIX identities to enable access to the files stored on legacy network appliance servers and storage devices. Centrify OpenLDAP also enables Linux and UNIX computers to search Active Directory domain controllers and global catalog servers for any information stored in Active Directory. If you have the appropriate permissions, you can also use the Centrify OpenLDAP proxy service to add, modify, or delete information stored in Active Directory.

What the OpenLDAP proxy provides

Many applications support the Lightweight Directory Access Protocol (LDAP) and require data stored in this format, but do not support Kerberos. In addition, many applications that support LDAP cannot search Active Directory directly because of the complexities of the Active Directory environment itself, such as the global catalog, multiple domains, multiple forests, and trust relationships.

The Centrify OpenLDAP proxy is an OpenLDAP server process that enables LDAP clients that are not Kerberos-enabled to search Active Directory efficiently and securely. By using the Centrify OpenLDAP proxy, applications that support LDAP can search complex Active Directory environments and authenticate users with Active Directory. Through the Centrify Agent, the Centrify OpenLDAP proxy enables you to resolve UID, GID, and group membership efficiently and collapse the entire Centrify hierarchical zone structure, including parent and child zone, and individual computer overrides into a single namespace for LDAP applications.

In addition, connecting to Active Directory typically requires an authenticated bind with a valid user name and password. Because the Centrify OpenLDAP proxy uses the Centrify Agent to connect to Active Directory and retrieve information, you can issue OpenLDAP commands without an authenticated bind.

The following diagram provides a simplified overview of the components.

Components

The key advantages to deploying the Centrify OpenLDAP proxy when you have LDAP clients where the Centrify Agent cannot be installed are as follows:

- You can use the Centrify OpenLDAP proxy server to run commands that retrieve or update information stored in Active Directory.
- The Centrify OpenLDAP proxy service uses the Centrify Agent to securely connect to Active Directory and retrieve user, group, and other information from the Active Directory domain controller.
- You can leverage the offline authentication and caching capabilities of the Centrify Agent for applications that support LDAP, but not Kerberos.
- Regardless of the complexity in Active Directory, including multiple domains and forests and parent and child zones, the Centrify OpenLDAP proxy treats the information stored in Active Directory as a single RFC2307-compatible namespace.

Enabling simple authentication

Users can be authenticated through simple authentication to the Centrify OpenLDAP proxy with their username and password. This is then converted to a secure Kerberos authentication by adclient.

By default, to authenticate users, adclient checks its credential cache data first, then, if not in cache, it refers to Active Directory. Allowing Centrify OpenLDAP proxy to use the adclient credential cache, enables authentication if adclient is in disconnected mode.

If you want to always authenticate through Active Directory:

To the slapd.conf file:

/etc/centrifydc/openldap/slapd.conf

Add:

cdc-auth-prefer-cache false

Enabling simple proxy mode

If either objectClass or objectCategory is not specified in the search filter, the search is in simple proxy mode. With simple proxy mode, all search filters are sent without translation through adclient to Active Directory. All results are returned as provided by Active Directory without translation or interpretation of results.

Accessing network appliance or storage servers

One of the most common uses for the Centrify OpenLDAP proxy service is to provide access to the files stored on legacy network appliance file servers and storage devices. Many organizations use network appliance file servers and storage area network devices to provide highly available and scalable data storage services that support multiple client access protocols—including NFS, CIFS and iSCSI—and multiple operating systems.

Supporting multiple protocols and operating systems, however, presents a challenge when users want to access files from computers with different operating systems. To ensure users are granted proper access to files stored on a network appliance or storage server, their identity attributes must be consistently defined for both UNIX and Windows operating systems.

For example, the identity attributes that allow access to the files on a network appliance or storage server might be UNIX profile attributes from a common NIS or LDAP repository. The UID and GID values establish file ownership and file access permissions. For Windows users to access the files stored on the network appliance or storage server, their Windows account must be mapped to the UNIX profile that grants them the appropriate file permissions.

Delinea

Mapping Active Directory users to UNIX profiles

Centrify enables you to map Active Directory users to one or more UNIX profiles. The UNIX profile contains each user's identity attributes. You can use this mapping of Active Directory account information to UNIX identity attributes to provide consistent file and directory ownership and access rights to files that are stored on a network appliance or storage server.

By mapping an Active Directory account to a UNIX profile, you can ensure that a user's identity is consistently maintained and that access to UNIX-hosted resources is properly protected regardless of the computer from which the user accesses the resource.

For network appliance or storage servers that are hosted on UNIX computers and require UNIX identity attributes to grant access, you can use the Centrify OpenLDAP proxy service to make the Active Directory-hosted user mapping information available through the LDAP or LDAPS protocol.

Configuring servers to use the proxy service

Before you can use the Centrify OpenLDAP proxy service to look up information stored in Active Directory, the network appliance, storage device, or file server you want to use must be configured to use LDAP to look up user and group information. In most cases, this is an option you configure when setting up a server or device.

If your vendor supports connecting to LDAP servers for authentication and authorization services, configuring the server or device to use the Centrify OpenLDAP proxy requires the following high-level steps:

1. Install Access Manager, create at least one zone, and add users to the zone.
2. Install the Centrify Agent on a Linux or UNIX computer and join the computer to an Active Directory domain.
3. Install the centrifydc-ldapproxy package on the Linux or UNIX computer.
4. Start the centrify-ldapproxy service and verify proper operation.
5. Set up the network appliance, storage device, or file server to use the Centrify OpenLDAP proxy service to look up user and group information.
6. Test the solution for proper end-to-end operation.

Installing the Centrify OpenLDAP proxy service

On most platforms, the centrifydc-ldapproxy package is available with the Centrify agent software package but is not installed by default. You can select the package in the installation script or install it using a native package installer.

To run the Centrify OpenLDAP proxy service, the computer must:

- Be joined to an Active Directory domain.
- Have the Centrify Agent installed and the adclient running.

In the following example, the agent is installed on a Linux computer and the computer is joined to the acme.org Active Directory domain.

To install the Centrify OpenLDAP proxy service on a Linux computer

1. Log on or switch to the root user, then navigate to the directory where you extracted Centrify files.

   For example, if you ran the gunzip and tar commands in the /tmp directory, change to the /tmp directory.

2. Run install.sh or a native package manager to install the files.

   For example, run the following command:

   ./install.sh

   You can type K to keep any existing packages you have installed. When you see the Install the CentrifyDC-ldapproxy package prompt, type Y. Follow the remaining prompts displayed to complete the installation.

   Alternatively, you can use a native package manager. For example on most Linux distributions, you can run a command similar to this:

   rpm -Uvh centrifydc-ldapproxy-release-arch.rpm

   If you are installing on Solaris, unzip and extract the contents of the package, then run a command like this:

   pkgadd –d CentrifyDC-ldapproxy -a admin

   If you are using an installation program, such as SMIT or YAST, see the documentation for that program.

3. If you want to start the ldapproxy service with parameters, configure the STARTUP-OPTS option.

   Run the appropriate command for your platform.

   - For CentOS, SLES

echo "STARTUP_OPTS=\"-h ldaps:///\"" >> /etc/sysconfig/centrify-ldapproxy

- For Debian

  echo "STARTUP_OPTS=\"-h ldaps:///\"" >> /etc/default/centrifyldapproxy

- For HPUX

  echo "STARTUP_OPTS=\"-h ldaps:///\"" >> /etc/rc.config.d/centrify-ldapproxy

- For AIX

  chssys -a "-d 0 -h ldaps:///" -s centrify-ldapproxy

- For Solaris without Service Management Facility (SMF)

  echo "STARTUP_OPTS=\"-h ldaps:///\"" >> /etc/centrifydc/openldap/centrify-ldapproxy.conf

- For Solaris with Service Management Facility (SMF)

  svccfg -s centrify-ldapproxy setprop 'slapd/STARTUP_OPTS=("-h""ldaps:///")'

4. Start the centrify-ldapproxy service.

   For example, on Linux computers:

   /usr/share/centrifydc/bin/centrify-ldapproxy start

5. Test the service by searching for an object in the Active Directory domain.

   For example, to search for groups in the domain, you might type commands like this:

   ```
   cd /usr/share/centrifydc/bin
   ldapsearch -h localhost -p 389 -x -b “dc=acme,dc=org”
   s sub "objectClass=group" -D
   "cn=amy.adams,cn=users,dc=acme,dc=org" -w 1234abcepassword
   ```

   The -h and -p options are required to connect to Active Directory using the proxy service and the Centrify Agent. If the LDAP proxy service is not on the local computer, use the -h option to specify the name of the computer where you have installed it.

   You can also connect to Active Directory directly using a valid user name and password. For example:

   ```
   ldapsearch -D "cn=amy.adams,cn=users,dc=acme,dc=org" -W
   -h dc2012.acme.org -p 389 -x -b "dc=acme,dc=org"
   -s sub "objectClass=group"
   ```

6. (Optional) Review and modify, if necessary, the default centrifyldapproxy service start-up script in the /etc/init.d/ directory.

   You can use the /usr/share/centrifydc/bin/centrifyldapproxy script to start, stop, restart or check the status of the Centrify OpenLDAP proxy service.

   Note: By default, the service starts automatically when the computer restarts.

Specifying the LDAP server

After you have installed and tested the Centrify OpenLDAP proxy service, the next step is to configure the network appliance, storage device, or file server to use the Centrify OpenLDAP proxy service to look up user and group information. In most cases, this involves setting configuration options to specify the computer where the Centrify OpenLDAP proxy service is running as the LDAP server you want to use in a local or system-wide ldap.conf file. You should consult the documentation provided by the vendor you are integrating with for details about how to set up LDAP integration.

Testing the solution

After you have configured the network appliance, storage device, or file server to use the Centrify OpenLDAP proxy service on a Centrifymanaged computer, you should verify that files created by a Windows user have the correct UID and GID to access those files from both a UNIX computer and a Windows computer.

Delinea

Manually starting the OpenLDAP service

Typically, the Centrify OpenLDAP proxy service automatically starts when the computer restarts. You have the option to manually start Centrify OpenLDAP proxy service.

The Centrify OpenLDAP proxy service is a modified version of the standard slapd LDAP server process. The Centrify version of the slapd process also uses a customized version of the standard LDAP server configuration file in the following location:

/etc/centrifydc/openldap/slapd.conf

This customized version of the slapd.conf configuration file is created automatically when you join a domain and is configured by default with Access Manager and domain-specific information. You can start or stop the slapd process at any time by using the centrify-ldapproxy script or directly from the command line.

To start the Centrify OpenLDAP proxy service directly from the command line using the default configuration file, you can run the following command:

/usr/share/centrifydc/libexec/slapd

or

/usr/share/centrifydc/bin/centrify-ldapproxy start

If you start the slapd process directly from the command line, you can also specify additional command line options just as you would for the standard slapd LDAP server process. For example, you can use the -f command line option to specify a different configuration file to use:

slapd -f /etc/centrifydc/openldap/slapd.conf

or

/usr/share/centrifydc/bin/centrify-ldapproxy start -f /
etc/centrifydc/openldap/slapd.conf

For more information about the command line options when starting the LDAP server directly from the command line, see the man page for the slapd process.

Note: On the computer that is using systemctl, if the slapd process crashes, the systemd process will restart the slapd process.

Sample deployment scenario

The following diagram illustrates a basic deployment scenario for a distributed site with minimal OpenLDAP proxy overhead. As depicted in this illustration, the legacy LDAP servers and devices support a redundant LDAP server for fault tolerance and failover.

Using OpenLDAP commands

The Centrify OpenLDAP proxy service includes a set of OpenLDAP commands that have been modified to support looking up information in Active Directory domain controllers and the global catalog. The Centrify distribution of OpenLDAP supports most of the standard options and syntax for performing LDAP operations, but the ldap commands in the Centrify distribution of OpenLDAP also support the following options that are not supported in a standard OpenLDAP distribution:

-m	Use the local machine credentials from the /etc/krb5.keytab file. This option requires root user access.
-r	Disable line wrapping when printing out LDIF entries.

The Centrify distribution of OpenLDAP also provides extended URL support for Active Directory. With Centrify LDAP commands, you can use the following URLs to connect to Active Directory computers:

ldap://domain_name	Connect to the appropriate domain controller for the specified domain within the Active Directory site.
ldap://	Connect to the joined domain.
gc://[domain_name]	Connect to the global catalog domain controller for the joined domain. You can use the optional domain_name parameter to specify a domain in a different forest.

The Centrify distribution of OpenLDAP includes the following commands:

- ldapsearch
- ldapadd
- ldapmodify
- ldapmodrdn
- ldapcompare
- ldapdelete

Note: The ldappasswd and ldapwhoami commands do not work with Active Directory. For more information about using the OpenLDAP commands or the standard options available, see the man page for each command.

Centrify OpenLDAP proxy commands attributes

The Centrify OpenLDAP proxy commands accept the following attributes.

- dn - Specifying the dn attribute returns only the distinguished name
- 1.1 - Specifying the 1.1 attribute returns only the distinguished name
- * - Specifying the asterisk (*) attribute return is situational:
  - If only * is specified, Centrify OpenLDAP proxy returns all our supported attributes.
  - If the * is specified with additional attributes, Centrify OpenLDAP proxy returns the given additional attributes.

Searching for users and groups

If you want to use ldapsearch to find a user, do not use objectclass=user or objectcategory=person to specify the filter. Instead, you should use objectclass=posixaccount. For example, to find the user with the UNIX name jtr enter a command similar to the following:

/usr/share/centrifydc/bin/ldapsearch -x -h localhost -D
“CN=Administrator,CN=Users,DC=pistolas,DC=org” -W -b
“dc=pistolas,dc=org” "(&(objectclass=posixaccount)(uid=jtr))"“

Optionally, use the UID number instead of the UNIX name:

"(&(objectclass=posixaccount)(uidNumber=1234567))"

Similarly, use objectclass=posixgroup to retrieve information on a group. This filter supports the following options:

- cn: Find a group with a given UNIX name
- gidNumber: Find a group with a given GID
- memberUID: Search for secondary group membership of given UNIX user.

Searching the global catalogs

In most cases, you use the Centrify OpenLDAP proxy service to search for information through the domain controller. However, you can also use the Centrify OpenLDAP proxy service to perform searches in the global catalog, if needed. The global catalog search is especially useful if you have a large, multiple-domain forest.

To specify that you want the Centrify OpenLDAP proxy service to search the global catalog, add “CN=$” to the front of the search base.

To search Active Directory for a specific account, use the syntax:

"(&(objectCategory=Person)(Name=amy.adams*))"

For example, in the global catalog, you might type a command similar

to the following:

/usr/share/centrifydc/bin/ldapsearch -h localhost -D
"cn=amy.adams,cn=NewUsers,dc=ajax,dc=org" -w password -x -b "cn=$"

By default the Centrify OpenLDAP proxy service is configured to disable anonymous binds. To allow anonymous binds:

1. Edit the /etc/centrifydc/openldap/slapd.conf file.
2. Remove or comment following line.

   require authc

If anonymous binds are disabled, you no longer need to specify the -D and -w parameters to invoke an ldapsearch. For example:

ldapsearch -h localhost -x -b "dc=wonder,dc=land"
"(&(objectClass=User)(displayName=Mister*))" displayName

Minimizing search traffic to adclient

To minimize the traffic to adclient and subsequently to Active Directory, during an ldapsearch, the Centrify OpenLDAP proxy implements memory cache. The Centrify OpenLDAP proxy memory cache is disabled by default.

To enable the Centrify OpenLDAP proxy memory cache, change slapd.conf to:

ldapproxy.cache.enabled true

Enabling encrypted communication

By default, communication between LDAP clients and the Centrify OpenLDAP proxy service is not encrypted. To secure communications between LDAP clients and the Centrify OpenLDAP proxy service using Transport Layer Security (TLS), you must create or obtain the required certificates and configure both the LDAP client and the LDAP server to use the certificates. In addition, you must configure the LDAP server with the certification authority (CA) certificate, its own server certificate, and a private key.

The current versions of the ldapsearch client and ldapproxy server support Transport Layer Security (TLS) v1.2.

Depending on your network topology, you might also need to modify client-side or server-side configuration settings to successfully return search results.

Preparing for auto-enrollment

You can configure the Centrify OpenLDAP proxy service to automatically get the certificate, private key, and CA chain for secure LDAP (ldaps) connections. To configure automatic enrollment for certificates, however, you must have an Active Directory domain controller that you can use as a certification authority for issuing certificates.

The following steps summarize how to prepare the domain controller:

1. Use Server Manager to add the Active Directory Certificate Services role to a domain controller.
2. In the Add Roles wizard, select the Certification Authority role service and follow the prompts displayed to configure the server role.
3. Open the Certificates MMC snap-in, select the domain controller certificate, right-click, then click Open.
4. Select the Details tab, click Copy to file, then follow the prompts displayed to export the certificate to a file.
5. From Administrative Tools, select Group Policy Management, then select an appropriate Group Policy Object for the forest and domain you want to edit.
6. Right-click the Group Policy Object, then click **Edit**.
7. Under Computer Configuration, expand Policies > Windows Settings > Security Settings, then select Public Key Policies.
8. Select Trusted Root Certificate Authorities, right-click to select **Import**, then follow the prompts displayed to import the certificate.
9. Select Certificate Services Client - Auto-Enrollment, then select **Enabled**.
10. From Administrative Tools, select Certification Authority, expand the name of the domain controller you are using as the certification authority, then select **Certificate Templates**.
11. Right-click to select Manage, select an appropriate template to use, such as the Computer template, right-click, then click **Duplicate Template** to open the properties page for the new template.
12. Type an appropriate name for the new template, such as Centrify OpenLDAP Proxy.
13. Click the Security tab, select the Domain Computers group, select Allow for the Autoenroll permission, then click **Apply**.

    You can set other properties on the remaining tabs, as needed. For example, you might want to click the Subject Name tab to change the subject name format to Fully distinguished name. When you are finished setting properties for the template, click **OK**.
14. In the Certification Authority console, select Certificate Templates, right-click to select New, then click **Certificate Template to Issue**.
15. Select the template you created, for example, select the Centrify OpenLDAP Proxy template, then click **OK**.

Updating the Centrify OpenLDAP proxy computer

After you have prepared the domain controller with the policy for certificate autoenrollment, you can use the following steps to provide the required certificate, private key, and certification authority.

1. Verify the computer where you are running the Centrify LDAP proxy service is joined to an Active Directory domain.
2. Change to the directory where certificates for auto-enrollment are located.

   cd /var/centrify/net/certs/

   You should see files similar to the following listed in the directory:

   auto_LDAPProxy.cert
   auto_LDAPProxy.chain
   auto_LDAPProxy.key
   trust_41DFF689876FCE52E02EE73FC7E3782964DC54BB.crl
   trust_F7842B2A65489F15A1722518E41F5E6B0F4FBC5E.cert

3. Run an openssl command similar to the following to create the certificate:

   openssl pkcs7 -in auto_LDAPProxy.chain -text -out auto_LDAPProxy_CA.pem print_certs

4. Add the following lines to /etc/centrifydc/openldap/slapd.conf configuration file. Comment out the old TLSCipherSuite line, as shown here.

   TLSCertificateFile /var/centrify/net/certs/auto_LDAPProxy_CA.pem
   TLSCertificateFile /var/centrify/net/certs/auto_LDAPProxy.cert
   TLSCertificateKeyFile /var/centrify/net/certs/auto_LDAPProxy.key
   TLSCipherSuite TLSv1.2
   # TLSCipherSuite SSLv3

   You should also review and modify other server configuration settings, if needed. For example, you might use settings similar to the following:

   # Require START TLS on port 389
   security tls=1
   # Require TLS v1.0 or better
   TLSProtocolMin 3.1
   TLSVerifyClient try

5. Add the following line to /etc/centrifydc/openldap/ldap.conf configuration file:

   TLS_CACERT /var/centrify/net/certs/auto_LDAPProxy_CA.pem

   You should also review and modify other configuration settings, if needed. For example, you might need to change the TIMEOUT value to allow clients to wait an appropriate number of seconds for a response:

   TIMEOUT 15

6. Restart the Centrify OpenLDAP proxy service.

   sudo /usr/share/centrifydc/bin/centrify-ldapproxy start -h ldaps:///

7. Test operation by running an OpenLDAP command, such as ldapsearch.

   /usr/share/centrifydc/bin/ldapsearch -x -H ldaps://localhost:636 -b 'cn=users,dc=win2012,dc=test' -D administrator@win2012.test -W "(cn=test_user)"

8. To confirm that TLSv1.2 is being used, use openssl s_client to connect to the slapd. For example, enter:

   $ openssl s_client -connect localhost:636 -showcerts -state -CAfile /etc/centrifydc/openldap/cacert.pem

9. Review the output from the previous command and confirm that the protocol is TLSv1.2, as shown here:

   ...
   SSL Session:
   Protocol : TLSv1.2

10. (Optional) Alternatively, to confirm that TLSv1.2 is used, run a software tool like Wireshark to capture and inspect the ldapsearch traffic.

Securing communication without auto-enrollment

If you are not using an Active Directory domain controller and autoenrollment for certificate distribution, you can manually configure the Centrify OpenLDAP proxy service to use the server certificate and private key you create.

The following steps summarize how you can manually configure the Centrify OpenLDAP proxy service to use certificates.

1. Use CA.sh to create the certificates:

   /usr/share/centrifydc/ssl/misc/CA.pl -newca

   /usr/share/centrifydc/bin/openssl req -new -nodes -keyout newreq.pem -out newreq.pem

   /usr/share/centrifydc/ssl/misc/CA.pl -sign

2. Install the certificates in the /etc/centrifydc/openldap directory.

   cp demoCA/cacert.pem /etc/centrifydc/openldap/cacert.pem

   mv newcert.pem /etc/centrifydc/openldap/servercrt.pem

   mv newreq.pem /etc/centrifydc/openldap/serverkey.pem

3. Add the following lines to /etc/centrifydc/openldap/slapd.conf configuration file:

   TLSCACertificateFile /etc/centrifydc/openldap/cacert.pem

   TLSCertificateFile /etc/centrifydc/openldap/servercrt.pem

   TLSCertificateKeyFile /etc/centrifydc/openldap/serverkey.pem

4. Add the following line to /etc/centrifydc/openldap/ldap.conf configuration file:

   TLS_CACERT /etc/centrifydc/openldap/cacert.pem

5. Start the slapd deamon using the following:

   /usr/share/centrifydc/libexec/slapd -h "ldaps:///"

   or

   sudo /usr/share/centrifydc/bin/centrify-ldapproxy start -h ldaps:///

Searching for automount maps and entries

You can use the Centrify ldapproxy service and ldapsearch command to find automount maps and automount map entries that you have stored in Active Directory. The following examples illustrate how to write filters to retrieve automount information. These examples assume you have added the following automount maps and map entires to Active Directory using Access Manager:

- The auto.home map has the map entries test1 and test2.
- The autotest map has the map entries test10 and test11.

To retrieve both maps, you might run a command with a filter like this:

```
ldapsearch -x -h localhost -b "DC=acme,DC=test" "(objectClass=automountMap)"
-D "cn=amy.adams,cn=users,dc=acme,dc=org" -w 1234abcepassword
```

The command returns attribute information for each map similar to this:

```
dn: cn=auto.home,cn=NisMaps,cn=global,cn=Zones,dc=acme,dc=test
automountMapName: auto.home
ou: auto.home
cn: auto.home
displayName: $CimsAutomountMapVersion1
objectClass: top
objectClass: automountMap
uSNChanged: 20046
```

To retrieve information for a specific map, you might run a command with a filter like this:

```
ldapsearch -x -h localhost -b "DC=acme,DC=test"
"(&(objectClass=automountMap)(automountMapName=auto.home))"
-D "cn=amy.adams,cn=users,dc=acme,dc=org" -w 1234abcepassword
```

To retrieve all map entries from both maps, you might run a command with a filter like this:

```
ldapsearch -x -h localhost -b "DC=acme,DC=test" "(objectClass=automount)"
-D "cn=amy.adams,cn=users,dc=acme,dc=org" -w 1234abcepassword
```

To retrieve information for a specific map entry, you might run a command with a filter like this:

```
ldapsearch -x -h localhost -b "cn=auto.home,DC=acme,DC=test"
"(&(objectClass=automount)(automountKey=test1))"
-D "cn=amy.adams,cn=users,dc=acme,dc=org" -w 1234abcepassword
```

For information about adding and managing NIS maps to Active Directory, see the *Network Information Service Administrator's Guide*.

Automatic translation to search for zone users

If you integrate the Centrify Agent with a software environment that has limited configuration options, a standard ldapsearch query might fail to return zone users and groups. If you encounter this issue, you can use a configuration parameter to automatically translate a standard search for Active Directory users and groups into a search query for zone users and groups.

You can set the ldapproxy.cdctranslate.fetchbydnuid parameter in the slapd.conf configuration file to true if you want a search for Active Directory users and groups to be automatically translated into a search for zone users and groups. The default is false. After changing the parameter setting, you should restart the centrify-ldapproxy service.

Note that the translation only applies if the ldapproxy.cdctranslate.fetchbydnuid parameter is set to true, and the following additional conditions are in the search request:

- For the search base, the first part of the DN must be "uid=unixname"
- The search scope base must be (0)
- The search filter must be (objectClass=*)

For example, automatic translation is performed if you run a command similar to the following after changing the ldapproxy.cdctranslate.fetchbydnuid parameter to true and restarting the centrify-ldapproxy service:

```
ldapsearch -x -D "cn=zoe,OU=ajax,dc=acme,dc=org" -w 1234abcepassword
-h localhost "(objectClass=*)" -b "uid=zoe,OU=ajax,dc=acme,dc=org"
-s base
```

Using workstation mode and Auto Zone

For most organizations, adding Linux or UNIX computers to an Active Directory domain involves creating one or more parent zones, adding Active Directory users and groups to the zone, and assigning one or more roles to the zone users. As an alternative to this process, you can create a single Auto Zone for all Active Directory users or a specific subset of Active Directory users.

Profiles are generated for all users in the forest

If you use Auto Zone, all of the profile attributes that are normally defined in the zone to which a computer is joined are generated automatically based on user attributes in Active Directory or based on a set of agent configuration parameters. By default, all Active Directory users and groups in for the forest automatically become valid users and groups on the computers joined to Auto Zone. The generated profiles have a unique UID and GID for each Active Directory user in the forest. The generated profile is what enables access to the computers joined to Auto Zone.

In addition, if you have Active Directory users in another forest that has a two-way trust relationship with the forest of the joined domain, all of those users are also valid users for the joined computer.

Note: Auto Zone does not support one-way trusts. If a computer is joined to a domain that has a one-way trust relationship with another domain, the users and groups in the trusted domain do not become valid users and groups on the computer.

Limiting users and groups in Auto Zone

If you want to use Auto Zone, but do not want to give all Active Directory users and groups a valid profile, you can use group policies or configuration settings to limit the generation of profiles and computer access to specific users and groups. For example, if you have a two Active Directory groups with users who need access to Linux, UNIX, or Mac OS X computers, you can use either group policies or configuration settings to specify that only the two groups who require profiles are valid Auto Zone users and all other Active Directory users should be ignored.

Auto Zone does not provide zone-specific features

If you decide to use Auto Zone, you should keep in mind that Auto Zone does not support any zone-specific features, such as the ability to define rights and roles, assign roles to users and groups, configure auditing, or keep legacy identity attributes on different computers.

If you want to configure role-based access rights, delegate administrative activity, or migrate existing users and groups, you should not use Auto Zone. If you have a large Active Directory forest, but only require automatic profile generation for a subset of users and groups, you might want to use a combination of hierarchical zone and Auto Zone.

Joining a domain as a workstation

Auto Zone is created automatically in Active Directory if you join a domain by running the adjoin command with the --workstation option.

What to do before joining Auto Zone

Before joining a computer to Auto Zone, be certain that the following are true:

- Active Directory identities are unique for the forest and any two-way trusted forest.
- The Active Directory users and groups require a single set of properties for all computers that join the domain through Auto Zone and do not need to be segregated into zones for any reason.
- All domains in the forest and any trusted external forest must be unique or the join will fail. In this case, you must manually configure a unique prefix for each trusted domain using configuration parameters.

Who should perform this task

A Linux or UNIX administrator with root permission on the computers you want to join to an Active Directory domain. The administrator must also know the password for an Active Directory domain administrator account.

How often you should perform this task

In most cases, you only do this once for each Linux or UNIX computer that needs to join an Active Directory domain as a workstation.

Rights required for this task

You must have an account with root permission to modify agent configuration files on managed computers or an administrative account with write permission to enable group policies on a Group Policy Object linked to a domain or organizational unit.

Steps for completing this task

The following instructions illustrate how to join Auto Zone using the adjoin command.

To join a computer to a domain as a workstation

1. Log on the computer with the Centrify Agent using an account with root privilege.
2. Open a terminal and execute the following command:

   adjoin domainName --workstation

   For example:

   [root@rhe5]#adjoin acme.com --workstation
3. Type the Active Directory administrator's password.

   Administrator@ACME.COM's password:

   Using domain controller: win-f7d27u7kl6m.acme.com writeable=true
   Join to domain:acme.com, zone: Auto Zone succesful
4. Run the adinfo command to verify the connection to Auto Zone:

   [root@rhe5]# adinfo
   Local host name: rhe5
   Joined to domain: acme.com
   Joined as: rhe5.acme.com
   Pre-win2K name: rhe5
   Current DC: win-f72d7u7kl6m.acme.com
   Preferred site: Default-First-Site
   Zone: Auto Zone

Last password set: 2012-09-30 18:08:34 PDT
CentrifyDC mode: connected
Licensed Features: Enabled

Generating profiles for specific users and groups

You can automatically generate profiles for specific users and groups by enabling group policies in a Group Policy Object for a domain, site, or organizational unit in an Active Directory forest or by specifying configuration settings on individual computers.

Rights required for this task

You must have an account with root permission to modify agent configuration files on managed computers or an administrative account with write permission to enable group policies on a Group Policy Object linked to a domain or organizational unit.

Who should perform this task

A Windows or UNIX administrator performs this task, depending on your organization's policies. In most cases, a Windows administrator is responsible for configuring group policies and modifying Group Policy Objects. If your organization uses local configuration settings, the UNIX administrator is usually responsible for this task.

Steps for completing this task using group policies

In most cases, you should use group policies in a Group Policy Object to identify the Active Directory users and groups for which you want to automatically generate profiles. The Group Policy Object enables you to centrally manage access to computers in the Auto Zone. You can enable and configure the following group policies to specify a subset of Active Directory users and groups that should have access to computers in Auto Zone:

- Specify AD users allowed in Auto Zone
- Specify groups of AD users allowed in Auto Zone
- Specify AD groups allowed in Auto Zone

The following instructions illustrate how to limit the valid users and groups in the Auto Zone using these group policy settings.

To specify users and groups to include in Auto Zone by using group policy settings

1. Identify or create an Active Directory group that includes all of the users that you want to give access to Centrify-managed computers.

   The group can be a domain local, global, or universal group. The group can include sub groups — members of these sub groups will also be included in Auto Zone.

2. Open Group Policy Management to create or select a Group Policy Object that is linked to a site, domain, or organizational unit.
3. Right-click the Group Policy Object, then select **Edit** to open Group Policy Management Editor.
4. Expand Computer Configuration > Policies > Centrify Settings > DirectControl Settings, click Adclient Settings.
   - Double-click "Specify groups of AD users allowed in Auto Zone" to specify users by Active Directory group without automatically generating profiles for the groups themselves.
   - Double-click Specify AD users allowed in Auto Zone to specify individual Active Directory users for which to automatically generate profile.
   - Double-click Specify AD groups allowed in Auto Zone to specify individual Active Directory groups for which to automatically generate profile.
5. Select Enabled, then click List to browse for the groups or users to include.
6. Click **Add**, enter search criteria, then click **Find Now**.
7. Select one or more groups or users from the list, then click **OK**.

Steps for completing this task using configuration parameters

In some cases, you might want to limit the Active Directory users and groups who have a profile generated by configuring parameters in the centrifydc.conf file on individual computers. For example, you might want to use configuration parameter settings if you don't want to implement or apply group policies on certain computers.

You can configure the following configuration parameters to specify a subset of Active Directory users and groups that should have access to computers in

Auto Zone:

- auto.schema.allow.users
- auto.schema.allow.groups
- auto.schema.groups

The following instructions illustrate how to limit the valid users and groups in the Auto Zone using these configuration parameters settings.

To specify users and groups to add to Auto Zone by using configuration parameters

1. On a Windows computer, in Active Directory Users and Computers, identify or create a group or group that includes all the users who you want to have access to your Centrifymanaged computers.
2. On each computer to add to Auto Zone, open the /etc/centrifydc/centrifydc.conf configuration file.
    - Find the auto.schema.allow.groups parameter and remove the comment (#) to add the names of groups separated by commas.
    - Find auto.schema.allow.users and remove the comment (#) to add the names of users separated by commas.
    - Find auto.schema.groups and remove the comment (#) to add the names of groups separated by commas.

      The configuration file contains comments that list the valid formats for user and group names. For more information about setting these parameters or editing the configuration file, see the*Configuration and Tuning Reference Guide*.
3. Save and close the file.

Troubleshooting authentication and authorization

This chapter describes how to use diagnostic tools and log files to retrieve information about the operation of Server Suite software and how to identify and correct problems within your environment.

Diagnostic tools and log files

All Centrify services include diagnostic tools and logging mechanisms to help you trace the source of problems if they occur. These diagnostic tools and log files allow you to periodically check your environment and view information about Centrify operation, your Active Directory connections, and the configuration settings for individual UNIX and Linux computers.

Although logging is not enabled by default for performance reasons, log files provide a detailed record of Centrify Agent (adclient) activity. This information can be used to analyze the behavior of adclient and communication with Active Directory to locate points of failure. However, log files and other diagnostic tools provide an internal view of operation and are primarily intended for Centrify experts and technical staff.

In most cases, you should only enable logging when you need to troubleshoot unexpected behavior, authentication failure, or problems with connecting to Active Directory or when requested to do so by Centrify Support. Other troubleshooting tools, such as command line programs, can be used at any time to collect or display information about your environment.

Analyzing information in Active Directory

One important way you can troubleshoot your environment is by running the Analyze command. The Analyze command enables you to selectively check the integrity of the information stored in Active Directory. With the Analyze wizard, you can check for a variety of potential problems, such as duplicate user IDs, duplicate groups, empty zones, orphaned data objects, or computers that have joined more than one zone.

Note: When you run the Analyze command, only the zones that are open are checked.

To check for problems with information in the Active Directory forest:

1. Open Access Manager.

   If you are prompted to connect to a forest, specify the forest domain or domain controller to which you want to connect.

2. In the console tree, select the Access Manager root node, right-click, then click **Analyze**.

3. Select the types of checks you want to perform, then click **Next** to generate the report.

All	Perform all of the data integrity checks. **Note** If you do not register the administrative notification handler through the Setup Wizard or manually using ADSI, you should periodically run the Analyze command with **All** or **Orphan UNIX data objects** selected.
Computers joined to multiple zones	Check for computers that have joined the domain using more than one zone. Each UNIX computer should only reside in one zone, but if you run the join command more than once, it is possible to have the same computer in more than one zone. This option checks for this problem.
Cyclic zone hierarchy	Check for a circular zone hierarchy. The console prevents you from creating a circular zone hierarchy, but it is possible to do so inadvertently when using ADEdit.
Duplicate groups in zones	Check for duplicate UNIX group names or group identifiers (GIDs) in each open Centrify zone.
Duplicate role assignment containers in computer	Check for computers that have more than one location to store role assignment information.
Duplicate service principal names in forest	Check for duplicate service principal names across the entire forest. Service principal names are required to be unique within an Active Directory forest.
Duplicate SFU zones	Check for duplicate SFU zones that are set to manage the same NIS domain.
Duplicate users in zones	Check for duplicate UNIX user names or user identifiers (UIDs) in each open Centrify zone.
Duplicate zone default container	Check for duplicate Zones parent container objects in the Active Directory forest.
Empty	

computer roles	Check for computer roles that contain no computers or role assignments.
Empty profiles in hierarchical zones	Check for hierarchical zones that contain users or groups that have no profile data defined.
Empty zones	Check for zones that have no computers, users, or groups.
Foreign Security Principal Clean Up	Check for foreign security principal objects whose corresponding security principal has been removed.
Incomplete user UNIX data	Check for users with missing UNIX profile attributes or who are missing a primary profile. This analysis option checks the entire zone hierarchy for profiles with missing attributes and for users who have multiple profiles defined but don not have a primary profile. Users with an incomplete profile or a missing primary profile will not be able to log on even if they are assigned a role with login rights. Note that a profile can be incomplete at any level of the zone hierarchy as long as it is complete at the level where a computer is joined.
Inconsistency in granting NIS server permissions	Check that there is a zone_nis_servers group in each zone that supports agentless authentication and that the group contains all the NIS servers that have been defined for the zone. The zone_nis_servers group is required to assign permissions to managed computers that act as NIS servers, and should not be manually deleted or modified. This option checks that the group exists and includes all of the computers acting as NIS servers to ensure data integrity.
Inconsistent computer object names	Check for discrepancy between the DNS name for a computer in Active Directory and its Centrify computer profile name.
Insufficient permission for agent version update	Check whether the computer object in Active Directory has sufficient permission to update the version number property of the Centrify Agent for *NIX in the computer's serviceConnectionPoint object. If the computer object does not have permission to change this property, the version number cannot be displayed.
Insufficient permission for OS version update	Check whether the computer object in Active Directory has sufficient permission to update the version number property of the operating system in the computer's serviceConnectionPoint object. If the computer object does not have permission to change this property, the operating system version number cannot be displayed.
Invalid right assignments	Check whether an invalid right has been assigned to a role. This error occurs if a right has been added to a role and subsequently the right becomes invalid. Generally, a right becomes invalid if it is edited with a third-party tool, such as ADSI Edit, and an attribute is set to an invalid value. For example, Access Manager creates Active Directory objects of type msDSAZOperation for command- and PAM-application-rights, and assigns a HEX value to the msDS-AzOperationId attribute of these objects. The range of reserved values for this attribute is as follows: Command: (HEX) 0500,0000 – 05FF,FFFF PAM application: (HEX) 0200,0000 – 02FF,FFFF If this attribute is set to a value that is out of the reserved range, the right will be invalid and will no longer appear in Access Manager. If the right has been assigned to a role, the Analyze Invalid right assignment check returns an error. You can select the error in the **Analysis Results** node and use the Action menu to delete it from the role if you wish.
Invalid role assignments	Check whether invalid role assignments exist in the zone. In most cases, invalid role assignments occur when a role assignment is defined for a computer account and the computer leaves a zone without cleaning up roleassignment objects.
Invalid role	Check for role assignments that contain multiple roles or multiple users. In most cases, this error only occurs if you are using third-party tools to edit role assignments. Centrify tools prevent you from creating invalid role assignments. Note that a role assignment consists of a

assignments (DZ V2)	single user and a single role. To assign multiple roles to a user, you create multiple role assignments, which are stored in the form of user@domain role/sourceZone; for example: qa1@acme.com login/engineering qa1@acme.com vi_power/engineering qa1@acme.com test/engineering
Orphan child zones	Check for child zones that have an invalid parent zone. The information identifying the parent-child zone relationship is stored in the child zone in the form of a HEX string and the name of the domain to which the parent zone belongs. If this identifier is deleted, or changed to an invalid format, or if the parent zone is deleted but the child zone remains in the domain, Analyze (Orphan child zones) returns an error. Note that this error typically occurs only if you use third-party tools to edit zone objects in Active Directory. If you delete a parent zone using Centrify tools, child zones are deleted as well.
Orphan role assignments	Check for role assignments that consist of a non-existent role or user, or that do not contain a role or user. In most cases, this error only occurs if you are using third-party tools to edit Centrify objects in Active Directory. If you delete a role or user using Centrify tools or using Active Directory Users and Computers, the role assignment will be deleted as well (the change will be visible after you refresh the display) and Analyze will not return an error.
Orphan zone data objects and invalid data links	Check for zone data that have no corresponding Active Directory objects or have invalid links to Active Directory objects. For example, if you delete an Active Directory user but do not remove the profile for this user in a zone, the zone profile becomes an orphan and is flagged as such by this option.
Restricted roles	Check for roles that have been assigned commands that cannot be executed. When rights are created, they can be defined to run in a restricted-shell role, in an enhanced role (with dzdo), or with both. If a command that has not been defined to run in a restricted-shell is added to a restricted-shell role, this check returns an error.
Zone created under another zone	Check for zone information created in another zone's parent container. Note that this check does not look at hierarchical zones because it is expected that child zones are physically contained in their parent zone.
Zone information in old format	Check for zone information stored in an obsolete Centrify zone format.
Zoneless computers	Check for computers that do not belong to any zone.

4. Review the result summary, then click **Finish**.
5. If the result summary indicates any issues, you can view the details by selecting **Analysis Results** in the console tree and viewing the information listed in the right pane. For example:

   Analysis results

   For additional information, select the warning or error, right-click, then select **Properties**. For example:

   Properties

Common scenarios that generate analysis results

For most organizations, it is appropriate to check the data integrity of the Active Directory forest on a regular basis. Although running the Analyze command frequently may not be necessary for small networks with few domain controllers, there are several common scenarios that you should consider to determine how often you should check the forest for potential problems. The most likely reasons for data integrity issues stem from:

- Multiple administrators performing concurrent operations.
- Administrators using different domain controllers to perform a single operation.

- Replication delays that allow duplicate or conflicting information to be saved in Active Directory.
- Insufficient permissions that prevent an operation from being successfully completed.
- Network problems that prevent an operation from being successfully completed.
- Partial or incomplete upgrades that result in inconsistency of the information stored in Active Directory.
- Using ADEdit rather than the Console to create, modify, or delete zone objects, which may lead to problems, such as inadvertently creating a circular zone structure or an empty profile.
- Using third-party tools, such as ADSI Edit, to edit objects directly in Active Directory, which may lead to corrupted or invalid zone objects.

Running Analyze periodically helps to ensure the issues these scenarios can cause are reported in the Analysis Results, so you can take corrective action.

Responding to analysis results

Depending on the type of warning or error generated in the Analysis Results, you might be able to take corrective action or access additional information by right-clicking a result, then selecting an appropriate action. For example, if a computer account lacks the permission required to update Active Directory with the operating system version currently installed, you can right-click the warning in the Analysis Result then select **Grant computer the rights to modify operating system properties**.

If right-clicking a result does not provide a responsive action, you should use Access Manager or ADEdit to correct the issue.

The following table describes the warnings and errors you may see in the Analysis Results after running the Analyze wizard and how to resolve potential issues.

If there are any computers joined to multiple zones, an error is displayed.	No responsive action can be taken directly within the Analysis Results for this issue. In general, this issue only occurs if an administrator runs adleave with the --force option then runs adjoin to join the computer to a different domain without removing the old computer profile from Active Directory. You should identify the appropriate zone for the computer, then use the Access Manager console to delete the computer profile from any additional zones.
If the parent-child relationship of any zones is circular, an error is displayed.	Break the circular relationship.
If there are any duplicate groups in a zone, a warning is displayed.	No responsive action can be taken directly within the Analysis Results for this issue. In general, this issue only occurs if multiple administrators perform concurrent operations or there are replication delays that allow a duplicate group profile to be added to a zone. For example, if two administrators add the same group to a zone using different domain controllers, there will be duplicate group profiles after the domain controllers complete replication. You should use the Access Manager console or ADSI Editor to delete the duplicate group profiles from the zone.
If any duplicate service principal names (SPNs) are found for users or computers in the forest, a warning is displayed.	No responsive action can be taken directly within the Analysis Results for this issue. Right-click the warning and click **Properties** to identify the duplicate SPN. Open the account properties for the user or computer and modify or remove the duplicate servicePrincipalName value. Alternatively, run the adjoin command with the -d or --forceDeleteObjWithDupSpn option. See the adjoin man page for additional information.
If there are any duplicate users in a zone, a warning is displayed.	No responsive action can be taken directly within the Analysis Results for this issue. In general, this issue only occurs if multiple administrators perform concurrent operations or there are replication delays that allow a duplicate user profile to be added to a zone. For example, if two administrators add the same user to a zone using different domain controllers, there will be duplicate user profiles after the domain controllers complete replication. You should use the Access Manager console or ADSI Editor to delete the duplicate user profiles from the zone.
If more than one Centrify SFU zone is found in the forest, a warning is	No responsive action can be taken directly within the Analysis Results for this issue. Because an SFU zone is associated with an Active Directory SFU schema extension, there should be a maximum of one SFU zone in an Active Directory forest. In general, this issue only occurs if multiple administrators perform concurrent

displayed.	operations or there are replication delays that allow a duplicate. You should use the Access Manager console or ADSI Editor to delete any duplicate SFU zones.
If a duplicate default parent container for zones is found, a warning is displayed.	No responsive action can be taken directly within the Analysis Results for this issue. In general, this issue only occurs if multiple administrators perform concurrent operations or there are replication delays that allow a duplicate default container for new zones. Having more than one default parent container for zones can result in an unexpected default value in the Create New Zone wizard. You should use the ADSI Editor to delete any duplicate Zones parent containers from the forest.
If a computer role does not have any member computers or role assignments, a warning is displayed.	If the computer role has no member computers, right-click the warning in the Analysis Results, then select **Add computers** to add computers, or Delete Computer Role to remove the computer role. If a computer role has computer members but no role assignments, the only available response from the Analysis Results zone is to delete the computer role. You can, however, select the computer role in the Console, and add role assignments to its Role Assignments node.
If a user or group profile has been added to a zone but has no attributes defined, an error message is displayed.	Right-click the warning in the Analysis Results, then select **Delete empty profile** to delete the profile from the zone, or **Modify profile** to define one or more attributes for the user or group.
If any zone does not contain users, groups, or computers, a warning is displayed for each type of object. For example, if a zone has computers and groups, but no users, only the user warning is displayed for that zone.	No responsive action can be taken directly within the Analysis Results for these issues. In general, this issue occurs early in a deployment before you have populated zones. You should use the Access Manager console to add missing objects to the zone. If the empty zone is not a valid zone, right-click the zone and select **Delete**.
If one or more secondary profiles are found for a user but no primary profile is found, a warning message is displayed.	Right-click the warning in the Analysis Results, then select **Promote secondary profile to primary** to select a secondary profile you want to make the primary profile for the user.
If a user's UNIX profile is incomplete in the entire zone hierarchy, a warning message is displayed.	Right-click the warning in the Analysis Results, then select **Modify zone profile** to define additional attributes to complete the user's profile.
If the Active Directory group zone_nis_servers is not found in a zone configured for agentless authentication, an error is displayed.	Right-click the error in the Analysis Results, then select **Create NIS servers group** to create the zone_nis_servers group for agentless authentication. Note that your account must have permission to create this object for the operation to be successful.
If the membership of the zone_nis_servers group is not consistent with the computers authorized as NIS servers, a "Membership inconsistent" error is displayed.	Right-click the error in the Analysis Results, then select **Fix group membership** to modify the membership list for the zone_nis_servers group.
If a zone is configured to support agentless authentication and the zone_nis_servers group exists but does not contain all computers in the zone, an informational alert is displayed.	No responsive action can be taken directly within the Analysis Results for these issues. You should verify that all of the computers you want to use as NIS servers in the zone are configured to allow agentless authentication.
If there is a discrepancy between the DNS name in AD and the Centrify computer profile name, a warning message is displayed.	Right-click the error in the Analysis Results, then select **Fix group membership** to

If a computer account does not have permission to write to the keywords attribute, an error is displayed.	Right-click the error in the Analysis Results, then select **Grant permission to computer account** to update the permissions on the computer account object.
If a computer account does not have permission to modify operating system properties, a warning is displayed.	Right-click the error in the Analysis Results, then select **Grant computer permission to modify operating system properties** to update the permissions on the computer account object.
If a right for a role is invalid, a warning message is displayed.	Right-click the error in the Analysis Results, then select **Delete Right** to delete the right from the role.
If a role assignment is invalid, a warning message is displayed.	
If multiple roles are assigned to a user, a warning message is displayed.	
If a child zone has an invalid parent zone, an error message is displayed.	
If an object has no parent object, a warning message is displayed.	
If a restricted-shell role is assigned a right that cannot be run in a restricted shell, a warning message is displayed.	Right-click the error in the Analysis Results, then select **Delete Commands** to remove the commands from the role, or select **Allow running in restricted role** to allow running the command in the restricted role.
If a zone was created using the version 2.x console and includes a Private Groups container, a warning is displayed.	If any computers in the zone are running version 2.x or 3.x agents, you should ignore this warning to ensure compatibility for those agents. If all of the agents in the zone have been upgraded, you can right-click the warning in the Analysis Results, then select **Remove privateGroupCreation attribute** to update the zone format.
If a computer profile was created using the version 2.x console, the warning "Unix computer is in old format" is displayed.	If any computers in the zone are running version 2.x or 3.x agents, you should ignore this warning to ensure compatibility for those agents. If all of the agents in the zone have been upgraded, you can right-click the warning in the Analysis Results, then select **Remove managedBy and unix_enabled attribute** to update the computer profile in the zone.
If a group profile was created using the version 2.x console, the warning "Unix group is in old format" is displayed.	If all of the agents in the zone have been upgraded, you can right-click the warning in the Analysis Results, then select **Remove managedBy attribute** to update the group profile in the zone.
If a user profile was created using the version 2.x console, the warning "Unix user is in old format" is displayed.	If all of the agents in the zone have been upgraded, you can right-click the warning in the Analysis Results, then select **Remove managedBy and app_enabled attribute** to update the user profile in the zone.
If a computer, group, or user profile exists, but no corresponding Active Directory computer, group, or user object is found, the warning "Orphan UNIX data object" is displayed.	In general, this issue occurs if an administrator removes an Active Directory computer, group, or user object manually using ADSI Editor or Active Directory Users and Computers but the corresponding data is not removed for the UNIX profile. Right-click the warning in the Analysis Results, then select **Remove orphan profile** to remove all of the UNIX properties associated with the orphan profile.
If a computer, group, or user profile has inconsistent links, an informational "Inconsistent links" alert is displayed.	Computer, group, and user profiles are associated with Active Directory computer, group, and user objects through either the managedBy attribute (agent version 2.x) or a parentLink value in the keywords attribute (agent version 3.x and later). If the links refer to different Active Directory objects, you will see this alert. Right-click the alert in the Analysis Results, then select **Overwrite with the active link** to remove outdated links.

If a computer, group, or user profile does not have a parentLink value defined, a “Missing parentLink” warning is displayed.	Right-click the warning in the Analysis Results, then select **Missing parentLink** to add the parentLink value to the keywords attribute.
If the parent container for a zone is another zone object, an error is displayed.	No responsive action can be taken directly within the Analysis Results for these issues. You should move the zone to another parent container or delete and recreate the zone in a different location.
The computer ObjectName contains Centrify information but it is not in a zone.	Right-click the warning in the Analysis Results, then select **Move to Zone** to search for and select the zone you want to place the computer in.

Configuring logging for the agent

By default, the Centrify Agent for *NIX logs errors, warnings and informational messages in the UNIX syslog and /var/log/messages files along with other kernel and program messages. Although these files contain valuable information for tracking system operations and troubleshooting issues, occasionally you may find it useful to activate agent-specific logging and record that information in a log file.

To enable logging on the Centrify Agent for *NIX

1. Log in as or switch to the root user.
2. Run the addebug command:

   /usr/share/centrifydc/bin/addebug on

   Note: You must type the full path to the command because addebug is not included in the path by default.

   Once you run this command, all of the Centrify Agent activity is written to the /var/log/centrifydc.logfile. If the adclient process stops running while you have logging enabled, the addebug program records messages from PAM and NSS requests in the /var/centrifydc/centrify_client.log file. Therefore, you should also check that file location if you enable logging.

For performance and security reasons, you should only enable logging when necessary, for example, when requested to do so by Centrify Support, and for short periods of time to diagnose a problem. Keep in mind that sensitive information may be written to this file and you should evaluate the contents of the file before giving others access to it.

When you are ready to stop logging activity, run the addebug off command.

Setting the logging level

You can define the level of detail written to the log by setting the log configuration parameter in the Centrify configuration file:

log: level

With this parameter, the log level works as a filter to define the type of information you are interested in and ensure that only the messages that meet the criteria are written to the log. For example, if you want to see warning and error messages but not informational messages, you can change the log level from INFO to WARN. By changing the log level, you can reduce the number of messages included in the log and record only messages that indicate a problem. Conversely, if you want to see more detail about system activity, you can change the log level to INFO or DEBUG to log information about operations that do not generate any warnings or errors.

You can use the following keywords to specify the type of information you want to record in the log file:

FATAL	Fatal error messages that indicate a system failure or other severe, critical event. In addition to being recorded in the system log, this type of message is typically written to the user's console. With this setting, only the most severe problems generate log file messages.
ERROR	System error messages for problems that may require operator intervention or from which system recovery is not likely. With this setting, both fatal and less-severe error events generate log file messages.
WARN	Warning messages that indicate an undesirable condition or describe a problem from which system recovery is likely. With this setting, warnings, errors, and fatal events generate log file messages.
INFO	Informational messages that describe operational status or provide event notification.

Logging for Access Manager

Although most logging activity focuses on the actions of the Centrify Agent, you can also enable or disable logging for the Access Manager console and configure the types of messages to record in the log file by selecting options in Access Manager.

To configure logging for operations handled through the Access Manager console:

1. Open Centrify Access Manager.
2. In the console tree, select **Centrify Access Manager**, right-click, then click **Options**.
3. Click the **Log Settings** tab, select the type of messages to log, then click **OK**.

If you enable logging, the log file is located by default in the C:\Users\user\AppData\Roaming\Centrify\DirectControl folder and is updated as you perform different operations in the Access Manager console.

Logging to the circular in-memory buffer

If the Centrify Agent for *NIX's adclient process is interrupted or stops unexpectedly, a separate watchdog process (cdcwatch) automatically enables an in-memory circular buffer that writes log messages passed to the logging subsystem to help identify what operation the adclient process was performing when the problem occurred. The in-memory buffer is also mapped to an actual file, so that if there's a system crash or a core dump, the last messages leading up to the event are saved. Messages from the in-memory circular buffer have the prefix _cbuf, so they can be extracted from a core file using the strings command.

The in-memory circular buffer allows debug-level information to be automatically written to a log file even if debugging is turned off. It can be manually enabled by restarting the adclient process with the -M command line option. The default size of the buffer is 128K, which should be sufficient to log approximately 500 messages. Because enabling the buffer can impact performance, you should not manually enable the circular buffer or modify its size or logging level unless you are instructed to make the changes by Centrify Support.

Collecting diagnostic information

You can use the adinfo command to display or collect detailed diagnostic and configuration information for a local UNIX computer. Options control the type of information and level of detail displayed or collected. The options you are most likely to use to collect diagnostic information are the --config, --diag, or --support options, which require you to be logged in as root. You can redirect the output from any adinfo command to a file for further analysis or to forward information to Centrify Support.

For more information about the options available and the information returned with each option, see the man page for adinfo.

To display the basic configuration information for the local UNIX computer, you can type:

adinfo

If the computer has joined a domain, this command displays information similar to the following:

```
Local host name: magnolia
Joined to domain: ajax.org
Joined as: magnolia.ajax.org
Current DC: ginger.ajax.org
Preferred site: Default-First-Site-Name
Zone: ajax.org/Ajax/Zones/corporate
Last password set: 2006-12-28 14:47:57 PST
CentrifyDC mode: connected
Licensed Features Enabled
```

Working with domain controllers and DNS servers

Delinea Agents are designed to perform the same set of DNS lookup requests that a typical Windows workstation performs to find the nearest domain controller for the local site. The DNS lookup request enables the Centrify Agent for *NIX to find domain controllers as they become available on the network or as the computer is relocated to another network location where different domain controllers are present. Centrify Agents also use DNS to find the Kerberos service providers and the global catalog service providers for the Active Directory forest.

In a typical Windows environment, the DNS server role is updated dynamically to contain the service locater (SRV) DNS entries for Active Directory's LDAP, Kerberos, and global catalog services, so this information is available for Centrify Agents to use. However, there are some configurations of DNS that might not provide all of the SRV records for the set of domain controllers that provide Active Directory service to the enterprise. You may also run into problems if DNS for the enterprise runs on UNIX servers that cannot locate your Active Directory domain controllers. The next sections describe how you can adjust DNS or Centrify Agent to ensure they work together properly in your environment.

Related topics

Configuring the DNS server role on Windows

One of the most common scenarios for running DNS in an environment with Active Directory is to add the DNS server role to a Windows domain controller or another Windows server.

If you are already using DNS in Active Directory and dynamically publishing DNS service records, no additional configuration should be necessary. If you are using DNS in Active Directory but have disabled dynamic updates, you should change the configuration for the DNS server role to allow dynamic updates. Making this change will allow Centrify Agents to properly locate domain controllers in the site and select an appropriate new domain controller if a connection to its primary domain controller is lost or the managed computer is moved to a new location on the network.

Configuring DNS running on UNIX servers

If your environment is configured to use UNIX-based DNS servers instead of Active Directory-based DNS servers and the UNIX system is configured to use DHCP, the nameserver entry in /etc/resolv.conf file is set automatically to point to a DNS server.

If this DNS server is aware of the Active Directory domain you want to join, no further changes are needed. If the DNS server identified as a nameserver in the /etc/resolv.conf file is not aware of the domain you are trying to join, for example, because you are using a test domain or a separate evaluation environment, you need to either disable DHCP or manually set the location of the Active Directory domain controller in the Centrify configuration file.

Checking whether DNS can resolve the domain controller

In most cases, you can verify whether a UNIX computer can locate the domain controller and related services by running the ping command and verifying connectivity to the correct Active Directory domain controller or by checking the nameserver entry in the /etc/resolv.conf file. This nameserver entry should be the IP address of one of the domain controllers in the domain you want to join.

If the ping command is successful, it indicates the DNS server is aware of the Active Directory domain you want to join and no further changes are needed. If the ping command is not successful, you will need to take further action to resolve the issue.

Resolving issues in locating Active Directory domain controllers

If the UNIX computer cannot find the Active Directory domain controller, there are several ways you can resolve the issue. Depending on your environment and specific situation, you should consider doing one of the following:

- Set up DNS on the target Active Directory domain controller and the manually configure the nameserver entry in the /etc/resolv.conf file to use that domain controller as described in Setting up DNS service on a target domain controller.
- Set the Centrify configuration file to manually identify the domain controllers you want to use as described in Setting the domain controller in the configuration file.

Setting up DNS service on a target domain controller

One of the simplest ways to ensure that the UNIX computers can locate the Active Directory domain controller and related services is to use the DNS service on the Active Directory domain controller as a DNS slave to the enterprise DNS servers. You can do this is by configuring the DNS server role on the Active Directory domain controller, then specifying that domain controller in the UNIX computer's /etc/resolv.conf file. You can then add a forwarder to the local DNS on the domain controller that will pass on all lookups that it cannot satisfy to an enterprise DNS server.

This configuration does not require any changes to the enterprise DNS servers. Any look up request from the domain controller is simply a query from another computer in the enterprise. However, the UNIX computers configured to use this slave DNS service will receive the appropriate Service Location (SRV) records and global catalog updates for the Active Directory domain controller. In addition, the DNS service on the domain controller can be configured to forward requests to the enterprise DNS servers so those requests can be answered when the local DNS service cannot respond.

Adding a DNS server role to an Active Directory domain controller

The specific steps for adding the DNS server role to a domain controller depend on the version of Windows Server you use. In most cases, you can use an administrative tool, such as Server Manager, to add roles. Follow the instructions displayed in the wizard to add the **DNS Server** server roles, configure the DNS server lookup zones, select the **Allow both nonsecure and secure dynamic updates** option.

After you have configured the DNS server role on the domain controller, the computer uses the local DNS server as its primary DNS server.

Configuring UNIX to use DNS service on the target domain controller

Once you have configured the DNS service to contain the required Active Directory entries, you simply need to modify the UNIX computer to send all DNS lookup requests to the newly configured DNS server.

To configure the UNIX computer to use the new DNS server:

1. Open the /etc/resolv.conf file.
2. Set the IP address of the nameserver entry to the IP address of the DNS server on the Active Directory domain controller you just configured.

Setting the domain controller in the configuration file

If you are not able to use DNS to locate the Active Directory domain controllers on your network, you can manually specify one or more domain controllers in the Centrify configuration file.

To manually specify a domain controller, add the following entry to the Centrify configuration file, /etc/centrifydc/centrifydc.conf:

dns.dc.domain_name: server_name [server_name ...]

For example, if you want to ensure the Centrify Agent uses the domain mylab.test and the domain controller named dc1.mylab.test, you could add the following line to the /etc/centrifydc/centrifydc.conf file:

dns.dc.mylab.test: dc1.mylab.test

Note: You must specify the name of the domain controller, not its IP address. In addition, the domain controller name must be resolvable using either DNS or in the local /etc/hosts file. Therefore, you must add entries to the local /etc/hosts for each domain controller you want to use if you are not using DNS or if the DNS server cannot locate your domain controllers.

To specify multiple servers for a domain, use a space to separate the domain controller server names. For example:

dns.dc.mylab.test: dc1.mylab.test dc2.mylab.test

The Centrify Agent will attempt to connect to the domain controllers in the order specified. For example, if the domain controller dc1.mylab.test cannot be reached, the agent will then attempt to connect to dc2.mylab.test.

If the global catalog for a given domain is on a different domain controller, you can add a separate dns.gc.domain_name entry to the configuration file to specify the location of the global catalog. For example:

dns.gc.mylab.test: dc3.mylab.test

You can add as many domain and domain controller entries to the Centrify configuration file as you need. Because the entries manually specified in the configuration file override any site settings for your domain, you can completely control the Centrify Agent for *NIX's binding to the domains in your forest through this mechanism.

Note: In most cases, you should use DNS whenever possible to locate your domain controllers. Using DNS ensures that any changes to the domain topology are handled automatically through the DNS lookups. The settings in the configuration file provide a manual alternative to looking up information through DNS for those cases when using DNS is not possible. If you use the manually-defined entries in the configuration file and the domain topology is changed by an Active Directory administrator, you must manually update the location of the domains in each configuration file.

Using the fixdns script

The Centrify Agent includes a fixdns script that you can use to inspect your environment and make the necessary configuration file changes for you.

To run this script, you need to specify the domain controller name and IP address:

fixdns domain_controller_name IP_address

For example if you intend to join the domain mytest.lab and the domain controller for that domain is dc1.mytest.lab and its address is 172.27.20.1, you would run the following command:

fixdns dc1.mytest.lab 127.27.20.1

The fixdns script will then make the necessary changes to the /etc/hosts and the Centrify configuration file.

Note: This script does not update the /etc/resolv.conf file. If the script cannot locate the domain controller using the existing /etc/resolv.conf settings, it will assume that you want to use settings from the configuration file.

What the Centrify DNS subsystem provides

Centrify provides a DNS subsystem that bypasses the local DNS resolver to address common issues that occur with many local DNS resolvers. These common issues for local DNS resolvers include:

- Degraded performance when connecting to a slow DNS server or when attempting to use dead DNS servers.
- Degraded performance when reacquiring a DNS server that went offline and has come back online.
- Degraded performance related to DNS timeouts.
- Platform-related DNS idiosyncrasies, such as MDNS, appending.LOCAL suffixes, and so on.

The Centrify DNS subsystem performs the following functions:

- Looks up hosts by name.
- Looks up hosts by IP address.
- Queries DNS service location records (SRV) to discover the domain controllers that support Active Directory services including KDC, KPASSWD, LDAP and the global catalog.

Resolving a host name or IP address

When the DNS client subsystem receives a DNS requests, it attempts to resolve the host name or IP address by first checking the /etc/hosts file. If the file contains a valid entry to resolve the specified host name or IP address, the DNS client subsystem processes the DNS request.

Entries in /etc/hosts must be in the following format:

IPv4_address hostname alias alias ...

where:

- IPv4_address must be in the first position
- hostname is a fully-qualified domain name and must be in the second position.
- aliases are optional and follow the address and hostname entries.

For example:

192.169.147.135 ginger.acme.com ginger

Note: Service (SRV) record queries cannot be satisfied from the /etc/hosts file.

If resolution by /etc/hosts is unsuccessful, the DNS subsystem attempts to select a DNS server that can be used to resolve the host name or IP address (as described in the next section, Selecting a DNS server).

Selecting a DNS server

If unable to resolve a host name or IP address by finding an entry in the /etc/hosts name (as described in Resolving a host name or IP address), the Centrify DNS subsystem attempts to find a DNS server to resolve the host name or IP address, as follows:

- It checks for a working DNS server that has already been selected (cached in memory and stored in /var/centrify/kset.dns.server), and if available, uses it.
- If a working DNS server is not already selected, it checks /etc/resolv.conf for configured DNS servers, and if populated, selects the fastest one from the list.

If no working DNS servers are found, the request fails.

At this point, DNS is considered down, and the Centrify DNS subsystem waits for the interval specified by the dns.dead.resweep.interval (default is 60 seconds), before attempting again to find a DNS server.

Specifying DNS-related parameters

Parameters in the Centrify configuration file control many aspects of Centrify DNS subsystem operation. Although you can set any of these parameters, the default settings should provide you with optimal DNS operation. See the Configuration and Tuning Reference Guide for details about any of these parameters.

The DNS subsystem periodically checks in the background to see if a DNS server that is faster than the currently selected one is available. The dns.alive.resweep.interval parameter determines how often this background check occurs; the default value is one hour (3600 seconds).

When a DNS server is selected, its address is stored in the kset.dns.server file, and it is used for all DNS requests until one of the following occurs:

- The selected server stops responding.
- A new server sweep discovers a faster DNS server and replaces it.
- The adclient process is stopped and restarted, which triggers a sweep for a new DNS server.
- The specified server is no longer in the list of servers in /etc/resolv.conf.

For the sweep, the dns.sweep.pattern parameter determines the probe pattern that is used to find a live DNS server; that is, it sets the protocol to use (TCP or UDP) and the amount of time to wait for a response. By default, this parameter specifies both a TCP and UDP probe.

The dns.timeout and dns.udp.retries parameters determine the amount of time to wait, and how often to re-send a request when the current server does not respond to a request. If the current server does not respond to a request within the specified time out period, it is considered down and Centrify looks for a different server. If it cannot find a live server, DNS is considered down, and the Centrify Agent for *NIX waits for the period of the dns.dead.resweep.interval parameter, 60 seconds by default, before performing a sweep to find a new server.

Filtering the objects displayed

For performance or security reasons, you might want to filter or limit the objects displayed in the Access Manager console. Depending on your environment, you might want to display more or less information by setting filter options. These filter settings enable you to control both the number and type of objects displayed. You should note, however, that these settings can affect the performance of the console.

To filter the objects listed in Access Manager:

1. Open Access Manager.
2. In the console tree, select **Access Manager**, right-click, then click **Options**.
3. Click the **Filter Settings** tab.
4. Select **Load all zones** to automatically open either all zones in the connected forest or all zones in a specific parent container.
    - If you select this option and **connected forest** all zones in the forest are opened automatically each time you start Access Manager. Selecting this option prevents you from opening or closing any zones manually. Depending on the number of zones you have, you might experience slower performance in the console if you select this option.
    - If you select this option and **container**, you can then click Browse to search for a container from which to automatically load zones. Selecting this option prevents you from opening or closing any zones manually. Depending on the number of zones you have in the selected container, you might experience slower performance in the console if you select this option.
5. Select **Show disabled Active Directory accounts** to display disabled computer and user accounts or uncheck this option to hide disabled objects.
6. Select **Show orphans** to display all users, groups, and computers that have a UNIX profile or uncheck this option to hide all orphan profiles.

   Orphan profiles are the service connection points that no longer have a corresponding Active Directory object. Hiding or removing orphan profiles can improve console performance. For information about locating orphan profiles by running an analysis on the Active Directory forest, see Analyzing information in Active Directory.
7. Select **Show Auto Zone** to display the users, groups, and computers that have joined the Auto Zone or uncheck this option to hide Auto Zone information.
8. Set the **Maximum number of items to be displayed in the list** option to limit the total number of objects displayed in the console, up to total maximum allowed (65535).

   This setting applies to all of the objects displayed in Access Manager, including zones, computers, users, groups, pending users, pending groups, NIS maps, and all defined rights, roles, and role assignments. Lowering the maximum number of items displayed improves performance when browsing the listed items. Note that this setting does not affect the number of items you can define, only the number displayed.
9. Click **OK**.

Authentication Service issues on

Be aware of the following issue when working with the Authentication Service on UNIX or Linux systems:

- The directory /var should not be NFS mounted or else DirectControl may not work properly. (Ref: IN-90009)
- Please see KB-9092 for further details about using common UNIX commands with Privilege Elevation Service restricted shells.

Using Centrify commands for administrative tasks

This chapter provides an overview of the Centrify command-line interface and a list of the command-line programs you can execute locally on Centrify-managed computers.

How and when to use command-line programs

UNIX command-line programs are installed by default when you install the Centrify Agent for *NIX. The commands are typically installed in one of the following directories:

/usr/sbin, /usr/bin
/usr/share/centrifydc /bin

The Centrify Agent includes a large number of command-line programs that enable you to perform a variety of administrative tasks directly from a UNIX shell or using a shell script. These command-line programs use the underlying adclient service library to perform important tasks on the computers you add to Active Directory domains. For example, there are commands that allow you to remove a computer from an Active Directory domain, change an Active Directory user's password, and return detailed diagnostic information about the operations of a host computer.

You can use command-line programs interactively or in shell scripts when you must take action directly on a Centrify-managed computer, or when taking action from a managed computer is most convenient. For example, individual users can use a command-line program to change their Active Directory password from a login shell without logging on to a Windows computer.

Some command-line programs perform specific tasks that you will only use infrequently or under specific conditions. Other programs perform common administrative tasks that you are likely to use repeatedly.

The most commonly used programs include the following:

- The adjoin command is the first command you use to add a local computer to an Active Directory domain.
- The adinfo command display summary or detailed diagnostic and configuration information for a computer and its Active Directory domain.
- The adpasswd command allows you to change an Active Directory account password from a Centrify-managed computer.
- The adgpupdate command allows you to force group policies to be refreshed immediately.
- The adleave command allows you to remove a managed computer from its current Active Directory domain or from the Active Directory forest entirely.

Displaying usage information and man pages

To display a summary of usage information for any command-line program, type the command and the --help or -h option. For example, to see usage information for the adleave command, type:

adleave --help

The usage information includes a list of options and arguments, and a brief description of each option. For example, if you specify adleave -h on the command line, the command displays the command-line syntax and a list of the valid options you can use when you execute adleave commands, similar to the following:

usage: adleave [options]
options:
-u, --user user[@domain] user name, default is administrator
-p, --password pw user password, prompts if absent
-s, --server ds domain server for leave operations
-Z, --zoneserver ds domain server for zone operations
useful if zone is in another domain
-C, --noconf do not restore PAM or NSS config
-G, --nogp do not restore Group Policy
-f, --force force local leave, no network activity
-v, --version print version information
-h, --help print this help information and exit

For more complete information about any command, you can review the information in the command's manual (man) page. For example, to see the manual page for the adleave command, type:

man adleave

Result codes used by multiple programs

Many Centrify command-line programs share a common set of result codes returned when an operation is successful or an error occurs. The following table lists the result codes that are reserved for use by Centrify command-line programs.

0	ERR_SUCCESS	Successful completion of the operation.
6	ERR_OTHERS	Miscellaneous errors occurred during the operation.
7	ERR_USAGES	Usage error occurred during the operation.
8	ERR_OP_ABORTED	Operation aborted by user.
9	ERR_ROOT_PRIV	Root privilege is required for the operation.
10	ERR_NOT_JOINED	Computer is not currently joined to any Active Directory domain.
11	ERR_ALREADY_JOINED	Computer is already joined to the current Active Directory domain.
12	ERR_JOINED_ANOTHER_DOMAIN	Computer is currently joined to another Active Directory domain.
13	ERR_ADCLIENT_DOWN	The adclient process is not running or not available.
14	ERR_ADCLIENT_DISCONNECTED	The adclient process is running in disconnected mode.
15	ERR_ADLCIENT_STARTUP	The adclient process failed to start.
16	ERR_DNS_TIMEOUT	The DNS server is not responding and may be down.
17	ERR_DNS_GENERIC	A generic DNS problem occurred during the operation.
18	ERR_INVALID_DOMAIN_NAME	The Active Directory domain name is incorrect or not found in DNS.
19	ERR_INVALID_LOGON	User name or password provided is not correct.
20	ERR_ACCOUNT_DISABLED	The account specified has been disabled.
21	ERR_ACCOUNT_EXPIRED	The account specified has expired.
22	ERR_ACCOUNT_EXISTS	The account specified already exists,
23	ERR_ACCOUNT_NOTFOUND	The account specified was not found in Active Directory.
24	ERR_PASSWORD_EXPIRED	The account password has expired.
25	ERR_ZONE_NOTFOUND	The zone cannot be found.
26	ERR_CONTAINER_NOTFOUND	Invalid Active Directory container object.
27	ERR_INSUFFICIENT_PERM	The account specified does not have permission to perform the operation.
28	ERR_CLOCK_SKEW	The time difference between system clocks is beyond the acceptable range.
29	ERR_COMPUTER_NAME	Invalid computer account.
30	ERR_CRED_INVALID	Invalid credentials.

31	ERR_SERVICE_TKT_INVALID	Invalid service ticket.
32	ERR_POLICY_NOT_MATCH	Policy not matched.
33	ERR_REJECT_CHG_PASSWD	Password change rejected.
34	ERR_WORKSTATION_DENY	Workstation denied.
35	ERR_NOT_FIND_USER	No matching user found.
36	ERR_NOT_FIND_GROUP	No matching group found.
37	ERR_NOT_CONNECT_ADCLIENT	An attempt to open a connection to the adclient process failed.
38	ERR_ADLCIENT_STOP	Unable to stop the adclient process.
39	ERR_QUOTA_EXCEEDED	The user has exceeded the number of join operations allowed.
40	ERR_OPEN_FILE	The attempt to open a file failed.
41	ERR_READ_FILE	The attempt to read a file failed.
42	ERR_COPY_FILE	The attempt to copy a file failed.

For information about command-specific result codes, see the manual page for individual commandline programs.

Delinea

Perform administrative tasks using commands

Most administrative tasks can be performed using Access Manager on a Windows computer or by using ADEdit commands or scripts from a Centrify-managed computer that has access to the Active Directory domain controller. In some cases, however, there are operations that you must or prefer to perform locally on a managed computer by executing commandline programs.

The command line programs allow you to perform administrative tasks—such as join or leave a domain or generate diagnostic information—directly in a UNIX shell. Many of the command-line programs require administrative privileges or must run using root to perform privileged operations. You can define command rights for these programs to grant permission to run them to other users.

The following table provides a summary of the command-line programs for access control and privilege management that are installed with the Centrify Agent for *NIX. For complete information about the options you can specify for any command, see the man page for that command.

adcache	Clear the local cache on a computer. You can use this command to clear all cached information or a specific cache file. You can also use the command to check a cache file for a specific key value and to reclaim disk space.
adcheck	Check the operating system, network, and Active Directory connections to verify that a computer is ready to join an Active Directory domain.
adchzone	Move a joined computer from a classic zone to a hierarchical zone. Before moving a computer with this command, you must use admigrate to migrate the classic zone to a hierarchical zone.
adclient	Start, stop, or manage operations for the Centrify Agent process on a local computer. In most cases, you should start and stop adclient using a startup script.
addebug	Start or stop detailed logging activity for the Centrify Agent (adclient) process on a local computer. If you do not specify an option, the addebug command displays its current status, indicating whether logging is active or disabled. You must be logged in as root to run this command.
addbloader	Create a database file with zone information. You can then use the adreport command to generate reports from this file, or read it with standard tools.
addns	Update DNS records on an Active Directory-based DNS server in environments where the DHCP server cannot update DNS records automatically.
adfinddomain	Display the domain controller associated with the Active Directory domain you specify.
adfips	Enable or disable FIPS-compliant encryption. You must be logged in as root to run this command.
adfixid	Resolve UID and GID conflicts and change the ownership of a local user's files to match the user and group IDs defined for the user in Active Directory.
adflush	Clear the cache on a local computer. Executing adflush with no options expires the domain controller and global catalog caches.
adgpupdate	Retrieve group policies from the Active Directory domain controller and apply the policy settings to the local computer and current user immediately.
adid	Display the real and effective UIDs and GIDs for the current user or a specified user.
adinfo	Display detailed Active Directory, network, and diagnostic information for a local computer. Options control the type of information and level of detail displayed.
adjoin	Add the local host computer to the specified Active Directory domain. You must log in as root to run the adjoin command.
adkeytab	Create and manage Kerberos key tables (*.keytab files) and coordinate changes with the Kerberos key distribution center (KDC) provided by Active Directory. The arguments required and options available depend on the operation you want to perform.

adleave	Remove the local host computer from its current Active Directory domain. You must log in as root to run the adleave command.
adlicense	Enable or disable licensed features on a local computer. You must log in as root to run the adlicense command.
admanagelocal	Display currently managed local accounts, status of local account management, and force a foreground sync of local accounts.
admigrate	Migrate information from a classic zone to a hierarchical zone. You can migrate a classic zone to a new peer hierarchical zone, or you can specify a parent zone for the migration.
adobfuscate	Obscure sensitive information, such as email addresses, host names, and user names, that might be recorded in a log file before sending the file to Centrify for analysis. You must create a pattern file to use with this command. The command reads the pattern file and replaces items matching the patterns specified with generic values.
adpasswd	Change the password of the user executing the command or change the password of another Active Directory user.
adquery	Query Active Directory for information about users and groups from the command line on a Centrify-managed computer. This command is provided for backward compatibility. In most cases, you should use adedit commands or scripts to perform administrative tasks in Active Directory from Linux or UNIX computers.
adreload	Force the Centrify Agent process (adclient) to reload the configuration properties in the /etc/centrifydc.conf file and in other files in the /etc/centrifydc directory.
adreport	Generate user, computer, command, and role assignment reports for a zone. You must run the addbloader command to create a database containing information about a zone before you can run this command to generate a report.
adrmlocal	Report and remove local user names that duplicate Active Directory user names.
adsendaudittrailevent	Specify where to send audit trail events. You can choose to send audit trail events to the syslog facility, the Centrify auditing service, or both.
adsetgroups	View or change the list of groups available for the current user.
adsmb	Perform file operations, such as get a file, write a file, or display the contents of a directory using the Centrify smb stack.
adupdate	Update user and group account information from the command line on Centrifymanaged computer. This command is provided for backward compatibility. In most cases, you should use adedit commands or scripts to perform administrative tasks in Active Directory from Linux or UJNIX computers.
dzdo	Execute a privileged command as root or another specified user. You must be assigned a role that grants privileged command rights to use this command.
dzedit	Edit a file as root or another user.
dzinfo	Display detailed information about the configuration of rights and roles for one or more specified users on the local computer. If you do not specify a user, the command returns information for the currently logged on user.
dzsh	Run commands in a restricted environment shell. This shell is a customized Bourne shell that provides environment variables, job control, command history, and access to specific commands defined by roles.
ldapadd	Open a connection to the Active Directory domain controller or another LDAP server to add new entries.
ldapcompare	Open a connection to the specified Active Directory domain controller or another LDAP server to compare LDAP entries. You can use this command to determine whether a specified entry has a particular attribute-value combination. The only information returned is whether the comparison evaluated to true or false. No other information about the entry is provided.

ldapdelete	Open a connection to the specified Active Directory domain controller or another LDAP server using the provided distinguished name and password to delete the specified entry or entries.
ldapmodify	Open a connection to the specified Active Directory domain controller or another LDAP server using the provided distinguished name and password to modify the specified entry or entries.
ldapmodrdn	Open a connection to the specified Active Directory domain controller or another LDAP server using the provided distinguished name and password to move or rename the specified entry or entries.
ldapsearch	Open a connection to the specified Active Directory domain controller or another LDAP server using the provided distinguished name and password to locate and retrieve the specified entry or entries.
nisflush	Clear the Centrify Network Information Service cache on a local computer, or restart the service without flushing the cache. You must be logged in as the root user to run this command.

Using Python with Centrify objects

You can use Python commands or scripts to interact with Centrify objects on Linux systems. Centrify provides two Python modules that you can use in Python scripts to communicate with the Centrify Agent for *NIX:

- **pylrpc**: Calls reference internal LRPC objects and methods.
- **pycapi**: Calls reference the Centrify API (CAPI) mainly for use with NSS and PAM.

Requirements

Python requirements:

- Use Python version 3.4 or later
- Add the following path to your PYTHONPATH variable:

  /usr/share/centrifydc/python/lib64

  For example, you can update the PYTHONPATH by running the following command:

  $export PYTHONPATH=/usr/share/centrifydc/python/lib64

In your python scripts, you can import either module into your script with an import statement, such as the following:

import pylrpc

import pycapi

There are some sample scripts included so that you can what kinds of things you can do. Example python scripts are installed at /usr/share/centrifydc/samples/python.

Python Pylrpc reference

This section covers the objects, methods, and other details for the Pylrpc module.

Pylrpc module objects

There are two objects in the Pylrpc module:

- Session

  This object works with the agent. When you construct this object, it creates a session with the agent automatically. When you delete this object, the session closes automatically.

- Error

  This is the type of exceptions that the Session object methods raise upon failure.

Pylrpc session object methods

This section lists out each method that you can use with the session object in the Pylrpc module.

__init__()

Opens a session with the agent.

adinfo()

Get joining settings and status of the local system

Parameters:

none

Returns:

A Python dictionary with keys and values that use the string type.

Raises:

- Error - if any error occurred

Example:

getUser(uid, option) and getUser(uname, option)

Query a user by UNIX UID, UNIX name or AD name

Parameters:

- uid (int) or name (str)
- option (int)
  - pylrpc.UNIX_ONLY : to ask adclient to return result only when the user is zone enabled

- pylrpc.CHECK_AD_FIRST: to ask adclient to ignore cache and read from AD if connected
- pylrpc.GROUP_MEMBERSHIP: to ask adclient to return user's group membership info
- pylrpc.EXPIRED_GRP_MEMBERS: when used with pylrpc.GROUP_MEMBERSHIP, ask adclient to trigger asynchronous group membership refresh for this user

Returns:

- Object (see Description of object below)

Raises:

- Error - if any error occurred

Example:

```
user = s.getUser("username", pylrpc.UNIX_ONLY)
user = s.getUser(999999, pylrpc.UNIX_ONLY | pylrpc.GROUP_MEMBERSHIP)

# Query an AD user by AD name

# by UPN or samAccountName@domain
user = s.getUser("Krusty@domain.com", pylrpc.GROUP_MEMBERSHIP)
# by NTLM name
user = s.getUser("domain.com+krusty", pylrpc.GROUP_MEMBERSHIP | pylrpc.CHECK_AD_FIRST)
# by Canonical name
user = s.getUser("domain.com/Users/krusty")
```

getGroup(gid, option) and getGroup(gname, option)

Query a zone group by gid or name

Parameters:

- gid (int) or name (str)
- option (int)
  - pylrpc.UNIX_ONLY : to ask adclient to return result only when the group is zone enabled
  - pylrpc.CHECK_AD_FIRST: to ask adclient to ignore cache and read from AD if connected
  - pylrpc.GROUP_MEMBERSHIP: to ask adclient to return group's group member info
  - pylrpc.EXPIRED_GRP_MEMBERS: when used with pylrpc.GROUP_MEMBERSHIP, ask adclient to trigger asynchronous member refresh for this group

Returns:

- Object (see Description of object below)

Raises:

- Error - if any error occurred

Example:

```
group = s.getGroup("username", pylrpc.UNIX_ONLY)
group = s.getGroup(999999, pylrpc.UNIX_ONLY | pylrpc.GROUP_MEMBERSHIP)

# Query an AD group by AD name

# by samAccountName@domain
group = s.getGroup("dba@domain.com", pylrpc.GROUP_MEMBERSHIP)
# by Canonical name
group = s.getGroup("domain.com/Users/dba")
```

flushCache(type)

Expire or flush adclient's cache

Parameters:

- type (int)
  - pylrpc.EXPIRE_OBJ_CACHE: force expire object data caches, equivalent to "adflush -e -fy"
  - pylrpc.FLUSH_DNS_CACHE: flush DNS cache, equivalent to "adflush -d -fy"
  - pylrpc.FLUSH_AUTH_STORE: flush authorization data cache, equivalent to "adflush -a -fy"
  - pylrpc.FLUSH_TRUSTS: flush domain trust cache, equivalent to "adflush -t -fy"
  - pylrpc.FLUSH_OBJ_CACHE: flush object data caches, equivalent to "adflush -o -fy"
  - pylrpc.FLUSH_BINDINGS: drop DC bindings, equivalent to "adflush -b -fy"
  - pylrpc.FLUSH_CONNECTORS: flush Centrify Connector info, equivalent to "adflush -c -fy"

Returns:

- True on success

Raises:

- Error - if any error occurred

Example:

refreshObject

force flush a single object out from object data cache

Parameters:

- type (int)
  - pylrpc.UserType
  - pylrpc.GroupType
- name (str)
  - Can be UNIX name or AD name

Returns:

- True on success

Raises:

- Error - if any error occurred

Example:

```
result = s.refreshObject(pylrpc.GroupType, "groupname")
```

Pylrpc Error object methods

The base class of Error is the Python Exception class.

Here's an example:

```
s = pylrpc.Session()

except pylrpc.Error as ex:
print("ERROR: %s, code= %s" % (ex.message(), ex.code()))
```

message()

The error message

Returns:

- message as (str)

code()

Returns the error code.

Returns:

- code as (int) (See codes and error messages)

Codes and error messages

9	Root privilege is required for the operation
10	The system is not joined to any domain
13	adclient is not running/not available
52	User not found in zone
35	Active Directory user not found
53	Group not found in zone
36	Active Directory group not found
6	Other misc errors

Pylrpc dictionary objects

Some of the pylrpc methods return objects, those are described below. A dictionary is a data type in Python that's used to store a set of key:value pairs.

Object	The Object is a dictionary object that stores the attributes of the object returned. For each item in the dictionary object, the key is a string, and the value is a list of bytes objects. If the attribute has only one value, the attribute will be a list with only one bytes object.

Python Pycapi Reference

This section covers the objects, methods, and other details for the Pycapi module.

Pycapi Module Methods

The following table provides a summary of the available methods in the pycapi module. Click the method name to go to the details for that method.

GetMajorVersion()	Returns the CAPI library's major version number.	int	The CAPI library's major version number
GetMinorVersion()	Returns the CAPI library's minorversion number.	int	The CAPI library's minor version number
Shutdown()	Does housekeeping in preparation for exiting a program that is using the CAPI library. Calling this function is optional, but if if the in-memory SID cache is enabled it will take care of freeing up any allocated memory associated with the cache.	n/a	
GetCdcCodeStr(code)	Returns the string associated with the supplied code. parameter: code (int) -code	string	The string associated with the code.
GetErrSystemStr(system)	Returns the name of the error subsystem with an ID. parameters: system (int) - error system ID	string	The name of the error subsystem.
DomainFromDN()	Returns the Active Directory domain name from the distinguished name or canonical name in upper case. Parameters: dn (string) - error system ID	string	The Active Directory domain name

Pycapi Module Objects

There are two objects in the Pycapi module:

- Session

  This object works with the agent. When you construct this object, it creates a session with the agent automatically. When you delete this object, the session closes automatically.

- Error

Session Object Methods

This section lists details about each method that you can use with the Session object.

–

Create a session with the agent using the open method.

–

Disconnect from the agent using the close method.

close()

Disconnect from the agent and free all resources associated with the session.

open(majorVersion, minorVersion)

Parameters:

- majorVersion(int): major version of required CAPI version
- minorVersion(int): minor version of required CAPI version

If you specify majorVersion:

- You must specify the major version of the Centrify API (CAPI). If the current version of CAPI is lower than the specified version, this method call fails.
- Optionally you can also specify the minorVersion.

If you don't specify the version parameters, the service doesn't do any version checking.

Raises

- Error - if any error occurred

getOption(option)

Get an option's current setting with an ID.

Parameters:

- option (int) - option ID (see Option constants)

Returns:

- value as (int)

Raises:

- Error - if any error occurred

setOption(option, value)

Set an option with an ID and a value.

Parameters:

- option (int): option ID (see Option in Constants)
- value (int): option value

Raises:

- Error - if any error occurred

setSessionID(id)

Set a session-specific string. This string will show up in the agent event logs to provide an easy way to track logging events specific to requests generated by this CAPI session.

Parameters:

- id (str) - session-specific string

Raises:

- Error - if any error occurred

isSessionConnected()

Check whether the session is connected to the DirectControl agent and the session is valid.

Returns:

- code as (int). If the session is connected and valid, the code value will be CODE_SUCCESS (see Code constants).

getSessionCode()

Get the code from the last session transaction.

Returns:

- code as (int) (see Code constants)

ldapFetch(domain, dn, attrs)

Fetch a specific object from Active Directory.

Parameters:

- domain (str) - domain to search in. Specify either a domain name, or "$" to use global catalog or "" to use the default domain controller.
- dn (str) - the DN to return. An empty string "" can be used to specify the DSE root.
- attrs (list of str) - the attributes to return. An empty list or None will return only the attributes DirectControl normally caches for the matched object.

Returns:

Object (see Object)

Raises:

Error - if any error occurred

lookupObjectByUnixId(type, id)

Look up a user or group by Unix ID.

Parameters:

- type (int) - object type (see Object type constants)
- id (int) - Unix user ID or group ID

Returns:

- Object (see Object)

Raises:

- Error - if any error occurred

lookupObjectByName(category, name)

Look up a user or group by name in a category.

Parameters:

- category (str) - category (see AD Category constants) to limit the search
- name (str) - user name or group name

Returns:

- Object (see Object)

Raises:

- Error - if any error occurred

lookupObjectByGuid(guid)

Look up a user or group by GUID.

Parameters:

- guid (str) - GUID

Returns:

- Object (see Object)

Raises:

- Error - if any error occurred

lookupObjectBySid(sid)

Look up a user or group by SID.

Parameters:

- sid (str) - SID

Returns:

- Object (see Object)

Raises:

- Error - if any error occurred

getDomainRids()

Get the domain map of all of the accessible domains with their corresponding RID information.

Returns:

- KeyValueSet (see KeyValueSet)

Raises:

- Error - if any error occurred. If the domain map construction is not complete, the code will be TRY_AGAIN.

networkChange()

Notify adclient that there was a network change on the system.

Returns:

- code as (int). If success, the code value will be CODE_SUCCESS (see Code constants)

ping()

Test the connection to the agent.

Returns:

- code as (int). If success, the code value will be CODE_SUCCESS (see Code constants)

getKerberosName(name, useSamName)

Get the Kerberos principal name of a user.

Parameters:

- name (str) - user name
- useSamName (int) - TRUE will use sAMAccount name (see Boolean constants)

Raises:

- Error - if any error occurred

authValidateAccount(name, flags)

Check a user account to see if any logon restrictions currently apply.

Parameters:

- name (str) - user name
- flags (int) - validate flags (see Validate Flag constants)

Returns:

- code as (int). If success, the code value will be CODE_SUCCESS (see Code constants)

authValidatePlainTextUserNonCDC(name, password)

Validate a non-DirectControl managed user.

Parameters:

- name (str) - user name
- password (str) - user password

Returns:

- code as (int). If success, the code value will be CODE_SUCCESS (see Code constants)

authValidatePlainTextUser(name, password)

Validate a user and password using Kerberos.

Parameters:

- name (str) - user name
- password (str) - user password

Returns:

- code as (int). If success, the code value will be CODE_SUCCESS (see Code constants)

systemHealthInfo(refresh=FALSE)

Return information about DirectControl's system health.

Parameters:

- refresh (int) - if FALSE, return information from last API call. If TRUE, send a probe to collect updated information. (See Boolean constants)

Returns:

- KeyValueSet (see KeyValueSet)

Raises:

- Error - if any error occurred

getForestList(flags)

Get the trusted forest information list.

Parameters:

- flags (int) - flags (see Get DC Flag constants)

Returns:

- ObjectList (see ObjectList)

Raises:

- Error - if any error occurred

getDomainList(flags)

Get the trusted domain information.

Parameters:

- flags (int) - flags (see Get DC Flag constants)

Returns:

- ObjectList (see ObjectList)

Raises:

- Error - if any error occurred

getDCInfo(name)

Get Information about a specific domain controller (DC).

Parameters:

- name (str) - name of the domain controller

Returns:

- Object (see Object)

Raises:

- Error - if any error occurred

getDomainControllers(name, flags)

Get a list of domain controllers for specific domain.

Parameters:

- name (str) - name of the domain
- flags (int) - flags (see Get DC Flag constants)

Returns:

- StringSet (see StringSet)

Raises:

- Error - if any error occurred

getAuditLevel(name)

Get audit level of a user.

Parameters:

- name (str) - user name

Returns:

- audit level as (int) (see Audit Level constants)

Raises:

- Error - if any error occurred

Throw Error exception in case of error.

Error Object Methods

The base class of Error is the Python Exception class.

message()

Returns a message as a string

Returns:

- message as (str) (see Audit Level constants)

code()

Returns code

Returns:

- code as (int) (see Code constants)

Pycapi Module Constants

This section lists out the different constant values that can be used with the Pycapi module.

Pycapi Dictionary Objects

Some of the pycapi methods return objects, those are described below. A dictionary is a data type in Python that's used to store a set of key:value pairs.

Object	The Object is a dictionary object that stores the attributes of the object returned. For each item in the dictionary object, the key is a string, and the value is a list of bytes objects. If the attribute has only one value, the attribute will be a list with only one bytes object.
ObjectList	A list of objects.
StringSet	A list of strings.
KeyValueSet	A dictionary of strings.

About Delinea Management Services for Mac

With Delinea Management Services for Mac, you can use Active Directory to centrally manage authentication, policy enforcement, single sign-on (SSO), and user self-service for popular endpoint devices running Mac operating systems.

A key component of Delinea Management Services for Mac is the *DirectControl agent* for Mac computers. You must install the agent on each computer that you want to integrate with Active Directory and manage through Delinea Access Manager.

After you install the agent on a Mac computer, you can perform many administration and configuration tasks on the computer to enable the computer to work with Delinea Management Services and with Active Directory.

Intended Audience

This guide is intended for Mac system administrators.

Topics Covered in this Guide

The following topics are covered:

Installing the DC Agent Creating Home Directories Working with Macs Understanding Group Policies Setting Computer-based Policies Setting User-based Policies Configuring a Mac for Smart Card Login Troubleshooting Installing and Removing the Agent

The *Administrator's Guide for Mac* provides information about the administration and configuration tasks that you perform on a Mac computer after you install the agent so that you can manage users, groups, computers, and zones with Access Manager. Additional topics, such as installing the agent, optionally enrolling the computer in the Delinea Platform, and troubleshooting issues after the agent is installed are also covered.

Specific areas of focus are as follows:

- This guide provides installation instructions and step-by-step instructions for configuring Mac computers to join an Active Directory domain through Auto Zone, which creates one large zone for all Mac computers. Auto Zone requires minimal configuration and is appropriate for most Mac environments. If your environment is larger, or more complex, and doesn't easily fit into Auto Zone, you must consult the *Planning and Deployment Guide* for detailed information on how to move your Mac users and computers to Active Directory and use Delinea zones to structure your environment.
- This guide explains how to handle issues and tasks that are specific or unique to a Mac environment.

This guide does not cover planning or Access Manager tasks handled through the Access Manager console. For more information about those topics, see Where to go for more information.

This guide assumes you have a working knowledge of performing administrative tasks in a Mac environment.

This section explains how to install the DirectControl Agent for a Mac computer.

Preparing to Install the DirectControl Agent for Mac

You must install the DirectControl Agent for Mac on each computer that you want to manage through Delinea and Active Directory. You can check the *Release Notes* included with the software, or visit the Delinea Web site (scroll to **Supported Platforms** and click the **Details** tab) to verify that each computer where you plan to install is running a supported version of the mac operating system.

> **Note**: The installation package also contains a utility, ADCheck, which verifies that each of your Mac computers is ready for installation of the DirectControl agent. ADCheck confirms that a computer is running a supported OS, has sufficient disk space to install the DirectControl agent, and that the domain you intend to join has functioning domain controllers and DNS servers. Information about running ADCheck is included in this documentation.

Installing the Agent on Apple M1 Mac Computers

Depending on whether you using the graphical installer or the command line version to install the DirectControl Agent for Mac on Apple M1 Mac computers, you may need to install some additional software.

- If you install the DirectControl Agent for Mac on an Apple M1 Mac computer using the graphical user interface, you might be asked to install Rosetta.

  Click **Install**, then enter your user name and password to allow installation to proceed.

  For more information, see https://support.apple.com/en-us/HT211861.

- If you install the DirectControl Agent for Mac on an Apple M1 Mac computer using the install.sh script, or by installing remotely, you might need manually install Rosetta first. Please run the following command with root privileges to install Rosetta 2:

  ```
  /usr/sbin/softwareupdate --install-rosetta --agree-to-license
  ```

Verifying DirectControl Agent for Mac Installation Prerequisites

Before installing the DirectControl Agent for Mac on your Mac computers, be certain that you or another administrator has installed Delinea Management Services on a Windows computer in the domain. Delinea Management Services includes the Access Manager Console, which is the primary management console for performing ongoing operations, including the application of group policies. Always install this console unless you are installing and running Delinea Express for Linux and UNIX, which does not contain a console component.

For information about other Delinea Management Services components, such as Zone Provisioning Agent, see the *Planning and Deployment Guide* and the *Administrator's Guide for Linux and UNIX*.

Deciding When and How to Join a Domain

Following installation, you will be prompted to join a domain. Whether to join a domain depends primarily on how you intend to join. Delinea provides two ways to join a domain:

- Through Auto Zone, which is the recommended method for installations with 1500 or fewer users. When joined through Auto Zone, all users and groups defined in Active Directory for the forest — as well as all Active Directory users defined in a forest with a two-way, cross-forest trust relationship to the forest of the joined domain — automatically become valid users and groups on the Mac computer.
- By connecting to a specific Delinea zone, which is the recommended method for installations with 1500 or more users, or for installations in which fine-tuned access control is needed. A zone is similar to an Active Directory organizational unit (OU) and allows you to organize the computers in your organization in meaningful ways to simplify account and access management and the migration of information from existing sources to Active Directory.

The assumption of this guide is that you are joining Auto Zone. After installation, you can follow the instructions to join the domain and with a few configuration steps all your Active Directory users will be able to log into this computer.

> **Note**: If you have a set of Apple Open Directory users, you should migrate them following installation but before joining a domain.

On the other hand, if your environment requires a zone structure, you must create that structure before joining a domain. Therefore, after installing the DirectControl agent, consult the *Planning and Deployment Guide* and the *Administrator's Guide for Linux and UNIX*, which explain in detail how to plan, create, and maintain an Active Directory installation of non-Windows computers with Server Suite.

Installing the DirectControl Agent

The DirectControl Agent for Mac can be installed in several different ways. The procedure in this section shows how do so by double-clicking the Delinea Installer package (DMG) and following the instructions displayed on the screen. This installation method is recommended for most users when installing on a single computer or a limited number of computers.

When you use the Delinea package installer, you will be prompted to join the domain. You may also join the domain after installation using either the adjoin command-line program or the Delinea Directory Access plug-in.

Delinea provides a number of other ways to install the DirectControl Agent for Mac

- By executing the DirectControl Agent for Mac installation script, install.sh in a Terminal window on a Mac computer and following the instructions displayed by the script.

  If you are an experienced UNIX administrator and are familiar with UNIX command-line installations, running install.sh is a good method to use. When you install using the install.sh script, you can automatically join an Active Directory domain as part of the installation process; see Installing Using the install.sh Script for details.

- By installing remotely, without user interaction, using Apple Remote Desktop. This is a good method to use if you are using Apple Remote Desktop for software distribution. With Apple Remote Desktop you can add pre- and post-installation scripts that allow you to join the remote computer to a domain after installation; see Installing Silently on a Remote Computer for details.

To install the DirectControl Agent for Mac on a Mac computer using the graphical user interface:

1. Before installing the DirectControl Agent for Mac, disable Apple's built-in Active Directory plug-in, and remove Active Directory from the Authentication, and Contacts search paths. For more information, see Disabling the Apple Built-in Active Directory Plug-in.
2. In addition, be certain that the Apple Directory Utility is closed.
3. Log on with the Administrator account.
4. Navigate to the directory on the CD or your local network where the agent package is located. For example, if you are installing from the Delinea CD, open the MacOS directory.
5. Double-click the DMG file, for example:

   centrifydc-release-mac10.10-x86_64.dmg

6. Double-click ADCheck to open the ADCheck utility.

   ADCheck performs a set of operating system, network, and Active Directory checks to verify that the Mac computer meets the system requirements necessary to install the DirectControl Agent for Mac and join an Active Directory domain.

7. Enter the domain you intend to join with the Mac computer and click **AD Check**; for example:

8. Review the results of the checks performed. If the target computer, DNS environment, and Active Directory configuration pass all checks with no warnings or errors, you should be able to perform a successful installation and join the specified domain. If you receive errors or warnings, correct them

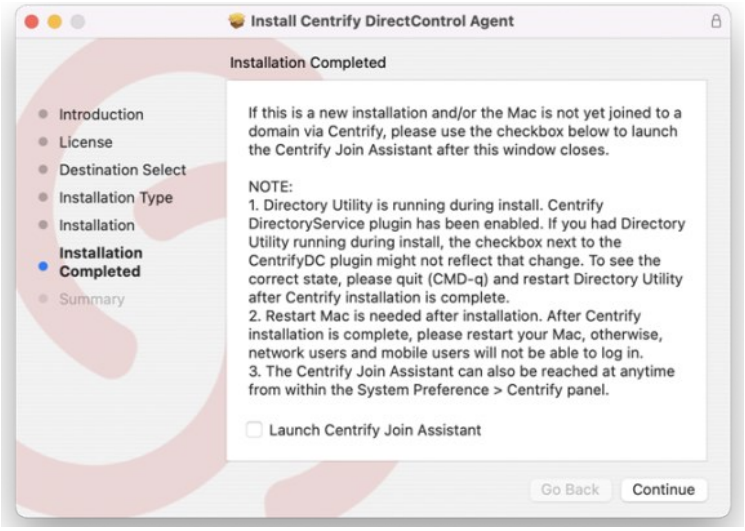
before proceeding with the installation; see the *Administrator's Guide for Linux and UNIX* for more information about ADCheck.

9. Double-click the DelineaDC package to open the Installer:

10. Review the information in the Welcome page, then click **Continue**.
11. Review or print the terms of the license agreement, then click **Continue**; click **Agree** to agree to the terms of the license agreement. Then click **Install** (note that you cannot change the volume on which the agent is installed — it must be on the same volume as Mac OS X).
12. If prompted, enter the administrator name and password, and click **Install Software** to install the DirectControl Agent for Mac.

If you see the following warning box, click **OK**. If you did not have Directory Utility running during the installation, you can ignore the warning. If Directory Utility was open, you can quit and restart it to show the correct status of the Delinea plug-in.

The installation process runs and presents the Installation Completed page once the DirectControl Agent for Mac is installed.



13. Select **Launch Delinea Join Assistant** if you want to join a domain, then click **Continue**.

    Note: If you know that you want to use Delinea zones in your environment, exit the installer now. You must create zones first, before you can join to one. Refer to Deciding When and How to Join a Domain for more information.

If you chose not to launch the Delinea Join Assistant before clicking Continue, the installer presents a summary indicating that the installation was successful. You can now close the installer.

If you chose to launch the Delinea Join Assistant, you can start the process of **Joining an Active Directory Domain** described in the next section.

Note: If the Mac system is MacOS 11 or later, you must configure full disk access for the DirectControl Agent for Mac before you join the system to an Active Directory domain.

Joining an Active Directory Domain

This topic shows how to use the Delinea Join Assistant to join a domain. To join a domain, you must be a domain admin or a domain user with permission to create computer objects. If necessary, your domain administrator can use the Delegation Wizard to delegate permission to create computer objects. Refer to Who Can Add a Workstation to a Domain for more information.

Note: Alternately, you may run the adjoin command-line utility, interactively or in a script, for each Macintosh computer you want to add to a

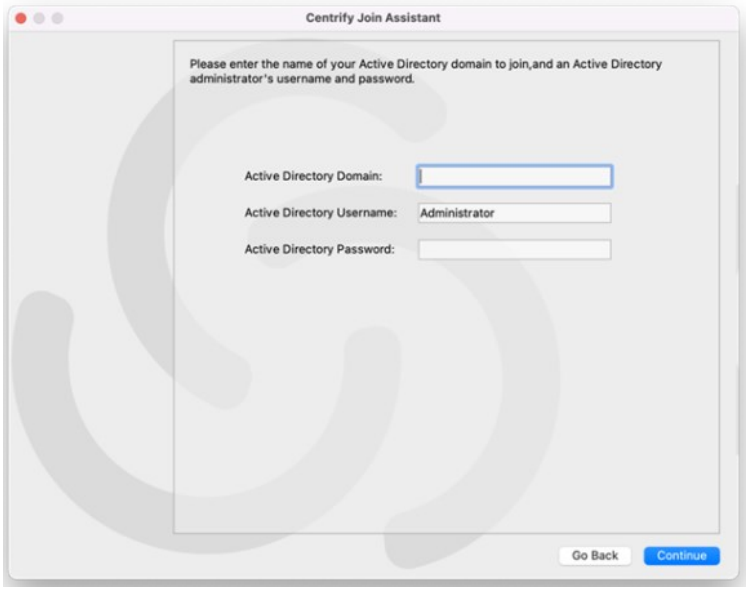
domain in the forest. See the *Administrator's Guide for Linux and UNIX* for details.

To join the Mac to a domain:

1. Launch the Delinea Join Assistant.

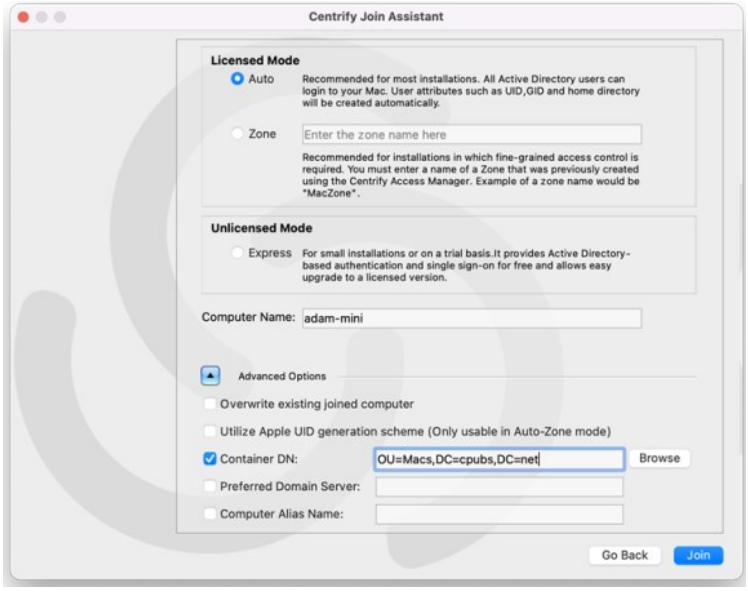
   There are two ways to launch the Delinea Join Assistant:

   - from the DirectControl agent installer, as described in Installing the DirectControl Agent for Mac.
   - click **Applications › Utilities › Delinea**, double-click **Delinea Join Assistant** to open it, then click **Continue** on the Welcome page



2. Enter the active directory domain that you want to join as well as administrator credentials for that domain, then click **Continue**.

   A page appears that allows you to select how to join the domain with an option to enroll in the Privileged Access Service.



3. Select from the following options:

Auto	Joins the computer through Auto Zone, which allows joining a computer with little or no configuration. This option is recommended for most installations.
Zone	Joins to the zone that you type in the box. Note that you must have created at least one zone before you can use this option.
Computer name	Defaults to the name of the computer on which you are running the join assistant, but you can change it if you want to use a different name for the local host in Active Directory.

Note: Enrollment is no longer supported.

4. (Optional) Click the arrow to expand the Advanced Options and select any Advanced Options that you want to use to join the device.

Overwrite existing joined computer	Overwrite the information stored in Active Directory for an existing computer account. This option allows you to replace the information for a computer previously joined to the domain. If there is already a computer account with the same name stored in Active Directory, you must use this option if you want to replace the stored information. You should only use this option when you know it is safe to force information from the local computer to overwrite existing information. Checking this option is the same as running the adjoin command with the `--force` option.
Container DN	Specify the distinguished name (DN) of the container or Organizational Unit in which you want to place this computer account. By default, computer accounts are created in the domain's default Computers container. Click **Browse** to browse Active Directory and select the container to use, or click Container DN and enter the name of the container in distinguished name format; for example, if the domain suffix is acme.com and you want to place this computer in the paris.regional.sales.acme.com organizational unit, you would type: `ou=paris, ou=regional, ou=sales` Checking this option is the same as running the adjoin command with the `--container` option.
Preferred Domain Server	Specify the name of the domain controller to which you prefer to connect. You can use this option to override the automatic selection of a domain controller based on the Active Directory site information. Checking this option is the same as running the adjoin command with the `--server` option.
Computer Alias Name	Specify an alias name you want to use for this computer in Active Directory. This option creates a Kerberos service principal name for the alias and the computer may be referred to by this alias. Checking this option is the same as running the adjoin command with the `--alias` option.

5. Click **Join**.

   Delinea Join Assistant informs you that you have successfully joined your Mac to your Active Directory domain at <mydomain.com>.

6. Click **Done** to close the Delinea Join Assistant.

   Your Active Directory users can now log on to the joined Mac computer, as described in Logging onto the Mac after Joining a Domain.

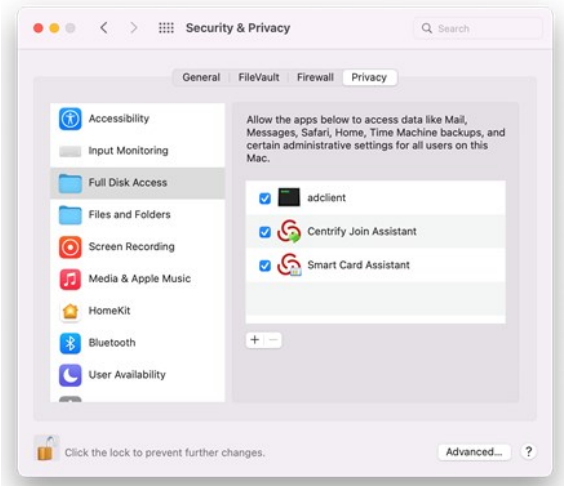
Configuring Full Disk Access for the DirectControl Agent for Mac

Due to a limitation of MacOS 11.x and MacOS 12.x, "Full Disk Access" is required for the DirectControl Agent for Mac. You can configure this yourself if you're an administrator on the computer, or you can set it by way of your MDM (Mobile Device Management) provider.

To configure full disk access as an administrator:

1. Log in to the Mac computer as an administrator user.
2. Open **System Preferences**.
3. Click **Security & Privacy.**

4. Click **Privacy**.
5. Click **Lock** and then enter the password or use TouchID to unlock.
6. In the left pane, scroll down and select **Full Disk Access**.
7. Click **+** (the plus button).
8. Press and hold these three keys together: Sshift + Command + G.
9. Enter the path "/usr/local/sbin/adclient" and click **GO**, then click **Open** to add the path.
10. Repeat step 7 and 8, then input the path "/Applications/Utilities/Centrify/Centrify Join Assistant.app" and click **GO**, then click **Open** to add the path.
11. Repeat step 7 and 8, then input the path "/Applications/Utilities/Centrify/Smart Card Assistant.app" and click **GO**, then click **Open** to add the path.
12. Click **Lock** again to lock the system preferences.



Configuring Full Disk Access Through Your MDM Provider

Contact your MDM provider for more information. Your MDM provider will need the following information:

```
% codesign -dv /usr/local/sbin/adclient
Executable=/usr/local/sbin/adclient
Identifier=adclient
...
% codesign -dr - /usr/local/sbin/adclient
Executable=/usr/local/sbin/adclient
designated => identifier adclient and anchor apple generic and certificate 1[field.1.2.840.113635.100.6.2.6] /* exists */ and certificate leaf[field.1.2.840.113635.100.6.1.13] /* exists */ and
certificate leaf[subject.OU] = "64CT837G5Z"
% codesign -dv /Applications/Utilities/Centrify/Centrify\ Join\ Assistant.app
Executable=/Applications/Utilities/Centrify/Centrify Join Assistant.app/Contents/MacOS/Centrify Join Assistant
Identifier=com.centrify.cdc.centrifyjoinassistant
...
% codesign -dr - /Applications/Utilities/Centrify/Centrify\ Join\ Assistant.app
Executable=/Applications/Utilities/Centrify/Centrify Join Assistant.app/Contents/MacOS/Centrify Join Assistant
designated => identifier "com.centrify.cdc.centrifyjoinassistant" and anchor apple generic and certificate 1[field.1.2.840.113635.100.6.2.6] /* exists */ and certificate
leaf[field.1.2.840.113635.100.6.1.13] /* exists */ and certificate leaf[subject.OU] = "64CT837G5Z"
% codesign -dv /Applications/Utilities/Centrify/Smart\ Card\ Assistant.app
Executable=/Applications/Utilities/Centrify/Smart Card Assistant.app/Contents/MacOS/SCTool
Identifier=com.centrify.cdc.smartcardassistant
...
% codesign -dr - /Applications/Utilities/Centrify/Smart\ Card\ Assistant.app
Executable=/Applications/Utilities/Centrify/Smart Card Assistant.app/Contents/MacOS/SCTool
designated => identifier "com.centrify.cdc.smartcardassistant" and anchor apple generic and certificate 1[field.1.2.840.113635.100.6.2.6] /* exists */ and certificate
leaf[field.1.2.840.113635.100.6.1.13] /* exists */ and certificate leaf[subject.OU] = "64CT837G5Z"
```

Configuring Full Disk Access for Apple Remote Desktop

If your organization uses Apple Remote Desktop to run any DirectControl Agent for Mac commands (such as adjoin, adleave, and so forth), you need to also set Full Disk Access for Apple Remote Desktop. You can do this either as an administrator user or through your MDM service, following the same procedures

as mentioned earlier.

If you're configuring full disk access as an administrator, the application path to add is as follows:

```
/System/Library/CoreServices/RemoteManagement/ARDAgent.app
```

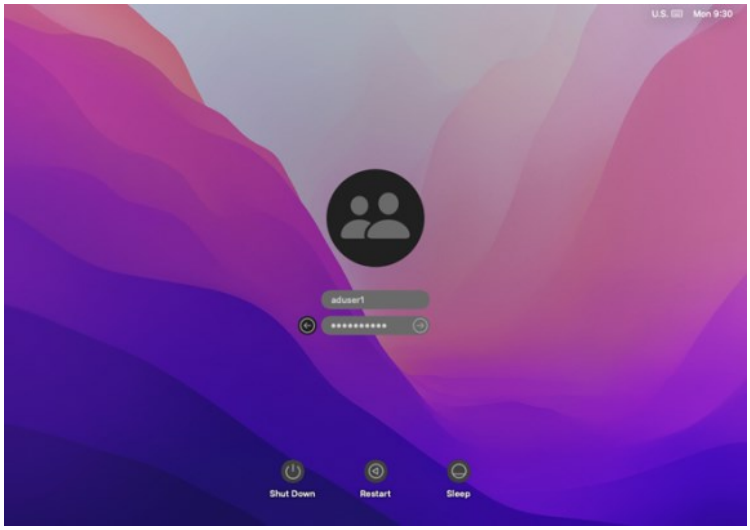
If you're configuring full disk access through your MDM provider, here's the information that your provider needs:

```
% codesign -dv /System/Library/CoreServices/RemoteManagement/ARDAgent.app
Executable=/System/Library/CoreServices/RemoteManagement/ARDAgent.app/Contents/MacOS/ARDAgent
Identifier=com.apple.RemoteDesktopAgent
...
% codesign -dr - /System/Library/CoreServices/RemoteManagement/ARDAgent.app
Executable=/System/Library/CoreServices/RemoteManagement/ARDAgent.app/Contents/MacOS/ARDAgent
designated => identifier "com.apple.RemoteDesktopAgent" and anchor apple
```

Logging onto the Mac After Joining a Domain

When using Auto Zone, all Active Directory users in the domain become valid users on a joined computer. To verify that the software is working properly, you can simply log into the Mac computer by using an Active Directory account.

On the Mac login screen, select **Other** and enter an Active Directory user name and password:



Upgrading The DirectControl Agent for Mac

In most cases, you can update agents on Mac computers by simply installing the new agent either directly or remotely on top of an existing agent. As a best practice, you should perform in-place upgrades using a local Mac administrative (admin) account or any other user account that has local administrative rights and reboot the computer after completing the upgrade. In most cases, you should not perform the upgrade while you are logged on as an Active Directory user in a currently active session.

In rare cases, you might be advised to run adflush to clear the Active Directory cache before performing an in-place upgrade. For example, if you are updating agents from version 4.x, or earlier, to 5.1.x, run adflush first to ensure a smooth upgrade. It is highly unusual for an upgrade to require you to leave and rejoin a managed Mac computer to the domain.

This section explains how to create different types of home directories for a Mac computer.

Understanding Home Directories

Whenever an Active Directory user logs in to a Mac computer, a home directory is created for the user. Mac provides three styles of home directory, which can be configured by an administrator to fit the type of user who will be using the computer, the type of computer, and the use to which the computer will be put. Auto Zone supports each of these styles:

- Local home directory — The user's home directory is created on the local computer in the Users folder with the user's login name (/Users/username).
- Network shared directory — The user's home directory is created on a network share.
- Portable home directory — The user's home directory is created on a network share and copied and synchronized to the local computer. This type of directory is also called a *mobile* home directory.

When you join a computer to a domain by connecting to Auto Zone, the home directory is created based on the following:

- Active Directory user settings; for example, an administrator can specify a network home directory in the Profile for an Active Directory user.
- Auto Zone default values; by default, Auto Zone is configured to support the creation of home directories in the Users folder on the local computer.
- Auto Zone parameters set in the configuration file, /etc/centrifydc/centrifydc.conf by an administrator or by a group policy. See the *Configuration and Tuning Reference Guide* for a description of all Auto Zone parameters.

The following sections explain in detail how to set up each type of user home directory.

Configuring a Local Home Directory

In general, you do not need to explicitly configure local home directories for your Active Directory users because Auto Zone is configured to work for Active Directory users exactly as if they were local users. That is, by default, an Active Directory user who logs in to a Mac computer that is joined to a domain through Auto Zone is given a local home directory at /Users/username. For example, for a user, Glen Morris, whose login name is gmorris, the local home directory is set to: /Users/gmorris.

Although it isn't necessary to explicitly configure the agent for local home directories, in some situations you might want to do so. For example, if a Windows user has a local home directories defined in their Active Directory profile, that home directory will be assigned when the user attempts to log in and may prevent the user from logging in. The agent provides a configuration parameter (auto.schema.use.adhomedir)that you can set to ignore home directories in an Active Directory profile and always set the home directory to the default (/Users/username).

To explicitly configure a computer for local home directories:

1. On the Mac computer, edit the configuration file, /etc/centrifydc/centrifydc.conf.
2. Add the following two parameters:

   auto.schema.use.adhomedir: false

   auto.schema.homedir: /Users/%{user}

   - Setting auto.schema.use.adhomedir to false configures the local computer to ignore any home directories that are set for users in Active Directory. This parameter is set to true by default.
   - Setting auto.schema.homedir: /Users/%{user} configures the local computer to set the home directory to /Users/username, where *username* is the user logon name defined in the user's Active Directory account. Note that this parameter is set to this value by default on all Mac computers.

     Note: If you plan to configure network-home or portable-home directories for this computer, you must set auto.schema.use.adhomedir to true, the default value, otherwise, the agent will ignore the network home directories that you specify for users in Active Directory.
3. Save and close the file.

Configuring a Network Home Directory

For each user whom you want to have a network home directory, you must specify the location in Active Directory.

Note: In earlier releases you had to first create a network home directory for a user if you planned to also create a portable home (mobile home) directory for that user. With the current release, you can create portable home directories for users without first creating network home

directories for those users.

To configuring a network home directory for a user connected to Auto Zone:

1. Create a network share to host the home directory.

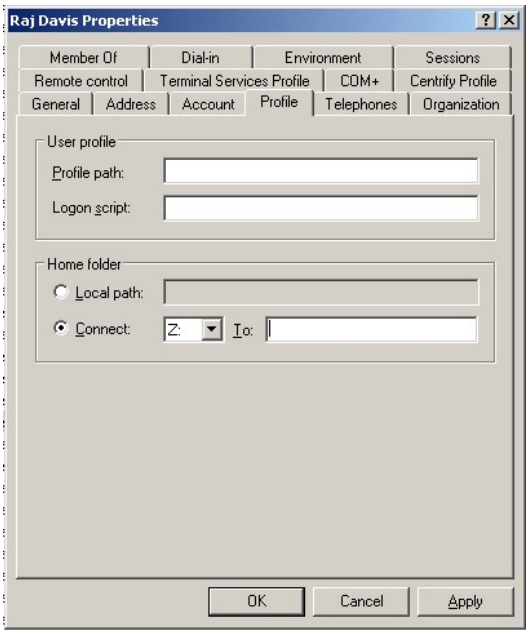
   For example, on the dc-demo server (acme.com domain), create a network share called MacUsers.

   You must assign appropriate permissions to the network shared directory so the Active Directory account is able to write to the user's home directory. One way to do this is to assign read/write permissions to Authenticated Users on the network share. Each home directory that is created inherits permission from the network share so the account of the logged-in user is granted write permission its network home directory. See Setting Shared Directory Permissions for more details about properly setting and fine-tuning network share permissions.

2. On a domain controller in the forest to which the Mac OS computer is joined, open Active Directory Users and Computers.

3. Select **Users**, select the user, then right-click the user and click **Properties**.

4. Click the **Profile** tab, then under **Home folder** select **Connect**.



5. In **Connect...To** type the location of the share you created in Step 1 by using the following format:

   ```
   //*Server/share/path
   ```

   For example:

   ```
   //dc-demo.acme.com/MacUsers/rdavis
   ```

6. Click **OK** to save the user profile.

7. (Optionally) By default, the agent is configured to use the Active Directory home folder if one is specified in a user's profile. However, to be explicit, you can edit the configuration file and add the following parameter:

   ```
   auto.schema.use.adhomedir: true
   ```

   Save and close the file.

8. Specify the type of share to mount for the network home directory on the Mac computer, SMB, or AFP.

   By default, the Mac computer will attempt to mount an SMB share for the network home. If you specified an AFP share, you must set the following parameter in the configuration file:

auto.schema.remote.file.service:AFP

Or enable the **Computer Configuration > Policies > Centrify Settings > DirectControl Settings > Adclient Settings > Auto Zone remote file service** group policy to specify SMB (the default) or AFP for all Mac computers.

9. Optionally, if you want the network home directory to be mounted automatically on the user's computer, enable the following group policy: **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Automount Settings > Automount user's Windows home**.

When the specified user next logs onto the Mac computer, the home directory will be created on the specified share. On the Mac computer, you should see the server and share under **SHARED** in the Finder.

Configuring a Portable Home Directory

You can create a portable home directory for a user and synchronize that directory with the share defined in the user's Centrify Profile. You can synchronize to /SMB/, /AFP/, or /Network/Servers (NFS) shares.

Advantages of a Portable Home Directory

- If a user does not have a portable home directory and the computer becomes disconnected from the domain controller (and therefore disconnected from Active Directory), the user can log in with Active Directory credentials only if the user's information exists in the Centrify cache. If there is any issue with the Centrify cache (for example, if the adflush --force command was issued to flush the cache immediately before the computer was disconnected from the domain), Active Directory users cannot log in unless they have portable home directories.
- Active Directory users without portable home directories are required to log in at least once in connected mode to populate their account information in the Centrify cache. If the computer is not connected to the domain controller, the Centrify cache is not updated with the initial set of Active Directory user data, and Active Directory users cannot log in. You use group policies to configure synchronization. These group policies perform the same function as the Mobility preferences that you can manage through Workgroup Manager.

The following sections describe the process of specifying the options for creating mobile accounts, and for specifying the options for synchronizing mobile accounts with the network home directory.

Before you begin you should have the following in place:

- A Group Policy Object that applies to a domain or OU that includes Mac users.
- A good understanding of the synchronization rules that you want to apply. The procedures in the following sections explain the group policies and options that you can enable, but you should consult the Mac OS X Server documentation for strategies about which options to apply.

This section describes the unique characteristics or known limitations that are specific to using Delinea Management Services on a Mac computer.

Specifying the Macintosh User's Home Directory Location

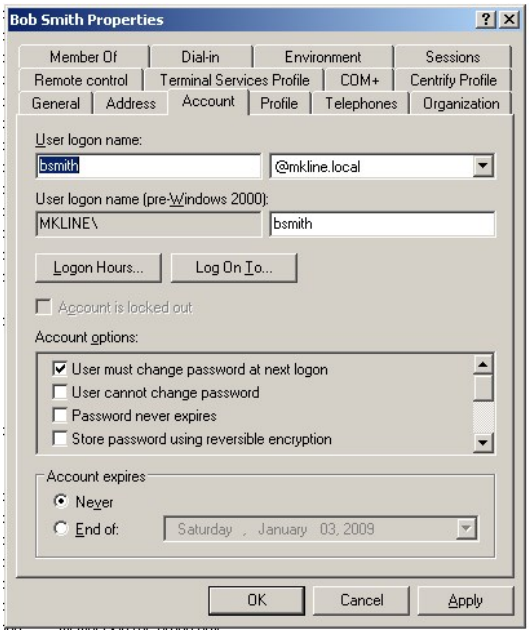
If you configure NFS, SMB, or AFP network file sharing for your Mac OS X computers, you can automatically mount and log on to file shares using Active Directory credentials.

To enable Mac OS X users to log on to file shares when the network is configured with NFS, SMB, or AFP network sharing:

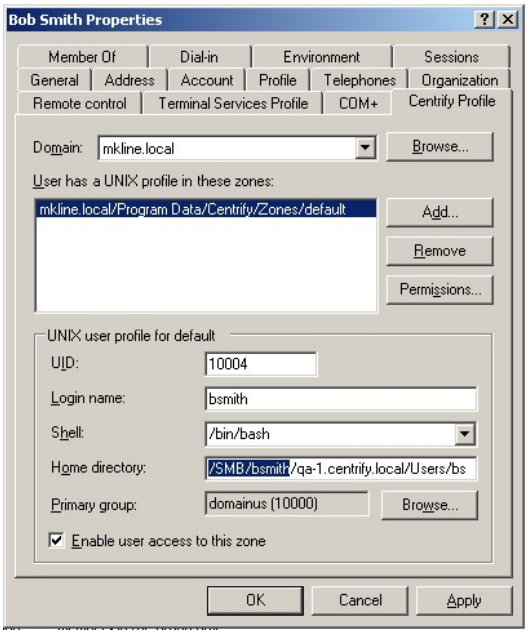
1. Open Active Directory Users and Computers or the Access Manager console.
2. Select the user account for which you want to enable automounting, right-click, then click **Properties**.
3. Click the **Delinea Profile** tab and set the **Home directory** path to use one of the following formats:
    - /Users/user_login_name to set the user's home directory to the default home directory location for all user home directories on Mac OS X computers.
    - /SMB/server_name/share[/path] to automount a file share on the SMB *server_name* you specify. Be certain to use the fully-qualified domain name for *server_name*, or the IP address. The short name does not work. For example:
      /SMB/myHost.acme.com/Users/isuzuki
    - /SMB/unix_username/server_name/share[/path] to automount a file share when you are using Fast User Switching on the SMB *server_name* you specify. Be certain to use the fully-qualified domain name for *server_name*, or the IP address. The short name does not work. For example:
      /SMB/isuzuki/myHost.acme.com/Users/isuzuki
    - /AFP/server_name/share[/path] to automount a file share on the Apple *server_name* you specify.
    - /AFP/unix_username/server_name/share[/path] to automount a file share when you are using Fast User Switching on the Apple *server_name* you specify.

      In specifying the remote SMB or AFP file share, you must use the uppercase letters SMB or AFP at the beginning of the path. If you use lowercase letters (smb or afp), automounting fails.

      Note: If you plan to use Fast User Switching to switch between Active Directory users on the same computer, you should use the /SMB/unix_username/server_name/share[/path] or /AFP/unix_username/server_name/share[/path] format to specify the user's home directory to prevent conflicts between users logging on using the same share. If you want to automount a share on an Apple file server using the Apple File Protocol (AFP), however, you must use Delinea 3.0.1 or later.
4. In Step 3, if you specified a network directory, make sure the Active Directory user logon name (pre-Windows 2000), also known as the samAccountName, matches the Mac login name (UNIX name). Otherwise, the login is not guaranteed to work on all Mac systems. The name must be eight characters or fewer because the UNIX name is automatically truncated to eight characters and won't match if the Active Directory name is longer. The Active Directory name is defined on the **Accounts** tab. To see an example, open the **Properties** page for a user and select **Account**.



Then select the **Delinea Profile** tab to see the UNIX name.



5. For the shared directory you specified in Step 3 (for example, Users), set 'full' permissions for authenticated users. See the section, Setting Shared Directory Permissions, for details on how to do this.

6. Verify that the computer on which the shared directory resides is configured on the DNS server with forward and reverse lookup zones by running the following commands in a terminal window:

   ```
   nslookup computerName.domainName
   ```

   for example:

   ```
   nslookup QA1.acme.com
   Server: acme.com
   ```

Address: 192.168.1.139

Name: QA1.acme.com

Address: 192.168.1.139

nslookup ipAddress

for example:

nslookup 192.168.1.139

Server: acme.com

Address: 192.168.1.139

Name: QA1.acme.com

Address: 192.168.1.139

If you get an error message such as this:

Can't find server name for address 192.168.1.139

it means a reverse lookup zone is not configured for the specified server. To configure DNS forward and reverse lookup zones, see the Microsoft Support Article 816518.

Populating the Home Directory on a Network Share

If you configure users to automount a network share when they log on, you must determine whether a home directory already exists on the network share for those users. If the individual user's home directory does not exist on the network share, Access Manager creates the home directory automatically the first time the user logs on.

Note: For NFS shares, Access Manager cannot create the home directory on the network share, so you must create the directory before users log in for the first time.

For example, assume you have defined the home directory in a user's Delinea Profile as: /SMB/demo-dc.acme.com/home/thomas, indicating that there is an SMB share on the server demo-dc and a shared folder named home where the user thomas has permission to list and create folders.

Note: For the server name, be certain to use the fully-qualified domain name, such as demo-dc.acme.com, and not the short version demo-dc.

When the zone user thomas logs on for the first time, Access Manager creates the new home directory thomas and populates it with the standard Mac OS X files and folders.

If the home directory specified in the Delinea Profile for a zone user exists prior to the user's first logon, Access Manager assumes that the directory is valid and contains the appropriate files, and it does not populate the directory with additional Mac-specific folders.

Defining a Home Directory in the Active Directory Profile

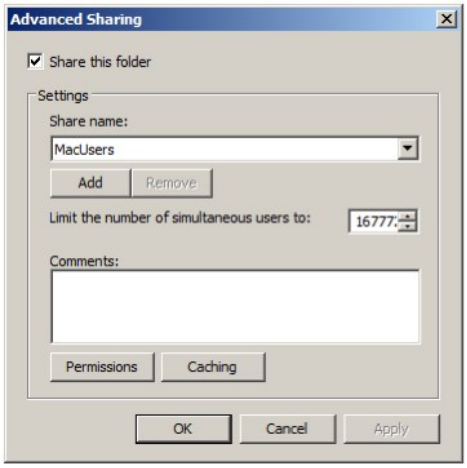
When you are configuring a network home directory for remote Mac users, the home directory is created automatically when users first log; it should not exist prior to that initial log on unless you want to prevent Access Manager from creating the home directory. Therefore, you should not define a home directory connection point in the Profile properties for new Active Directory users or new mobile user accounts. Instead, you should allow Access Manager to create and populate the remote home directory. However if you need to synchronize a network home directory from a local home directory as part of your migration process, the network home directory must exist prior to migration. If you are synchronizing from a local home directory to a remote share, you can create the remote home directory manually, or click the **Profile** tab and set the connection path.

Setting Shared Directory Permissions

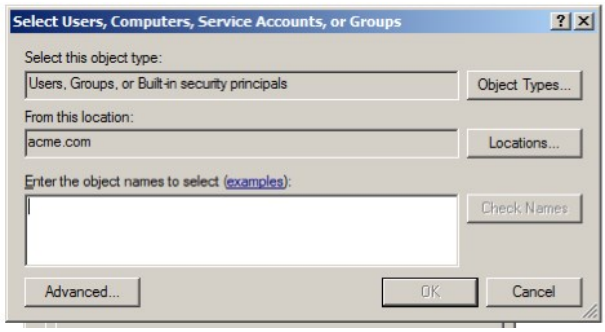
All users who are set up with a network home or portable home directory must have proper permissions to the shared directory in which the home directories are created. Initially, you can provide access to the shared directory through the Windows built-in security group, Authenticated Users. Later, you can fine tune permissions for this group based on your company's file-sharing needs. For example, if an administrator pre-creates home directories for each user before they log in, users only need Read access to the shared directory to access their home directories.

To set permissions for the shared directory for network home and portable home directories:

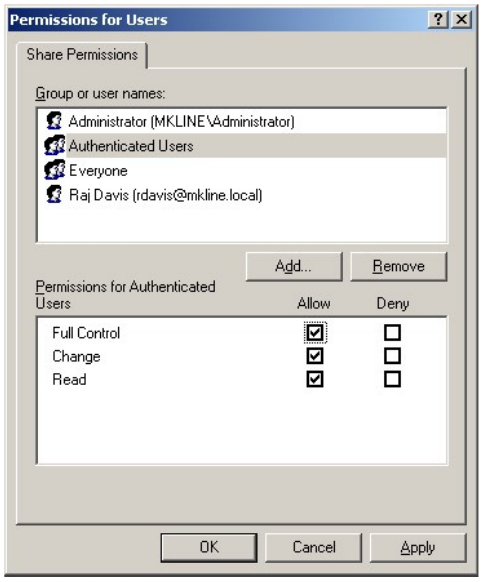
1. On the network share computer, select the directory to share (for example, MacUsers). Right-click, click **Properties** and click the **Sharing** tab; then click **Advanced Sharing**; for example:



2. Make sure **Share this folder** is selected. Click **Permissions**, then click **Add**:



3. Type auth and click **OK** to return the Authenticated Users group. Select **Authenticated Users**, then click **Allow** for **Full Control**. Click **OK** to set permissions for authenticated users, then click **OK** again to close the properties page.



4. Verify that Authenticated Users have proper permissions on the **Security** tab as well as on Share Permissions. Ordinarily, these permissions are applied automatically because the Active Directory Users group, which includes authenticated users, inherits Full Control to the shared folder, but if permissions were altered on the Security tab and they are insufficient, users may be unable to log in.

Click the **Security** tab and select **Authenticated Users** (or if it is not already in the Group or user names box, click **Add** to add it).

5. Select **Full control** and click **OK** to save and close the Properties page.

   Assigning permissions to Authenticated Users on the network home share directory means that each home folder will inherit permissions that enable logged-in users to access their home directories. It also means that every user will have access to every other user's home directory. To change this access, you can set permissions on the individual home directories. For information about fining tuning permissions for individual users, see the next section, **Limiting Users Access to Other Users' Home Folders**.

Limiting Users Access to Other Users' Home Folders

The previous section explained how to assign permissions to a network-home shared folder, which are consequently inherited by the home folders created in the shared folder. Because permissions are inherited, each user has equal access to every other user's home folder. This section explains how to fine tune permissions to limit user's access to their own home folder.

To limit users access to their own home folder:

1. Select the network share you assigned permissions to in the previous section.
2. Select one of the user home directories in the network share.
3. Click the **Security** tab.
4. Click **Advanced** and **Change Permissions**.
5. Deselect **Include inheritable permissions from the object's parent**.
6. Click **Remove** when prompted.
7. Click **Add**.
8. Type users and click **Return**.
9. Select the following permissions for Users:
   - Traverse folder / execute file
   - Read Attributes
   - Read Extended Attributes
   - Create files / Write Data
   - Create Folder / Append Data
10. Click **OK**, and **OK** again until you have saved all open dialogs and closed the Properties page.

Enabling Users to Manage Their Print Queues

On Mac computers, Delinea Active Directory users are unable to manage their own print jobs. For example, if they attempt to pause, stop, or resume one of their own print jobs, they are prompted to supply the name and password of a user in the "Print Operator" group, otherwise, they cannot continue. Delinea supplies the group policy, *Map zone groups to local group*, that you can use to enable all Mac users authenticated through Active Directory to manage their printers.

This policy gives members of a specified zone group (an AD group, or AD group that has been added to a Delinea zone) the privileges that belong to members of a local group on the local group. For example, as explained in the following procedure, mapping an AD group to the local _lpoperator and _lpadmin groups, provides members of the AD group with the privileges to manage print jobs on the local Mac computer when they log in.

To map a zone group to local _lpoperator and _lpadmin groups:

For purposes of illustration, this procedure asks you to create a **MacPrint** group and then add specific users to the group to provide them with printing privileges on Mac computers. You could also map an existing AD group to the local _lpoperator and _lpadmin groups, or create a new group with a different name.

1. On a Windows computer, open Active Directory Users and Computers
2. Select **Users**, right-click and select **New > Group**.
3. Enter a name for the group, such as MacPrint and select **Global** and **Security**.
4. Double-click the group and select the **Members** tab
5. Click **Add** and select the AD users who you want to provide with printing privileges on Mac computers.
6. Open the Access Manager Console
7. Expand the zone hierarchy as well as the zone containing Mac computers.
8. Expand **UNIX Data**, select **Groups**, then right-click and select **Create UNIX Group**.
9. Find and select the AD group you created (MacPrint) and click **OK** to add it to the zone.
10. Open the Group Policy Management Editor and select the GPO that you use for Mac OS X computers.
11. Click **Computer Configuration > Policies > User Configuration > Policies > Delinea Settings > Mac OS X Settings > Accounts**.

12. Double-click **Map zone groups to local group**.
13. Click the **Policy** tab and click **Enabled**.
14. Click **Add** and do the following:
    1. In **Local Group**, type _lpoperator to add the printer operators group.
    2. In **Zone Group** click **Browse**.
    3. Find and select the AD zone group you created (MacPrint), then click **OK** to map MacPrint to the printer operators group.
    4. Click **Add** again and in **Local Group** type _lpadmin to add the printer admin group.
    5. In **Zone Group**, click **Browse** then find and select MacPrint again to map MacPrint to the printer admin group.
15. Click **OK** to save the policy.

The first time users attempts to manage their printer, for example by pausing the printer, they will be prompted for credentials for a user in the "Printer Operator" group. They can simply enter their own name and password. Subsequently, they can manage the printer without supplying credentials.

Setting Up Authenticated Printing

In a Windows Active Directory environment that requires authentication for printing services, Mac users who are already authenticated must provide credentials again when using a Windows network printer. To provide single-sign on when using printers, the Delinea DirectControl Agent for Mac includes an authenticated printer plug-in that enables users to send print jobs to printers on the Windows network without requiring them to enter credentials again. This plug-in uses the user identifier (UID) of the user printing a job to find the user account to authenticate, then validates the user's Kerberos credentials through Active Directory. If the user's credentials are not available, the print job will fail.

Understanding Printing on Mac OS X

Mac uses the Common UNIX Printing System (CUPS) to manage printing services. Although you can access the CUPS facility directly to manage printers, in general you do not need to do so. Printers are managed through the Print and Scan system preference, which uses the CUPS facility. For example, when you add a printer through Print and Scan, the CUPS facility does the following:

- Creates a Postscript Printer Description (PPD) file that defines the printer. The file is given the name of the printer and resides in the /etc/cups/ppd directory; for example, /etc/cups/ppd/laserjet2.ppd.
- Modifies the CUPS configuration file, /etc/cups/printers.conf, with information about the new printer.

One method to set up authenticated printing for all Mac computers in your environment is to configure an authenticated printer on one (template) computer, then export the files that CUPS creates to define this printer (*printerName*.ppd and printers.conf) to each of your Mac computers. You can use group policy to export these files to all your Mac computers.

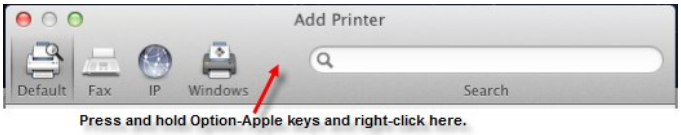
You can also configure printing directly with CUPS commands.

To set up authenticated printing for multiple printers using the Delinea plug-in, first identify the printer to configure, including the server that hosts it; for example, HPLaserJet2.@dc01.

1. On the Mac computer that you will use to define an authenticated printer template, open **System Preferences > Print & Scan** (**Print & Fax** on older systems), then click the plus sign (+) and select **Add Other Printer or Scanner**.

2. Double-click the **Advanced** icon in the toolbar.

   Note: If the Advanced option is not showing, press and hold the **Option** and **Apple** keys and right-click in the open area in the toolbar next to the Windows icon and select **Customize Toolbar**. Drag the Advanced icon to the toolbar and click **Done**. Then double-click it.



3. Scroll in the **Type** drop-down list and select **Windows Printer via Delinea** from the list.

   Note that after you make this selection, the URI scheme in the Device URI window changes to cdcsmb://, which specifies the Delinea plugin.

4. Type the complete URI specification for the printer in the form:

   scheme://servername/sharename

   for example:

```
cdcsmb://printserver.acme.com/hplaserjet2
```

Note: A URI specification does not accept spaces. If the printer share name contains spaces, you must replace them with %20 (ASCII code for space); for example, to specify the **HP Color LaserJet 4** printer:

```
cdcsmb://printserver.acme.com/HP%20Color%20LaserJet%204
```

5. Type a name for the printer; for example HPLaserJetMac.

   When you type the URI for the printer, the first part of the name automatically appears in the **Name** field. You can change that name now. This is the name that will appear in the list of printers in the Print and Scan system preference and in the list of available printers when a user prints a document. It is also the name of the PPD (Postscript Printer Description) file that the CUPS facility creates for each printer that is added to your Printer preferences.

   Type an optional description in **Location** to assist users in locating the printer.

6. In the **Print Using** window, specify the type of the printer, which enables you to properly manage the printer.

   For example, if you have drivers installed for the printer, click **Select Printer Software** and select the appropriate item such as **HP Laserjet 4300**, then click **OK**.

   You can also specify **Generic Postscript Printer**, or click **Other** to browse for drivers or printer software.

   Click the **Add** button to add the printer to the list of available printers.

7. Repeat this procedure for as many printers as you want to make available for authenticated printing.

You can now use the Copy Files group policy to copy the new *printerName*.ppd file and updated CUPS configuration file (printers.conf) to the appropriate locations on each of your Mac computers in the domain.

To copy printer files to other computers:

1. In the Finder on the Mac template computer, navigate to the /etc/cups directory by clicking **Go > Go to Folder**, then type /etc/cups and click **Go**.
2. Select printers.conf and copy it to the desktop. When prompted, enter your administrator password to copy the file.
3. Open the ppd folder (/etc/cups/ppd). Select the files for all the authenticated printers you defined in the previous procedure and copy them to the desktop.
4. On the desktop, change the file permissions for the printers.conf and *.ppd files so you can copy them to sysvol:
   1. Select the files and click **File > Get Info**.
   2. For each open dialog box, expand **Sharing & Permissions**, then click the lock icon and provide administrator credentials for making changes. Set the permissions for **everyone** to **Read only**.
   3. Reset the lock and close all the open dialogs.
5. On the Windows domain controller create a sub-directory for the printer file in SYSVOL.

   SYSVOL is a well-known shared directory on the domain controller that stores server copies of public files that must be shared throughout the domain. You can use it to copy the printer definition and configuration files to all Mac computers that join the domain.

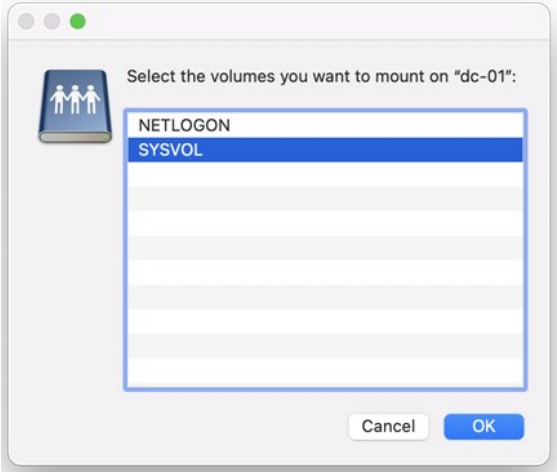
   SYSVOL is located at:

   ```
   C:WindowsSYSVOLsysvoldomainName
   ```

   For example, assuming the domain is acme.com, and using the name MacPrinters for the directory, create the following directory:

   ```
   C:WindowsSYSVOLsysvolacme.comMacPrinters
   ```

6. On the Mac computer, copy the files from the desktop to SYSVOL on the Windows domain controller. If you are connected to the domain, you should see the domain controller in the Finder. If the domain controller is not visible in the Finder, connect to it:
   1. Click **Go > Connect to Server** and select the domain controller.
   2. When prompted select SYSVOL; for example:



3. Navigate to the MacPrinters directory you created, for example by clicking **acme.com** then **MacPrinters**.
4. Drag the printer files to MacPrinters.

7. Configure the Copy Files group policy.
    1. On the Windows domain controller, open the Group Policy Management Editor and select the GPO that is used to manage Mac computers.
    2. Navigate to **Computer Configuration > Policies > Common UNIX Settings** and double-click **Copy Files**.
    3. In **Copy file policy setting**, select **Enabled**.
    4. Click **Add**, then **Browse**. Double-click to open the directory you created for the printer files in Step 5 (for example, MacPrinters).
    5. Select the printers.conf file. Filename now shows MacPrinters/printers.conf.
    6. In **Destination**, type /etc/cups. This group policy will copy printers.conf to the /etc/cups directory of each computer that joins the domain.
    7. Select **Use destination file ownership and permissions**. The file will be assigned the default ownership and permissions:

        owner: root (0)

        group: lp (26)

        permission 0600 (rw- --- ---)
    8. Select **OK** to add the printers.conf file.
8. Click **Add** again and browse to MacPrinters to add the PPD files.
    1. Select one of the PPD files you copied to the MacPrinters directory.
    2. In **Destination**, type /etc/cups/ppd.
    3. Select **Use destination file ownership and permissions**. The file will be assigned the default ownership and permissions:
        owner: root (0)

        group: lp (26)

        permission 0644 (rw- r-- r--)
    4. Click **OK** to add the file.
9. Repeat the sub-steps in Step 8 for each of the PPD files that you have defined, then click **OK** to enable the policy.

    This group policy will copy each *printerName*.ppd file to the /etc/cups/ppd directory of every computer to which the policy applies and that is joined to the domain.

10. Run the adgpupdate command on each target Mac computer to trigger an update of group policies and execute the new Copy Files policy.

    By default, group policies are updated automatically every 90 minutes, so you can skip this step and wait for the automatic update if you wish. You should also log out and back in again on each computer to update the printer configuration dialogs.

Removing a Printer Definition from Client Computers

This section explains how to remove printer definitions that you created for Mac computers in the domain. It assumes that you set up the Copy Files group policy to add printer definitions to each of your joined Mac computers, as explained in Setting up Authenticated Printing.

To remove a printer definition from computers in a domain:

1. Identify the name of the PPD file to delete in /etc/cups/ppd; for example, laserjet4300.ppd.
2. On the Mac template computer (the computer on which you originally defined the authenticated printer), open **System Preferences > Print & Scan**. Select the printer to delete, click the minus (-) button, then click **Delete Printer**.

   Deleting the printer removes the printer from the list, updates the /etc/cups/printers.conf file by removing the definition of the deleted printer, and removes the *printerName*.ppd file from the /etc/cups/ppd directory.
3. Copy the updated printers.conf file to the desktop and change the permissions to **everyone: Read only**.
4. Copy the updated printers.conf file to the SYSVOL and replace the existing file; also remove the PPD file for the deleted printer.

   SYSVOL is a well-known shared directory on the domain controller that stores server copies of public files that must be shared throughout the domain. When authenticated printing was set up, the CUPS configuration file, printers.conf was placed in the SYSVOL/acme.com/MacPrinters folder.

   SYSVOL is located at:

   C:WindowsSYSVOLsysvoldomainName

   If you are connected to the domain, you should see the domain controller in the Finder. If the domain controller is not visible in the Finder, connect to it:

   1. Click **Go > Connect to Server** and select the domain controller.
   2. When prompted, select **SYSVOL**; for example:

      
   3. Navigate to the directory you created (*domainName*/*subdirectory*), for example by clicking **acme.com** then **MacPrinters**.
   4. Drag the printer configuration file to this directory.
   5. Remove the PPD file for the deleted printer.
5. Remove the deleted printerName.ppd file from the Copy Files policy.
   1. On the Windows domain controller, open the group policy editor and select the policy to edit, such as **Default Domain Policy**.

2. Navigate to **Computer Configuration > Policies > Common UNIX Settings** and double-click **Copy Files**.
3. Select the file to delete and click **Remove**.
4. Click **OK** to save the updated policy.

6. Configure the **Specify commands to run** group policy to remove the deleted *printerName*.ppd file from all the Mac computers in the domain.

    1. In the same folder of the group policy editor (Common UNIX Settings), open the Specify commands to run policy and select **Enabled**.
    2. Click **Add**.
    3. In **Run command**, enter a command similar to the following to remove the *printerName*.ppd file from the /etc/cups/ppd directory on each computer:

        ```
        rm /etc/cups/ppd/*printerName*.ppd; for example:

        rm /etc/cups/ppd/laserjet4300.ppd
        ```

    4. Click **OK** to save the policy.

The next time group policy is updated on computers in the domain (every 90 minutes by default), the following occurs:

- The Copy Files group policy copies the updated printers.conf file to each computer.
- The Specify commands to run group policy removes the specified PPD file on each computer.

Setting Up Local and Remote Administrative Privileges

Delinea provides two group policies to set administrative privileges on the local computer

- Map zone groups to local admin groups allows you to specify one or more zone groups to map to the local admin group. Members of the specified group are given administrative privileges on Mac computers managed by Access Manager.
- Enable administrator access groups allows users in the zone group *ard_admin* to access a computer via Apple Remote Desktop with full privileges.

This section shows you how to use these policies together to enable local and remote administrative access to Mac computers.

To enable remote and local access for a group:

1. Create an Active Directory group, for example, *My_Mac_Admins*, and add users who you want to have administrative privileges.
2. Create an Active Directory group that is a Domain Local Security group. For convenience, name it *ard_admin*.
3. Add *My_Mac_Admins* as a member of *ard_admin*.
4. Create a Delinea zone group, *My_Mac_Admins* and map it to the Active Directory group *My_Mac_Admins*.

    Note: If the local computer is connected to the domain through Auto Zone, you cannot create a zone group because there are no zones. However, all Active Directory groups are valid for the joined computer, so you can map any group, such as *My_Mac_Admins*, to the local admin group, but you need to know the group's UNIX name, which you can retrieve on the local computer, by using the adquery command, as follows

    ```
    [root]#adquery group -n
    ```

    For example, the following shows an adquery command and the name it returns:

    ```
    [root]#adquery group -n |grep -i Mac_Admins   my_mac_admins
    ```

5. Create a zone group, *ard_admin*, and map it to the Active Directory group *ard_admin*.

    Note: This zone group must be named *ard_admin*.

6. In the Group Policy Editor, edit the group policy for the domain, then click **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Accounts > Map zone groups to local admin group**.
7. Open the policy, select **Enable**, then click **Add**. Enter *My_Mac_Admins* (or the name retrieved from the adquery -n command in Step 4), then click **OK**.

    This step maps *My_Mac_Admins* to the admin group on the local computer and gives members of *My_Mac_Admins* all privileges.

8. Click **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Remote Management > Enable administrator**

access groups.

9. Open the policy and select **Enable**.

   This step allows members of *ard_admin* to access a computer via Apple Remote Desktop with full privileges. In Step 7, you effectively gave members of *My_Mac_Admins* administrative privileges. Since *My_Mac_Admins* includes members of *ard_admin*, members of *ard_admin* now have full local and remote administrative access.

Querying User Information for Active Directory Users

When you run commands or use applications that look up user information in the directory, the local Mac directory service is always consulted first before the look-up request is made to Active Directory. If a local user exists with the same name as a UNIX profile name that has been defined for the zone, a lookup request such as id *username* will return the UID and GID associated with the local user account from the local directory service rather than the information associated with the UNIX profile defined in Active Directory.

For example, if you have a UNIX profile in Active Directory for the user mia with the UID of 10024 and the user's primary group is mia with the GID of 10024 and the user is also a member of the Active Directory group users and GID of 10001, running the id mia command returns the following information from Active Directory:

```
uid=10024(mia) gid=10024(mia) groups=10024(mia), 10001(users)
```

However, if there is also a local user account with the same user name of mia, but with a UID of 502 and a primary group named *mia* with a GID of 502, running id mia returns the information for the local user retrieved from the Mac directory service, then any additional group membership information retrieved from Active Directory. For example:

```
id mia

uid=502(mia) gid=502(mia) groups=502(mai), 10001(users)
```

Because the Mac directory service is queried first, the information for the local user mia takes precedence over the information defined in Active Directory. To avoid retrieving the information for a local user instead of the UNIX profile defined in Active Directory, you should make sure that the UNIX profile user names in Active Directory are different from the local user or disable local user accounts.

Migrating from Open Directory to Active Directory

If you install the Delinea DirectControl Agent for Mac in an environment where existing Mac users and computers are managed with Open Directory, you may need to migrate the account information and home directories for those users from the Open Directory environment to Delinea Active Directory. Open Directory and Active Directory support three types of users:

- Local users
- Network home users
- Portable home, or mobile home, users

For example, you may need to migrate existing mobile user accounts from Open Directory to Active Directory or migrate local home directories to a network share.

To migrate users with existing mobile accounts from Open Directory to Active Directory:

1. Create a copy of the user's local home directory in a temporary location if you have enough disk space to do so. This copy can serve as a backup to restore the user's home directory if you run into any synchronization problems.

2. Log on to the Mac client as an administrator.

3. Disable the LDAP service.

   Open the Directory Utility and select the **Services** tab; then deselect **LDAPv3** and click **Apply**.

4. Open a Terminal window and run the following Directory Service command to delete the user's record:

   ```
   dscl /Local/Default -delete /Users/userName
   ```

   where *userName* is a local user; for example, to delete the record for cain:

   ```
   dscl /Local/Default -delete /Users/cain
   ```

5. Navigate to the /Users/user_name/Library/Mirrors directory and delete this folder.

6. Join the Mac computer to an Active Directory domain and restart the computer to shut down and restart services.
7. Create an Active Directory user account for the Open Directory user account, if one does not already exist.

   If you are creating a new Active Directory user, use Active Directory Users and Computers to add the user account.
8. Add the Active Directory user to the Mac computer's zone and define the Delinea Profile for the user:
   - Use the same user name, UID, and GID as the Open Directory user account. You can change this information later with the adfixid program, but for migration you must use the same values.
   - Set the home directory for the user to the appropriate network share using the /SMB/share/path or /AFP/share/path syntax. For example, /SMB/cain/server2003.myDomain.com/Users/cain.

     Note: For synchronizing new mobile user accounts, the empty home directory must exist on the network share. If the user home directories are on the same network share as you previously used with Open Directory, logging on with the new Active Directory account should not affect the files available on the share.

     Because GID values of 0 to 99 are usually reserved for system accounts, you may see a warning message when you save the user's profile if the user's primary GID value is less than 99.

If you have Open Directory users that do not have mobile accounts or portable home directories and you want to synchronize their local home directories with their network home, you should first use the Workgroup Manager to create mobile accounts for those users to establish a portable home directory. You can then follow the steps above to synchronize the portable home directories with their network home directory. If you don't want to synchronize the local home directory with the home directory on the network share, you can simply create Active Directory accounts for the Open Directory users and remove the local user records; see Mapping Local User Accounts to Active Directory for information about removing local user records.

Changing the Delinea UIDs and GIDs

To change the UID and GID values in Delinea Active Directory to match the existing values:

1. Log in to the Mac computer as a local administrator.
2. Open a terminal session.
3. Open the user's home folder and type:

   ```
   ls -ln total 32
   -rw-r--r--@ 1 505 505 3 Mar 26 2007 .CFUserTextEncoding
   -rw-r--r--@ 1 505 505 6148 Mar 26 2007 .DS_Store
   -rw------- 1 505 505 74 Mar 26 2007 .bash_history
   drwx------@ 3 505 505 102 Mar 26 2007 Desktop
   drwx------@ 3 505 505 102 Mar 26 2007 Documents
   drwx------@ 19 505 505 646 Mar 26 2007 Library
   drwx------@ 3 505 505 102 Mar 26 2007 Movies
   drwx------@ 3 505 505 102 Mar 26 2007 Music
   drwx------@ 4 505 505 136 Mar 26 2007 Pictures
   drwxr-xr-x@ 4 505 505 136 Mar 26 2007 Public
   drwxr-xr-x@ 5 505 505 170 Mar 26 2007 Sites
   ```

   The third column shows the UID (505 in this example) and the fourth column shows the GID (also 505).
4. On the Windows workstation, open the Access Manager console. Expand the zone, expand users, and double-click the user to open the property page.
5. Type 505 for the UID.
6. To change the GID, you need to either change the GID of the group to which the user belongs (which will change for all users who belong to that group) or create a new group. To create a new group:

- Open ADUC. Then right-click **Users > New > Group**. Enter a name for the group and click **OK**.
- In the Access Manager console, right click **Groups > Create UNIX Group**. Search for the group you created. Change the GID to the desired value (for example, 505) and click **OK**.

7. To change the GID of the existing group to which the user belongs, expand **Groups** and double-click the group name. Change the GID to the desired value (for example, 505). Click **Yes** on the warning message.

Modifying the Mac UID and GID to Match AD

To change the existing UID and GID to match the values in Active Directory depends on whether you have a local home directory, a network home directory, or a mobile home directory.

To change the existing UID and GID if you have a local home or network home directory:

1. Log in to the Mac computer as a local administrator.
2. Open **Applications > Directory Utility > Services**. Double-click **Active Directory**, then click **Unbind**. Enter your administrator name and password if necessary.
3. Use the ADJoin tool (either the GUI or the command-line version) to connect to an Active Directory domain.
4. Open a terminal session and type the following:

   ```
   id userName
   ```

   Note the primary group. For example:

   ```
   id cain

   ...

   gid=10000(support)
   ```

5. Type:

   ```
   chown -R userName:primaryGroupName /Users/userName
   ```

   For example, for a local home directory:

   ```
   chown -R cain:support /Users/cain
   ```

   For example, for a network home directory:

   ```
   chown -R cain:support /SMB/Users/cain
   ```

To change the existing UID and GID if you have a mobile home directory:

1. Be certain the local home directory is synchronized with the network home directory.
2. Log in to the Mac computer as a local administrator.
3. Open **Applications > Directory Utility > Services**. Double-click **Active Directory**, then click **Unbind**. Enter your administrator name and password if necessary.
4. Use the ADJoin tool (either the GUI or the command-line version) to connect to an Active Directory domain.
5. Open a terminal session and type the following Directory Service command to delete the cached local user:

   ```
   dscl . -delete /Users/userName
   ```

   For example:

   ```
   dscl . -delete /Users/cain
   ```

6. Then type the following commands to remove the home directory so that it syncs again from the network and remove the local copy of mcx so you are prompted to create a mobile account:

   ```
   rm -rf /Users/userName
   ```

```
rm -rf /Library/Managed Preferences/userName
```

7. On the Windows Active Directory computer, set the **User Configuration > Policies > Centrify Settings > Macintosh Settings > Mobility Synchronization Settings** group policies.

   Note: Mobile home directory synchronization is no longer supported since macOS 10.12.

Converting a Local User to an Active Directory User

Although local user accounts can co-exist with Active Directory user accounts, in some cases, you may want to convert some or all of your local accounts to Active Directory user accounts. Converting local users to Active Directory users simplifies account management, but requires you to take some steps manually.

On Mac computers, the local account database is always checked for authentication before Active Directory. If a local user has the same username as an Active Directory user, the local user account is used for authentication. If the local user's password is different from the Active Directory user's password whether logging on using the Mac login window, or remotely (for example, using telnet or ssh), the local user password is required for authentication to succeed. Although authentication succeeds, Access Manager will generate a username conflict warning.

In most cases, you should remove or convert local user accounts to avoid conflicts between Active Directory and local user accounts and to ensure Active Directory password and configuration policies are enforced. If you need to keep local user accounts, you should ensure the logins are distinguishable from Active Directory accounts. For more information, see the Planning and Deployment Guide.

To convert a local Mac user to an Active Directory user:

1. Open a Terminal window and run the following Directory Service command to delete the user's record:

   ```
   dscl /Local/Default -delete /Users/userName
   ```

   where *userName* is a local user; for example, to delete the record for cain:

   ```
   dscl /Local/Default -delete /Users/cain
   ```

   Although the user record is deleted, the home directory for the user (/Users/cain), including all sub-directories and files, still exists. When you create an Active Directory user with the same name, this user will have access to everything in the existing local home directory.

2. On a Windows computer, use Active Directory Users and Computers to create an Active Directory user account for the local user account (for example, cain), if one does not already exist.

3. In the Access Manager console add the Active Directory user to the appropriate zone and define the Delinea Profile for the user. Set the home directory for the user:

   Note: The default home directory for Mac users is the /Users directory, unlike most UNIX systems where /home is the default by convention.

   - To a local home directory: /Users/*userName*; for example, /Users/cain.
   - To an appropriate network share using the /SMB/share/path or /AFP/share/path syntax. For example, /SMB/cain/server2003.myDomain.com/Users/cain. See Configuring a network home directory.
   - To a network home directory. If you wish to create a mobile account for the user and synchronize the user's folders the next time the user logs on, see Configuring a Portable Home Directory.

4. Reboot the Mac computer, then log in as the new Active Directory user.

Migrating a User from Apple's Active Directory Plugin to Delinea Active Directory

When you create an Active Directory user by using the Mac Directory Utility Active Directory plug-in it creates numeric user (UID) and group (GID) identifiers. When you migrate a current Active Directory user to Delinea Management Services for Mac, the Access Manager console creates a UID and GID that are different than the current UID and GID. When an Active Directory user attempts to log in after the agent is installed, the changed UID and GID cause ownership and permission problems with the user's home directory.

There are two basic approaches to solving this problem:

- Changing the Delinea UIDs and GIDs
- Modifying the Mac UID and GID to Match AD

Using Apple's Scheme to Generate UIDs And GIDs For Mac Users

By default, Delinea uses a different scheme than the Apple Active Directory plugin to generate numeric user (UID) and group (GID) identifiers for Mac users added to Active Directory. If you use the default Delinea scheme to generate identifiers, you must resolve UID and GID conflicts after migrating users. For example, after migrating you can change ownership on the existing files (see Modifying the Mac UID and GID to Match AD otherwise users have Delinea-generated UIDs whereas their files belong to Apple-generated UIDs so users will be unable to access files and folders in their home directories.

On the other hand, Delinea allows you to use the Apple scheme, rather than the default Delinea scheme, to create UIDs and GIDs for migrated users. This method ensures compatibility with Mac tools, such as ExtremeZ-IP, that require UIDs and GIDs generated with the Apple scheme, not the Delinea scheme.

This section explains how to create Apple-generated UIDs and GIDs for Mac users who you are adding to Active Directory with Delinea Management Services for Mac when a computer is connected to Delinea Active Directory through Auto Zone.

> **Note**: If your computer is joined to a zone, however you are adding users to the zone, you can choose to use the Apple scheme to generate UID and GID values. For example, you can specify the Apple scheme with adedit, with the Zone Provisioning Agent, and in the Access Manager Console.

Delinea provides the auto.schema.apple_scheme parameter to enable use of the Apple schema for generating UIDs for new users. The recommended way to set this parameter is by way of group policy so that you can set it for a group of computers. You may also set the parameter on individual computers by editing the Delinea configuration file

To use group policy to enable the Apple scheme for generating UIDs and GIDs:

1. If you are generating new UIDs and GIDs for files that reside remotely in AFP or NFS mounted shares, back up the UIDs and GIDs on the computer where the share resides by executing a command similar to the following:

   ```
   adquery user > olduid
   ```

   > **Note**: You do not need to perform this step for Samba shares.

2. On a Windows computer, open the Group Policy Management Editor and edit a group policy object that applies to Mac computers.
3. Expand **Computer Configuration › Policies › User Configuration › Policies › Centrify Settings › Direct Control Settings › Adclient Settings**, and double-click **Generate New UID/GID using Apple scheme in Auto Zone**.
4. Select **Enabled** and click **OK** to set the policy.

To edit the configuration file and enable the Apple scheme for generating UIDs and GIDs on a single computer:

1. If you are generating new UIDs and GIDs for files that reside remotely in AFP or NFS mounted shares, back up the UIDs and GIDs on the server where the computer resides by executing a command similar to the following:

   ```
   adquery user > olduid
   ```

   > **Note**: You do not need to perform this step for Samba shares.

2. Log in to a Mac computer.
3. Edit the Delinea configuration file: /etc/centrifydc/centrifydc.conf.
4. Find the following parameter, remove the comment and set its value to true:

   ```
   auto.schema.apple_scheme: true
   ```

You may also enable the Apple scheme to set the primary GID for users if you wish.

> **Note**: You may set the primary GID in this way only if the parameter auto.schema.private.group is set to false. Otherwise, the primary GID is set to the value of the user's UID.

To enable the Apple scheme for generating the primary GID:

1. If you are generating new UIDs and GIDs for files that reside remotely in AFP or NFS mounted shares, back up the UIDs and GIDs on the computer where the share resides by executing a command similar to the following:

   ```
   adquery user > olduid
   ```

   > **Note**: You do not need to perform this step for Samba shares.

2. In the Group Policy Management Editor, edit a group policy object that applies to Mac computers, expand **Computer Configuration › Policies ›**

User Configuration > Policies > Centrify Settings > Direct Control Settings > Adclient Settings, and double-click **Set user's primary gid in Auto Zone**.

3. Select **Enabled**.
4. In **Set user's primary gid in Auto Zone**, type -1.

   The primary GID for each user will be generated by the Apple scheme, as specified with the "Generate New uid/gid using Apple scheme in Auto Zone" group policy, which you enabled in the previous procedure.
5. Click **OK** to save the setting.

After setting these policies, run adgpupdate to update the group policies you just set, and flush the cache on each joined computer to update the UID and GID values for any existing users.

To flush the cache on each Mac computer:

1. Log in to a Mac computer and open the Terminal application.
2. Execute the following command as root:

   adflush

New users who you migrate to Active Directory from the Apple Active Directory plug-in will automatically keep the same UID, GID, and primary GID values that they had before migration, and their home ownership will work properly.

After you flush the cache, any existing users and groups will have their UID, GID, and primary GID values changed from the Delinea scheme to the Apple scheme. However, ownership of files and folders in home directories will still belong to the Delinea UID and GID. To change ownership to the new UID and GID generated by the Apple scheme, run the fixhome.pl script as explained in the following procedure.

To correct file ownership by running fixhome.pl

Note: If you generated new UIDs and GIDs for files that reside remotely in AFP or NFS mounted shares, the fixhome.pl script does not have permission to change UIDs and GIDs in the share, and you must manually update the UIDs and GIDs on the server where the share folders reside. In this scenario, skip to *Workaround for AFP and NFS Mounted Shares* below and continue from there.

For Samba shares and local UIDs and GIDs:

1. Log in on a Mac computer for which you have changed UID and GID values to the Apple scheme.
2. Execute the following command as root:

   /usr/local/share/centrifydc/sbin/fixhome.pl

The script changes ownership of files and folders in the home directory of all Active Directory users from the Delinea-generated UID or GID to the Apple-generated UID or GID.

The script uses /Users as the root for all home directories. You may specify a different home root if necessary by using the --dir option. Use the --help option to see a list of options that you can specify with this command:

```
/usr/local/share/centrifydc/sbin/fixhome.pl --help
```

For example, you can run the command in test mode to see the changes that will be made, but without committing the changes:

```
[root]#/usr/local/share/centrifydc/sbin/fixhome.pl --test

User Home UID Map GID Map

user1 /Users/user1 796918879=>558948313 20=>5287576209
```

Or you could update specific users rather than all users:

```
[root]#/usr/local/share/centrifydc/sbin/fixhome.pl --include user2
```

Workaround for AFP and NFS Mounted Shares

For AFP and NFS mounted share folders (or remote file systems), fixhome.pl does not have permission to change the UID/GID of files in the folder. Perform the

following steps to work around this issue:

1. On the server where the share folders reside, open the UID/GID backup file to have access to the old UID/GID strings.
2. On the server where the share folders reside, change the old UIDs and GIDs to the new UIDs and GIDs one at a time by executing commands similar to the following:

```
find ShareFolder -user previous_uid -group previous_gid -exec chown new_uid:new_gid {} ;
```

To enable the Apple scheme for mobile users:

Additional steps are required to enable the Apple scheme for mobile users. After enabling the Apple scheme as described in the preceding sections, you must ensure that the UID and PGID for the mobile user's local user record match the UID and PGID used by the DirectControl agent.

1. Change the UID and PGID in the local user record so that they match the IDs used by the agent:
    1. Open **Users and Groups**.
    2. Right-click the mobile user account.
    3. Choose **Advanced Options**, and change the UID and PGID so that they match the IDs used by the agent.
2. After changing the UIDs and PGIDs of mobile users, run the fixhome.pl script as described above in *To correct file ownership by running fixhome.pl*.

To use the Zone Provisioning Agent to enable the Apple scheme for generating UIDs and GIDs:

1. Ensure that the Zone Provisioning Agent is configured as described in the section "Configure the Zone Provisioning Agent" in the *Planning and Deployment Guide*.
2. Ensure that zone provisioning groups are created and configured as described in Chapter 8, "Preparing the Environment for Migration of Existing Users and Groups" in the *Planning and Deployment Guide*.
3. Start Access Manager.
4. In the console tree, expand the **Zones** node.
5. Select the top-level parent zone, right-click, then click **Properties**.
6. Click the **Provisioning** tab.
7. Click **Enable auto-provisioning for group profiles**.
8. Click the Find icon to search for and select the primary group (typically the Domain Users group) as the Source Group.
9. Select **Generate using Apple scheme** as the method for assigning a new GID to new UNIX group profiles.

    This method generates group GIDs based on the Apple algorithm for generating numeric identifiers from the Active Directory group's objectGuid. This option is only supported for hierarchical zones.
10. Select a method for assigning a new group name to new UNIX group profiles:
    - **SamAccountName attribute** generates the group name for the new UNIX group profile based on the samAccountName value.
    - **CN attribute** can be used if you verify the common name does not contain spaces or special characters. Otherwise, you should not use this option.
    - **RFC 2307 attribute** can be used if you have added the RFC 2307 groupName attribute to Active Directory group principals. Otherwise, you should not use this option.
    - **Zone default value** to use the setting from the Group Defaults tab for the zone. In most cases, the default is a variable that uses the sAMAccountName attribute.
    - By default, all UNIX group names are lowercase and invalid characters are replaced with underscores.
11. Click **OK** to save your changes.

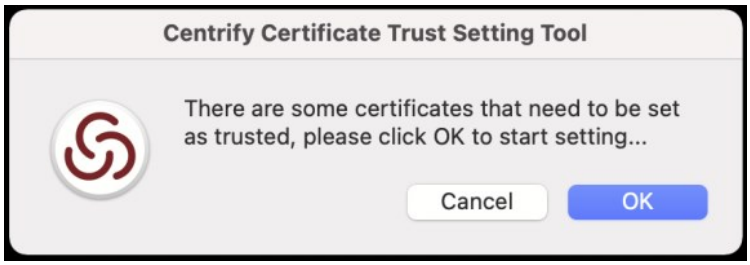
Configuring Auto-Enrollment

Delinea uses the Microsoft Windows certificate auto-enrollment feature to make certificates available to UNIX and Mac computers. If auto-enrollment is enabled, when a UNIX or Mac computer joins a domain, certificates are requested from the Certification Authority based on particular templates, and the certificates are installed on the joined computer

To enable auto-enrollment:

- Enable auto-enrollment for the group policy.
- Create a certificate template with auto-enrollment enabled.

> **Note**: As of MacOS Big Sur (11.0), Apple no longer allows silently adding root certificates to Keychain with a trusted setting. If there are some root certificates installed from your domain by the Delinea Agent, the Delinea Certificate Trust Setting Tool will open automatically. Please follow the instructions to set certificates as trusted.



Configuring 802.1X Wireless Authentication

This section explains how to configure Active Directory and Mac to authenticate Active Directory users by using a Microsoft RADIUS server with the 802.1X PEAP (MSCHAPv2) protocol over a wireless network from a Mac computer.

On Mac OS X, 802.1X wireless authentication does not rely on Delinea Access Manager or Apple's Active Directory plugin but is configured primarily through group policies that apply to the Windows server and the Mac computers.

System Configuration for 802.1X Wireless Authentication

The following table summarizes the environment that is needed for 802.1X wireless authentication:

Windows side	Windows Server 2003 R2 Enterprise Edition Domain Controller (supports PEAP) with Internet Authentication Service (IAS) installed; on Windows server 2003, RADIUS server is part of IAS. or Windows Server 2008 R2 Enterprise Edition Domain Controller (supports PEAP/TLS) with Network Policy Server (NPS) installed; on Windows Server 2008, Radius server is part of NPS.
	Active Directory on the Windows Server
	Group Policy Management Console (GPMC), which is required to configure 802.1x group policies and deploy certificates.
	Certificate Services, which is required to obtain the required certificates.
	Access Manager console 5.1.*x* or later, which is required to set group policies that apply to Mac computer.
Mac side	DirectControl agent 5.0.1-171 or later to enforce group policies on the Mac computer.
Wireless access point device	Supports 802.1x wireless authentication through one of these protocols: * WPA Enterprise WPA2 Enterprise 802.1X WEP (the name can be different, for example, RADIUS)

> **Note**: Although it is possible to configure other RADIUS servers for 802.1X wireless authentication, or use other protocols, this document focuses on the Microsoft RADIUS server and the PEAP and TLS protocols.

These instructions assume that you have a RADIUS server properly configured for 802.1X wireless authentication, so that you can now proceed to configure your Mac environment. For a description of how the RADIUS server must be configured to support 802.1X wireless authentication on Mac OS X, see the section below named *Confirming that Windows Server Supports Certificate Auto-enrollment*. Click a link if you have questions about whether your RADIUS server is configured properly with regard to any particular item:

Of course, there are other configuration steps that are required to set up a RADIUS server, such as configuring the RADIUS client and configuring a remote access policy, however, the important consideration for Mac 802.1X authentication is that the specified certificate and private key have been created and deployed to the domain. When a Mac computer joins a Windows domain, Access Manager automatically finds certificates on the Domain Controller and adds them as trusted certificates to Keychain Access on the Mac computer.

Once you are certain that the RADIUS server is properly configured, you can configure your Mac environment; see the following section for instructions on configuring OS X 10.7 or later.

Configuring Mac OS X 10.7 or Later for 802.1X Wireless Authentication

Mac OS X 10.7 changed the way to create and manage profiles such that configuring 802.1X wireless authentication varies significantly between 10.7 and earlier versions of OS X. This section explains how to configure a Mac OS X 10.7 or later computer for 802.1X wireless authentication.

Before configuring your Mac environment, be certain that the RADIUS server is configured as described above in the section, *System Configuration for 802.1X Wireless Authentication*. This configuration includes a domain root CA certificate or RAS/IAS server certificate, as well as a private key that are required to be trusted on the Mac computer.

However, there are no manual steps that you must perform to trust these certificates on your Mac computers. As mentioned previously, when a computer is joined to a domain, Access Manager automatically looks for certificates on the domain controller, and adds these certificates and the private key to the system Keychain on the Mac computer.

Through group policy settings you can use these certificates to create two different types of system profiles

- To create a system profile that allows users to authenticate to an 802.1X-protected ethernet network, see the next procedure, *To configure Mac OS X 10.7 or Later to Create an 802.1X Ethernet Profile*.
- To create a system profile that allows users to authenticate to an 802.1X wireless network, see the procedure further down, *To configure Mac OS X 10.7 or Later to Create an 802.1X WiFi Profile*.

The certificate template — as well as a certificate chain file and private key — are pushed to `/var/Centrify/net/certs` on the Mac computer when it joins the domain. Before you configure the group policy for the Mac computer, if you want to verify that auto-enrollment is operating correctly, you can open a Terminal window on the Mac computer and run a command similar to the following to check that the certificate has been downloaded to the computer:

```
admin$ls /var/Centrify/net/certs |grep -i auto_
...
auto_TemplateName.cert
auto_TemplateName.chain
auto_TemplateName.key
```

You should see three `auto_` files as shown in the example.

To configure Mac OS X 10.7 or later to create an 802.1X Ethernet profile

1. On a Windows computer, open the Group Policy Management Editor and edit a group policy object that applies to Mac computers.
2. Expand **Computer Configuration > Policies > User Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Settings**, and double-click **Enable Ethernet Profile**.
3. Select **Enable**, then click **Add**.
4. Type the name of the auto-enrollment machine certificate that has been pushed down from the Windows domain server.

   When pushed to a Mac computer, certificate names are prepended with `auto_`; for example:

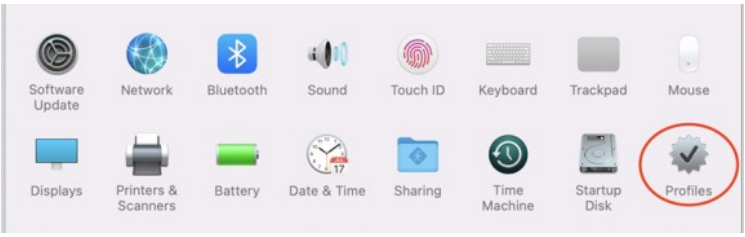
   ```
   auth_Centrify-1X
   ```

   This group policy runs a script that looks for the specified certificate template in the /var/Centrify/net/certs directory (which contains the certificate templates pushed down to Mac when they join the domain) and creates a WiFi profile from this certificate.
5. Click **OK** to save the profile information and **OK** again to save the policy setting.

   Note: This group policy will take effect at the next group policy update interval, or you can run `adgpupdate` in a terminal window on the Mac computer to have the policy take effect immediately.

When the group policy takes effect, it runs a script to create an ethernet profile for the computer from the certificate template and private key downloaded from the domain controller. This policy supports the TLS protocol for certificate-based authentication. The Mac computer is now configured for access to the radius access point.

On the Mac computer you can view the profile in System Preferences.



To configure Mac OS X 10.7 or later to create an 802.1X WiFi profile

1. On a Windows computer, open the Group Policy Management Editor and edit a group policy object that applies to Mac computers.
2. Expand **Computer Configuration › Policies › User Configuration › Policies › Centrify Settings › Mac OS X Settings › 802.1X Settings**, and double-click **Enable Wi-Fi Profile**.
3. Select **Enable**, then click **Add**.
4. Enter the following information for the Wi-Fi profile:

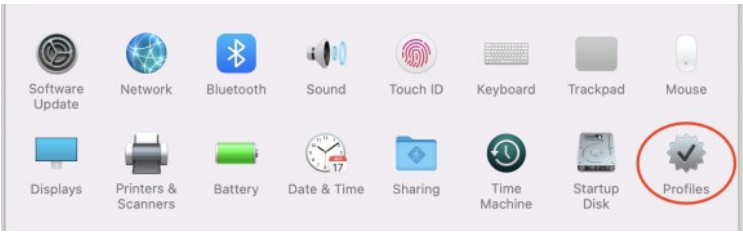
SSID	Type the SSID for the wireless network.
Template name	Type the name of the auto-enrollment machine certificate that has been pushed down from the Windows domain server. When pushed to a Mac computer, certificate names are prepended with auto_; for example: auth_Centrify-1X This group policy runs a script that looks for the specified certificate template in the /var/Centrify/net/certs directory (which contains the certificate templates pushed down from the domain controller) and creates an ethernet profile from this certificate.
Security type	Select the Security type from the drop-down list.
Other options	Select one or more of the following options: **Auto join**: Select this option to specify that the computer automatically join a Wi-Fi network that it recognizes. Do not select this option to specify that the logged in user must manually join a Wi-Fi network. **Hidden network**: Select this option if the Wi-Fi network does not broadcast its SSID.

1. Click **OK** to save the profile information and **OK** again to save the policy setting.

   Note: This group policy will take effect at the next group policy update interval, or you can run adgpupdate in a Terminal window on the Mac computer to have the policy take effect immediately.

When the group policy takes effect, it runs a script to create a WiFi profile for the computer from the certificate template and private key downloaded from the domain controller. This policy supports WEP or WPA/WPA2 security with the TLS protocol for certificate-based authentication. The Mac computer is now configured for access to the radius access point.

On the Mac computer you can view the profile in System Preferences.



Confirming that Windows Server Supports Certificate Auto-enrollment

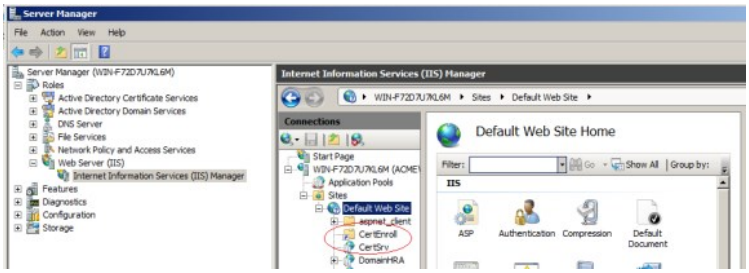
This section describes how the RADIUS server must be configured to support 802.1X wireless configuration for Mac computers.

Internet Information Services (IIS) Supports CertEnroll and CertSrv URLs

IIS must support the CertEnroll and CertSrv URLs to enable web-based access to certificate tasks.

To verify that Iis supports the CertEnroll and CertSrv URLs

1. On the Windows Certificate Authority server, click **Start > Administrative Tools > Server Manager** to open Server Manager.
2. Expand **Roles > Web Server (IIS)** and click **Internet Information Services (IIS) Manager**.
3. In the right, **Connections** pane, expand **Sites > Default Web Site** and you should see CertEnroll and CertSrv:



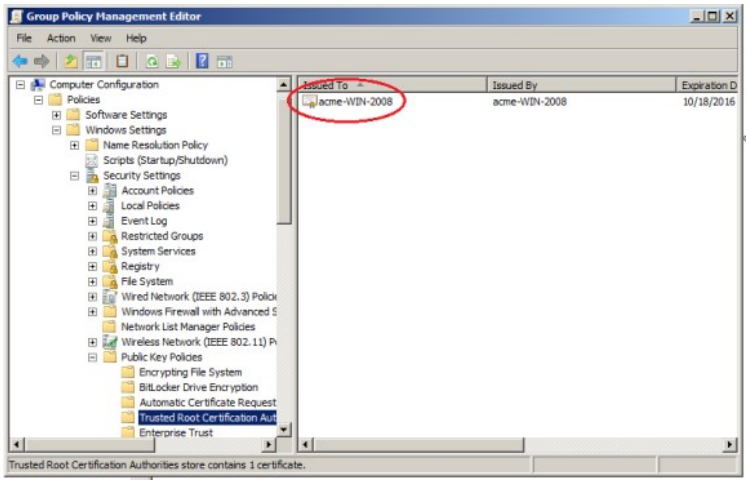
Windows Public Key Group Policies are Set to Trust the Root Certificate Authority and Enroll Certificates Automatically

Through group policy settings, the root certificate must be imported into the Trusted Root Certification Authorities group policy and set to enroll certificates automatically.

To verify that Windows public key group policies are set to trust the root certificate authority and enroll certificates automatically

1. On the Windows Certificate Authority server, click **Start > Administrative Tools > Server Manager** to open the Group Policy Management Editor.
2. Expand **Computer Configuration > Policies > Windows Settings > Security Settings > Public Key Policies** and select **Trusted Root Certification Authorities**.

   You should see your root certificate:



3. Expand **Computer Configuration > Policies > Windows Settings > Security Settings > Public Key Policies** and double-click **Certificate Services Client - Auto-Enrollment**.

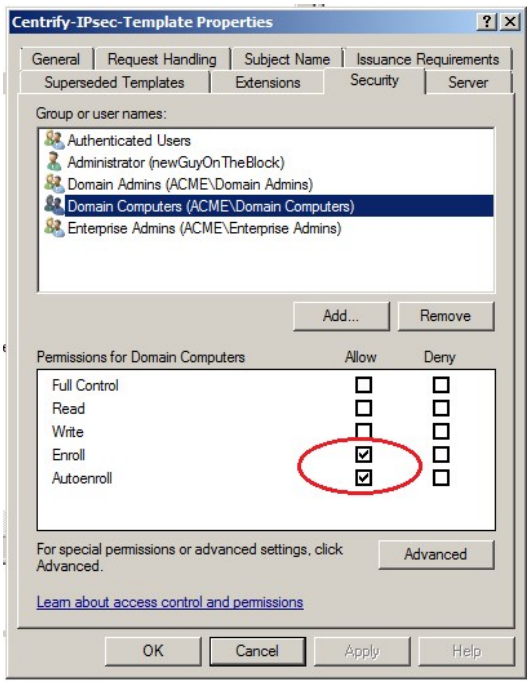
4. In **Configuration Model** select **Enabled**.
5. Select both boxes, **Renew expired certificates** and **Update certificates that use certificate templates**.
6. Click **OK** to save the policy.

A Certificate Template is Configured to Automatically Enroll Domain Computers

To automatically enroll domain computers, you must have a certificate template that supports auto-enrollment for domain computers.

To configure a certificate template to automatically enroll domain computers

1. On the Windows Certificate Authority server, open an mmc console that contains the Certification Authority and Certificates snap-ins (**Start > Run >** mmc.exe).
2. If snap-ins for Certificate Templates, Certificates, and Certifications Authority are not displayed under Console Root in the navigation pane, add them now. To do so, click **File > Add/Remove Snap-in**.
    1. Select **Certificate Templates** and click **Add**.
    2. Click **Certificates** and click **Add**.
    3. Select **Computer Account** and click **Next**.
    4. Select **Local computer** and click **Finish**.
    5. Select **Certification Authority** and click **Add**.
    6. Select **Local computer** and click **Finish**.
    7. Click **OK**.
3. Select **Certificate Templates (domainController)** in the navigation pane.
4. In **Certificate Templates**, duplicate the Workstation Authentication certificate. Right-click **Workstation Authentication** and select **All Tasks > Duplicate Template**.
5. Perform the following steps in the **Properties of New Template** dialog:
    1. In the **General** tab, type a template name of your choice (for example, **Mac Auto-Enroll Certificates**) in the **Template name** field (do not use special characters such as brackets and asterisks). Type the same name in the **Template display name** field so that the template displays by that name in the Certificate Templates list.
    2. In the **Extensions** tab, select **Application Policies > Edit**. In the resulting dialog, select **Add > Server Authentication** and click **OK**.
    3. In the **Extensions** tab, verify the **Client Authentication** is already in the application policy list. If it is not, add it in the same way that you added the **Server Authentication** policy.
    4. In the **Subject Name** tab, select **Build from this Active Directory information**. In the **Subject name format** field, select **Fully distinguished name**. In the **Include this information in alternate subject name** list, select **User Principle Name (UPN)**.
    5. In the **Security** tab, select **Domain Computers (domainController)** and ensure that the template is enabled for Enroll and Autoenroll.



6. Click **Apply** and **OK** to save your settings.

6. Verify that the new template has been added to the certification authority.

   Expand **Console Root > Certification Authority > domainController** and select **Certificate Templates**. You should see that the certificate template that you have configured for auto-enrollment is contained in the certification authority for the domain:

   If the new certificate template is not contained in the certification authority, add it now:

   1. In the navigation pane, right-click **Certification Templates** under **Console Root > Certification Authority >** domainController.
   2. Select **New > Certificate Template to Issue**.
   3. Scroll to the newly created template, select it, and click **OK**.

7. Enable the following group policy:

   - On Windows 2008: **Computer configuration > Policies > Windows Settings > Security Settings > Public Key Policies > Certificate Services Client - Auto-Enrollment Settings**.
   - On Windows 2012: **Computer configuration > Policies > Windows Settings > Security Settings > Public Key Policies > Certificate Services Client - Auto-Enrollment**

     Note: To enable a group policy, open the Group Policy Management console by selecting **Start > Administrative Tools > Group Policy Management**. In the Group Policy Management console navigation pane, expand **Group Policy Management >**

ForestName > **Domains** > DomainName > **Group Policy Objects**. Right-click **Default Domain Policy** and select **Edit**. In the resulting Group Policy Management Editor, navigate to the group policy described above and double-click the group policy. In the resulting dialog, select **Enabled** in the **Configuration Model** field.

8. On the Mac computer, download the certificates by executing the following commands in a terminal window:

   ```
   sudo adflush
   ```

   ```
   adgpupdate
   ```

9. Verify that the certificates were downloaded:

   1. On the Mac computer, open Keychain Access and verify that the certificates are there.
   2. On the Mac computer, verify that the certificates are in /var/Centrify/net/certs.
   3. On the Windows Certificate Authority server, open the Certification Authority console (**Start** > **Run** > certsrv.msc) and verify that the certificates are in the **Issued Certificates** folder.

A Certificate Template is Configured to Automatically Enroll Domain Users

To automatically enroll domain users, you must have a certificate template that supports auto-enrollment for domain users.

To configure a certificate template to automatically enroll domain users

1. On the Windows Certificate Authority server, open an mmc console that contains the Certification Authority and Certificates snap-ins (**Start** > **Run** > mmc.exe).
2. Verify that the snap-ins described in Step 2 are present under Console Root in the navigation pane. If they are not, add them now as described in Step 2.
3. Select **Certificate Templates (domainController)** in the navigation pane.
4. In **Certificate Templates**, duplicate the User certificate. Right-click **User** and select **All Tasks** > **Duplicate Template**.
5. Perform the following steps in the **Properties of New Template** dialog:
   1. In the **General** tab, type a template name in the **Template name** field. Type the same name in the **Template display name** field so that the template displays by that name in the Certificate Templates list. For Mac, you can specify a name of your choice (do not use special characters such as brackets and asterisks). For mobile devices, the template name *must* be **User-ClientAuth**.
   2. In the **Security** tab, select **Domain Users (domainController)** and ensure that the template is enabled for Enroll and Autoenroll.
   3. Optionally, in the **Subject Name** tab, select **Build from this Active Directory information**. De-select the **Include email in subject name** and **E-mail name** check boxes. If you perform this step, Active Directory users do not need an email address.
6. Verify that the new template has been added to the certification authority as described in Step 6. If the new certificate template is not contained in the certification authority, add it now as described in Step 6.
7. Enable the following group policy:
   - On Windows 2008: **Computer configuration** > **Windows Settings** > **Security Settings** > **Public Key Policies** > **Certificate Services Client - Auto-Enrollment Settings**.
   - On Windows 2012: **Computer configuration** > **Windows Settings** > **Security Settings** > **Public Key Policies** > **Certificate Services Client - Auto-Enrollment**.

     Note: See Step 7 for details about how to enable the group policy.
8. On the Mac computer, download the certificates by executing the following commands in a terminal window.

   As the local Administrator:

   ```
   sudo adflush
   ```

   As an Active Directory user:

   ```
   adgpupdate
   ```

9. Verify that the certificates were downloaded:

1. On the Mac computer, open Keychain Access and verify that the certificates are in the Login keychain.
2. On the Mac computer, verify that the certificates are in ~/.centrify/:

```
ls -l ~./centrify/
```

Configuring Single Sign-On for SSH and Screen Sharing

On OS X 10.10 and later, you can change configuration settings to allow single sign-on for SSH and Screen Sharing using Kerberos. Kerberos authorization for SSH and Screen Sharing allows you to establish an SSH or Screen Sharing connection to configured target machines joined to the same domain within the same single sign-on (SSO) session. In addition to authorizing SSH or Screen Sharing for the currently logged in user, you can authorize SSH or Screen Sharing for a different smart card user (for example, an admin user) by obtaining that user's Kerberos credentials.

To configure SSH SSO

Note: Smart card authentication for SSH sessions across different forests or domains is not supported.

1. Verify that all client and target machines are joined to the same AD domain.

   See **Joining an Active Directory Domain** for more information.

2. Enable GSSAPIAuthentication and GSSAPIDelegateCredentials in the /etc/ssh/ssh_config (/etc/ssh_config on OS X 10.10) file on both the client and target machine.

   ```
   GSSAPIAuthentication yes

   GSSAPIDelegateCredentials yes
   ```

3. Enable GSSAPIAuthentication and GSSAPIKeyExchange in the /etc/ssh/sshd_config (/etc/sshd_config on OS X 10.10) file on both the client and target machine.

   ```
   GSSAPIAuthentication yes

   GSSAPIKeyExchange yes
   ```

   Note: As of macOS 10.12, Apple's built-in ssh server no longer supports as the target machine. You can still use SSH SSO to login to other server machines, such as Linux/UNIX machines.

4. Enable adclient.krb5.autoedit on the target machine.

   The easiest way to do this is enabling the **DirectControl Settings > Kerberos Settings > Manage Kerberos configuration** group policy.

5. Restart Delinea Management Services on the target machine.

   ```
   $ sudo /usr/local/share/centrifydc/bin/centrifydc restart
   ```

   The logged in user can now open SSH connections to the target machine using a FQDN.

   ```
   $ ssh hostname.domainname
   ```

To configure Screen Sharing SSO

Note: Single sign-on for Screen Sharing requires Mac OS X 10.11 or higher.

1. Verify that both the client and target machines are updated to at least Delinea Management Services 5.3.1.

   ```
   $ adinfo -v

   adinfo (CentrifyDC 5.3.1-xxx)
   ```

   If an update is necessary, refer to Upgrading the Delinea DirectControl Agent for Mac for instructions and best practices.

2. Open **System Preferences > Sharing**, then select **Screen Sharing** and specify which users can initiate Screen Sharing sessions in the **Allow access for:** list.

Note: Only Screen Sharing supports SSO, as Remote Management can not allow access for network users.

The logged in user can now open Screen Sharing connections to the target machine using a FQDN.

```
$ open vnc://hostname.domainname
```

To obtain Kerberos credentials for a smart card user for SSH or Screen Sharing SSO

1. Complete all the steps in **To Configure SSH SSO** and **To Configure Screen Sharing SSO** above.
2. Insert the user's smart card into the reader.
3. Obtain Kerberos credentials from the smart card currently in the reader and use those credentials to authorize SSH.

   For multi-user PIV cards or multi-user smart cards:

   ```
   $ /usr/local/bin/sctool -a unixName
   ```

   For all other smart cards:

   ```
   $ /usr/local/bin/sctool -k userPrincipalName
   ```

   Refer to **Understanding sctool** for more information about the sctool `-a` and `-k` options.

   After unlocking the smart card, you can now open SSH or Screen Sharing connections to the target machine using the obtained Kerberos credentials.

Configuring FileVault 2

FileVault 2, available in OS X 10.8 and later, allows encryption of an entire drive to keep data secure. Although you can enable FileVault 2 through System Preferences on your Mac computers, using Delinea Management Services for Mac to configure FileVault 2 through group policy provides the advantage of creating an institutional recovery key for each of your Mac computers. Two different recovery key approaches—institutional and personal—guarantee that you will always have access to all of your encrypted computers, even if users forget their passwords.

For more information about FileVault 2, see the following Apple Knowledge Base article: "OS X: About FileVault 2".

How Filevault2 Protection Is Enabled by Delinea

Delinea relies on two features to enable FileVault 2 protection

- The "Managed By" user setting, which specifies an Active Directory user who can manage and unlock an encrypted disk.

  You specify the "Managed By" user in Active Directory Users and Computers on the domain controller. The "Managed By" user is associated with the Mac computer object, so it is possible for each computer to have its own "Managed By" user.

- The FileVault recovery key, which can be either one "institutional" key that is applied to multiple Mac computers, or computer-specific keys which are generated individually for each Mac computer.
  - If you choose to use one institutional key, you first create a FileVaultMaster certificate, which is applied to Mac computers through the Enable FileVault 2 group policy.

    When you enable the Enable FileVault 2 group policy, the FileVaultMaster certificate is applied to Mac computers automatically at the next scheduled group policy update interval. Or, you can apply the FileVaultMaster certificate immediately by executing the adgpupdate command.

  - If you choose to use computer-specific keys that are unique to each Mac computer, you do not create a FileVaultMaster certificate.

Instead, the key is generated automatically when the “Managed By” user logs into the Mac computer for the first time and then logs out. The key, which is the “Managed By” user’s personal key, is then stored in the computer’s computer object in Active Directory.

>**Note**: Enabling the Enable FileVault 2 group policy does not enable FileVault 2 protection on the Mac computers to which the group policy is applied. Instead, FileVault 2 protection is enabled on Mac computers as described in the remainder of this section.

The following list describes the overall process that results in FileVault 2 protection being enabled on a Mac computer.

1. The “Managed By” user is set in ADUC for one or more Mac computers.
2. The Enable FileVault 2 group policy is enabled.
   - If you select the **Use Institutional Recovery Key** option in the group policy, the FileVaultMaster certificate is applied to Mac computers. In this situation, all of the Mac computers to which the group policy was applied use the same key.
   - If you did not select the **Use Institutional Recovery Key** option in the group policy, a recovery key is not generated until the “Managed By” user logs into a Mac computer.
3. A user logs into a Mac computer. If FileVault 2 protection is not already enabled on the computer, the user’s Active Directory credentials are checked to verify that the user is the “Managed By” user. For this step to complete successfully, one of the following conditions must exist:
   - The Mac computer must be able to communicate with the domain controller (that is, it must be in connected mode), or
   - If the Mac computer is disconnected from the domain controller, locally cached AD user credentials must be available in the Delinea cache.
4. When the user is verified to be the “Managed By” user, one of the following actions takes place:
   - If you selected the **Use Institutional Recovery Key** option in the Enable FileVault 2 group policy, the FileVaultMaster certificate data is used to enable FileVault 2 protection on the computer.
   - If you did not select the **Use Institutional Recovery Key** option in the Enable FileVault 2 group policy, a personal recovery key is created for the computer and stored in the computer object in Active Directory. The personal recovery key is used to enable FileVault2 protection on the computer.

FileVault 2 Configuration Overview

Configuring a Mac computer for FileVault 2 protection requires configuration steps on both the Mac computer and the domain controller (or any Windows computer on which you can configure Group Policy on the domain controller). The following is a list of the major steps in the process, with links to each procedure that you must complete.

1. Create FileVault master keychain. The master keychain contains a private key that can be used to unlock the encrypted disk.

   Note: This step is required only if you are using one institutional key for multiple Mac computers. If you are using computer-specific (“personal”) keys, go to Step 4.

2. Export certificate from FileVault master keychain and upload it to a domain server. Uploading the certificate to a domain server allows you to select it when you enable the “FileVault 2” group policy.

   Note: This step is required only if you are using one institutional key for multiple Mac computers. If you are using computer-specific (“personal”) keys, go to Step 4.

3. Enable BitLocker Recovery Password Viewer in Active Directory.

   This step is required only if you are using computer-specific (“personal”) keys. If you are using one institutional key for multiple Mac computers, go to Step 4.

4. Assign an Active Directory user who is authorized to manage an encrypted disk. FileVault 2 requires that you specify one or more “Managed By” users who can manage the encrypted disk, including the ability to lock and unlock it.

5. Enable the Enable FileVault 2 group policy. Enabling the “FileVault 2” group policy applies the FileVaultMaster certificate to Mac computers.

6. Set up and verify FileVault 2 protection. After FileVault 2 protection is enabled, the disk encryption process begins after the FileVault-authorized user logs off the computer.

Before You Begin Configuring Filevault 2

Be aware of the following requirements and limitations when configuring FileVault 2 through Delinea group policy:

- The Mac computer must be running OS X 10.9 or above.
- The Mac computer must have a recovery partition — generally, this partition is created by default during Mac OS X or macOS installation.
- FileVault 2 must *not* be enabled on the Mac computer (through the Security & Privacy System Preference).

If it is already configured, configuring FileVault 2 through Delinea Management Services for Mac will have no effect.

- Enabling FileVault 2 protection disables auto log on for the Mac computer.
- FileVault 2 protection does not support smart card authentication at start up of the computer.

  The Apple technical white paper, "Best Practices for Deploying FileVault2" provides more information about using FileVault 2; specifically, the section "Two Factor Authentication" discusses the limitations of using FileVault 2 with alternate authentication methods such as smart cards.

Create Filevault Master Keychain

The procedure described in this section is required only if you are using one institutional key for multiple Mac computers. If you are using computer-specific ("personal") keys, go to the section below, **Assign an Active Directory User Who is Authorized to Manage an Encrypted Disk**.

On the Mac computer, you create a FileVault master keychain, which contains a private key that can be used to unlock the encrypted drive on the computer.

You can create the master keychain through the Mac user interface, or by executing commands in the Terminal application. Instructions are provided for each procedure.

> **Note**: If the computer already has a FileVault master keychain, you can skip this procedure and go to Export certificate from FileVault master keychain and upload it to a domain server.

To create a master keychain through the user interface

1. On a computer running OS X 10.9 or above, log on with an administrator's account and open **System Preferences**, then double-click **Users & Groups**.
2. If necessary, click the lock icon and enter credentials to authenticate.
3. Select an administrator's account, then click the service icon (⚙) and select **Set Master Password** from the pop-up menu.

4. Create a master password by typing it in **Master password** and re-typing in **Verify**.
5. Click **OK** to save the master password.

Setting a master password creates a keychain file in the following location:

/Library/Keychains/FileVaultMaster.keychain

This file contains the private key required to unlock the encrypted disc and is the only recovery method you will have for encrypted disc recovery. Store FileVaultMaster.keychain in a safe location, such as an external drive or an encrypted disk image on another physical disk.

To create a master keychain by executing commands in the Terminal application

1. On a Mac computer, open the Terminal application.
2. Run the following command:

   sudo security create-filevaultmaster-keychain
3. Enter the password for the root account when prompted as follows:

   To proceed, enter your password or type Ctrl-C to abort
4. Enter the master password to create when prompted to do so:

   password for new keychain
5. Retype the new master password when prompted to do so:

   retype password for new keychain

   You will see a message that the new password is being created:

   Generating a 2048 bit key pair; ...

Setting a master password creates a keychain file in the following location:

/Library/Keychains/FileVaultMaster.keychain

This file contains the private key required to unlock the encrypted disc and is the only recovery method you will have for encrypted disc recovery. Store FileVaultMaster.keychain in a safe location, such as an external drive or an encrypted disk image on another physical disk.

Export Certificate from Filevault Master Keychain and Upload it to a Domain Server

The procedure described in this section is required only if you are using one institutional key for multiple Mac computers. If you are using computer-specific ("personal") keys, go to the section below **Assign an Active Directory User Who is Authorized to Manage an Encrypted Disk**.

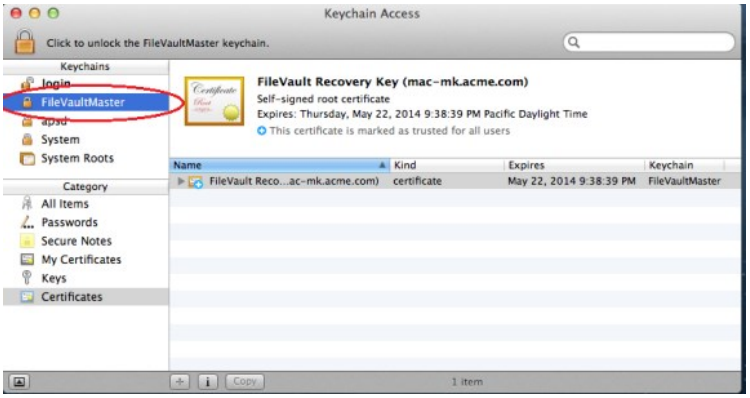
After you create a master password, as explained in the previous section, you must export the certificate associated with the master keychain to make it available for upload to the domain controller.

You can export the certificate by using the Mac user interface, or by executing commands in the Terminal application. Instructions are provided for each procedure.

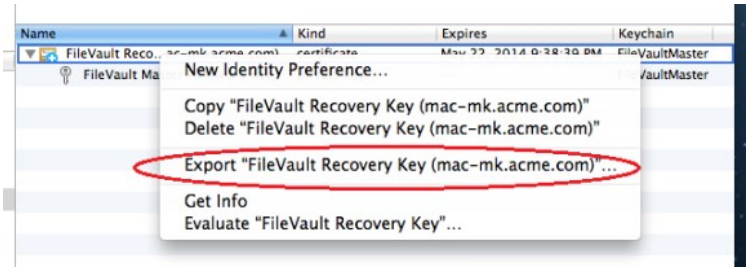
To export the certificate by using the Keychain Access utility

1. On the Mac computer, open the Keychain Access utility, or double-click the FileVaultMaster.keychain file, which is at the following location:

   /Library/Keychains/FileVaultMaster.keychain
2. Enter you password if prompted to do so.
3. In **Keychains**, select **FileVaultMaster**.



4. Select the certificate, **FileVault Recovery Key** in the right pane and expand it; then right-click and select **Export "FileVault Recovery Key"**.



5. Enter the following information for saving the certificate:

   - **Save As**: Type a name for the certificate, such as "FileVaultMasterCert".
   - **Where**: Navigate to a folder in which to save the certificate.
   - **File Format**: Select **Certificate (.cer)** from the scroll-down list.

     The certificate is now available for upload to a domain controller.

6. Copy the certificate to a location on a server that is accessible from the computer that you use to configure Group Policy for the domain.

   Later, when you enable the group policy to turn on FileVault 2 protection (see **Enable the Enable FileVault 2 Group Policy** below), you must be able to access this certificate from the domain controller on which you are running the Group Policy Editor.

To export the certificate by using Terminal commands

1. On the Mac computer, open the Terminal utility application.
2. Run the following command:

   ```
   sudo security export -k /PathToKeychain -t certs -f x509 -o /PathToCert
   ```

   Note: The sudo command is required only if FileVaultMaster.keychain is owned by root.

where:

- *PathToKeychain* is the path to FileVaultMaster.keychain; for example:

  /Library/Keychains/FileVaultMaster.keychain

- *PathToCert* is the path to the location in which to export the certificate; for example:

  /Documents/FileVaultMaster.cer

The certificate is now available for upload to a domain controller.

1. Copy the certificate to a location on a server that is accessible from the computer that you are using to configure Group Policy for the domain.

   Later, when you enable the group policy to turn on FileVault 2 protection (see **Enable the Enable FileVault 2 Group Policy** below), you must be able to access this certificate from the domain controller on which you are running the Group Policy Editor.

Enable Bitlocker Recovery Password Viewer in Active Directory

The procedure described in this section is required only if you are using computer-specific ("personal") keys. If you are using one institutional key for multiple Mac computers, go to **Assign an Active Directory User Who is Authorized to Manage an Encrypted Disk**, below.

To enable the BitLocker Recovery Password Viewer feature in Active Directory

1. On the domain controller, open **Administrative Tools > Server Manager**.
2. In the navigation pane, right-click **Features** and select **Add Features**.
3. In the Add Features wizard, expand **Remote Server Administration Tools > Feature Administration Tools**, select **BitLocker Drive Encryption Administration Utilities**, click **Next**, and click **Install**.
4. After the BitLocker Drive Encryption Administration Utilities are installed, click **Close**.
5. To verify that the BitLocker Drive Encryption Administration Utilities are installed:
   1. Open Active Directory Users and Computers.
   2. Navigate to **domaincontroller > Domain Controllers**.
   3. In the right-hand ADUC pane, right-click the domain controller and select **Properties**.
   4. If the BitLocker Drive Encryption Administration Utilities installed correctly, the Properties dialog contains a **Bitlocker Recovery** tab. On that tab, a "No items in this view" message displays. That message is normal, and does not indicate a problem with the BitLocker Drive Encryption Administration Utilities installation.

Assign an Active Directory User Who is Authorized to Manage an Encrypted Disk

Before enabling FileVault 2, you must assign a user account that is able to open the disk for the Mac computer after it is encrypted by FileVault 2. This setting specifies the "Managed By" user for a computer.

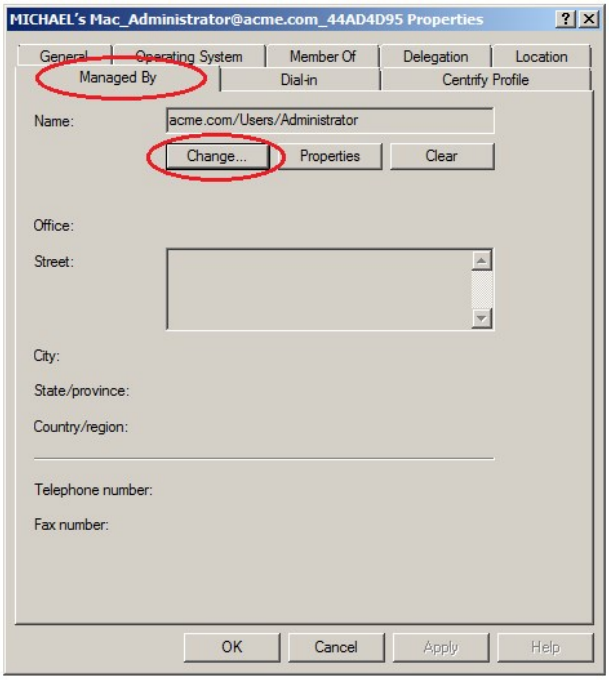
> **Note**: Enabling the "FileVault2" group policy, as explained in the next section, encrypts the entire disk for the computer. The user account that you assign in the current procedure will be authorized to access the disk during boot up so that this account will be able to log on. You can later add other accounts, but for now, this is the only account that will be able to log on to this computer.

The "Managed By" user account must be an Active Directory mobile user account. Configuring a Portable Home Directory for information about the steps you must take to create a mobile user account.

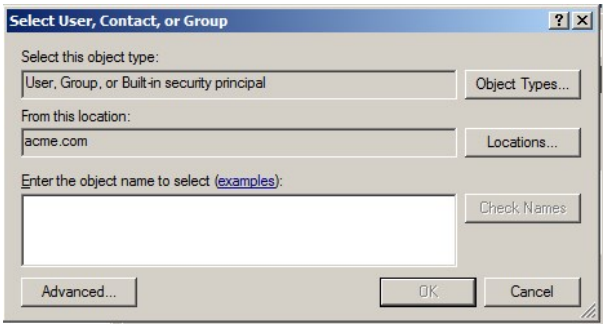
> **Note**: After you enable a user account to open an encrypted disk at start up, you cannot remove that account from the list. If you no longer want this user account to be able to unlock the disk, you can delete the account from Active Directory. Before doing so, be certain that you have at least one other account that can unlock the hard disk on this computer, otherwise you will no longer be able to access this computer.

To assign an account that can unlock the encrypted disk

1. On a domain controller, open Active Directory Users and Computers
2. Expand the domain object and navigate to the container that contains the Mac computer, for example, **Computers**.
3. Select the Mac computer that you plan to encrypt, right-click and select **Properties**.
4. Click the **Managed By** tab.



5. Click **Change**.
6. Enter the all or part of the name to search for (make certain that **User** is selected in **Object Type**) and click Check Names.



7. If the name is correct, click **OK** then **OK** again to save your changes.

Enable the Enable Filevault 2 Group Policy

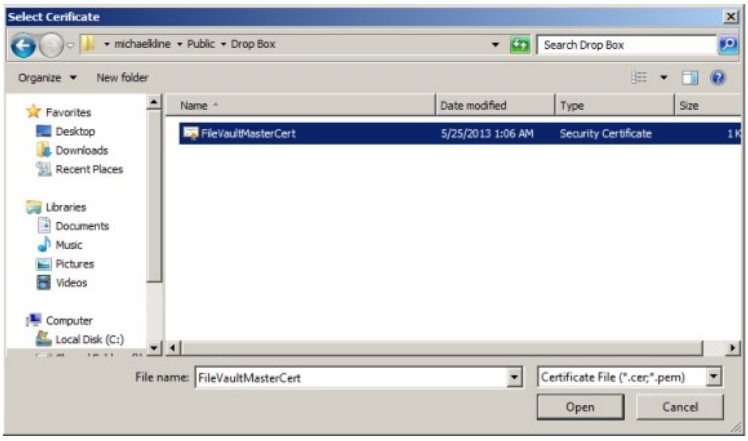
Next, enable the "Enable FileVault 2" group policy to encrypt the disk. When you enable this group policy, you select whether to use one institutional key for multiple Mac computers, or computer-specific ("personal") keys.

To enable the Enable FileVault 2 group policy

1. On a Windows computer, open the Group Policy Management Editor.
2. Select a Group Policy Object that applies to the Mac computer you are planning to encrypt, then right-click and select **Edit**.
3. Open **Computer Configuration > User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy**, then double-click **Enable FileVault 2**.
4. Click **Enable**.
5. Specify whether to use one institutional key for multiple Mac computers, or computer-specific ("personal") keys:

- To use one institutional key for multiple Mac computers, select **Use Institutional Recovery Key**. Then click **Select** to select the FileVault keychain certificate that you created earlier as described above in **Create FileVault Master Keychain**. If you select this option, the FileVaultMaster certificate is distributed to all of the Mac computers to which the group policy applies. Go to Step 6 and continue from there.
- To use computer-specific ("personal") keys, leave **Use Institutional Recovery Key** unchecked. In this situation, a personal recovery key is created for the Mac computer and stored in the computer object in Active Directory. The key is created and sent to the computer object in Active Directory after the "Managed By" user reboots the Mac computer (or restarts the agent), logs in, logs out, and provides the user password as described below in **Set Up and Verify FileVault 2 Protection**. The personal recovery key is used to enable FileVault2 protection on the Mac computer. Go to Step 8 and continue from there.

6. In the Explorer dialogue, navigate to the folder in which you uploaded the certificate.
7. Select the certificate and click **Open**.



8. Click **OK** to enable the group policy.

   This group policy will automatically take effect at the next group policy update interval. To have it take effect immediately, run the following command in the Terminal application on the Mac computer:

   ```
   adgpudate
   ```

   If you selected **Use Institutional Recovery Key** in Step 5, the FileVaultMaster certificate name, a thumbnail, and the expiration date are displayed in the Group Policy.

   Note: The expiration date is not important because OS X does no revocation checking on this certificate.

The selected certificate should have the following usages: “Digital Signature”, “Key Encipherment”, “Data Encipherment” and “Key Certificate Sign”. If the certificate does not have these usages, an error message will appear:

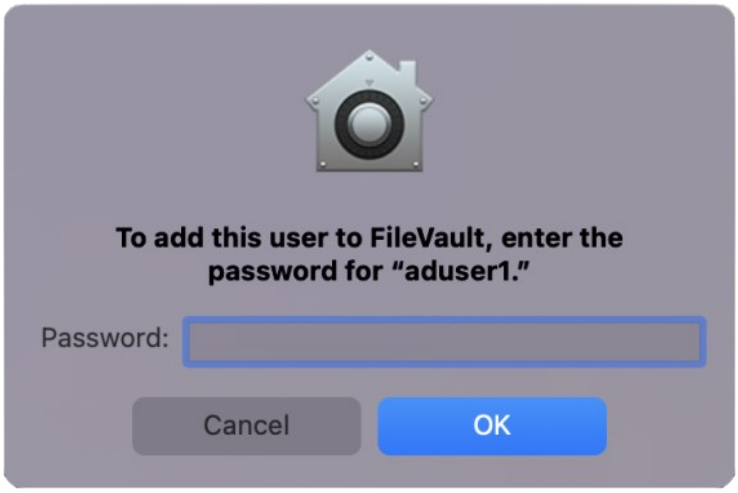
Set Up and Verify Filevault 2 Protection

FileVault 2 protects a Mac computer by encrypting the entire hard drive when a FileVault-authorized user (the “Managed By” user) logs out. To set up FileVault 2 for the first time, you must log on to the Mac computer as the “Managed By” user, then log out, as explained in the following procedure. After FileVault 2 is set up, only a FileVault 2-authorized user may start up the Mac computer. You may add more authorized users if you wish, or maintain a single account.

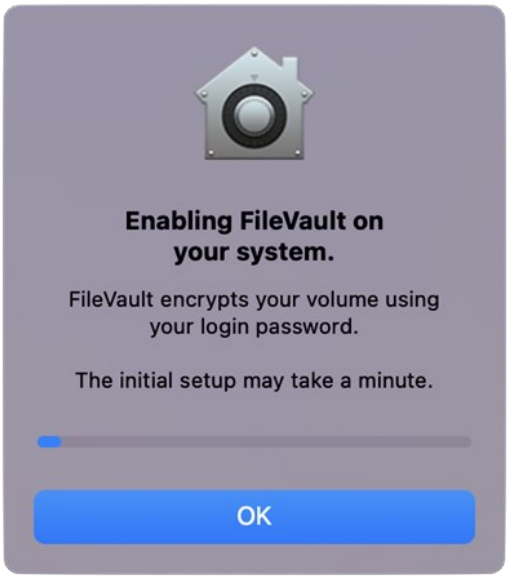
> **Note**: Although starting up the Mac computer requires a user account that is authorized to decrypt the start up disk, after the computer has started, this user account may log out to allow other user accounts to log in.

To set up FileVault 2 protection

1. Log on to the Mac computer with the “Managed By” account that you specified above in **Assign an Active Directory User Who is Authorized to Manage an Encrypted Disk**.
2. Log the “Managed By” user out of the Mac computer, and when prompted, enter the user’s password to set up FileVault 2 protection.



The system displays a message that it is enabling FileVault protection, and when finished, restarts the computer.



3. Log back on to the Mac computer with the "Managed By" account.

   The log on screen will show the FileVault 2-authorized user alone, because this is the only user authorized to open the start up disk.

4. Open **System Preferences**, click **Security & Privacy** and click the **FileVault** tab to verify details about FileVault protection.

5. Log out the FileVault-authorized user.

   The log on screen now shows all users who are authorized for the computer.

A FileVault-authorized user is always required to start up the computer because the start up disk is encrypted. However, after the computer is running, any authorized user can log on to the computer. At this point, you have specified a single authorized account. To add more FileVault-authorized users, see the next section, **Adding FileVault-Authorized Users**.

Adding Filevault-Authorized Users

You can assign only one user as the "Managed By" user for the computer in Active Directory. If you want to authorize additional users to manage FileVault 2 protection, you must do so on the Mac computer by performing either one of the following procedures.

To authorize FileVault 2 users by using System Preferences

1. On the Mac computer, open **System Preferences > Security & Privacy**.
2. Click the **FileVault** tab, and if necessary, unlock the padlock.
3. Click the **Enable Users** button and an account list pops up.
4. Click **Enable Users** to add and enter password of that user.

To authorize FileVault 2 users by using Terminal commands

1. On the Mac computer, open the Terminal application.

2. Run the following command:

   ```
   sudo fdesetup add -usertoadd user1
   ```

   If prompted, enter the sudo password.

3. When prompted, enter the primary FileVault-authorized user name — this is the user who you specified to manage FileVault 2 (in the section above, **Assign an Active Directory User Who is Authorized to Manage an Encrypted Disk**).

4. When prompted, enter the password for the primary FileVault-authorized user.

5. When prompted, enter the password for the new user who you specified on the command line (user1 in this example).

Changing FileVault 2 Settings

After you enable FileVault 2, the settings that you are most likely to change at a later time are the "Managed By" user and the FileVaultMaster certificate.

To change the "Managed By" user on a Mac computer

1. Disable FileVault 2 manually on the Mac computer as described below in **Disabling FileVault 2 Protection**.
2. On the domain controller, change the "Managed By" user as described in the section above, **Assign an Active Directory User Who is Authorized to Manage an Encrypted Disk**.
3. Ensure that the Mac computer can communicate with the domain controller (that is, it is in connected mode) so that it can fetch the new "Managed By" user information from Active Directory.

After you complete these steps, FileVault 2 protection is enabled on the Mac computer the next time the new "Managed By" user logs into the Mac computer.

To change the FileVaultMaster certificate

> **Note**: The procedure described in this section is supported only if you are using one institutional key for multiple Mac computers (that is, if you selected **Use Institutional Recovery Key** in **Enable the Enable FileVault 2 Group Policy**, above).

1. Disable FileVault 2 manually on each Mac computer that will use the new FileVaultMaster certificate. In most situations, this includes all computers to which the Enable FileVault 2 group policy is applied.
2. Specify a new FileVaultMaster certificate in the Enable FileVault 2 group policy as described in **Enable the Enable FileVault 2 Group Policy**, above.
3. Execute the adgpupdate command to have the Enable FileVault 2 group policy implement the new FileVaultMaster certificate on the Mac computers.

   If you do not execute adgpupdate, the old FileVaultMaster certificate is used until the next scheduled group policy update interval.

After you complete these steps:

- All Mac computers on which you disabled FileVault 2 (in Step 1) will use the new FileVaultMaster certificate the next time the "Managed By" user logs in.
- FileVault 2 protection is enabled on a Mac computer the next time the "Managed By" user logs into that Mac computer.

Disabling FileVault 2 Protection

The only way to disable FileVault 2 protection is manually on the Mac computer. You cannot disable it by disabling the Enable FileVault 2 group policy.

You can disable FileVault 2 protection through the Security & Privacy System Preference, or by issuing commands in the Terminal application — view one or the other of the two sets of instructions that follow.

To disable FileVault 2 protection by using Security & Privacy preferences

1. On the Mac computer, open **System Preferences > Security & Privacy** and click the FileVault tab.
2. Click the padlock and enter authentication information to unlock System Preferences.
3. Click **Turn Off FileVault**.
4. Click the padlock to secure the changes.
5. Restart the Mac computer.

The disk is no longer encrypted and all authorized users, not just FileVault-authorized users, should be visible on the log on screen.

To disable FileVault 2 protection by issuing Terminal commands

1. On the Mac computer, open the Terminal application.
2. Enter the following command:

   ```
   sudo fdesetup disable
   ```

3. Enter the root password when prompted.
4. Enter the password for the user account that is authorized to lock or unlock the disk.

   This is the password for the user who you assigned in Active Directory to manage the Mac OS X computer.

5. Restart the Mac computer.

The disk is no longer encrypted and all authorized users, not just FileVault-authorized users, should be visible on the log on screen.

What Happens if the Filevault-Authorized User's Password is Reset?

If the password is reset while the computer is off or not connected to the domain, the password will not be immediately updated so the user must first log in with the old password, then back in with the new password.

For example, follow these steps for a sample set up such as the following:

- The Mac computer is turned off.
- FileVault 2 is enabled.
- user1 is the primary FileVault 2 authorized user.

1. An administrator changes the user1 password in Active Directory Users and Computers (through Reset Password), and informs user1 of the change.
2. You start up the computer, log on as user1, and enter the new password, which fails.
3. Enter the old password, which works.
4. Restart the computer, log on and enter the new password, which should be successful.

Restoring the Filevault User List After Adflush

In Server Suite, if your FileVault 2 user list contains mobile users from another forest with one-way trust (that is, cross-forest mobile users), it is possible that those users will be removed from the FileVault 2 user list after you execute adflush or adflush -f.

After you upgrade to release 2015.1 or later, perform the following steps to ensure that cross-forest mobile users are added to the FileVault 2 user list permanently:

1. Execute the following command:

   ```
   adflush -f
   ```

   Executing this command removes the 2015-format, temporary GUID from cross-forest mobile users.

2. Execute the following command for each cross-forest mobile user that you want to add permanently to the FileVault 2 user list:

   ```
   adquery user -guid cross-forest-mobile-user-name
   ```

   Executing this command assigns a new, permanent GUID to each user that you specify.

3. Execute the following command for each cross-forest mobile user that you want to add to the FileVault 2 user list:

   ```
   fdesetup add -usertoadd cross-forest-mobile-user-name
   ```

   Executing this command adds the specified user to the FileVault 2 user list.

4. Execute the following command to verify that the users are added to the FileVault 2 user list:

   ```
   fdesetup list
   ```

How to Recover an Encrypted Disk

If a user forgets the password for their encrypted disk, you can unlock the disk for them using the institutional recovery key that you created. See the following two Web articles for information:

- Apple Support: "OS X: How to create and deploy a recovery key for FileVault 2".

  Note that you have already created the recovery key — you only need to read the information in the "Recovery" section.

- "Unlock or decrypt your FileVault 2-encrypted boot drive from the command line"

Deploy Configuration Profiles to Multiple Computers

This section explains how to deploy mobile configuration profiles to multiple computers by using a group policy setting (Install mobileconfig Profiles).

> **Note**: You can create mobile configuration profiles in a number of ways, for example by using the iPhone Config utility or OS X Server Profile Manager. This document assumes that you have already created a profile that you want to deploy, but does not show you how to do so.

You can deploy either computer or user profiles. For computer profiles, this feature requires OS X 10.7 or higher. For user profiles, this feature requires OS X 10.9 and higher.

The process for deploying a mobile configuration profile is as follows:

1. Create the mobile configuration profile.
2. Create a subdirectory in SYSVOL on the domain controller and copy the mobile configuration profile file to this directory. SYSVOL is a well-known shared directory on the domain controller that stores server copies of public files that must be shared throughout the domain.
3. Enable the "Install mobileconfig Profiles" group policy and specify the name of the file that you copied to SYSVOL.
4. The mapper script for the group policy runs on each Mac computer controlled by the GPO (when a user logs in or runs adupdate), downloads the profiles from the Active Directory server, and installs them in the Profiles system preference.

To create a subdirectory in SYSVOL:

1. Log in to the domain controller.
2. Change to the SYSVOL directory.

   For example, go to this directory:

   C:WindowsSYSVOLdomain

3. Create a new folder named mobileconfig.

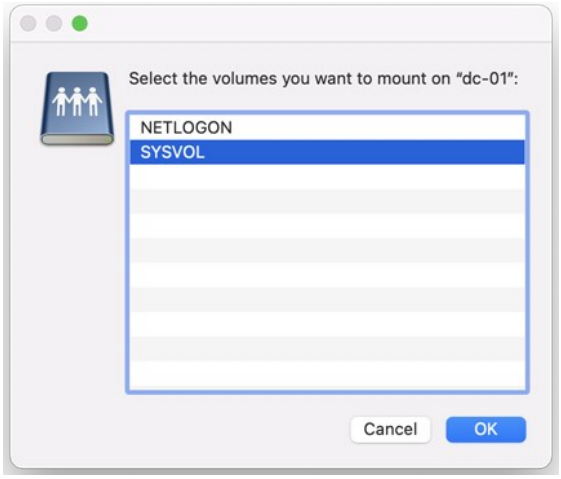
   > **Note**: Be certain that the name of the folder is exactly as shown in the step above. The group policy setting allows you to specify the name of the file but it always looks in SYSVOL\mobileconfig. Likewise, do not create sub-folders — the group policy does not look in sub-folders.

To copy configuration files to SYSVOL on the domain controller:

1. In the Finder on the Mac computer navigate to the folder that contains the profile to copy.
2. Select the file, for example, settings_for_all.mobileconfig and copy it to the desktop. When prompted, enter your administrator password to copy the file.
3. On the desktop, change the file permissions for settings_for_all.mobileconfig as follows, so you can copy it to SYSVOL:
   1. Select the file and click **File > Get Info**.
   2. In the dialog box, expand **Sharing & Permissions**, then click the lock icon and provide administrator credentials for making changes. Set the permissions for **everyone** to **Read only**.
   3. Reset the lock and close the open dialog.
4. On the Mac computer, copy the file from the desktop to SYSVOL on the Windows domain controller. If you are connected to the domain, you should see the domain controller in the Finder. If the domain controller is not visible in the Finder, connect to it:

   1. Click **Go > Connect to Server** and select the domain controller.

   2. When prompted select **SYSVOL**; for example:



3. Navigate to the mobileconfig directory you created, for example by clicking **acme.com** then **mobileconfig**.
4. Drag the settings_for_all.mobileconfig file to mobileconfig.

To configure the "Install MobileConfig Profiles" group policy:

1. On the Windows domain controller, open the Group Policy Management Editor and select the GPO that is used to manage Mac computers.
2. Navigate to **Computer Configuration > Policies > Mac OS X Settings > Custom Settings** and double-click **Install MobileConfig Profiles** to install a machine profile.

   To install a user profile, navigate to **User Configuration > Policies > Mac OS X Settings > Custom Settings** and double-click **Install MobileConfig Profiles**.
3. Select **Enabled**.
4. Click **Add**, then enter the name of the file that you copied to SYSVOL, for example, settings_for_all.mobileconfig.

   Be certain to include the .mobileconfig suffix.
5. Click **OK** to add the settings_for_all.mobileconfig file.
6. Click **OK** to enable the policy.

   This group policy will copy the settings_for_all.mobileconfg file, and install the profile, on every computer to which the GPO applies and that is joined to the domain. Note that after the profile is installed, it is deleted from the Mac computer.
7. Run the adgpupdate command on each target Mac computer to trigger an update of group policies and execute the new Install MobileConfig Profiles policy settings.

   By default, group policies are updated automatically every 90 minutes, so you can skip this step and wait for the automatic update if you wish.

Note the following about this process:

- If you add a profile file to SYSVOL, but do not specify it in the group policy setting, the profile will not be installed. Likewise, if you specify a file in the group policy that does not exist in SYSVOL, the profile will not be installed.
- If you add new files to the existing list in the group policy, those profiles will be installed — existing profiles will not be touched.
- If you remove a file from the group policy list (after the profile for the file was installed), the profile for that file will be uninstalled from the managed Mac computers.
- If you modify a file, the corresponding profile will be reinstalled.
- If two or more profile files have the same payloadIdentifier attribute, only one of them will be installed.
- If you change the group policy to "Disabled" or "Not Configured", all existing profiles that were installed previously by the group policy will now be uninstalled from the managed Mac computers.

  Note: The "Install MobileConfig Profiles" group policy only supports macOS 10.15 and lower.

Centrify group policies allow administrators to extend the configuration management capabilities of Windows Group Policy Objects to managed Mac computers and to users who log on to Mac computers. This chapter provides an overview to using the Delinea Mac group policies that can be applied to Mac computers and users

For reference information about the Mac OS X-specific computer and user policies that you can set, see the following topics.

- Setting Computer-based Group Policies
- Setting User-based Group Policies

For additional information about creating and using group policies and Group Policy Objects, see your Windows or Active Directory documentation, such as https://technet.microsoft.com/en-us/windowsserver/bb310732.aspx.

For information about other Centrify group policies that are not specific to Mac computers and users, see the *Group Policy Guide*.

The following topics are covered:

Understanding Group Policies and System Preferences

In many organizations, administrators who have both Windows and Mac computers in their organization want to manage settings for their Windows and Macintosh computers and users using a standard set of tools. In a Windows environment, the standard method for managing computer and user configuration settings is through Group Policy Objects applied to the appropriate site, domain, or organizational unit (OU) for different sets of computer and user accounts.

Delinea provides this capability for Mac computers and users through a group policy extension. The Delinea administrative template for Mac OS X (centrify_mac_settings.xml or centrify_mac_settings.adm) provides group policies that can be applied from a Windows server to control Mac OS X settings and behavior. These group policies can be applied to Mac OS X computers and to users who log on to those computers

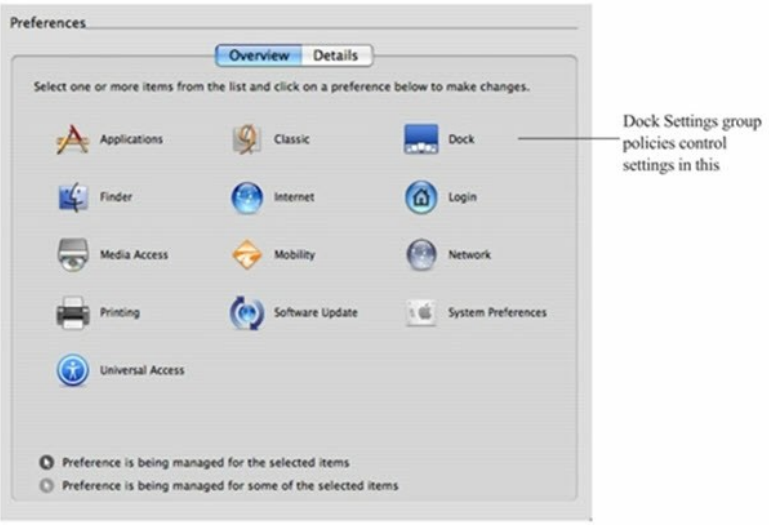
Through the Delinea administrative template for Mac OS X, Windows administrators using the Group Policy Management Editor can centrally access and control native Mac system preferences.

In the current Delinea administrative template for Mac OS X, Centrify group policies control settings for Personal, Hardware, Internet & Network, and System preferences, including:

- Accounts, (General) Appearance, Desktop & Screen Saver, Dock, Energy Saver, Network, Security & Privacy, Sharing, Software Update, and so on.

When you enable a group policy in a Windows Group Policy Object, you effectively set a corresponding system preference on the local Mac computer where the group policy is applied. For example, if you enable the group policy **Computer Configuration > Delinea Settings > Mac OS X Settings > Security > Require password to unlock each secure system preference**, it is the same as selecting the General tab of the Security & Privacy system preference, then clicking the **Require an administrator password to access system preferences with lock icons** option on a local Mac OS X computer. Once the group policy is enabled in the Windows Group Policy Object and updated on the local Mac computer, the corresponding option is checked:

In addition to the system preferences that are typically set on individual computers, there are many Mac configuration settings that are typically set from a Mac OS X server using the Workgroup Manager. These workgroup policies control application or media access, synchronization rules for mobile user accounts, the look and operation of the Dock, and other settings. The Delinea administrative template for Mac provides centralized access to many of these Workgroup Manager settings, including Applications, Dock, Media Access, Mobility, Software Update, and System Preferences.



Note: Not all group policies apply to all versions of the Mac operating environment or all computer models. If a particular system preference does not exist, is not applicable to the installed operating system, or is implemented differently on some computers, the group policy setting may be ignored or overridden by a local setting.

Group policies are available after you install the Delinea administrative template for Mac as described in **Installing the Administrative Template**, below. After you install the administrative template, the Windows administrator can use Active Directory MMC snap-ins or the Group Policy Management Console to create and link Group Policy Objects to sites, domains, or organizational units that include Mac computers that are joined to an Active Directory domain. Administrators can then use the Group Policy Management Editor to enable and configure the specific policies they want to enforce on Mac computers that are joined to the Active Directory domain.

See the *Group Policy Guide* for more information about using Active Directory Users and Computers or using the Group Policy Management Console or adding other Delinea administrative templates to a Group Policy Object.

Linking Group Policy Objects

To apply group policies to Mac computers, you can link an existing group policy object (GPO) that you are using for a Windows or UNIX computer, or create a new GPO to link to a domain or OU that contains your Mac computers and users. In general, it is recommended that you create an OU specifically for your Mac computers and link a new GPO to that OU. However, there is no problem adding the Mac group policies to an existing GPO and configuring policies for Mac computers; Mac OS X-specific policies that are applied to Windows or UNIX computers are simply ignored.

You apply GPOs to Mac users the same way; link the GPO to an OU containing the users. Group policies are only applied to users and computers in the organizational unit (OU) linked to the Group Policy object (GPO) and any of the child OUs. If your users and computers are in different OUs (which is common), Delinea recommends using user Group Policy loopback processing to make sure user policies are applied to everyone who logs on to a Mac. This is a standard Microsoft Group Policy that applies to every user to the computer. See Setting User-based Group Policies for more information about applying user policies.

Installing Mac Group Policies

Centrify group policies for Mac consist of two components

- The DirectControl agent for Mac and its associated configuration and system plug-in files that reside on the Mac computer. The DirectControl agent and related files determine the policies that have been applied to the local computer, or to the user who is logging on, and implement the policy through system preferences or other local configuration settings. This guide assumes that you have installed the DirectControl agent on your Mac computers.
- An administrative template (.xml or .admx file) that describes the policy settings available to the Group Policy Management Editor. The administrative template must be installed on a Windows computer that has the Group Policy Management Editor and the Delinea Group Policy Management Editor Extension. The Group Policy Management Editor and the Delinea Group Policy Management Editor Extension must be available for you to enable and configure policies. See the *Mac Quick Start Guide* for more information.

Installing the Administrative Template

Delinea provides templates in both XML and ADMX format. In most cases it is best to use the XML templates, which provide greater flexibility, such as the ability to edit settings after setting them initially, and in many cases contain validation scripts for the policies implemented in the template

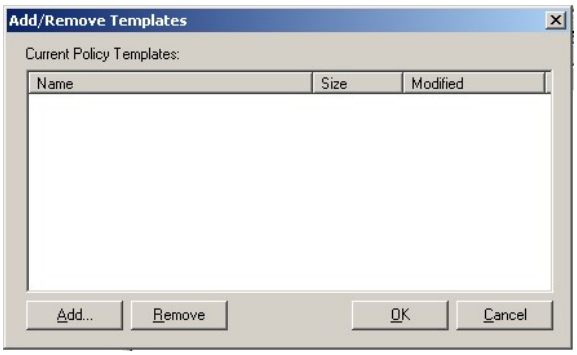
However, in certain cases, you may want to add templates by using the ADMX files. For example, if you have implemented a set of custom tools for the Windows ADMX-based policies, and want to extend those tools to work with the Delinea policies, you can implement the policies with ADMX template files. The Group Policy Management Editor will automatically read all ADMX files stored in the %systemroot%PolicyDefinitions folder.

The ADMX templates do not support extended ASCII code for locales that require double-byte characters. For these locales, you should use the XML templates.

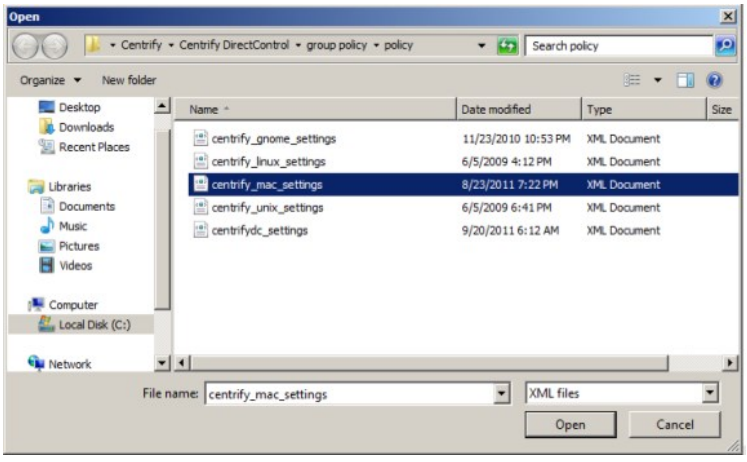
To install the Delinea XML administrative template for Mac group policies

This procedure assumes that you are using the Group Policy Management Console and have created a Mac OS X-specific GPO. For information about using a different console, such as ADUC, see the *Group Policy Guide*.

1. Open the Group Policy Management Console and select the Group Policy Object that you are using for Mac computers, right-click, then click **Edit** to open the Group Policy Management Editor.
2. Expand **Computer Configuration › Policies** and select **Delinea Settings**. Right click and click **Add/Remove Templates**.
3. Click **Add**, then navigate to the directory that contains the Delinea centrify_mac_settings.xml administrative template. By default, Delinea administrative templates are located in the C:Program Files\Common Files\Centrify Shared\Group Policy Management Editor Extension\policy folder.

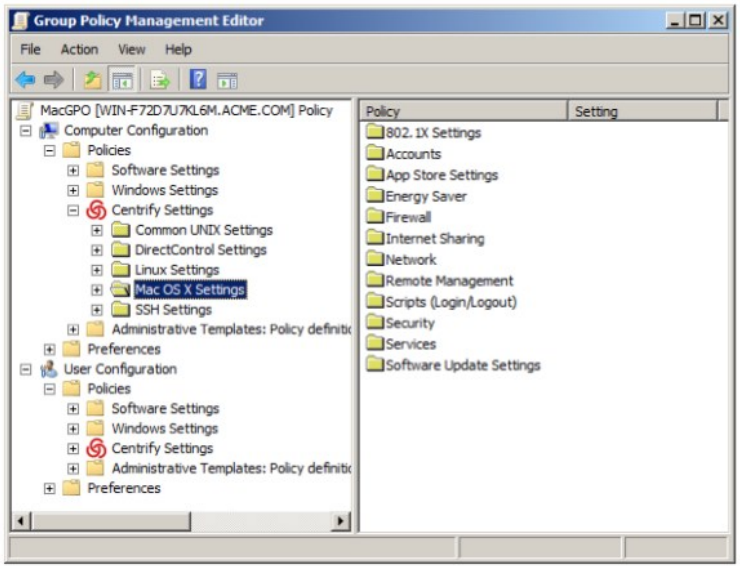


4. Select the centrify_mac_settings.xml file, then click **Open** to add this template to the list of Policy Templates.



5. Click **OK**.

You should now see the categories of Mac group policies listed as **Mac OS X Settings** under Delinea Settings in the Group Policy Management Editor. For example:



> **Note**: If you update Delinea to a new version, new templates may be included with the installation. To make any new policies included in the templates available for use, you must reapply each template by following the steps in one of these procedures. If you see the message, The selected XML file already exists. Do you want to overwrite it?, click **Yes**. This action overwrites the template with any new or modified group policies. It does not affect any configuration in the template that has been applied; that is, any policies that you have enabled remain enabled.

Setting Mac Group Policies

Like other group policies, policies for Mac users and computers are organized into categories within the Group Policy Management Editor under **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings** (Setting Computer-based Group Policies) or **Delinea Settings > Mac OS X Settings** (Setting User-based Group Policies). In general, these categories map directly to different types of Mac system preferences and individual policy settings within the categories map to specific settings within the system preference.

Normally, once enabled, policies get applied at the next group policy refresh interval, after the user logs out and logs back in, or after the computer has been rebooted. Some Mac group policies, however, require the user to log out and log back in or the computer to be rebooted. The description of each group policy indicates whether the policy can be applied "dynamically" at the next refresh interval or requires a re-login or a reboot.

You may also update group policies manually by running the adgpupdate command on an individual computer. See the next section, **Updating Configuration Policies Manually**.

> **Note**: The system preference updated on an individual computer must be closed, then reopened for the group policy setting to be visible.

In most cases, group policies can be Enabled to activate the policy or Disabled to deactivate a previously enabled policy. Changing a policy to Not Configured has no effect for any Mac group policies. Once a group policy is set on a local computer, it remains in effect even if the computer leaves the Active Directory domain. The administrator or users with an administrative account can change settings manually at the local computer, but any manual changes are overwritten when the group policy is applied.

Updating Configuration Policies Manually

Although there are Windows group policy settings that control whether group policies should be refreshed in the background at a set interval, Delinea also provides a command line program to manually refresh group policy settings at any time. This command line program, adgpupdate, forces the adclient daemon to contact Active Directory and collect group policy settings. With the adgpupdate command, you can specify whether you want to refresh computer configuration policies, user configuration policies, or both.

When you run the adgpupdate command, the adclient daemon does the following:

- Contacts Active Directory for computer configuration policies, user configuration policies, or both. By default, adclient collects both computer and user configuration policies.
- Determines all of the configuration settings that apply to the computer, the current user, or both, and retrieves those settings from the System Volume (SYSVOL).

- Writes all of the configuration settings to a virtual registry on the local computer.
- Starts the runmappers program to initiate the mapping of configuration settings using individual mapping programs for user and computer policies.
- Resets the clock for the next refresh interval.

For more information about using the adgpupdate command, see the adgpupdate page or *Using adgpupdate* in the *Administrator's Guide for Linux and UNIX*.

Applying Standard Windows Policies to Mac OS X

Every Group Policy Object includes several default Windows-based group policy categories and default Windows-based administrative templates for user and computer configuration. Most of the settings in the default Windows policies and administrative templates only apply to Windows computers and Windows user accounts. However, some of the common Windows configuration settings for password enforcement, such as the policies for minimum password length and complexity, do apply to Mac computers. If these settings are enabled for a Group Policy Object applied to a site, domain, or OU that includes Mac OS X computers, the settings are enforced for Mac users and computers.

The following sections describe the standard Windows group policies that you can apply to Mac computers and users and where you can find these policies when viewing a Group Policy Object in the Group Policy Management Editor.

Group Policy Refresh and Loopback Processing

The **Computer Configuration > Administrative Templates > System > Group Policy** object contains the following policies that you can use to control how group policies are refreshed and applied.

- Turn off background refresh of Group Policy
- Group Policy refresh interval for computers
- User Group Policy loopback processing mode

Synchronizing Time

By default, the local Network Time Protocol (NTP) Client is enabled and synchronizes your computer's clock to the Domain Controller. If you do not want your local NTP service to synchronize to the NTP service on the Domain Controller, explicitly disable the (Windows) Enable Windows NTP Client group policy. You can also synchronize to a different NTP server by specifying one in the Configure Windows NTP Client group policy.

To set these policies, in the Group Policy Editor, click **Computer Configuration > Administrative Templates > System > Windows Time Service > Time Providers**. The following policies are available to control time synchronization settings.

- Enable Windows NTP Client
- Configure Windows NTP Client

Specifying Time Sync Polling Interval

The **Computer Configuration > Administrative Templates > System > Windows Time Service > Global Configuration Settings** policy allows you to control the max polling interval with the MaxPollInterval option.

Configure Interactive Log On

Select the **Computer Configuration > Windows Settings > Security Settings > Local Policies > Security Options** object to configure the following policies related to interactive log on.

> **Note**: These policies apply to SSH login only, not to login through the graphical user interface.

- Interactive logon: Message text for users attempting to log on
- Interactive logon: Prompt user to change password before expiration

Set Password Requirements

Select the **Computer Configuration > Windows Settings > Security Settings > Account Policies > Password Policy** object to set password requirements.

- Enforce password history
- Maximum password age
- Minimum password age

- Minimum password length
- Password must meet complexity requirements
- Store passwords using reversible encryption

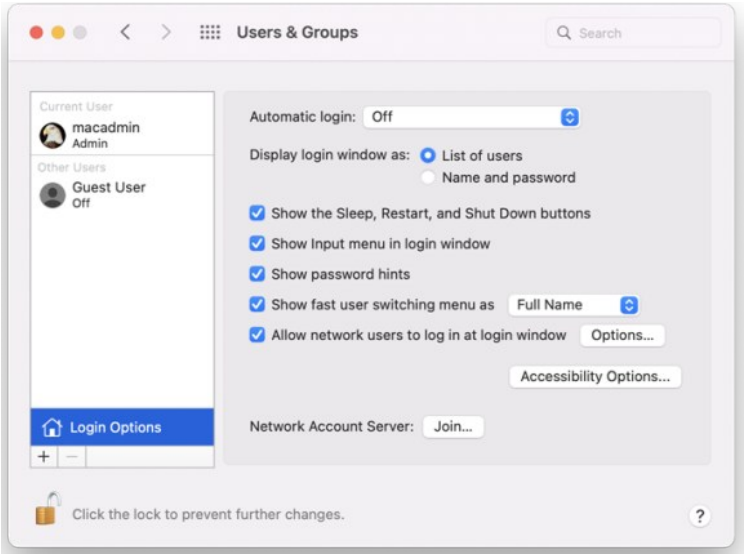
Configuring Mac-specific Parameters

Most configuration parameters apply to both Mac or only to actual UNIX or Linux systems. All these parameters are described in the *Configuration and Tuning Reference Guide*. However, the following parameters apply only to Mac OS X and are described in this section.

- adclient.autoedit.mac.netlogin
- adclient.mac.map.home.to.users
- adclient.network.wait.max
- mac.auto.generate.new.login.keychain
- mac.protected.keychain.enable
- mac.protected.keychain.user.default
- mac.protected.keychain.delete
- mac.protected.keychain.lock.inactivity
- mac.protected.keychain.lock.when.sleeping
- mac.keychain.sync.enabled
- mac.keychain.sync.polling.interval
- smartcard.pin.caching.disable
- logger.login.log

adclient.autoedit.mac.netlogin

System Preferences > Users & Groups (Accounts) has a login option: **Allow network users to log in at login window**:



If this option is deselected, Active Directory users will not be able to log into the computer. The configuration parameter adclient.autoedit.mac.netlogin controls whether this option can be deselected by users. By default, the parameter is true in the /etc/centrifydc/centrifydc.conf file:

```
adclient.autoedit.mac.netlogin: true
```

In this case, even if a user deselects the box, the box is selected again when adclient is restarted, effectively preventing a user from deactivating network login.

If you want to allow a user to deactivate network login, set the parameter to false. If a user deselects network login in **System Preferences > Accounts**, the next time adclient starts, network users will be unable to log in to the computer.

adclient.mac.map.home.to.users

On some versions of Mac OS X, /home is an automount point. If a zone user's home directory is set to /home/username, the operating system cannot create the

home directory and the user cannot log in. Therefore, you should not specify /home/username as the home directory for any Mac OS X users, but since this is a typical UNIX home directory, there may be Active Directory users who have a /home/username home directory.

To avoid potential problems, you can configure Delinea to change /home/username to /Users/username (the default Mac OS X home directory), in one of two ways:

- Enable the group policy, Map /home to /Users.
- Set the parameter, adclient.mac.map.home.to.users to true to enable the change for the local computer only; for example:

  adclient.mac.map.home.to.users:true

adclient.network.wait.max

The Delinea agent for Mac OS X performs network checks during startup to determine whether the device is connected to the domain. The adclient.network.wait.max parameter sets the maximum time the agent waits for the network before deciding to boot in either connected or disconnected mode. The default value is five seconds.

If DNS latency is high in your environment, the agent might determine that the device is in a Disconnected state too soon.

You can increase the value for the adclient.network.wait.max parameter if it's appropriate for your network environment; however, this might result in increased boot times.

logger.login.log

Login events are captured in /var/log/centrifydc-login.log by default. You can turn off this feature by setting the logger.login.log parameter to off. Refer to Collecting Information Specific to Login Events for more information about /var/log/centrifydc-login.

mac.auto.generate.new.login.keychain

Use this parameter to automatically generate a new login keychain if a user's keychain password does not match the password they used to successfully login.

The default value is false.

Refer to Auto Generate New Login Keychain for more information about the group policy that controls this parameter.

mac.protected.keychain.enable

Setting this parameter to true creates a new keychain protected by either an asymmetric token stored on a smart card or by a password, depending on the log in type.

The default value is false.

Refer to Enable Protected Keychain for more information about the group policy that controls this parameter.

> **Note**: Changing the group policy setting for this parameter does not change the parameter's value in this file. The two are set independently, with the group policy setting taking priority.

mac.protected.keychain.user.default

Setting this parameter to true sets the protected keychain as the default keychain for that user.

The default value is true.

Refer to Enable Protected Keychain for more information about the group policy setting that controls this parameter.

> **Note**: Changing the group policy setting for this parameter does not change the parameter's value in this file. The two are set independently, with the group policy setting taking priority.

mac.protected.keychain.delete

Setting this parameter to true deletes the existing password-protected Login Keychain after logging in.

The default value is false.

> **Note**: This parameter only works if mac.protected.keychain.enable is set to true.

Refer to Enable Protected Keychain for more information about the group policy setting that controls this parameter.

> **Note**: Changing the group policy setting for this parameter does not change the parameter's value in this file. The two are set independently, with the group policy setting taking priority.

mac.protected.keychain.lock.inactivity

Use this parameter to set the period of inactivity in minutes to automatically lock the protected keychain.

The default value is 0, which means the protected keychain is never automatically locked.

Refer to Lock Protected Keychain after Number of Minutes of Inactivity for more information about the group policy that controls this parameter.

> **Note**: Changing the group policy setting for this parameter does not change the parameter's value in this file. The two are set independently, with the group policy setting taking priority.

mac.protected.keychain.lock.when.sleeping

Setting this parameter to true locks the protected keychain when the Mac sleeps.

The default value is false.

Refer to Lock Protected Keychain When Sleeping for more information about the group policy that controls this parameter.

> **Note**: Changing the group policy setting for this parameter does not change the parameter's value in this file. The two are set independently, with the group policy setting taking priority.

mac.keychain.sync.enabled

This configuration parameter enables Keychain synchronization for the users on a mac.

If this parameter is enabled, the current login user will receive a password change notification when his/her password is changed remotely. When the user clicks on the notification, the Delinea Keychain Sync utility appears and allows the user to synchronize the Keychain password.

> **Note**: Password changes can only be detected when the machine is in connected mode.

The default value is false.

Refer to Enable Keychain Synchronization for more information about the related group policy.

mac.keychain.sync.polling.interval

This configuration parameter sets the password change detection interval when mac.keychain.sync.enabled is enabled.

This parameter determines the time (in minutes) between checking for changed passwords. There is a random zero to five minute variance in the actual interval each device is checked for a changed password to maintain performance. As a result, the minimum interval is five minutes.

> **Note**: Valid intervals are between 5 minutes and 1440 minutes (1 day).

The default value is 30.

Refer to Enable Keychain Synchronization for more information about the related group policy.

Centrify group policies allow administrators to extend the configuration management capabilities of Windows Group Policy Objects to managed Mac computers and to users who log on to Mac computers. This chapter provides reference information for the Centrify Mac group policies that can be applied specifically to Mac computers

The computer-based group policies are defined in the Centrify Mac administrative template (centrify_mac_settings.xml) and accessed from **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings**. See Understanding Group Policies for Mac Users and Computers for general information about how Delinea uses group policies to manage Mac settings and for information on how to install the group policy administrative templates.

For reference information about user-based policies, see Setting User-based Group Policies.

For information, see Applying Standard Windows Policies to Mac OS X and Configuring Mac-specific Parameters.

> **Note**: For more complete information about creating and using group policies and Group Policy Objects, see your Windows or Active Directory documentation. For more information about adding and using other Centrify group policies that are not specific to Mac computers and users, see the *Group Policy Guide*

Setting Computer-Based Policies for Mac

The following table provides a summary of the group policies you can set for Mac computers. These group policies are in the Centrify Mac administrative template (centrify_mac_settings.xml) and accessed from **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings**.

Allow Certificates with No Extended Key Usage Certificate Attribute	For smart card log in, allow the use of certificates that do not contain the extended key usage (EKU) attribute. This is a Windows policy that is defined in the **Administrative Templates > Windows Components > Smart Card** folder using an adm template.
Map /home to /Users	Map the /home/*username* directory to /Users/*username*. This is a Mac OS X-specific policy but defined in the **Direct Control Settings > Adclient Settings** folder using the centrifydc_settings.xml template.
802.1x Settings	Create login and system profiles for wireless authentication. These group policies correspond to 802.1X Options in the **Networks** system preference.
Accounts	Control the look and operation of the login window on Mac computers and map zone groups to the local administrator group. These group policies correspond to Login Options in the **Accounts** system preference.
App Store Settings Deprecated	Control the users and groups who can access the App Store. These group policies correspond to settings in the Sleep and Options panes in the **Energy Saver** system preference.
Custom Settings	Customize and install configuration profiles.
Energy Saver	Control sleep and wake-up option on Mac computers. These group policies correspond to settings in the Sleep and Options panes in the **Energy Saver** system preference.
Firewall	Control the firewall configuration on Mac computers. These group policies correspond to settings in the Firewall pane of the **Sharing** system preference.
Internet Sharing	Manage Internet connections on Mac computers. These group policies correspond to settings in the Internet pane of the **Sharing** system preference.
Network	Control DNS searching and proxy settings. These group policies correspond to settings in the TCP/IP and Proxies panes of the **Network** system preference.
Remote Management	Control Apple Remote Desktop access for zone users. These group policies correspond to the **Manage > Change Client Settings** options in Apple Remote Desktop.

Security & Privacy	Control security settings on Mac computers. These group policies correspond to settings in the **Security** system preferences.
Services	Control access to various services on Mac computers. These group policies correspond to settings in the Services pane of the **Sharing** system preference.
Software Update Settings	Control the options for automatic software updates on Mac computers. These group policies correspond to settings in the **Software Update** system preference.

For information about specific policies and how to set them, see the policy description (Explain text) or the corresponding discussion of the specific system preference or individual setting in the Mac Help.

Allow Certificates with no Extended Key Usage Certificate Attribute

Path

Computer Configuration › Policies › Administrative Templates: Policy Definitions› Windows Components› Smart Card.

Description

The group policy, "Allow certificates with no extended key usage certificate attribute" is defined in a Windows administrative template file (.adm), not in centrify_mac_settings.xml, and is in Administrative Templates, not in Mac Settings.

To enable or disable this policy, click **Computer Configuration › Policies › Administrative Templates: Policy Definitions › Windows Components › Smart Card**.

Enabling this policy setting allows the use of certificates for smart card login that do not have the Extended Key Usage (EKU) attribute set. Normally, certificates that are used for smart card login require this attribute with a smart card logon object identifier.

When you enable this policy, it sets the smartcard.allow.noeku parameter to true in the Centrify configuration file. Certificates with the following attributes can also be used to log on with a smart card:

- Certificates with no EKU
- Certificates with an All Purpose EKU
- Certificates with a Client Authentication EKU

If you disable or do not configure this policy setting (and do not set the smartcard.allow.noeku parameter to true in the Centrify configuration file) only certificates that contain the smart card logon object identifier can be used with smart card log in.

After changing the value of this parameter, you must re-enable smart card support by running the following sctool command as root:

```
[root]$ sctool -E
```

> **Note**: You must also specify the --altpkinit or --pkinit parameter when you run sctool with the -E option.

Map /home to /Users

Path

Computer Configuration › Policies › Centrify Settings › DirectControl Settings › Adclient Settings.

Description

The Mac group policy, Map /home to /Users is defined in the centrifydc_settings.xml file, not in centrify_mac_settings.xml, and is in Delinea Settings, not in Mac Settings.

To enable or disable this policy, click **Computer Configuration › Policies › Centrify Settings › DirectControl Settings › Adclient Settings**.

On some versions of Mac OS X, /home is an automount point. If a zone user's home directory is set to /home/*username*, the operating system cannot create the home directory and the user cannot log in. Therefore, you should not specify /home/*username* as the home directory for any Mac users, but since this is a typical UNIX home directory, there may be Active Directory users who have a /home/*username* home directory. To avoid potential problems, enable this

group policy, Map /home to /Users, to configure Delinea to change /home/*username* to /Users/*username* (the default Mac home directory). If you do not enable this policy, the change does not take effect.

This policy modifies the adclient.mac.map.home.to.users parameter in the Centrify configuration file.

802.1X Settings

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Settings** to create profiles for wireless network authentication. The profiles you specify with these group policies are created in the Network system preferences pane.

Enable Machine Ethernet Profile

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings > Enable Machine Ethernet Profile

Description

Enable this policy to create an 802.1X ethernet profile so users can authenticate to an 802.1X-protected network by using the specified machine certificate.

> **Note**: This group policy only supports macOS 10.15 and lower.

This policy supports the TLS protocol for certificate-based authentication for computers.

Before you can enable this policy, you must have a Windows server configured for 802.1X wireless authentication. The configuration includes certificate templates that are configured for auto-enrollment of domain computers and automatically downloaded to Mac computers when they join the domain. See Configuring 802.1X Wireless Authentication for details about what you must configure before enabling the current policy.

After enabling this policy, set the following:

- **Template Name**: Type the name of the auto-enrollment machine certificate that has been pushed down from the Windows domain server.

  When pushed to a Mac computer, certificate names are prepended with auto_; for example:

  auth_Centrify-1X

This group policy runs a script that looks for the specified certificate template in the /var/centrify/net/certs directory (which contains the certificate templates pushed down from the domain controller) and creates an Ethernet profile from this certificate.

Once enabled, this policy takes effect dynamically at the next group policy refresh interval.

Enable Machine Wi-Fi Profile

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings Enable Machine Wi-Fi Profile

Description

Enable this policy to create an 802.1X Wi-Fi profile for wireless network authentication for a computer.

> **Note**: This group policy only supports macOS 10.15 and lower.

This policy supports WEP or WPA/WPA2 security with the TLS protocol for certificate-based authentication for computers.

Before you can enable this policy, you must have a Windows server configured for 802.1X wireless authentication. The configuration includes certificate templates that are configured for auto-enrollment of domain computers and automatically downloaded to Mac computers when they join the domain. See Configuring 802.1X Wireless Authentication for details about what you must configure before enabling the current policy.

After enabling this policy, set the following:

- **SSID**: Type the SSID for the wireless network.
- **Template Name**: Type the name of the auto-enrollment machine certificate that has been pushed down from the Windows domain server.

  When pushed to a Mac computer, certificate names are prepended with auto_; for example: auth_Centrify-1X

  This group policy runs a script that looks for the specified certificate template in the /var/centrify/net/certs directory (which contains the certificate templates downloaded from the domain controller) and creates a WiFi profile from this certificate.
- **Security Type**: Select the security type from the drop-down list.
- **Other options**: Select one or more of the following options:
  - **Auto join**: Select this option to specify that the computer automatically join a Wi-Fi network that it recognizes. Do not select this option to specify that the logged in user must manually join a Wi-Fi network.
  - **Hidden network**: Select this option if the Wi-Fi network does not broadcast its SSID.
  - **Proxy PAC URL**: The URL of the PAC file that defines the proxy configuration. You can enter any string without spaces.
  - **Proxy PAC Fallback**: Allows the device to connect directly to the destination if the PAC file is unreachable. This option is disabled by default.

Once enabled, this policy takes effect dynamically at the next group policy refresh interval.

Enable User Ethernet Profile

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings > Enable User Ethernet Profile

Description

Enable this policy to create an 802.1X ethernet profile so users can authenticate to an 802.1X-protected network by using the specified user certificate.

> **Note**: This group policy only supports macOS 10.15 and lower.

This policy supports the TLS protocol for certificate-based authentication for users.

By default, the auto-enrolled user certificates are pushed down to ~/.centrify/autouser_(name).{cert.key.chain}. Certificates are also imported into each user's login keychain.

Before you can enable this policy, you must have a Windows server configured for 802.1X wireless authentication. The configuration includes certificate templates that are configured for auto-enrollment of domain computers and automatically downloaded to Mac computers when they join the domain. See Configuring 802.1X Wireless Authentication for details about what you must configure before enabling the current policy.

Users must perform these steps after login to authenticate to the network as the user:

1. Select **System Preferences > Network > Ethernet**.
2. If there are any pre-existing 802.1X connections, click **Disconnect** to disconnect the pre-existing connections. For example, if a machine 802.1X Ethernet policy has been set, the computer will already be authenticated using the machine credential.
3. Click Connect. This action prompts the user with a list of available user identities in *certificate-key* pair format.
4. Choose the appropriate auto-enrolled user identity.

Enable User Wi-Fi Profile

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings > Enable User Wi-Fi Profile

Description

Enable this policy to create an 802.1X Wi-Fi profile for wireless network authentication for a user.

> **Note**: This group policy only supports macOS 10.15 and lower.

This policy supports the TLS protocol for certificate-based authentication for users.

By default, the auto-enrolled user certificates are pushed down to ~/.centrify/autouser_(name).{cert.key.chain}. Certificates are also imported into each user's login keychain.

The resulting profile is signed using the first available auto-enrolled machine certificates, which are under /var/centrify/net/certs/auto_(name).{cert.key.chain}. If an auto-enrolled machine certificate is not available, the profile will be unsigned.

Before you can enable this policy, you must have a Windows server configured for 802.1X wireless authentication. The configuration includes certificate templates that are configured for auto-enrollment of domain computers and automatically downloaded to Mac computers when they join the domain. See Configuring 802.1X Wireless Authentication for details about what you must configure before enabling the current policy.

After enabling this policy, set the following:

- **SSID**: Type the SSID for the wireless network.
- **Security Type**: Select the security type from the drop-down list.
- **Other options**: Select one or more of the following options:
  - **Auto join**: Select this option to specify that the computer automatically join a Wi-Fi network that it recognizes. Do not select this option to specify that the logged in user must manually join a Wi-Fi network.
  - **Hidden network**: Select this option if the Wi-Fi network does not broadcast its SSID.
  - **Proxy PAC URL**: The URL of the PAC file that defines the proxy configuration. You can enter any string without spaces.
  - **Proxy PAC Fallback**: Allows the device to connect directly to the destination if the PAC file is unreachable. This option is disabled by default.

Users must perform these steps after login to authenticate to the network as the user:

1. Select **System Preferences > Network > Wi-Fi**.
2. If there are any pre-existing 802.1X connections, click **Disconnect** to disconnect the pre-existing connections. For example, if a machine 802.1X Ethernet policy has been set, the computer will already be authenticated using the machine credential.
3. Click **Connect**. This action prompts the user with a list of available user identities in *certificate-key* pair format.
4. Choose the appropriate auto-enrolled user identity (a *certificate-key* pair).

Specify System Profile (Deprecated)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings > Specify System Profile (Deprecated)

Description

This group policy is provided for backward compatibility with Mac OS X 10.6. If your environment does not contain any 10.6 computers, do not use this group policy.

Enable this policy to specify 802.1X system profile for wireless network authentication.

System profile can establish a wireless connection without a user login.

To add a system profile, enable the policy and click **Add** to enter the profile name and setting, then type a name for the profile.

The setting must follow this format:

- Network;Security Type;Authentication Method, where each field is separated by a semi-colon (;)
- Network is the wireless network name
- Security type is one of 802.1X WEP, WPA Enterprise, WPA2 Enterprise
- Authentication method is one or more of the following, separated by commas: TTLS, PEAP, LEAP, MD5

For example:

OFFICE1;WPA Enterprise;PEAP

OFFICE2;802.1X WEP;TTLS,PEAP

Automatically turn on Airport; to automatically turn on AirPort device if this type of profile is specified. Otherwise, the status of the AirPort device will not change.

Once enabled, this policy takes effect dynamically at the next group policy refresh interval.

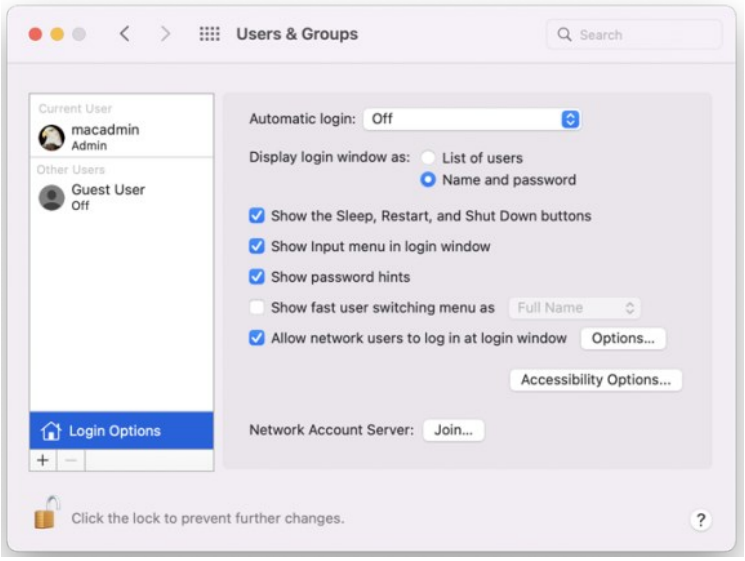
Accounts

Path

Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Accounts

Description

Use the **Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Accounts** settings to manage the options from the Accounts ( ) system preference on Mac computers. These group policies correspond to the options displayed when you select the **Accounts** system preference, then click **Login Options**. For example:



Set Login Window Settings

Path

Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Accounts › Set login window settings

Description

Configure the Login Options on a computer. If you enable this policy, you can configure the Login Window to:

- Display a text string as a login banner. The Banner you specify is displayed when the user is prompted to log on.
- Display a List of Users or a Name and Password field. Displaying the Name and Password requires users to provide their account name and password, and is more secure than displaying a list of user names.
- Show the Restart, Sleep, and Shut Down buttons.
- Show the Input menu in the login window to allow users to change the current Keyboard Layout.
- Show password hints in the login window.
- Use VoiceOver at the login window.
- Enable fast user switching.
- Display the HostName, IP Address, and OS X or macOS Version. Users need to click the clock in the top right corner to view each field.
- Disable reopening applications when logging back in. Check this to always uncheck the **Reopen Windows when logging back in** checkbox at

logout, restart, or shutdown.

- Hide all Local Users with a UID less than 500.
- Enabling the options in this group policy is the same as clicking **Login Options** in the Accounts system preference and setting the corresponding login window options.

  Note: This policy does not impact lock screens. It only impacts the login window.

  Note: If you click **Enable Fast User Switching**, this setting does not take effect until the Login Options in the Accounts system preference is opened manually by a user on the local host. This step is required to display the list of users in the upper-right corner of the menu bar. After users log on, the user's full name, short name, or icon identifier is displayed in the menu bar. If you want to change how users are displayed in the menu, you also must do so manually from the Login Options in the Accounts system preference.

Once enabled, this group policy takes effect when users log out and log back in or when the computer is rebooted.

Map Zone Groups to Local Admin Group

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Accounts > Map zone group to local admin group

Description

Specify one or more zone groups to map to the admin group on the local computer. Members of the groups you specify here have administrative privileges on the local computer, including:

- The use of sudo command in a shell
- The ability to unlock and make changes to System Preferences.

Be certain to create a zone group in Access Manager (or adedit) and add users who you want to have administrative privileges on managed Mac computers.

Note: If the local computer is connected to the domain through Auto Zone, you cannot create a zone group because there are no zones. However, all Active Directory groups are valid for the joined computer, so you can map any group to the local admin group, but you need to know the group's UNIX name, which you can retrieve on the local computer by using the adquery command, as shown in the following example.

```
[root]#adquery group -n
```

To set this policy

1. Open the policy and select **Enabled**.
2. Click **Add**.
3. Enter the name of a zone group in the box (or the UNIX group name if connected through Auto Zone). Then click **OK**.

Map Zone Groups to Local Group

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Accounts > Map zone group to local group

Description

Specify one or more zone groups to map to a Mac local group on the local computer. Members of the zone groups you specify here will be given the privileges of the local group on the local computer; for example:

- If you map to the _lpadmin and _lpoperator local groups, members of the zone group can manage printer settings on the local computer.
- If you map to the admin local group, members of the zone group obtain administrator privileges on the local computer.

  Note: To obtain administrator privileges for a zone group, you can either map to the local admin group with this policy, or use the Map zone groups to local admin group policy. However, do not do both as the results are unpredictable.

Be certain to create a zone group in Access Manager (or adedit) and add users who you want to have administrative privileges on managed Mac computers.

Note: If the local computers is connected to the domain through Auto Zone, you cannot create a zone group because there are no zones.

However, all Active Directory groups are valid for the joined computer, so you can map any group to the local admin group, but you need to know the group's UNIX name, which you can retrieve on the local computer, by using the adquery command, as follows

```
[root]#adquery group -n
```

To set this policy

1. Open the policy and select **Enabled**.
2. Click **Add**.
3. Enter the name of a local group and of a zone group in the respective boxes (or the UNIX group name if connected through Auto Zone), then click **OK**.

   You can repeat this step multiple times to map the zone group to more than one local group.

App Store Settings Deprecated

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > App Store Settings (Deprecated)

Description

Note: This policy has been deprecated and is no longer supported. Enabling it will have no effect. It is provided simply to allow you to disable the policy if it was set in an earlier version of the product. You can use the **Application Access Settings (deprecated)** group policies to control access to the App Store if you wish.

Prohibit Access to the App Store (Deprecated)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > App Store Settings (Deprecated) > Prohibit Access to the App Store (Deprecated)

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > App Store > Prohibit Access to App Store** group policy to control access to the App Store.

By default, all users can access the App Store. Enable this group policy to prohibit access to App Store to all users except the root user and those you specifically authorize with the options, **Allow these users to access App store**, and **Allow these groups to access App Store**.

You can set the following options with this policy:

Allow these users to access App Store	The names of local or AD users who are allowed to access the App Store. When this policy is enabled, only users on this list and the root user are allowed to access the App Store.
Allow these groups to access App Store	The names of local or AD groups that are allowed to access the App Store. When this policy is enabled, only users in the specified groups, and the root user, are allowed to access the App Store.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Custom Settings

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Custom Settings

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Custom Settings** group policy settings to customize

and install configuration profiles. The “Install MobileConfig Profiles” policy installs a device profile. To install a user profile, use the same policy in **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Custom Settings.**

Enable Profile Custom Settings

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Custom Settings > Enable profile custom settings

Description

Enable this group policy to use the Custom payload to specify preference settings for applications that use the standard plist format for their preference files.

> **Note**: This group policy only supports macOS 10.15 and lower.

You can use this GP to add specific keys and values to an existing preferences plist file. However, not all applications work with managed preferences, and in some cases only specific settings can be managed.

By default, you should place the plist files with preference settings in the folder \\domain\SYSVOL\<domain>\customsettings.

To add a file, click **Add** and enter name of a file that you placed in the SYSVOL location. The file you specify is relative to this path:

\\domain\SYSVOL\domain\customsettings

For example, if you enter:

com.apple.plist

the file that is imported is:

\\domain\SYSVOL\domain\customsettings\com.apple.plist

Install MobileConfig Profiles

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Custom Settings > Install MobileConfig Profiles

Description

Enable this group policy to install mobile configuration profiles on managed Mac computers.

> **Note**: There is a Computer Configuration version of this policy (which installs device profiles) and a User Configuration version (which installs user profiles).

> **Note**: This group policy only supports macOS 10.15 and lower.

Before enabling this policy, you must create a directory and copy mobile configuration files to SYSVOL on the domain controller. SYSVOL is a well-known shared directory on the domain computer that stores server copies of public files that must be shared throughout the domain.

Specifically, create the following directory on the domain controller:

\\domainName\SYSVOL\domainName\mobileconfig

and copy one or more mobile configuration profile files to this directory. See Deploy Configuration Profiles to Multiple Computers for details on how to do this.

To specify mobile configuration files to install, enable the policy, then click **Add**. Enter the name of a mobile configuration file that you placed in SYSVOL on the domain controller. Include the .mobileconfig suffix with the name.

If you specify a file that is not in the SYSVOL mobileconfig directory, the profile will not be installed.

If you add new files to the existing list in the group policy, those profiles will be installed — existing profiles will not be touched. If you remove previously specified files, the profiles defined by these files will be uninstalled.

If you add two or more profile files that have the same payloadIdentifier, only one of them will be installed.

If you change the group policy to “Disabled” or “Not Configured”, all existing profiles that were installed previously by the group policy will now be uninstalled

from the managed Mac computers.

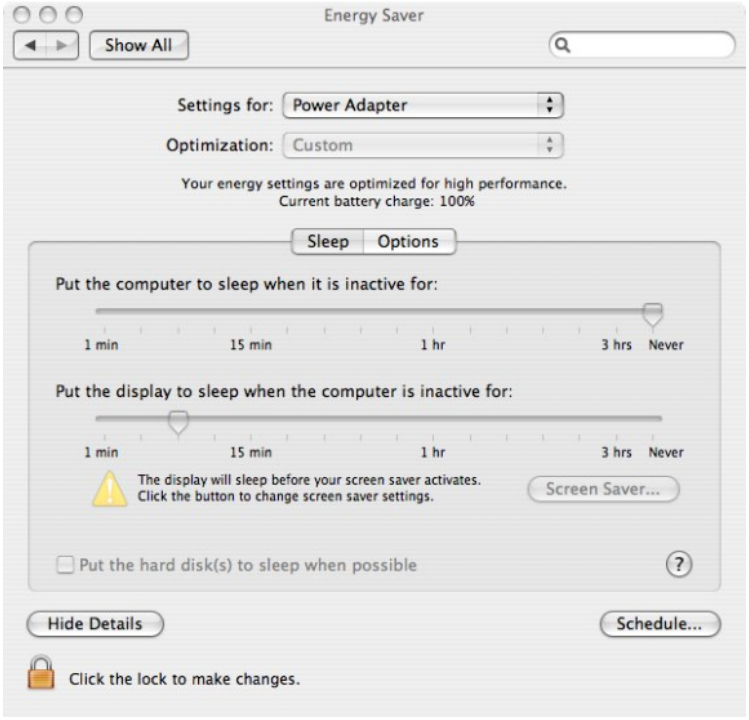
Energy Saver

Path

Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Energy Saver

Description

Use the **Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Energy Saver** settings to manage sleep and wake-up options from the Energy Saver ( ) system preference on Mac computers. For example:



You can configure power options or schedule startup and shutdown times.

Open the appropriate folder to set power options when running on AC power or battery power. Each folder has the identical set of group policies:

- On AC power
- On battery power

Allow Power Button to Sleep the Computer

Path

Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Energy Saver › Allow power button to sleep the computer

Description

Allow the power button to sleep the computer.

Enabling this group policy is the same as selecting the **Allow power button to sleep the computer** option in the Options pane of Energy Saver system preference.

This policy can take effect dynamically at the next group policy refresh interval.

Put The Hard Disk(s) to Sleep When Possible

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Put the hard disk(s) to sleep when possible

Description

Put computer hard disks to sleep when they are inactive.

Enabling this group policy is the same as selecting the **Put the hard disk(s) to sleep when possible** option in the Sleep pane of Energy Saver system preference.

This policy can take effect dynamically at the next group policy refresh interval.

Restart Automatically After a Power Failure

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Restart automatically after a power failure

Description

Enable to set the computer to automatically restart after a power failure.

Enabling this group policy is the same as selecting the **Restart automatically after a power failure** option in the Options pane of Energy Saver system preference.

This policy can take effect dynamically at the next group policy refresh interval.

Set Computer Sleep Time

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Set computer sleep time

Description

Specify the number of minutes of inactivity to allow before automatically putting a computer into the sleep mode.

If you enable this group policy, the period of inactivity you specify applies only when the computer is using its power adapter. If the computer is inactive for the number of minutes you specify, it is put in sleep mode.

Enabling this group policy is the same as selecting a time using the **Put the computer to sleep when it is inactive for** slider in the Sleep pane of Energy Saver system preference.

To prevent the computer from ever going into sleep mode, enter 0 for the number of minutes, or disable the policy.

This policy can take effect dynamically at the next group policy refresh interval.

Set Display Sleep Time

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Set display sleep time

Description

Specify the number of minutes of inactivity to allow before automatically putting the display into the sleep mode.

If you enable this group policy, the period of inactivity you specify applies when the computer is using its power adapter. If the computer is inactive for the number of minutes you specify, the display is put in sleep mode.

Enabling this group policy is the same as selecting a time using the **Put the display to sleep when it is inactive for** slider in the Sleep pane of Energy Saver system preference.

To prevent the display from ever going into sleep mode, enter 0 for the number of minutes, or disable the policy.

This policy can take effect dynamically at the next group policy refresh interval.

Wake When the Modem Detects a Ring

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Wake when the modem detects a ring

Description

Automatically take a computer out of sleep mode when the modem detects a ring. This group policy allows a computer that has been put to sleep to remain available to answer the modem.

This policy can take effect dynamically at the next group policy refresh interval.

Wake for Ethernet network administrator access

Automatically take a computer out of sleep mode when the computer receives a Wake-on-LAN packet from an administrator. This group policy allows a computer that has been put to sleep to remain available to network administrator access.

Enabling this group policy is the same as selecting the **Wake for Ethernet network administrator access** option in the Options pane of Energy Saver system preference.

This policy can take effect dynamically at the next group policy refresh interval.

Scheduled Events

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Scheduled events

Description

To configure sleep/shutdown times and startup times, open the Scheduled events folder (**Computer Configuration Policies > Centrify Settings > Mac OS X Settings > EnergySaver > Scheduled events**).

Set Machine Sleep/Shutdown Time

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Scheduled events > Set machine sleep/shutdown time

Description

Specify a time to shut down or put the computer to sleep.

Enabling this group policy is the same as selecting the **Schedule** button in the Energy Saver system preference, then specifying times and days to shut down or put the computer to sleep.

After enabling this policy, specify values for the following:

- **Action**: Select **sleep** or **shutdown**
- **Set machine sleep/shutdown time**: Enter a time in the format HH:mm using a 24 hour clock; for example, to shut down or put the computer to sleep at 10:05 P.M:

22:05

- **Sleep/shutdown machine on every:** Select the days of the week on which to shut down or sleep the computer at the specified time. All days are selected by default.

This policy can take effect dynamically at the next group policy refresh interval.

Set Machine Startup Time

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Energy Saver > Scheduled events > Set machine startup time

Description

Specify a time to start up the computer.

Enabling this group policy is the same as selecting the **Schedule** button in the Energy Saver system preference, then specifying times and days to start up the computer.

After enabling this policy, specify values for the following:

- **Set machine startup time**: Enter a time in the format HH:mm using a 24 hour clock; for example, to start up the computer at 7:55 A.M.:

07:55

- **Start machine on every**: Select the days of the week on which to start the computer at the specified time. All days are selected by default.

This policy can take effect dynamically at the next group policy refresh interval.

Firewall

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall** settings to manage the firewall options on Mac computers.

Enabling the Centrify firewall group policies is the same as setting options from **System Preferences > Security > Firewall**.

> **Note**: With the Centrify Firewall Group Policies, you can allow all incoming connections, or limit connections to the specified services and applications. You cannot block all connections:

In addition, group policies are available for the Advanced firewall settings, Enable Firewall Logging, and Enable Stealth Mode.

Enable Firewall

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall > Enable firewall

Description

Prevent incoming network communication to all services and ports other than those explicitly enabled for the services specified in the Services pane of the Sharing system preferences.

This group policy turns on default firewall protection.

- Block all incoming connections:

  Block all incoming connections except those required for basic Internet services, such as DHCP, Bonjour, and IPSec.

- Automatically allow signed software to receive incoming connections:

  Allows software signed by a valid certificate authority to provide services accessed from the network. This setting will not take effect if **Block all incoming connections** is selected.

This policy takes effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable iChat

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall > Enable iChat

Description

On Mac OS X Servers, enabling this policy has no effect. If the firewall is enabled, the iChat service is not allowed through the firewall.

If the firewall is enabled, enabling this group policy is the same as clicking the **On** checkbox to allow communication through the firewall for iChat Bonjour. If you do not enable this group policy, traffic for iChat Bonjour will be blocked from the local computer.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable iPhoto Sharing

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall > Enable iPhoto Sharing

Description

On Mac OS X Servers, enabling this policy has no effect. If the firewall is enabled, the iPhoto Sharing service is not allowed through the firewall.

If the firewall is enabled, enabling this group policy is the same as clicking the **On** checkbox to allow communication through the firewall for iPhoto Bonjour Sharing. If you do not enable this group policy, traffic for iPhoto Bonjour Sharing will be blocked from the local computer. Users will be able to access iPhoto collections on other computers, but the local computer cannot be used to serve any iPhoto collections.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable iTunes Music Sharing

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall > Enable iTunes Music Sharing

Description

Enabling this group policy is the same as clicking the **On** checkbox to allow communication through the firewall for iTunes Music Sharing.

On Mac OS X Servers, enabling this policy has no effect. If the firewall is enabled, the iTunes Music Sharing service is not allowed through the firewall.

If you do not enable this group policy, traffic for iTunes Music Sharing will be blocked from the local computer. Users will be able to access iTunes collections on other computers, but the local computer cannot be used to serve any iTunes collections.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Network Time

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall > Enable network time

Description

On Mac OS X Servers, enabling this policy has no effect. If the firewall is enabled, the Network Time service is not allowed through the firewall.

If the firewall is enabled, enabling this group policy is the same as clicking the **On** checkbox to allow communication through the firewall for Network Time. If you do not enable this group policy, traffic from the Network Time service will be blocked.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Block UDP Traffic

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall > Block UDP traffic

Description

Enabling this group policy is the same as clicking the **Block UDP Traffic** checkbox in the Advanced firewall settings.

This group policy does not block UDP communications that are related to requests initiated on the local computer.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Firewall Logging

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Firewall > Enable firewall logging

Description

Log information about firewall activity, including all of the sources, destinations, and access attempts that are blocked by the firewall. The activity is recorded in the secure.log file on the local computer.

Enabling this group policy is the same as clicking the **System Preferences > Security > Firewall** then clicking **Enable Firewall Logging** in the Advanced firewall settings.

On Mac OS X Servers, enabling this policy has no effect.

This policy takes effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Stealth Mode

Prevent uninvited traffic from receiving a response from the local computer.

Enabling this group policy is the same as clicking the **System Preferences > Security > Firewall** then clicking **Enable Stealth Mode** in the Advanced firewall settings.

If you enable this group policy, the local computer will not respond to any network requests, including ping requests. Because the computer will not reply to ping requests, using this policy may prevent you from using network diagnostic tools that require a response from the local computer.

On Mac OS X Servers, enabling this policy has no effect.

This policy takes effect dynamically at the next group policy refresh interval without rebooting the computer.

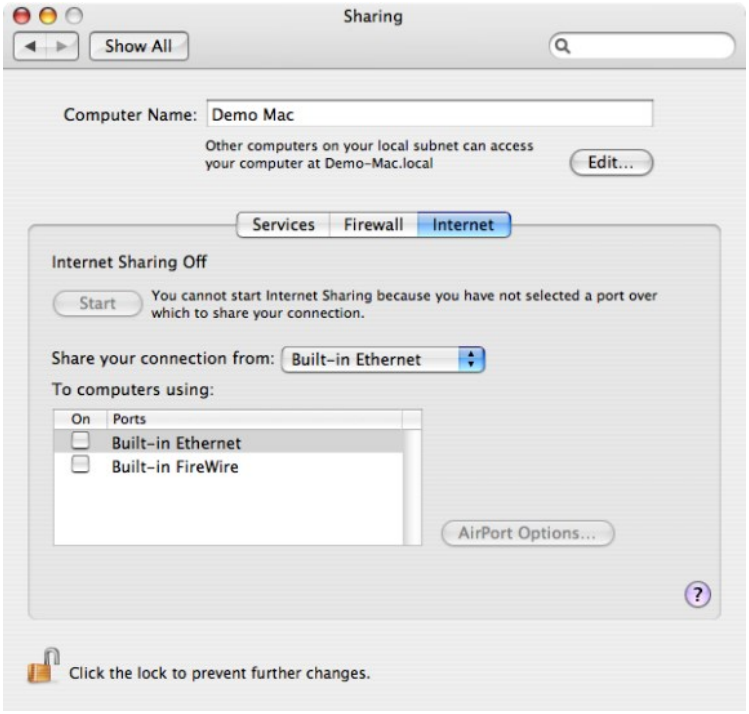
Internet Sharing

Path

Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Internet Sharing

Description

Use the **Computer Configuration › Policies › Centrify Settings › Mac OS X Settings ›Internet Sharing** group policy to prevent any kind of Internet sharing on the local computer. This group policy can only be used to prevent Internet sharing. Although this group policy corresponds to a setting on the Internet pane of the Sharing ( ) system preference, you can not use it to start Internet sharing, configure the shared connection, or set any other options. For example:



Disallow All Internet Sharing

Path

Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Internet Sharing › Disallow all Internet Sharing

Description

Prevent any kind of Internet sharing on the local computer. Enabling this group policy is the same as clicking **Stop** to prevent other computers from sharing an Internet connection on a local computer in the Internet pane of the Sharing system preference.

For this group policy, clicking Disabled or Not Configured has no effect. If you have previously Enabled the group policy, Internet sharing will remain off until you manually start it on the local computer.

Once enabled, this group policy takes effect when users log out and log back in, or dynamically at the next group policy refresh interval without rebooting the computer.

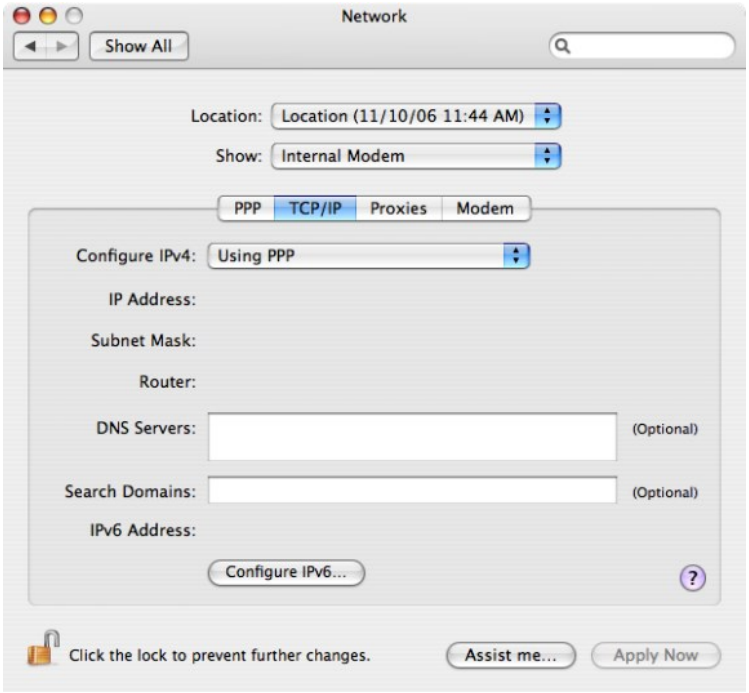
Network

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network** settings to manage DNS search requests and proxy settings. These group policies correspond to settings in the TCP/IP and Proxies panes of the Network ( ) system preference on Mac computers. For example:



Legacy Location Settings

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings

Description

Use **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings** to configure network settings for the Automatic network location.

Adjust List of DNS servers

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings > Adjust list of DNS servers

Description

Control the list of DNS servers when performing DNS lookups.

To use this policy, click **Enabled**, then click **Add**, type the IP address for a DNS server, then click **OK** to add the server to the list of DNS servers. Add as many servers as you want in this manner. When you are finished adding the servers, click **OK** to close the dialog box.

At any time while the policy is enabled, you can select an address in the list and click **Edit** to change the address, or **Remove** to remove it as a DNS server.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Adjust List of Searched Domains

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings > Adjust list of searched domains

Description

Control the list of domains to search when performing DNS lookups.

To use this policy, click **Enabled**, then click **Add**, type a domain name, then click **OK** to add the domain to the list of domains to search. Add as many domains as you want in this manner. When you are finished adding the domains to search, click **OK** to close the dialog box.

At any time while the policy is enabled, you can select a domain in the list and click **Edit** to change the name, or **Remove** to remove it as a domain to be searched.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Configure Proxies

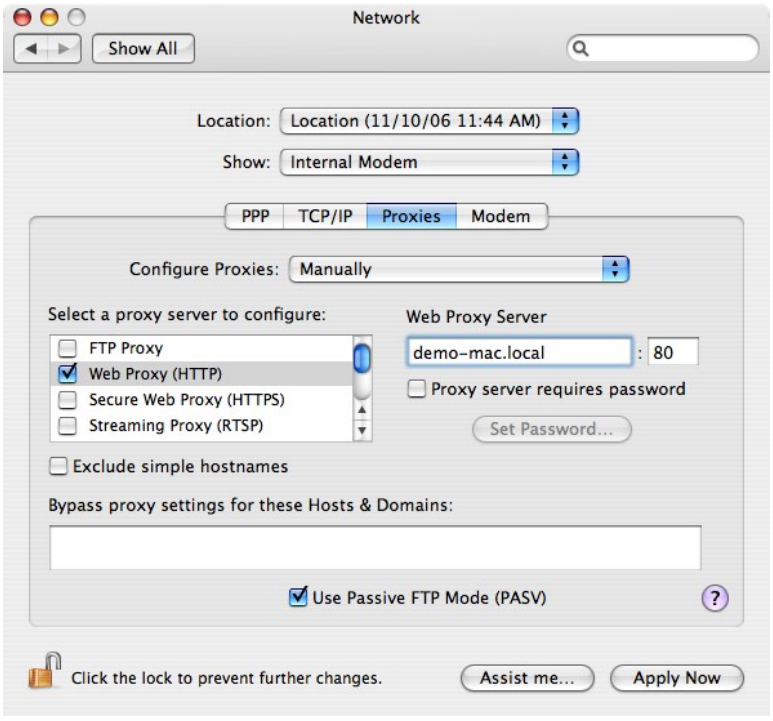
Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings > Configure Proxies

Description

Configure proxy servers to provide access to services through a firewall.

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Configure Proxies** settings to manage settings on the Proxies panes of the Network system preference. For example:



These group policies enable you to configure the host names (or IP addresses) and port numbers for the computers providing specific services, such as File Transfer Protocol (ftp), Hypertext Transfer Protocol (http), and HTTP over Secure Sockets Layer (https), through a firewall. A proxy server is a computer on a local network that acts as an intermediary between computer users and the Internet to ensure the security and administrative control of the network.

Enable Proxies

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings > Configure Proxies > Enable Proxies

Description

Configure the host name (or IP address) and port number for the computers providing specific services. Within this category, you can enable the following proxy servers:

- Use the **Enable FTP Proxy** policy to configure the host name and port number for the FTP proxy server (FTP protocol).
- Use the **Enable Web Proxy** policy to configure the host name and port number for the Web proxy server (HTTP protocol).
- Use the **Enable Secure Web Proxy** policy to configure the host name and port number for the Secure Web proxy server (HTTPS protocol).
- Use the **Enable Streaming Proxy** policy to configure the host name and port number for the Streaming proxy server (RTSP protocol).
- Use the **Enable SOCKS Proxy** policy to configure the host name and port number for the Streaming proxy server (SOCKS protocol).
- Use the **Enable Gopher Proxy** policy to configure the host name and port number for the Gopher proxy server.
- Use the **Enable Streaming Proxy** policy to configure the host name and port number for the Streaming proxy server (RTSP protocol).
- Use the **Enable Proxies using a PAC file** policy to configure proxy servers from a proxy configuration file.

These policies can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Exclude Simple Hostnames

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings > Configure Proxies > Exclude simple hostnames

Description

Prevent requests to unqualified host names from using proxy servers. If you enable this policy, users can enter unqualified host names to contact servers directly rather than through a proxy.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Use Passive FTP Mode (PASV)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings > Configure Proxies > Use Passive FTP Mode (PASV)

Description

Use the FTP passive mode (PASV) to access Internet sites when computers are protected by a firewall.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Bypass Proxy Settings for these Hosts & Domains

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy location settings > Configure Proxies > Bypass Proxy settings for these Hosts & Domains

Description

Specify fully-qualified host names and domains for which you want to bypass proxy settings.

You should use this policy to define the hosts or domains that should never be contacted by proxy.

To use this policy, click **Enabled**, then click **Add**, type a host or domain name, and click **OK** to add the entry to the Show Contents list.

Each host or domain should be listed as a separate line in the Hosts and Domains list. For each host or domain, click **Add**, type the host or domain name, and click **OK** to add the host or domain as a new entry in the list. When you are finished adding items to the list, click **OK** to close the policy dialog box.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Location 1 and Location 2

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Location 1

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Location 2

Description

Use **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Location 1** to configure network settings for an additional network location. The group policies in Location 2 are identical, and allow you to configure network settings for another network location.

Adjust List of DNS Servers

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Location 1/Location 2 > Adjust list of DNS servers

Description

Control the list of DNS servers when performing DNS lookups.

To use this policy, click **Enabled**, then click **Add**, type the IP address for a DNS server, then click **OK** to add the server to the list of DNS servers. Add as many servers as you want in this manner. When you are finished adding the servers, click **OK** to close the dialog box.

At any time while the policy is enabled, you can select an address in the list and click **Edit** to change the address, or **Remove** to remove it as a DNS server.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Adjust List of Searched Domains

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Location 1/Location 2 > Adjust list of searched domains

Description

Control the list of domains to search when performing DNS lookups.

To use this policy, click **Enabled**, then click **Add**, type a domain name, then click **OK** to add the domain to the list of domains to search. Add as many domains as you want in this manner. When you are finished adding the domains to search, click **OK** to close the dialog box.

At any time while the policy is enabled, you can select a domain in the list and click **Edit** to change the name, or **Remove** to remove it as a domain to be searched.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Network Location

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Location 1/Location 2 > Enable network location

Description

Enable all network location settings under the current location category and set its location name. This policy must be enabled to apply settings in this location category (for example, Location1).

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Configure Proxies

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Location 1/Location 2 > Configure Proxies

Description

Configure proxy servers to provide access to services through a firewall. The group policies in this folder are the same as the ones in Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Network > Legacy Location settings> Configure Proxies. Refer to Configure Proxies for more information.

Remote Management

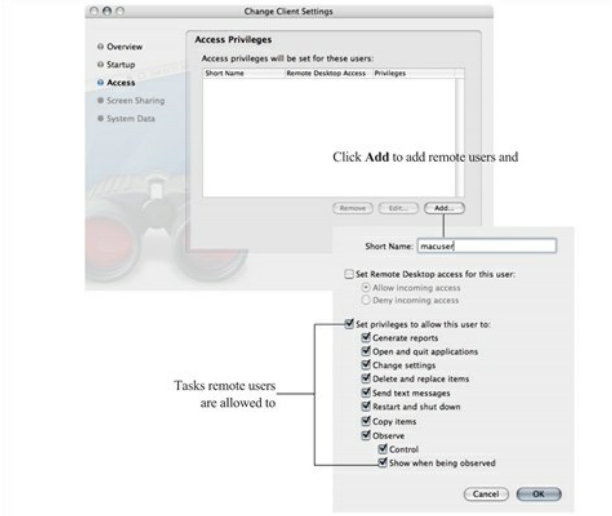
Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Remote Management

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Remote Management** settings to control Apple Remote Desktop access for zone users. You can use these group policies to give Active Directory group members permission to remotely control Mac computers without physically having to activate the Apple Remote Desktop on the remote Mac computer.

The Remote Management group policies correspond to the **Manage > Change Client Settings** options in Apple Remote Desktop and are similar to access privileges defined on a client computer using the Sharing system preference. For example:



> **Note**: Because the group policies correspond to the **Manage > Change Client Settings** options in Apple Remote Desktop, the group policy settings are not displayed in the local system preference on the Mac client. Although the tasks you can assign to different groups by group policy correspond to tasks you can assign using the local Sharing system preference on a Mac client computer, the group policy settings do not update the local system preference to display check marks for the tasks that the remote users have been given permission to perform.

Enable Administrator Access Groups

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Remote Management > Enable administrator access groups

Description

Allow all users who are members of the following Apple Remote Desktop administrator groups to access this computer using Apple Remote Desktop.

Before enabling this group policy, you should create each Active Directory security group you intend to use and add a UNIX profile for each group to the zone, using the exact UNIX group names (ard_admin, ard_reports, ard_manage, ard_interact).

> **Note**: Creating UNIX profiles with these group names displays a warning message because the names are longer than eight characters. You can safely ignore this warning message.

Enabling this policy allows users in the following groups to manage Mac computers through Apple Remote Desktop:

- ard_admin gives all members of the group the ability to remotely control the computer desktop.
- ard_reports gives all members of the group the ability to remotely generate reports on the computer.
- ard_manage gives all members of the group the ability to manage the computer using Apple Remote Desktop. Users in this group can perform the following tasks by using Apple Remote Desktop:
  - Generate reports
  - Open and quit applications
  - Change settings
  - Copy Items
  - Delete and replace items
  - Send text messages
  - Restart and shut down
- ard_interact gives all members of the group the ability to interactively observe or control the computer using Apple Remote Desktop.

  Users in this group can perform the following tasks by using Apple Remote Desktop:
  - Send text messages
  - Observe
  - Control

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

See Setting Up Local and Remote Administrative Privileges for information on how to use this group policy with the Map Zone Groups to Local Admin Group policy to enable both local and remote administrative access for the same group of users.

Scripts (Login/Logout)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout)

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout) > Specify multiple login scripts** group policy to deploy login scripts that run when an Active Directory or local user logs on. When you use this group policy, the login scripts are stored in the Active Directory domain's system volume (sysvol) and transferred to the Mac computer when the group policies are applied. Login scripts are useful for performing common tasks such as mounting and un-mounting shares

This policy is also available as a user policy. If you specify scripts using both the computer and user policies, the computer scripts are executed first.

Specify Multiple Login Scripts

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout) > Specify multiple login scripts

Description

Specify the names of one or more login scripts to execute when an AD or local user logs on. The scripts you specify run simultaneously in no particular order.

Before enabling this policy, you should create the scripts and copy them to the system volume (sysvol) on the domain controller. By default, the login scripts are stored in the system volume (SYSVOL) on the domain controller in the directory:

```
\\domain\SYSVOL\domain\Scripts
\scriptname1
\scriptname2
...
```

After enabling this policy, click **Add** and enter the following information:

- **Script**: The name of the script and an optional path, which are relative to \\domain\SYSVOL\domain\scripts\

  For example, if the domain name is ajax.org and you enter a script name of start.sh, the script that gets executed on the domain controller is:

  \\ajax.org\SYSVOL\ajax.org\Scripts\mlogin.sh

You can specify additional relative directories in the path, if needed; for example, if you type submlogin.sh, the file that gets executed is:
\\ajax.org\SYSVOL\ajax.org\Scripts\sub\mlogin.sh

- **Parameters**: An optional set of arguments to pass to the script. These arguments are interpreted the same way as in a UNIX shell; that is, space is a delimiter, and backslash is an escape character. You can also use $USER to represent the current user's name. For example:

```
arg1 arg2 arg3
arg1 'a r g 2' arg3
```

  Note: Be certain authenticated users have permission to read these files so the scripts can run when they log in.

Once this group policy is enabled, it takes effect when users log out and log back in.

Scripts (LaunchDaemons)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (launchDaemons)

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (LaunchDaemons) > Specify multiple LaunchDaemon scripts** group policy to deploy scripts that run when launchd starts (system boot up). When you use this group policy, the LaunchDaemon scripts are stored in the Active Directory domain's system volume (sysvol) and transferred to the Mac computer when the group policies are applied. Using LaunchDaemons to run scripts allows you to run the scripts as root, where the **Specify multiple login scripts** group policy can only be run as the logged in user.

Refer to the following Apple resources to learn more about Launch Daemons and Agents.

- https://developer.apple.com/library/content/documentation/MacOSX/Conceptual/BPSystemStartup/Chapters/CreatingLaunchdJobs.html
- https://developer.apple.com/library/content/technotes/tn2083/_index.html#//apple_ref/doc/uid/DTS10003794

Specify Multiple LaunchDaemon Scripts

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (launchDaemons) > Specify multiple LaunchDaemon scripts

Description

Enable this group policy to specify multiple scripts to run automatically when launchd starts (system boot up).

The scripts you specify run simultaneously in no particular order.

Before enabling this policy, you should create the scripts and copy them to the system volume (sysvol) on the domain controller. By default, the LaunchDaemon scripts are stored in the system volume (SYSVOL) on the domain controller in the directory:

```
\\domain\SYSVOL\domain\Scripts
\scriptname1
\scriptname2
...
```

After enabling this policy, click **Add** and enter the following information:

- **Script**: The name of the script and an optional path, which are relative to \\domain\SYSVOL\domain\scripts\.

For example, if the domain name is ajax.org and you enter a script name of startup.sh, the script that gets executed on the domain controller is:

\\ajax.org\SYSVOL\ajax.org\Scripts\startup.sh

You can specify additional relative directories in the path, if needed; for example, if you type submlogin.sh, the file that gets executed is:
\\ajax.org\SYSVOL\ajax.org\Scripts\sub\startup.sh

- **Parameters**: An optional set of arguments to pass to the script. These arguments are interpreted the same way as in a UNIX shell; that is, space is a delimiter, and backslash is an escape character. For example:

arg1 arg2 arg3
arg1 'a r g 2' arg3

Security & Privacy

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy

Description

Use the Centrify group policies found in **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy** to manage the Keychain, public and private keys, and the options from the Security & Privacy () system preference on Mac OS X computers.

Auto Generate New Login Keychain

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > Auto Generate New Login Keychain

Description

Use this policy to automatically generate a new login keychain if a user's keychain password does not match the password they used to successfully login, resulting in the message "the system was unable to unlock your login keychain".

This commonly occurs if someone has changed their account password on another system.

If this policy is enabled, a new keychain will be generated when a password sync issue is discovered. This new keychain will be set as the default login keychain and the previous keychain will be moved to a backup.

Delinea recommends disabling this policy if you plan to use Enable Keychain Synchronization.

This policy is disabled by default.

Certificate Validation Method

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Certificate validation method

Description

Specify the certificate validation method to use for the Mac computer.

> **Note**: This group policy has no effect on the "Keychain Access > Preferences > Certificates" settings. Keychain Access > Preferences are per-user settings, which are not used by a Mac computer during login. This group policy changes Centrify SmartCardTool > Revocation settings, which represent the system settings used by a Mac computer during login.

This policy allows you to choose either one, or both of the two common methods for verifying the validity of a certificate:

- **Certificate Revocation List**: Use a certificate revocation list (CRL) from a revocation server.
- **Online Certificate Status Protocol**: Use an online certificate status protocol (OCSP) responder to validate certificates.

  If you select this option, you can specify a local responder to override the one provided in the certificates.

For each validation option, you can select one of the following settings:

- **Off**: No revocation checking is performed.
- **Best attempt**: The certificate passes unless the server returns an indication of a bad certificate.

  This setting is recommended for most environments.
- **Require if cert indicates**: If the URL to the revocation server is provided in the certificate, this setting requires a successful connection to a revocation server as well as no indication of a bad certificate.

  Specify this option only in a tightly controlled environment that guarantees the presence of a CRL server or OCSP responder. If a CRL server or OCSP responder is not available, SSL and S/MIME evaluations could hang or fail.
- **Require for all certs**: This setting requires successful validation of all certificates.

  Use only in a tightly controlled environment that guarantees the presence of a CRL server or OCSP responder. If a CRL server or OCSP responder is not available, SSL and S/MIME evaluations could hang or fail.
- **Local Responder**: If you choose to validate the certificate via OCSP, you can specify a local responder to override that provided in the certificates.
- **Priority**: The priority determines which method (OCSP or CRL) is attempted first.

  If the first method chosen returns a successful validation, the second method is not attempted, unless you choose to require both.

Disable Automatic Login

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Disable automatic login

Description

Disable the automatic login setting. If you enable this group policy, it overrides the Login Options set in the General tab of the Security & Privacy system preference.

For this group policy, clicking Disabled or Not Configured has no effect.

Once enabled, this group policy takes effect when the computer is rebooted.

Disable Location Services

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Disable Location Services

Description

Disable the “Enable Location Services” setting. If you enable this group policy, it overrides the Enable Location Services setting in the Privacy tab of the Security & Privacy system preference.

> **Note**: As of MacOS Catalina, it is not enough to wait for the next group policy refresh or execute adgpupdate. You also need to restart the Mac for this GP to take effect.

For this group policy, clicking Disabled or Not Configured has no effect.

Once enabled, this group policy takes effect at the next group policy refresh interval.

Enable Smart Card Support

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Enable smart card support

Description

Enable users to logon with smart cards. If you enable this group policy, it adds smart card support to the authorization database on Mac computers that are linked to the group policy object.

Delinea smart card support for macOS is based on the macOS modern native framework, CryptoTokenKit

See Configuring a Mac Computer for Smart Card Login for details.

Select **Enable smart card support for the SUDO command**, then when executing the SUDO command, smart card user can authenticate identity by smart card PIN.

Select **Enable smart card support for the SU command**, then when executing the SU command, smart card user can authenticate identity by smart card PIN.

Select **Enable smart card support for the LOGIN command**, then when executing the LOGIN command, smart card user can authenticate identity by smart card PIN.

Select **Enforce smart card login**, then only smart card users with a smart card can log in to the Mac machine.

Edit **Exception group** to add a exception group for the "Enforce smart card login", then any users belong to this group always can log in to the Mac machine by a username and password. In general, we recommend set a exception group, for example, admin, when **Enforce smart card login** is selected.

Select one of options in **Certificate trust behavior** to set smart card certificate trust behavior, the meaning of number:

0: Smart card certificate trust isn't required.

1: Smart card certificate and chain must be trusted.

2: Certificate and chain must be trusted and not receive a revoked status.

3: Certificate and chain must be trusted and revocation status is returned valid.

Once enabled, this policy takes effect dynamically at the next group policy refresh interval.

Enable FileVault 2

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Enable FileVault 2

Description

This group policy allows you to select whether to use one institutional key for multiple Mac computers, or computer-specific ("personal") keys.

To use one institutional key for multiple Mac computers, select **Use Institutional Recovery Key**. Then click **Select** to select the certificate that contains the FileVault master keychain that can unlock the encrypted disk. You must already have created a FileVault master keychain and exported the certificate for the master keychain to a Windows domain server before you perform this step.

To use computer-specific ("personal") keys instead of one institutional key, leave **Use Institutional Recovery Key** unchecked. In this situation, a personal recovery key is created for the Mac computer and stored in the computer object in Active Directory. The key is created and sent to the computer object in Active Directory after the "Managed By" user logs in, logs out, and provides the user password.

This policy is available only for OS X 10.9 and later.

For complete instructions, see Configuring Filevault 2.

> **Note**: Enabling this group policy does not immediately enable FileVault 2 protection on a Mac computer. FileVault 2 protection is enabled when the FileVault-enabled user (that is, the "Managed By" user) logs on to the computer. Disabling this group policy does not disable FileVault 2 protection — disabling FileVault 2 can only be done manually.

Once enabled, this group policy takes effect at the next group policy update interval or when you execute the `adgpupdate` command.

Enable Gatekeeper

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Enable Gatekeeper

Description

Enable the Gatekeeper feature, which controls access to the Mac App store. This policy overrides the "Allow applications downloaded from" setting on the General tab of the Security & Privacy system preference pane.

After enabling the policy, select one of the following options:

- **Mac App Store** Only allow installation of applications that have been downloaded from the Mac App store.
- **Mac App Store** and identified developers. Only allow installation of applications that have been downloaded from the Mac App Store or were created by Apple-sanctioned developers.
- **Anywhere** Allow installation of any applications.

Enable Keychain Synchronization

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Enable Keychain synchronization

Description

This group policy controls whether to enable keychain synchronization, which synchronizes the login keychain to the login user's AD password when a password change is detected.

> **Note**: Keychain synchronization is password-focused and should not be used in smart card environments.

Set the **Password change detection interval (minutes)** option to determine the time (in minutes) between checking for changed passwords. There is a random zero to five minute variance in the actual interval each device is checked for a changed password to maintain performance. As a result, the minimum interval is five minutes.

The default value is 30 minutes.

The **Store AD password in the login Keychain** option is used to streamline updates of the user's login Keychain password. If this option is enabled the Keychain Sync utility stores the user's AD password in the login keychain the next time the user logs in. If the password is changed after the policy is enabled but before the previous password is stored in the login keychain, the keychain sync application requests the previous password.

When this option is selected, the user's AD password is encrypted using a static AES256 key that is unique to that user and stored in the login Keychain as an application password. The key and password are added to the keychain using the SecItemAdd API. In addition, an Access Control List ensures that only the Keychain Sync utility can access the key used to encrypt and decrypt the password.

Delinea recommends disabling Auto Generate New Login Keychain before enabling this policy

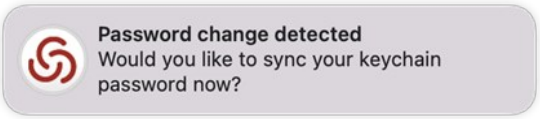
Please note the following limitations with the **Store AD Password in the login Keychain** option:

- This option only works on macOS 10.12 or later.
- The user's AD password is inaccessible when the login keychain is locked.

  The most common scenario that causes this is if a user's AD password is changed and the user logs out before synchronizing the keychain, then logs back in. When the user logs back in, the password check fails due to the new password, locking the login Keychain and preventing the Keychain Sync utility from accessing it.
- Password changes can only be detected when the machine is in connected mode.

User experience when the AD password is already stored in the login Keychain

1. The login user receives a password change notification when his/her password is changed remotely.

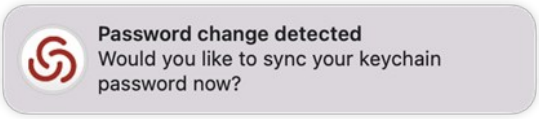


2. When the user clicks **Yes** on the notification, the Delinea Keychain Sync utility appears and asks for the current password to synchronize the keychain.

After entering the current password and clicking **OK**, the Keychain Sync utility synchronizes the login keychain with the new password.

User experience when the AD password is not yet stored in the login Keychain

1. The login user receives a password change notification when his/her password is changed remotely.

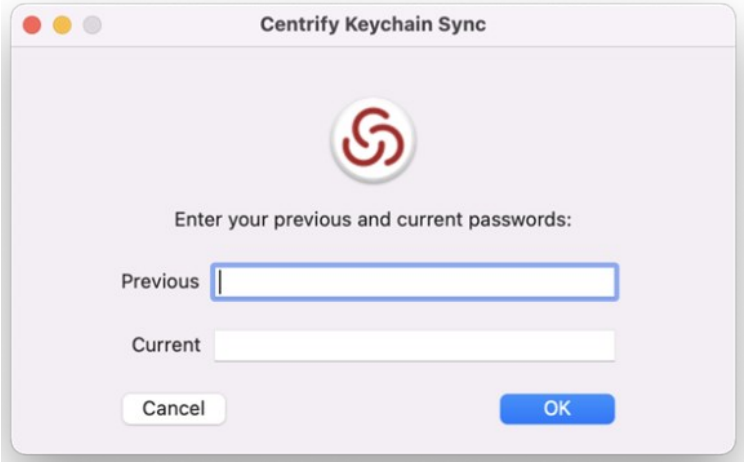


2. When the user clicks **Yes** on the notification, the Delinea Keychain Sync utility appears and asks if the user remembers the previous password.

3. The user clicks **Yes** or **No**.

- If the user clicks **No**, the Keychain Sync utility creates a new login keychain.

- If the user clicks **Yes**, the Keychain Sync utility asks for the previous and current passwords.



After entering the previous and current passwords and clicking **OK**, the Keychain Sync utility synchronizes the login keychain with the new password.

Log Out After Number of Minutes of Inactivity

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Log out after number of minutes of inactivity

Description

Specify the number of minutes of inactivity to allow on a computer before automatically logging out the current user. The default value is 5 minutes.

Setting the value to less than 5 minutes disables automatic logout. If you plan to disable automatic logout, it is recommended that you set the value to 0 to preserve backward compatibility.

> **Note**: Disabling this policy does not disable automatic logout.

This policy takes effect when users log out and log back in after the next group policy refresh.

Require a Password to Wake this Computer from Sleep or Screen Saver

##Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > Require a password to wake this computer from sleep or screen saver

Note: This group policy only supports macOS 10.15 and lower.

##Description

Lock the computer screen when the computer goes into sleep or screen saver mode and requires users to enter a user name and password to unlock the screen.

Enabling this group policy is the same as clicking the Require a password to wake this computer from sleep or screen saver option in the Security system preference.

After this group policy is enabled, it takes effect dynamically at the next group policy refresh interval.

Require Password to Unlock Each Secure System Preference

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Require password to unlock each secure system preference

Description

Lock sensitive system preferences to prevent users who aren't administrators from changing them. This group policy requires users to provide an administrator's password to unlock each secure system preference before they can make changes.

If you enable this policy, users must provide an administrator password to access any secure system preference. If the current user is logged on as an administrator and this policy is not configured or disabled, the user can access and change secure system preferences without providing the administrator password.

This policy can take effect dynamically at the next group policy refresh interval.

Use Secure Virtual Memory

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Use secure virtual memory

Description

Prevent passwords from being recoverable from virtual memory.

Any time a password is entered, it is possible for system to write that password in a block of memory that it dumps to a file in /var/vm, making the password recoverable.

Enabling this group policy ensures that the virtual memory /var/vm files are encrypted, preventing any passwords written there from being recovered.

This policy can take effect dynamically at the next group policy refresh interval.

Allow All Applications to Access the Auto-Enrollment Private Key(S)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Public Key Policies > Allow all applications to access the auto-enrollment private key(s)

Description

Enabling this policy allows all applications to access the auto-enrollment private key(s) in the System keychain.

See Configuring Auto-Enrollment for more information about auto-enrollment keys.

Note: This setting only applies to a new auto-enrollment private key(s); it will not update already imported auto-enrollment private key(s) that are in the System keychain.

Allow Specific Applications to Access the Auto-Enrollment Private Key(S)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Public Key Policies > Allow specific applications to use the auto-enrollment private key(s)

Description

Enabling this policy allows specified applications to access the auto-enrollment private key(s) in System keychain.

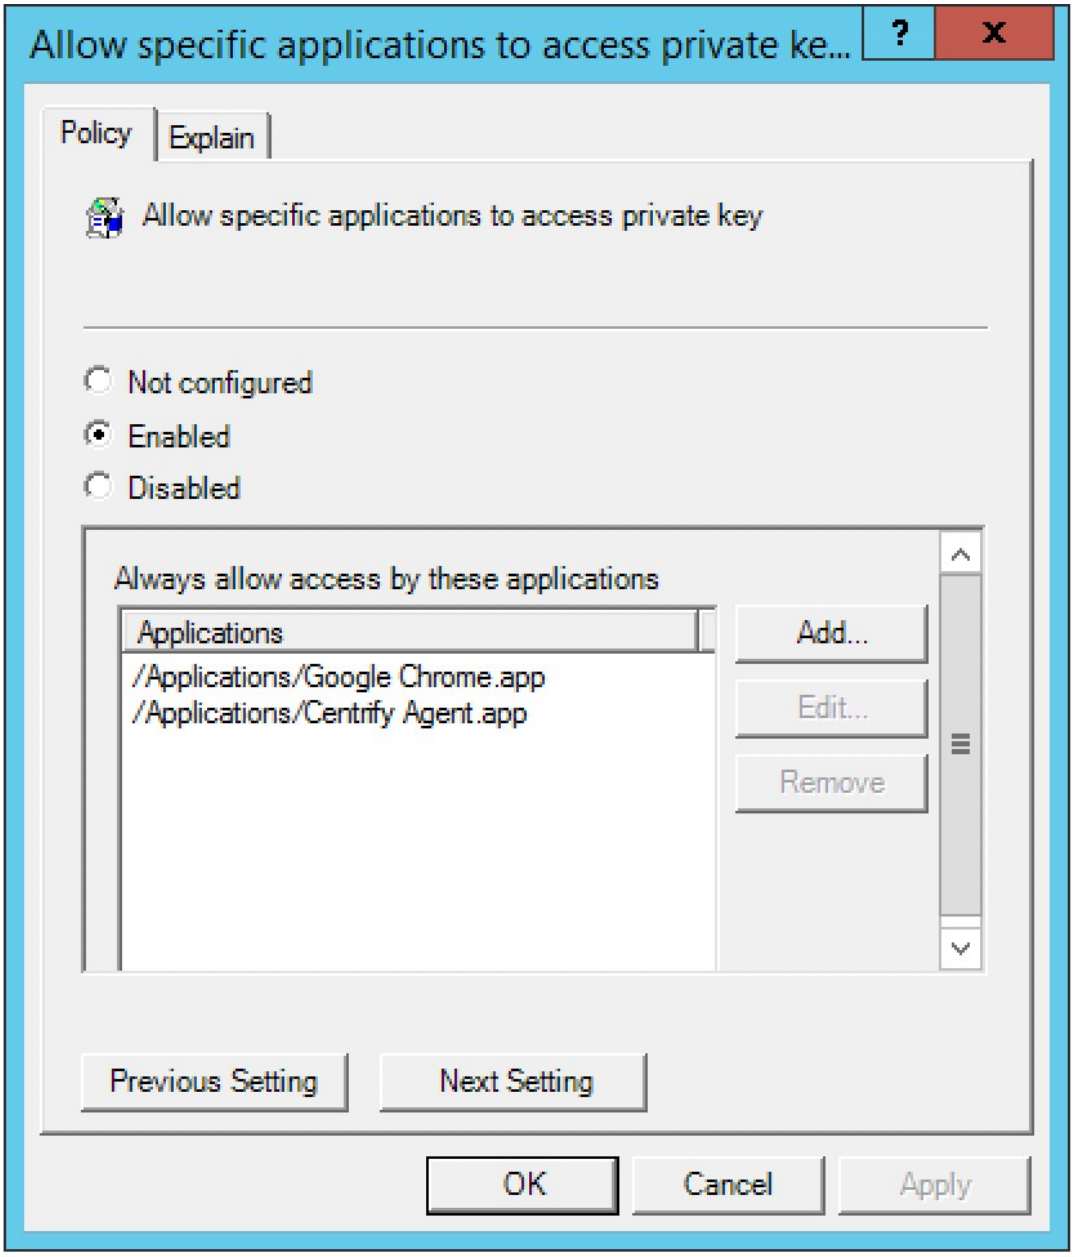
After you enable this policy, click **Add** to enter the path to the application you want to allow access to the auto-enrollment private key, then click **OK**. You can click **Add** again to add additional applications.

For example, to give Google Chrome and Delinea Agent access to the auto-enrollment private key, enter the application path for Google Chrome:

```
/Applications/Google Chrome.app
```

Click **OK**. Then click **Add** and enter the application path for Delinea Agent:

```
/Applications/Centrify Agent.app
```



After this group policy is enabled, the list of applications specified in the group policy are added to the access control list of the auto-enrollment private key in System keychain.

See Configuring Auto-Enrollment for more information about auto-enrollment keys.

> **Note**: This setting only applies to a new auto-enrollment private key. It does not change auto-enrolled private keys that are already in the keychain.

If the group policy **Allow all applications to access the auto-enrollment private key(s)** (above) is enabled, this group policy will be ignored.

Do Not Allow the Private Key(S) to be Extractable

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Public Key Policies > Do not allow private key(s) to be extractable

Description

Enabling this policy prevents exporting the auto-enrollment private key(s).

> **Note**: This setting only applies to a new auto-enrollment private key. It does not change the auto-enrolled private key(s) that are already in the keychain.

Store The Private and Public Key(S) Only in the Keychain

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Public Key Policies > Store the private and public key(s) only in the keychain

Description

Enable this group policy to store the auto-enrollment key(s) only in the keychain.

User certificate auto-enrollment always uses the Keychain and is not controlled by any Group Policy.

> **Note**: 802.1X profiles installed through the "Mac OSX Settings -> 802.1X Settings" Group Policies will no longer be signed if this GP is enabled before profiles are installed.

Services

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services** settings to manage access to the service options from the Sharing () system preference on Mac computers. These group policies correspond to the options displayed on the Services pane. For example:

Enable Personal File Sharing

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Personal File Sharing

Description

Allow users on other Mac computers access to Public folders on the local computer. If you enable this group policy, all users can access files in the Public folder through the Apple File Sharing protocol. Users with appropriate permission can also access other folders on the local computer if properly authenticated.

Enabling this group policy is the same as opening the Sharing system preference, selecting **File Sharing**, then clicking the **Options** button and selecting the **Share Files and Folders using AFP** option.

On Mac OS X Servers, enabling this policy has no effect.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Windows Sharing

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Windows Sharing

Description

Allow users on Windows computers access to shared folders on the local computer through SMB/CIFS file shares.

Enabling this group policy is the same as opening the Sharing system preference, selecting **File Sharing**, then clicking the **Options** button and selecting the **Share Files and Folders using SMB** option.

On Mac OS X Servers, this policy has no effect.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Personal Web Sharing

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Personal Web Sharing

Description

Allow users on other computers to view Web pages in each user's sites folder on the local computer.

Enabling this group policy is the same as opening the Sharing system preference and selecting the Web Sharing option.

On Mac OS X Servers, enabling this policy has no effect.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Remote Login

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Remote Login

Description

Allow users on other computers to access this computer using SSH.

Enabling this group policy is the same as opening the Sharing system preference and selecting the Remote Login option.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable FTP Access (deprecated)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable FTP Access

Description

Allow users on other computers to exchange files with this computer using FTP applications.

Enabling this group policy is the same as opening the Sharing system preference, selecting **File Sharing**, then clicking the **Options** button and selecting the **Share Files and Folders using FTP** option.

On Mac OS X Servers enabling this policy has no effect.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Apple Remote Desktop

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Apple Remote Desktop

Description

Allow others to access this computer using the Apple Remote Desktop program.

Enabling this group policy is the same as opening the Sharing system preference and selecting the Remote Management option.

If you enable this group policy, you can set the following access privileges:

- Allow guest users to request permission to control the screen
- Prevent VNC viewers from controlling the screen.

Because allowing VNC viewers to control the screen requires setting a password to take control of the screen and this behavior presents a potential security issue, this group policy can only be used to disallow VNC access.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Remote Apple Events

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Remote Apple Events

Description

Allow applications on other Mac computers to send Apple Events to the local computer.

Enabling this group policy is the same as opening the Sharing system preference and selecting the Remote Apple Events option.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Printer Sharing

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Printer Sharing

Description

Allow other people to use printers connected to the local computer.

Enabling this group policy is the same as opening the Sharing system preference and selecting the Printer Sharing option.

On Mac OS X Servers, enabling this policy has no effect.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Enable Xgrid

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Services > Enable Xgrid

Description

Allow clustered Mac OS Xgrid controllers to distribute tasks to the local computer for completion.

Enabling this group policy is the same as opening the Sharing system preference and selecting the Xgrid Sharing option.

On Mac OS X Servers enabling this policy has no effect.

This policy can take effect dynamically at the next group policy refresh interval without rebooting the computer.

Software Update Settings

Path

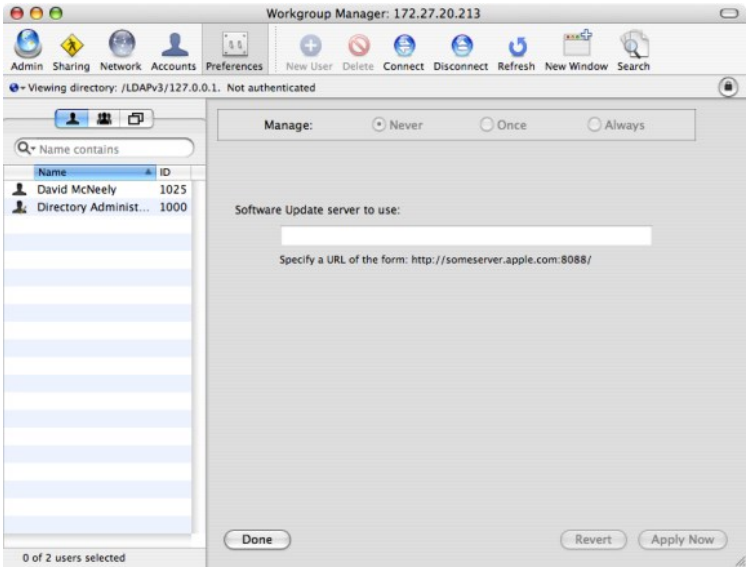
Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Software Update Settings

Description

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Software Update Settings** group policies to manage software updates. The group policies in this category enable you to set the interval for checking for software updates and to identify a specific server from which updates should be received.

These group policies correspond to settings you make using the Software Update ( ) system preference on client Mac OS X computers and the Software Update preference in the Workgroup Manager on Mac OS X servers. For example, the interval for checking for software updates is typically configured Software Update system preference on client Mac computers:

Note: Identifying a software update server to use for downloading updates is configured on a Mac OS X server using the Software Update preference in the Workgroup Manager. For example:



The software update group policies are computer policies, applied as the root user, and apply to all users of the computer. Setting these group policies updates the plist files for individual users with the group policy parameters, such as update server URL, update interval, and so on. However, to prevent local users from using Software Update in System Preferences to manually set software update server parameters, an administrator should also limit access to the Software Update Preferences Pane by setting the group policy, **Limit Items Shown in System Preferences**, and then enabling the group policy, **Enable System Preferences Pane: System** › **Enable Software Update**.

Otherwise, you may see anomalous behavior. For example, a user can open Software Update and change parameters, such as disabling software updates (by deselecting Check for updates). If the user then re-enables software updates, the update server resets to the Apple software update server, not the server specified in the software update server group policy. However, at the next login, or at the next adgpupdate period, the Server URL and other group parameters will be re-applied.

The Software Update Settings contain separate folders that allow you to specify a different update server for each operating system version that you are running. For example, if you have computers with different versions of OS X in your environment, you can specify a different update server for each one by enabling the Specify software update server policy in each of the version-specific folders. In order to do this you must enable Use version specific settings.

If you do not enable Use version specific settings, Legacy Settings are used instead. If you applied Software Update Settings to computers running previous versions of the product, those settings are in Legacy Settings, though you may update them if you wish.

Note: The Automatically download and install software updates policy applies to all computers, regardless of version.

Automatically Check For Software Updates (Legacy, Currently Supported)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Software Update Settings > Automatically check for software updates (Legacy, Currently supported)

Description

Note: There are actually separate versions of this policy in version-specific folders.

Periodically check for updated versions of the software installed on the local computer and automatically download and install newer versions. You can configure the version-specific versions of this policy the same way you can configure the Software Update system preference for the corresponding operating system version.

This policy takes effect when users log out and log back in.

Use Version Specific Settings

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Software Update Settings > Use version specific settings

Description

Enable the use of version-specific settings.

You can then set platform-specific preferences settings for each platform in your environment, which enables you to specify a different update server depending on the version of Mac OS X running on a computer. For example, if you have only 10.10 computers, you can enable this policy and then use Mac OS X 10.10 settings. If you have 10.10 and 10.9 computers, enable this policy, and then configure the version-specific policies as appropriate:

- Mac OS X 10.10 Settings
- Mac OS X 10.9 Settings

If this policy is disabled or not configured, Legacy Settings are used instead of version-specific settings. Likewise, Delinea versions prior to 4.4.2 always use Legacy Settings and ignore this policy setting.

If you configured Software Update Settings with a version of the product prior to 4.4.2, these settings are saved to Legacy Settings when you upgrade to the current Delinea version. You can keep or edit these settings as you wish.

Specify Software Update Server (Legacy, Currently Supported)

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Software Update Settings > Specify software update server (Legacy, Currently supported)

Description

Note: There are actually separate versions of this policy in version-specific folders.

This enables you to specify a separate update server based on the version of the Mac OS X computer.

Type the URL that identifies the computer you are using as the software update server. It is recommended that you specify the hostname of the server rather than the IP address; for example:

```
http://myHost.local:8088
```

In addition, to ensure that DNS associates the hostname of the update server with the IP address, add a line such as the following to the `/etc/hosts` file:

```
192.168.2.79 myHost.local
```

where: `192.168.2.79` is the IP address of the update server and `myHost.local` is the hostname.

This policy can take effect dynamically at the next group policy refresh interval.

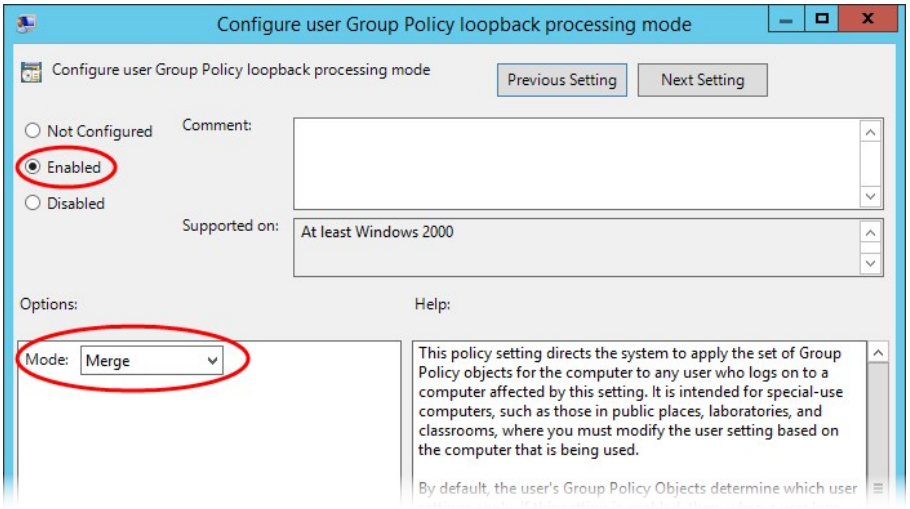
Centrify group policies allow administrators to extend the configuration management capabilities of Windows Group Policy Objects to managed Mac computers and to users who log on to Mac computers. This chapter describes the Mac group policies that can be applied to Mac users

The user-based group policies are defined in the Centrify Mac administrative template (centrify_mac_settings.xml) and accessed from **User Configuration > Policies > Centrify Settings > Mac OS X Settings**.

Group policies are only applied to users and computers in the GPO's linked OU and any child OUs. If your users and computers are in different OUs (which is common), Delinea recommends using user Group Policy loopback processing to make sure user policies are applied to everyone who logs on to a Mac. This is a standard Microsoft Group Policy that applies to every user to the computer.

To implement user Group Policy loopback processing mode

1. In the Group Policy Management Editor, navigate to **Computer Configuration > Administrative Templates > System > Group Policy > Configure user Group Policy loopback processing mode**.
2. Enable the policy, set **Mode:** to **Merge**, then click **OK**.



See https://technet.microsoft.com/en-us/library/cc978513.aspx for more information about loopback processing.

See Understanding Group Policies for Mac Users and Computers for general information about how to use group policies to manage Mac settings and for information on how to install the group policy administrative templates.

> **Note**: For additional information about creating and using group policies and Group Policy Objects, see your Windows or Active Directory documentation. For more information about adding and using other Centrify group policies that are not specific to Mac computers and users, see the *Group Policy Guide*.

Setting User-Based Policies

This section describes user-based policies for Mac that you can set. The following table provides a summary of the group policies you can set for Mac users. These group policies are in the Centrify Mac administrative template (centrify_mac_settings.xml) and accessed from **User Configuration > Policies > Centrify Settings > Mac OS X Settings**.

> **Note**: Group policies are only applied to users and computers in the GPO's linked OU and any child OUs. Enable **Computer Configuration > Administrative Templates > System > Group Policy > Configure user Group Policy loopback processing mode** in Merge mode to make sure user policies are applied to everyone who logs on to a Mac.

802.1X Wireless Settings	Create user profiles for wireless authentication. This group policy corresponds to 802.1X Options in the **Networks** system preference.

Application Access Settings (deprecated)	Control the specific applications users are either permitted to use or prohibited from using. These group policies correspond to **Applications** preferences set in the Workgroup Manager.
Desktop Settings	Control the desktop and screen saver options for users on Mac computers. These group policies correspond to settings in the **Desktop & Screen Saver** system preference.
Dock Settings	Control the look and operation of the Dock displayed on the user's desktop. These group policies correspond to **Dock** preferences set in the Workgroup Manager.
Finder Settings	Specify whether to use the standard Finder, or the Simple Finder, which restricts users to applications and folders in the Dock.
Folder Redirection	Redirect specified network home folders to the local computer to improve performance.
Import Settings	Specify plist files to import preferences from another computer. This group policy corresponds to the import plist functionality in Workgroup Manager.
Login Settings	Specify frequently used applications, folders, and server connections to open when a user logs in. This group policy corresponds to the login functionality in Workgroup Manager.
Media Access Settings	Control the specific media types users are either permitted to use or prohibited from using. These group policies correspond to **Media Access** preferences set in the Workgroup Manager.
Mobility Settings	Control the synchronization rules applied for users access services from mobile devices. These group policies correspond to **Mobility** preferences set in the Workgroup Manager.
Scripts (Login/Logout)	Specify login and logout scripts that run when Active Directory users log on or log out.
Security & Privacy Settings	Control the secure login options for users on Mac computers. These group policies correspond to settings in the **Security** system preference.
System Preference Settings	Control the specific system preferences displayed for users. These group policies correspond to **System Preferences** set in the Workgroup Manager.

802.1X Wireless Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings

Description

Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X** settings to create profiles for wireless network authentication. The profiles you specify with these group policies are created in the Network system preferences pane.

Specify User Profiles (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > 802.1X Wireless Settings > Specify User Profiles (Deprecated)

Description

Enable this policy to specify 802.1X User Profiles for wireless network authentication.

When using a user profile, a user will be prompted for username and password to authenticate to a wireless network after login.

To add a user profile

1. Enable the policy and click **Add** to enter the profile name and setting.
2. Type a name for the profile.
3. Type the setting using the following format:
    - Network;Security Type;Authentication Method, where each field is separated by a semi-colon ;.
    - Network is the wireless network name
    - Security type is one of 802.1X WEP, WPAEnterprise, WPA2 Enterprise
    - Authentication method is one or more of the following, separated by commas: TTLS, PEAP, TLS, EAP-FAST, LEAP, MD5

For example:

OFFICE1;WPA Enterprise;PEAP

OFFICE2;802.1X WEP;TTLS,PEAP

Set the **Automatically turn on Airport** option to automatically turn on AirPort device if this type of profile is specified. Otherwise, the status of the AirPort device will not change.

Once enabled, this policy takes effect dynamically at the next group policy refresh interval.

Application Access Settings (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings

Description

Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings** group policies to manage the applications Mac users are allowed to open or prevented from opening.

These group policies correspond to settings you can make using the Applications preference in the Workgroup Manager.

Permit/Prohibit Access to Application List: Applescript (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings > Permit/prohibit access to application list: AppleScript

Description

Select the specific applications in the Finder's Applications/AppleScript folder that users are permitted to use if you selected **Users can only open these applications**, or not allowed to use if you selected **Users can open all applications except these**.

This policy is only effective if the **Permit/prohibit access to applications** group policy is enabled. If the **Permit/prohibit access to applications** group policy is not configured or disabled, this group policy is ignored.

Once enabled, this group policy takes effect dynamically at the next group policy refresh interval.

Permit/Prohibit Access to Application List: Applications (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings > Permit/prohibit access to application list: Applications

Description

Select the specific applications in the Finder's Applications folder that users are permitted to use if you selected **Users can only open these applications**, or not allowed to use if you selected **Users can open all applications except these**.

This policy is only effective if the **Permit/prohibit access to applications** group policy is enabled. If the **Permit/prohibit access to applications** group policy is not configured or disabled, this group policy is ignored.

Once enabled, this group policy takes effect dynamically at the next group policy refresh interval.

Permit/Prohibit Access to Application List: Server (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings > Permit/prohibit access to application list: Server

Description

Select the specific applications in the Finder's Applications/Server folder that users are permitted to use if you selected **Users can only open these applications**, or not allowed to use if you selected **Users can open all applications except these**.

This policy is only effective if the **Permit/prohibit access to applications** group policy is enabled. If the **Permit/prohibit access to applications** group policy is not configured or disabled, this group policy is ignored. In addition, this policy is only applicable for Mac OS X Server computers.

Once enabled, this group policy takes effect dynamically at the next group policy refresh interval.

Permit/Prohibit Accesst to Application List: Utilities (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings > Permit/prohibit access to application list: Utilities

Description

Select the specific applications in the Finder's Applications/Utilities folder that users are permitted to use if you selected **Users can only open these applications**, or not allowed to use if you selected **Users can open all applications except these**.

This policy is only effective if the **Permit/prohibit access to applications** group policy is enabled. If the **Permit/prohibit access to applications** group policy is not configured or disabled, this group policy is ignored.

Once enabled, this group policy takes effect dynamically at the next group policy refresh interval.

Permit/Prohibit Access to Applications (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings > Permit/prohibit access to applications

Description

Allow other policies to specify the applications that users are permitted to access or prohibited from accessing. You must enable this policy for any other application access group policies to take effect. Once enabled, only the applications explicitly specified in Application List policies are permitted or prohibited.

If you enable this policy, in **Access mode**, select one of the following:

- **Users can only open these applications** to grant access only to the applications you select with the other application access policies.

  Note: If you select the option, **User can also open all applications on local volumes**, users can access any local applications. Restrictions only apply to applications on CDs, DVDs, or external disks.

- **Users can open all applications except these** to prevent access only to the applications you select with the other application access policies.

You can also set the following options in this group policy:

- Select **User can also open all applications on local volumes** to allow access to applications on a computer's local hard drive.

  If selected, users can access any local applications in addition to the applications explicitly approved using the other application access policies. If you uncheck this option, users can only access applications on CDs, DVDs, or external disks that have been explicitly approved.

- Select **Allow approved applications to launch non-approved applications** to allow approved applications to open applications that aren't explicitly approved.

  For example, if users click a link in an email message, this option allows the email application to open a browser to display the Web page even if the browser is not listed as an approved application. To prevent approved applications from opening applications that aren't explicitly approved, uncheck

this option.

- Select **Allow UNIX tools to run** to allow applications or the operating system to run tools, such as the QuickTime Image Converter, without explicitly listing them as approved applications.

  These tools usually operate in the background, but can be run from the command line. If you want to prevent access to these tools, do not check this option.

Once enabled, this group policy takes effect dynamically at the next group policy refresh interval.

Permit/Prohibit Access to the User-Specific Applications (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Application Access Settings > Permit/prohibit access to the user-specific applications

Description

Define a list of additional applications that users are permitted to run if you selected **Users can only open these applications**, or not allowed to use if you selected **Users can open all applications except these**. If enabled, you must specify the CFBundleIdentifier to identify the application; for example, for the Firefox browser, the CFBundleIdentifier is: org.mozilla.firefox. To find the CFBundleIdentifier complete the following steps:

1. In the Finder, locate the application to control.
2. Control-click or right-click the application, then select **Show Package Contents**.
3. If necessary, expand the **Contents** folder, then open info.plist with a text editor.
4. Find the string: CFBundleIdentifier.

   On the next line is the application's CFBundleIdentifier; for example:

```
org.mozilla.firefox
```

1. Use org.mozilla.firefox to identify the Firefox browser.

To add an application to the list, select **Enabled**, then click **Add** and enter the CFBundleIdentifier and click **OK**.

You may also control access to system preference panes by using the CFBundleIdentifier. You can find the CFBundleIdentifier for system preference panes in /System/Library/PreferencePanes. You can specify any application object that has a CFBundleIdentifier in its info.plist file.

> **Note**: Some applications may not have a CFBundleIdentifier (when you right-click the application name, there is no **Show Package Contents** menu item). In this case, you cannot add the application to the list of permitted or prohibited applications.

This policy is only effective if the **Permit/prohibit access to applications** group policy is enabled. If the **Permit/prohibit access to applications** group policy is not configured or disabled, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

Automount Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Automount Settings

Description

Use the Automount Settings to automatically mount network shares and the user's Windows home directory when a user logs in.

Automount Network Shares

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Automount Settings > Automount network shares

Description

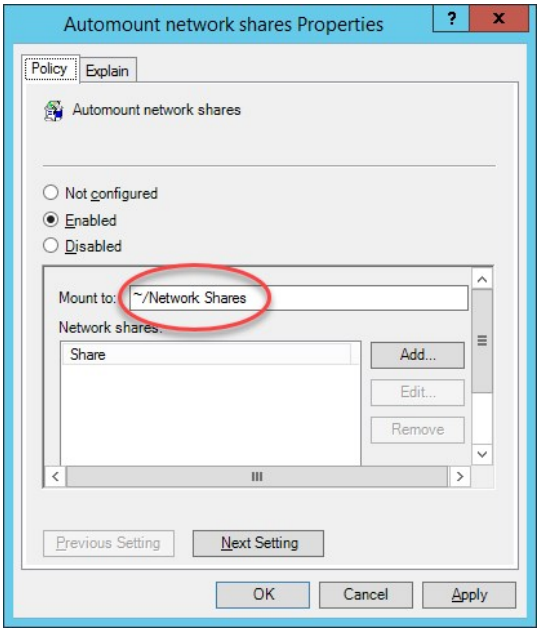
Specify the network shares to automatically mount when a user logs in. The default network share mount location is *User_Home*/Network Share.

This policy supports SMB, AFP, and NFS shares.

To add a share

1. Enter a path to mount the share in the **Mount to:** field.

   The path should start with / or ~. The default value is ~/Network Shares. In this case, network share folders would be mounted under the directory Network Shares of user's home directory.



2. Click **Enabled**, then click **Add** and enter the share in one of the following formats:

keyword://server/share

where:

- keyword is one of smb, nfs, afp
- server is the name or IP address of the server and can include a user or user and password in the form: user:@server or user:password@server.
- share can include spaces and be followed by a subdirectory.

For example, the following are all valid share specifications:

smb://acme.com/MacUsers

smb://acme.com/Mac Users

smb://acme.com/MacUsers/Shared_resources

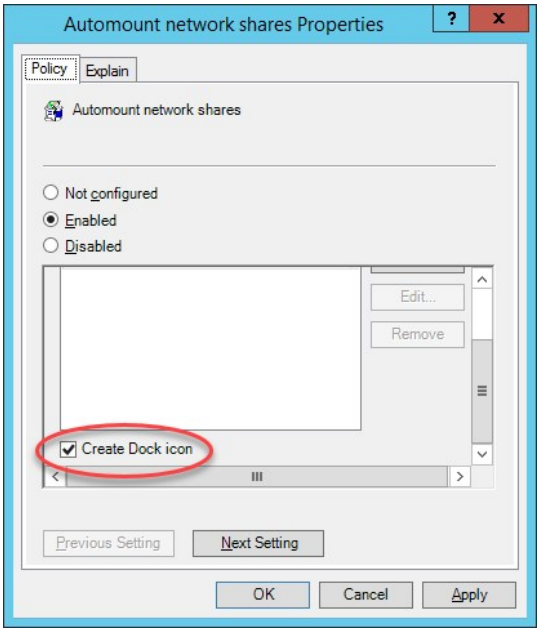
smb://jsmith:pass1234@acme.com/MacUsers

afp://acme.com/Users_server

nfs://acme.com/MacUsers

nfs://192.168.0.1/MacUsers

1. (Optional) Select **Create Dock icon** to create a link to the network share in the user's Dock.



Once enabled, this policy takes effect when a user logs out and back in to a computer.

Automount User's Windows Home

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Automount Settings > Automount user's Windows home

Description

Automatically mount the user's Windows home directory when the user logs in.

Specify the Windows home directory by using the Profile tab for a user in Active Directory Users and Computers (ADUC).

Once enabled, this policy takes effect when a user logs out and back in to a computer.

Create Alias Instead of Symbolic Link

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Automount Settings > Create alias instead of symbolic link

Description

This group policy is provided for compatibility with Delinea releases earlier than 2015. If you are using release 2015 or later, do not use this group policy.

In releases prior to 2015, the default mount point for network shares was /var/centrify/mnt/user. Starting with release 2015, the default mount point for network shares is User_Home/Network Share.

In Delinea releases prior to 2015, the "Automount network shares" group policy creates symbolic links to the specified shared network directories. However, certain versions of Microsoft Office are unable to save files to a shared folder by using the symbolic link (the link is greyed-out). The "Create alias instead of symbolic link" group policy corrects the problem by creating an alias instead of a symbolic link. In release 2015 or later, because of the new mount location, symbolic links are not required, and this group policy has no effect.

If you enable this group policy, the alias points to network shares that are automatically mounted when a user logs in.

> **Note**: The operating system treats an alias as a file, which means that you cannot use the Terminal program to access files or folders that are pointed to by the alias.

Once enabled, this policy takes effect when a user logs out and back in to a computer.

Custom Settings

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Custom Settings

Description

Use the **User Configuration › Policies › Centrify Settings › Mac OS X Settings › Custom Settings › Install MobileConfig Profiles** group policy to install mobile configuration profiles. This policy installs a user profile. To install a device profile, use the same policy in **Computer Configuration › Centrify Settings › Mac OS X Settings › Custom Settings.**

Install MobileConfig Profiles

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Custom Settings › Install MobileConfig profiles

Description

Enable this group policy to install mobile configuration profiles on managed Mac computers.

> **Note**: There is a Computer Configuration version of this policy (which installs device profiles) and a User Configuration version (which installs user profiles).

> **Note**: This group policy only supports macOS 10.15 and lower.

Before enabling this policy, you must create a directory and copy mobile configuration files to SYSVOL on the domain controller. SYSVOL is a well-known shared directory on the domain computer that stores server copies of public files that must be shared throughout the domain.

Specifically, create the following directory on the domain controller: `\\domainName\SYSVOL\domainName\mobileconfig`

and copy one or more mobile configuration profile files to this directory. See Deploy Configuration Profiles to Multiple Computers for details on how to do this.

To specify mobile configuration files to install, enable the policy, then click **Add**. Enter the name of a mobile configuration file that you placed in SYSVOL on the domain controller. Include the `.mobileconfig` suffix with the name.

If you specify a file that is not in the SYSVOL mobileconfig directory, the profile will not be installed.

If you add new files to the existing list in the group policy, those profiles will be installed — existing profiles will not be touched. If you remove previously specified files, the profiles defined by these files will be uninstalled.

If you add two or more profile files that have the same `payloadIdentifier`, only one of them will be installed.

If you change the group policy to "Disabled" or "Not Configured", all existing profiles that were installed previously by the group policy will now be uninstalled from the managed Mac computers.

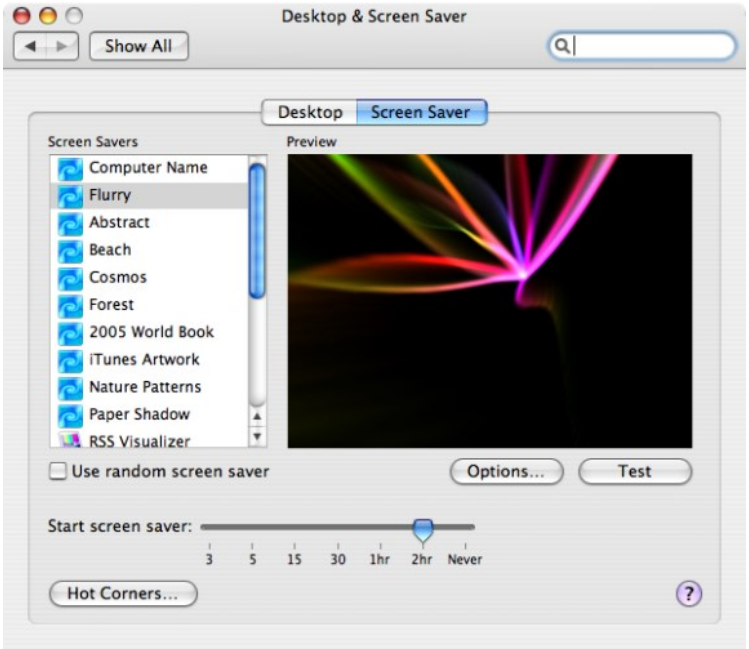
Desktop Settings

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Desktop Settings

Description

Use the **User Configuration › Policies › Centrify Settings › Mac OS X Settings › Desktop Settings** group policy to manage the start time for the screen saver from the Desktop & Screen Saver () system preference on Mac computers. This group policy corresponds to the **Start screen saver** option displayed on the Screen Saver pane. For example:



Set Computer Idle Time for Starting Screen Saver

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Desktop Settings > Set computer idle time for starting screen saver

Description

Select the length of time to wait before starting the screen saver. If you enable this group policy, you can specify the number of minutes to wait while a computer is not in use before starting the screen saver. For example, if you want the screen saver to start after a computer has been idle for 10 minutes, you can set Start screen saver to 10 minutes.

Disabling this policy does *not* disable the screen saver. To disable the screen saver, enable this policy and set the value to 0.

Although you may specify values greater than 60 minutes, and the screen saver works appropriately, the Macintosh Screen Saver dialog box shows values that are greater than 60 as **Never**.

Enabling this group policy is the same as selecting when to start the screen saver using the **Start screen saver** slider in the Desktop & Screen Saver system preference.

Once enabled, this group policy takes effect when users log out and log back in.

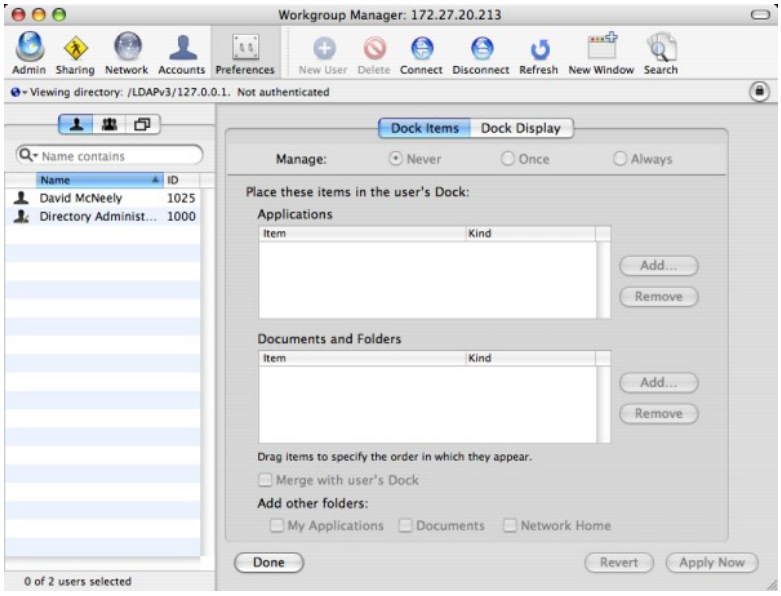
Dock Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings

Description

Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings** group policies to manage the characteristics of the Dock for Mac users. These settings correspond to the Dock preferences you can manage using the Workgroup Manager. In the Workgroup Manager, the Dock Items pane controls the items placed in the Dock and whether the workgroup Dock is merged with the user's Dock, and the Dock Display pane controls attributes such as the Dock size, magnification, position, and animation. For example:



Add Other Folders to the Dock

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Add other folders to the Dock

Description

Add icons for the other commonly-used folders to the Dock. You can choose to add the following folder icons to the Dock:

- My Applications
- Documents

The **My Applications** folder contains aliases to all approved applications you have defined in the Application list. If you do not manage access to applications, all available applications are included in the My Applications folder. If you enable Simple Finder, you should display the My Applications folder.

The **Documents** folder is the Documents folder found in the user's home folder. For example, the /Users/username/Documents folder for local user accounts.

Once enabled, this group policy takes effect when users log out and log back in.

Adjust the Dock's Icon Size

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Adjust the Dock's icon size

Description

Set the approximate size of Dock icons in pixels. The valid settings for the Dock size range from 16 pixels (small) to 128 pixels (large). The default size is 80 pixels.

> **Note**: This setting is approximate because the actual size of Dock icons depends on screen resolution and the number of icons in the Dock.

Once enabled, this group policy takes effect when users log out and log back in.

Adjust the Dock's Magnified Icon Size

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Adjust the Dock's magnified icon size

Description

Set the level of magnification to use for items in the Dock. If you enable this group policy, icons in the Dock are magnified to display in a larger size as the pointer moves over them. The valid settings for Dock magnification range from 16 pixels for minimum magnification to 128 pixels for maximum magnification. The default size is 80 pixels.

If you do not configure or disable this group policy, icons in the Dock are not magnified when the pointer moves over them.

Once enabled, this group policy takes effect when users log out and log back in.

Adjust the Dock's Position on Screen

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Adjust the Dock's position on screen

Description

Specify the location for displaying the Dock on the screen. If you enable this group policy, you can position the Dock on the left, bottom, or right of the screen. The default location for displaying the Dock is at the bottom of the screen.

Once enabled, this group policy takes effect when users log out and log back in.

Adjust The Effect Shown When Minimizing the Dock

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Adjust the effect shown when minimizing the Dock

Description

Specify the effect to use when a window or application is minimized and placed in the Dock. The valid effects are:

- Genie
- Scale
- Suck

Once enabled, this group policy takes effect when users log out and log back in.

Animate Opening Applications

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Animate opening applications

Description

Animate application icons so that the icon displayed in the Dock bounces when the user opens the application.

Once enabled, this group policy takes effect when users log out and log back in.

Automatically Hide and Show the Dock

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Automatically hide and show the Dock

Description

Hide the Dock from view automatically. If you enable this policy, the Dock is hidden during normal operation. The Dock is then automatically displayed again if the pointer moves over the position on the screen where the Dock is located.

Once enabled, this group policy takes effect when users log out and log back in.

Lock the Dock

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Lock the Dock

Description

Lock the applications displayed in the Dock. If you enable this policy, icons cannot be moved into or out of the Dock.

Once enabled, this group policy takes effect when users log out and log back in.

Place Applications in Dock

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Place applications in Dock

Description

List the applications to include in the Dock. After you enable this policy, click **Add** to enter the path to the application you want included in the Dock. Then click **OK**. You can click **Add** again to add additional applications. For example, to add Firefox and Chess icons to the Dock, type the application paths:

/Applications/Firefox.app

Click **OK**. Then click **Add** and enter:

/Applications/Chess.app

The icons for the applications you specify are placed to the left or above the separator line in the Dock in the order you enter them, up to 10 items. if you add more than 10 the order may be random. If the path to an application is incorrect, a question mark (?) is displayed in the Dock in place of the application's icon.

This group policy does not sort icons from the initial system list. To sort these items, such as the Mail application icon, you can add the item to the list.

Once enabled, this group policy takes effect when users log out and log back in.

Place Documents and Folders in Dock

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Place documents and folders in Dock

Description

List the documents or folders to include in the Dock. After you enable this policy, click **Add** to enter the path to the folder or document you want to include in the Dock. Then click **OK**. You can specify additional folders or documents by clicking **Add** again. For example, to add the Users folder and the Copyright.txt document to the Dock, type the paths to each:

/Users

Click **OK**, then click Add and type:

/Documents/Copyright.txt

The icons for the items you specify are placed to the left or above the separator line in the Dock. Items are sorted in the order you enter them up to 10 items. If you specify more than 10 items the order may be random. If the path to an item is incorrect, a question mark (?) is displayed in the Dock.

> **Note**: You may not specify the path to a network share; for example, smb://serverName. Network share paths are implemented as aliases, which work differently than folder and document paths. If you specify a network share, a question mark (?) is displayed in the Dock.

Once enabled, this group policy takes effect when users log out and log back in.

Merge with User's Dock

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Dock Settings > Merge with user's Dock

Description

Merge the Workgroup Dock settings with the user's Dock.

Once enabled, this group policy takes effect when users log out and log back in.

Finder Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Finder Settings

Description

Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Finder Settings** group policies to configure Finder commands, preferences and views.

The **Configure Finder Commands (Deprecated)** policy, below, allows you to control which commands are available in the Apple menu and Finder menus for users.

The **Configure Finder Preferences (Deprecated)** policy, below, enables you to specify the type of Finder for the user environment. After enabling the policy, you can choose one of two types from the drop-down list:

- **Normal Finder** applies the standard Mac desktop. This is the default value, and is the environment that all users will have if the policy is not enabled.
- **Simple Finder** restricts users to applications that are in the Dock.

When Simple Finder is enabled, users cannot open applications, open, modify, or delete documents, or create folders in the Finder. They also cannot mount network drives. They can only use items that are in the Dock. Use the **Dock Settings** policies above to configure the Dock; for example, enable **Place Applications in Dock** and **Place Documents and Folders in Dock** to control the applications and folders that users can access.

The **Configure Finder Preferences (Deprecated)** policy, below, enables you to control the arrangement and appearance of items on the user's desktop, in Finder windows, and in the top-level folder of the computer.

Configure Finder Commands (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Finder Settings > Configure Finder commands (Deprecated)

Description

Specify the commands in Finder menus and the Apple menu that are available to users. Select commands from the following list:

- **Connect to Server**

  Select to allow users to connect to a remote server by choosing 'Connect to Server' in the Finder Go menu. Deselect to prevent users from accessing this command.

- **Go to iDisk**

  Select to allow users to connect to an iDisk by choosing 'Go to iDisk' in the Finder Go menu. Deselect to prevent users from accessing this command.

- **Eject**

  Select to allow users to eject discs (for example, CDs, DVDs, floppy disks, or FireWire drives). Deselect to prevent users from ejecting disks.

- **Burn Disc**

  Select to allow user on computers with relevant hardware to burn discs. Deselect to prevent users from burning disks.

- **Go to Folder**

  Select to allow users to open a specific folder by choosing the 'Go to Folder' command in the Finder Go menu. Deselect to prevent users from using the

'Go to Folder' command.

- **Restart**

  Select to allow users to restart the computer they're using, or deselect to prevent them from restarting the computer.

- **Shut Down**

  Select to allow users to shut down the computer they're using, or deselect to prevent them from shutting down the computer.

Once enabled, this group policy takes effect when users log out and back in.

Configure Finder Preferences (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Finder Settings > Configure Finder preferences (Deprecated)

Description

Configure Finder preferences, including whether to use normal or Simple Finder, which items to show on the desktop, how a new window behaves, and whether to show filename extensions and the Empty Trash warning.

Select from the following options:

- **Finder type**

  Select the normal Finder or Simple Finder as the user environment. The normal Finder looks and acts like the standard Mac desktop. Simple Finder removes the ability to use a Finder window to access applications or modify files, limiting users' access to only what is in the Dock. In addition, users can't mount network volumes, create folders, or delete files.

- **Show these items on the Desktop**

  Choose whether users see icons for local hard disks, external disks, CDs (DVDs and iPods), and connected servers on the desktop.

  If you hide them, icons for disks and servers still appear in the top-level folder when a user clicks the Computer icon in a Finder window's toolbar.

- **New Finder window shows**

  Select **Home** to show items in the user's home folder, or select **Computer** to show the top-level folder, which includes local disks and mounted volumes.

- **Always open folders in a new window**

  Select this option to display folder contents in a separate window when a user opens a folder.

- **Always open windows in column view**

  Select this option to display folders in column view, which maintains a consistent view across windows.

- **Show warning before emptying the Trash**

  Select this option to display the normal warning when a user empties the Trash, or deselect it if you don't want users to see this message.

- **Always show file extensions**

  Select this option to show filename extensions (such as .txt or .jpg) that identify the file type; or deselect it to hide filename extensions.

  Once enabled, this group policy takes effect when users log out and back in.

- **Configure Finder views**

  Enable this group policy to control Finder views, for example the arrangement and appearance of items on a user's desktop, in Finder windows, and in the top-level folder of the computer.

The options in **Desktop View** allow you to adjust the size and arrangement of icons on the desktop.

Use **Icon Size** to adjust the icon size.

Use **Icon Arrangement** to specify how to arrange icons:

- To keep items aligned in rows and columns, select **Snap to grid**.
- To arrange items by criteria such as name or type (for example, all folders grouped together), select **Keep arranged by**.

Items in Finder windows are viewed in a list or as icons and you can control aspects of how these items look.

Default View settings control the overall appearance of all Finder windows. **Computer View** settings control the view for the top-level computer folder, showing hard disks and disk partitions, external hard drives, mounted volumes, and removable media (such as CDs or DVDs).

In **Icon View**, use **Icon Size** to adjust the size of icons.

Use **Icon Arrangement** to specify how to arrange icons:

- To keep items aligned in rows and columns, select **Snap to grid**.
- To arrange items by criteria such as name or type (for example, all folders grouped together), select **Keep arranged by**.

In **List View**, set the following:

- Select **relative dates** to show an item's creation or modification date relative to today, rather than as a fixed date; for example, Today or Yesterday, instead of 3/24/10.
- Select **Calculate folder sizes** to calculate the total size of each folder shown in a Finder window, which can take a lot of time depending on the size of the folder.

In **Icon Size**, select Select **small** or **big** for the size of icons in list view.

Once enabled, this group policy takes effect when users log out and back in.

Folder Redirection

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Folder Redirection

Description

Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Folder Redirection** group policies to redirect specified folders from a network home directory to the local computer.

When you set up a network home directory, all home directory files are written to the network share. Some folders, such as /Library/Caches, get heavy I/O from Apple and third-party applications, which may cause performance issues. The folder redirection policies enable you to redirect specific folders, such as /Library/Caches, to the local computers, which can result in dramatic performance improvements.

Folder Redirection contains two folders with identical sets of four policies:

- **Folder redirection actions at login time** applies the specified policy when the user logs in. For example, at login delete a folder in the network home directory and create a symbolic link to it on the local computer.
- **Folder redirection actions at logout time** applies the specified policy when the user logs out. For example, at logout, delete the symbolic link on the local computer (created at login) and restore the original folder to the network home directory.

After enabling the policy, click **Add**, then enter the following:

- **Path** The path to the folder on the network share. You do not need to specify the actual network share location — you can simply use the tilde (~) for the user's home directory; for example, ~/Library/Caches specifies the /Library/Caches directory in the user's network home directory.
- **Link** The location to create or delete on the local computer. For example:

  /tmp/Library/Caches
- If you wish, you can use the syntax %@ to specify the logged in user's name. For example:

  /tmp/%@/Library/Caches

If cain is the logged in user, the folder that is created is:

`/tmp/cain/Library/Caches`

The Folder Redirection policies are listed here and explained below:

- Delete path
- Delete symbolic link and restore
- Delete and create symbolic link
- Rename and create symbolic link

Delete path

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Folder Redirection > Folder Redirect Actions at Login/Logout Time > Delete path

Description

Deletes the specified directory from the network home directory. For example, to delete the /Library/Caches file from each user's home directory, enter the following in the **Path** box:

~/Library/Caches

Typically, you enable this policy for the **login time** folder.

> **Note**: You are not required to enter anything in the **Link** box for this group policy, and in fact, anything you enter in this box will be ignored. All the policies in this folder are implemented with the same UI and the other policies require the Link box so it appears for this policy as well.

Once this group policy is enabled, it takes effect when users log in (enabled for **login time** folder) or log out (enabled for **logout time** folder).

Delete Symbolic Link and Restore

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Folder Redirection > Folder Redirect Actions at Login/Logout Time > Delete symbolic link and restore

Description

Deletes a previously defined symbolic link on the local computer and restores the specified directory to the network home directory. Typically, you use this policy with the Rename and create symbolic link policy. For example:

At login (using Rename and create symbolic link) you save ~/Library/Caches in the network home directory to a temporary folder and redirect it to a folder on the local computer, for example /tmp/user/Library/Caches. At logout, you can enable Delete symbolic link and restore to delete the symbolic link and restore the folder on the network home directory, by specifying the following:

- **Path**: ~/Library/Caches
- **Link**: /tmp/%@/Library/Caches

where: %@ specifies the logged in user's name on the local computer.

Once this group policy is enabled, it takes effect when users log in (enabled for **login time** folder) or log out (enabled for **logout time** folder).

Delete and Create Symbolic Link

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Folder Redirection > Folder Redirect Actions at Login/Logout Time > Delete and create symbolic link

Description

Deletes the specified directory from the network home directory and creates a symbolic link to it on the local computer.

For example, to delete the user's /Library/Caches policy from the network home directory and create a link to it on the local computer, specify the following after enabling the policy:

- **Path**: ~/Library/Caches
- **Link**: /tmp/%@/Library/Caches

where %@ specifies the logged in user's name on the local computer. For example, if cain is the logged in user, the cache files are written to:

/tmp/cain/Library/Caches

Once this group policy is enabled, it takes effect when users log in (enabled for **login time** folder) or log out (enabled for **logout time** folder).

Rename And Create Symbolic Link

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Folder Redirection > Folder Redirect Actions at Login/Logout Time > Rename and create symbolic link

Description

Renames the specified directory in the network home directory to a temporary folder and creates a symbolic link to it on the local computer.

For example, to rename the user's /Library/Caches policy on the network home directory and create a link to it on the local computer, specify the following after enabling the policy for the **login time** folder:

- **Path:** ~/Library/Caches
- **Link:** /tmp/%@/Library/Caches

where %@ specifies the logged in user's name on the local computer. For example, if cain is the logged in user, the cache files are written to:

/tmp/cain/Library/Caches

To restore the original /Library/Caches directory, use the Delete symbolic link and restore policy (enabled for the **logout time** folder).

Once this group policy is enabled, it takes effect when users log in (enabled for **login time** folder) or log out (enabled for **logout time** folder).

Import Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Import Settings

Description

Mac OS X uses plist files to store application and other preferences. Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Import Settings** group policies to import plist files to customize your preferences:

- **Import plist files.** This group policy allows you to import preferences from another computer to computers in your Delinea-managed domain. To do so you:
  - Copy the plist files you want to use to the system volume on the domain controller.
  - Use the Import plist files group policy to import the plist files to computers in the domain.

This group policy automatically processes plist files to extract MCX settings when the files are imported.

- **Import MCX setting plist files.** This group policy is similar to the **Import plist file** group policy, except that it does not process any data from the inputted plist files. This group policy copies the exact content (that is, the "raw" content) from the plist file and imports it to the Active Directory user record.

When you import the plist files, Delinea copies them to the appropriate directories on the local computers to implement the preferences that they control.

You can gather and copy plist files from multiple computers and paste them to the sysvol directory on the domain controller, but a more structured approach is to set up a preferences 'template' computer, that is, a computer that is set up with your desired preferences. Then you can copy the appropriate plist files to sysvol on the domain controller. Finally, you can use either of the group policies described here to import the plist files to Delinea-managed computers in the domain.

Mac OS X stores plist files in the /Library/Preferences directory and in the /Users/userName/Library/Preferences directory.

The following section shows specifics of using these group policies.

Import plist Files

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Import Settings > Import plist files

Description

Specify the names of plist files to import from the system volume (SYSVOL) — similar to importing plist files in Mac Workgroup Manager. By default, the system volume folder is at: \\domain\SYSVOL\domain\plist.

Before enabling this policy, you should copy all the plist files to import to the system volume (sysvol) on the domain controller.

To add a file, select **Enabled**, click **Add**, then type a filename.

The path you type in **plist file** is relative to \\domain\SYSVOL\domain\plist. For example, if the domain name is ajax.org and you enter a plist file named com.apple.MCX.plist, the file that gets imported is:

\\ajax.org\sysvol\ajax.org \com.apple.MCX.plist

You can specify additional relative directories in the path, if needed.

Once this group policy is enabled, it takes effect when users log out and log back in.

Import MCX Setting plist Files

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Import Settings > Import MCX setting plist files

Description

Enable this group policy to import raw MCX settings plist files from SYSVOL. By default the folder is \\<domain>\SYSVOL\<domain>\mcxplist, similar to importing plist files in Mac Workgroup Manager.

The plist file path that you specify is relative to this path:

\\<domain>\SYSVOL\<domain>\mcxplist

For example, if you specify this path:

com.apple.MCX.plist

the following plist file is imported:

\\<domain>\SYSVOL\<domain>\mcxplist\com.apple.MCX.plist

This group policy is similar to "Import plist files". However, instead of extracting MCX settings from the plist file like "Import plist files" does, this policy imports the entire plist file without processing it.

An example plist file format is as follows:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE plist PUBLIC "-//Apple//DTD PLIST 1.0//EN" "http://www.apple.com/DTDs/PropertyList-1.0.dtd">
<plist version="1.0">
<dict>
   <key>mcx_application_data</key>
   <dict>
```

```
    <key>TARGET</key>
    <dict>
      <key>Forced</key>
      <array>
        <dict>
          Settings
        </dict>
      </array>
    </dict>
  </dict>
</dict>
</plist>
```

In this example, TARGET is the targeted MCX settings (such as com.apple.dock or com.apple.finder)

The recommended way to obtain the plist file with the correct format is by using the dscl command, and reading the MCX settings attribute of the user object that has the same MCX settings configured. Then copy the exact MCX settings and paste them into a plist file.

For example:

```
dscl /CentrifyDC read /Users/XXXX MCXSettings
```

where *XXXX* is an Active Directory user with the desired MCX settings.

Login Settings

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Login Settings

Description

Use the **User Configuration › Policies › Centrify Settings › Mac OS X Settings › Login Settings** group policy to specify frequently used items, such as applications, folders, or server connections to automatically open when a user logs in.

After enabling this policy, you can do the following:

- Use the **Add** button to specify the path to applications to open.
- In the **Network Home** area, use the **Add** button to specify URLs for servers to connect to; use the check box to specify whether to automatically connect the logged in user to the specified servers.
- Use the other check boxes to control whether users have the ability to add or remove login items.

The following table shows specifics of using this group policy.

> **Note**: Only the **Login items** area is visible when you first open the properties page for the group policy. Use the scroll bar to see the **Network share** area and other items that you can configure with this policy.

Enable Login Items

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Login Settings › Enable login items

Description

Specify the names of applications, folders, and server locations to open automatically when a user logs in. Select **Enable**, then do any or all of the following:

- **Login items**. To add an application to open automatically, click **Add**, then type the path to the application; for example:

```
/Applications/TextEdit.app
```

To initially hide the application, select **Hide**. The application will open, but its window and menu bar remain hidden until the user activates the application (for example, by clicking the application icon in the doc).

Click **OK** to save the item you entered. You can click **Add** as often as necessary to add multiple applications. You can also select an item in the window and click **Edit** to change it, or **Remove** to delete it.

- **Network share**. To add access to a network share, click **Add**, then type the URL in one of the following formats:

```
smb://server/share

smb://server/hidden$

smb://server/share/subdir

smb://user:password@server/share

smb://user:@server/share

afp://server/share

nfs://server/share

nfs://192.168.0.1/share
```

To automatically connect the user to the share with the user's login name and password, select **Authenticate selected share point with user's login name and password**.

> **Note**: If you uncheck this option, the share name must comply with RFC 1738 - Uniform Resource Locators (URL), which specifies that special characters need to be encoded, for example, by using `%20` instead of a space.

If the network share can be authenticated using Kerberos, this option can be ignored. If the network share cannot be authenticated using Kerberos, and this option is unchecked, then the user will be prompted for a username and password.

If a username is specified in the URL for the network share, then checking this option will still mount the share as the login user, while deselecting this option will mount the share as the user specified in the URL. For example, if network share is `smb://mount_user:password@server/share`, checking the option will mount the share as `login_user`, while deselecting the option will mount the share as `mount_user`.

Click **OK** to save the item you entered. You can click **Add** as often as necessary to add multiple shares. You can also select an item in the window and click **Edit** to change it, or **Remove** to delete it.

- Select **User may add and remove additional items** to allow users to add items to the list and remove items from the list.

  Deselect this box to prevent users from adding items or removing the items that you have specified. Note that they can remove login items that they specified on their own.

- Select **User may press Shift to keep items from opening** to allow user's to stop items from opening by holding down the Shift key during login until the Finder appears on the desktop.

  Deselect this option to prevent users from stopping applications from opening automatically.

Once enabled, this group policy takes effect when users log out and log back in.

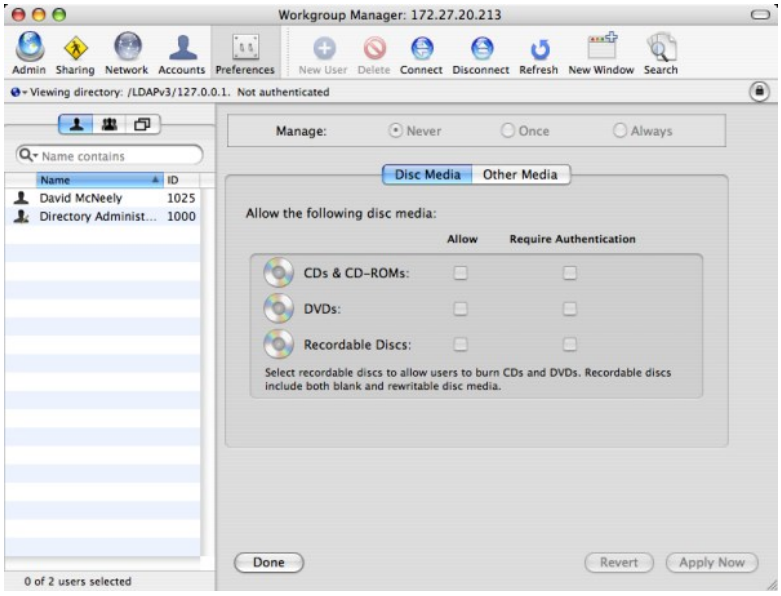
Media Access Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings

Description

Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings** group policies to manage the access to discs and other media for Mac users. These group policies enable you to control access to specific types of media, such as CDs or DVDs, but you cannot restrict access to specific discs or to specific items, such as music or movies, on a disc type users are permitted to access. These settings correspond to the Media Access preferences you can manage using the Workgroup Manager. For example:



Permit/Prohibit Access: CDs and CD-ROMs

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings > Permit/prohibit access: CDs and CD-ROMs

Description

Control whether users can access data and applications on CDs and CD-ROMs. The valid options are:

- **allow** to allow access to CDs and CD-ROMs without authentication.
- **allow, require authentication** to require users to provide credentials for authentication before allowing them access to CDs and CD-ROMs.
- **deny** to prevent users from accessing any data or applications on CDs and CD-ROMs.

Once this group policy is enabled, it takes effect when users log out and log back in.

Permit/Prohibit Access: DVDs

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings > Permit/prohibit access: DVDs

Description

Control whether users can access data and applications on DVDs. The valid options are:

- **allow** to allow access to DVDs without authentication.
- **allow, require authentication** to require users to provide credentials for authentication before allowing them access to DVDs.
- **deny** to prevent users from accessing any data or applications on DVDs.

Once this group policy is enabled, it takes effect when users log out and log back in.

Permit/Prohibit Access: Recordable Discs

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings > Permit/prohibit access: Recordable Discs

Description

Control whether users can record or access data and applications on recordable discs. The valid options are:

- **allow** to allow access to recordable discs without authentication.
- **allow, require authentication** to require users to provide credentials for authentication before allowing them access to recordable discs.
- **deny** to prevent users from accessing any data or applications on recordable discs.

Allowing users access to recordable discs enables users to burn CDs and DVDs. Recordable discs can be blank or rewritable disc media.

Once this group policy is enabled, it takes effect when users log out and log back in.

Permit/Prohibit Access: Internal Discs

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings > Permit/prohibit access: Internal Discs

Description

Control whether users can access data and applications on internal discs. The valid options are:

- **allow** to allow read and write access to internal discs without authentication.
- **allow, read-only** to allow read-only access to the media.
- **allow, require authentication** to require users to provide credentials for authentication before allowing them access to the media.
- **allow, require authentication, read-only** to require users to provide credentials for authentication before allowing them access to internal discs, and grant **read-only access to the media** if authentication is successful.
- **deny** to prevent users from accessing any data or applications on internal discs.

Once this group policy is enabled, it takes effect when users log out and log back in.

Permit/Prohibit Access: External Discs

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings > Permit/prohibit access: External Discs

Description

Control whether users can access data and applications on external discs. External disks include floppy disks, FireWire drives, and all other external storage devices except CDs and DVDs. The valid options are:

- **allow** to allow read and write access to external discs without authentication.
- **allow, read-only to allow read-only access to** external discs.
- **allow, require authentication** to require users to provide credentials for authentication before allowing them access to external discs.
- **allow, require authentication, read-only** to require users to provide credentials for authentication before allowing them access to external discs, and grant **read-only access to the media** if authentication is successful.
- **deny** to prevent users from accessing any data or applications on external discs.

Once this group policy is enabled, it takes effect when users log out and log back in.

Eject All Removable Media at Logout

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Media Access Settings > Eject all removable media at logout

Description

Control whether removable media, such as CDs, DVDs, Zip disks, or FireWire drives, are automatically ejected when users log out. If you enable this group policy, CDs, DVDs, and other disk media are automatically ejected when users log out to ensure removable media is properly disconnected and put away when users end their sessions.

Once this group policy is enabled, it takes effect when users log out and log back in.

Mobility Settings

Use the **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Mobility Settings** group policies to control if macOS creates a Mobile Account for the Active Directory user when logging in.

Configure Mobile Account Creation

Path

Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Mobility Settings > Configure mobile account creation

Description

Configure whether mobile accounts are created when users log in.

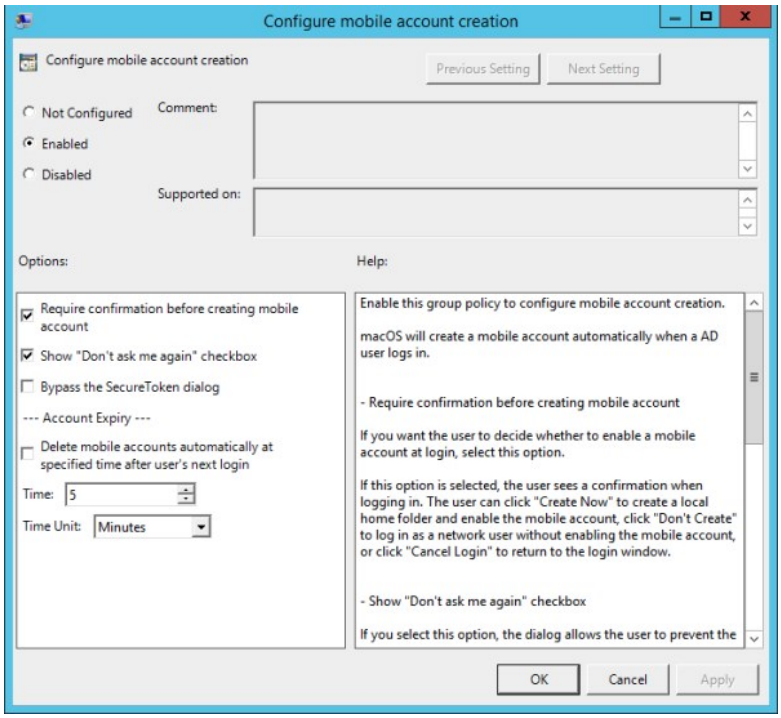
Check **Require confirmation before creating mobile account** to allow users to decide whether to enable a mobile account at login. Users see a confirmation dialog when logging in and can click one of the following:

- "Create Now" to create a local home folder and enable the mobile account.
- "Don't Create" to log in as a network user without enabling the mobile account.
- "Cancel Login" to return to the login window.

Select **Show "Don't ask me again" checkbox** to provide a check box that allows users to prevent display of the mobile account creation dialog on that computer in the future. Users who select "Don't ask me again" and click "Don't Create", are not asked to create a mobile account on that computer (unless they hold down the Option key during login to redisplay the dialog).

Select **Bypass the SecureToken dialog** so that the system will bypass the secure token authorization dialog. The Active Directory user can continue to create a mobile account. However, if this volume is encrypted, the Active Directory mobile user may not be able to log in with this account when the computer starts. This dialog only affects APFS volumes.

Select **Delete mobile accounts automatically at specified time after user's next login** so that MacOS will delete the mobile account and its local home folder automatically after a period of inactivity.



Printing settings

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Printing Settings › Specify printer list (with model)

Description

Use the **User Configuration › Policies › Centrify Settings › Mac OS X Settings › Printing Settings › Specify printer list (with model)** group policy to specify a list of printers for a user.

The printers that are available to a user are a combination of those specified in this policy and those added through System Preferences on the local computer. Note that this policy allows an administrator to control whether the user can add or see printers on the local computer, or is only allowed to use the managed printers specified by this policy.

Specify a managed list of network printers that are available to a user on this computer. Printers specified by this policy use a generic PostScript driver.

To add a printer, click **Add** and enter the following information:

- **Name**: A name of your choosing for the printer.
- **DeviceURI**: The device Uniform Resource Identifier, which specifies the device that is assigned to the printer (see **Specifying the Device URI**, below); for example:
  - socket://192.168.0.20:9100 (which identifies the protocol, IP address, and port number)
  - cdcsmb://dc1.acme.com/HPLaserJet2 (which identifies a Windows printer added using the Delinea protocol and identified by hostname.)
- (Optional) **Model**: The printer driver for the printer model (see **Specifying the Model (printer driver)**, below); for example: HP Photosmart C6100 series. Fax

You can use the following options to control access to the printers on the local computer:

- **Allow user to modify the printer list**: Check this option to allow local users to make changes in System Preferences to the printers that have been added by this policy, including deleting them.

  Deselect this option to prevent local users from modifying the printers added by this policy.

- **Allow printers that connect directly to user's computer**: Check this option to allow users to add their own local printers.

  Deselect this option to prevent users from adding local printers.

- **Require an administrator password**: Check this option to require an administrator's password when adding local printers.

- **Only show managed printers**: Check this option to allow local users to use only the managed printers specified by this option.

  Printers added locally, for example, through System Preferences, will not be visible.

  Deselect this option to allow local users to use printers added locally, as well as the managed printers added by this policy.

Printers added through this group policy appear after the next group policy refresh interval.

Specifying the Device URI

When you add a printer through the **Specify printer list** group policy, or locally by using the **Print & Scan, Add Printer** advanced options, the printer is implemented through the Common UNIX Printing System (CUPS), which was developed by Apple for Mac OS X and other UNIX-like operating systems.

The CUPS system supports the following device Uniform Resource Identifier (URI) protocols that you can use to specify the printers to add.

AppSocket or Jetdirect Protocol

The AppSocket, or JetDirect, protocol normally prints over port 9100 and uses the socket URI scheme:

socket://ip-address-or-hostname

socket://ip-address-or-hostname:port-number

Internet Printing Protocol (IPP)

CUPS supports IPP natively. IPP printing normally happens over port 631 and uses the http and ipp URI schemes:

ipp://ip-address-or-hostname/resource

ipp://ip-address-or-hostname:port-number/resource

http://ip-address-or-hostname:port-number/resource

Line Printer Daemon Protocol (LPD)

LPD is the original network printing protocol and is supported by many network printers. LPD printing normally happens over port 515 and uses the lpd URI scheme:

lpd://ip-address-or-hostname/queue

lpd://username@ip-address-or-hostname/queue

Windows Printer via Delinea

When Mac users print on a Windows network printer, they must authenticate separately. Specifying a Windows printer via Delinea allows users to access the printer without providing credentials as they have already been authenticated through Active Directory.

Delinea printing normally happens over port 445 and uses the cdcsmb URI scheme

cdcsmb://server_fqdn/printersharename

Windows

Windows printing normally happens over port 445 and uses the smb URI scheme:

> **Note**: You can use the Delinea protocol (cdcsmb), if you want to use Windows network printers without providing credentials each time.

smb://workgroup/server/printersharename

smb://ip-address-or-hostname/printersharename

smb://username:password@workgroup/ip-address-or-hostname/printersharename

smb://username:password@ip-address-or-hostname/printersharename

Specifying the Model (printer driver)

Model specifies the model name of the added printer and is used to determine which device driver to associate with the printer. Be certain to specify model correctly, otherwise, if model is not specified, or does not match a driver installed on the client Mac OX X computer, Generic PostScript driver will be selected for the printer, which may result in fewer printing options.

To find the correct model name, take one of these two approaches:

Use Printers & Scanners to identify the model:

1. On a Mac OX X computer, open **System Preferences > Printers & Scanners**.
2. Click **Add (+)** to add a printer.
3. When you select a printer, the correct model name appears on the "Use" drop down menu.

Use lpinfo to identify the model

1. On a Mac OX X computer, open the Terminal application.
2. Run the following command to obtain the list of all the models available:

   "lpinfo -m" command

   In the output from lpinfo, the correct model string appears right after *.ppd.gz. For example:

   Library/Printers/PPDs/Contents/Resources/HP Photosmart C6100 Series Fax.ppd.gz HP Photosmart C6100 series. Fax

   The model string is:

   HP Photosmart C6100 series. Fax
3. Type this in the group policy's **Model** field.

Scripts (Login/Logout)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout)

Description

Use the **User Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout)** group policies to deploy login and logout scripts that run when an Active Directory user logs on or logs out. When you use these group policies, the login and logout scripts are stored in the Active Directory domain's system volume (sysvol) and transferred to the Mac computer when the group policies are applied. Login and logout scripts are useful for performing common tasks such as mounting and un-mounting shares.

> **Note**: When these group policies are enabled, the first login by an AD user will restart the login script and return the user to the login window. Subsequent logins by this user or a different user occur normally and the changes generated by the script happen immediately.

Specify Login Script (Deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout) > Specify login script

Description

Specify the name of a login script to execute when users log on. You can specify only one file as the login script.

Before enabling this policy, you should create the login script and copy it to the system volume (sysvol) on the domain controller. By default, the login script is stored in the system volume (SYSVOL) on the domain controller in the directory:

```
\\domain\SYSVOL\domain\Scripts\scriptname
```

The script path you type in **Login script** is relative to \\domain\SYSVOL\domain\scripts\. For example, if the domain name is ajax.org and you enter a script name of mlogin.sh, the script that gets executed on the domain controller is:

```
\\ajax.org\SYSVOL\ajax.org\Scripts\mlogin.sh
```

You can specify additional relative directories in the path, if needed.

> **Note**: Be certain authenticated users have permission to read this file so the script can run when they log in.

By default, the script runs with the Active Directory user's permissions. If the script contains commands that require root permission to run, select **Run with root user privileges**.

Once this group policy is enabled, it takes effect when users log out and log back in.

> **Note**: The first AD user to log in is taken back to the login screen. Subsequent logins by this user or a different user occur normally and changes generated by the script happen immediately.

Specify Logout Script

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout) > Specify logout script

Description

Specify the name of a logout script to execute when users log out. You can specify only one file as the logout script.

Before enabling this policy, you should create the logout script and copy it to the system volume (SYSVOL) on the domain controller. By default, the logout script is stored in the system volume (SYSVOL) on the domain controller in the following directory:

```
\\domain\SYSVOL\domain\Scripts\scriptname
```

The script path you type in **Logout script** is relative to: \domain\SYSVOL\domain\scripts\.

For example, if the domain name is ajax.org and you enter a script name of mlogout.sh, the script that gets executed on the domain controller is:

```
\\ajax.org\SYSVOL\ajax.org\Scripts\mlogout.sh
```

> **Note**: Be certain authenticated users have permission to read this file so the script can run when they log out.

By default, the script runs with the Active Directory user's permissions. If the script contains commands that require root permission to run, select **Run with root user privileges**.

Once this group policy is enabled, it takes effect when users log out and log back in.

Specify Multiple Login Scripts

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Scripts (Login/Logout) > Specify multiple login scripts

Description

Specify the names of one or more login scripts to execute when a user logs on. The scripts you specify run simultaneously in no particular order.

This policy is also available as a computer policy. If you specify scripts using both the computer and user policies, the computer scripts are executed first.

Before enabling this policy, you should create the scripts and copy them to the system volume (sysvol) on the domain controller. By default, the login scripts are stored in the system volume (SYSVOL) on the domain controller in the directory:

```
\\domain\SYSVOL\domain\Scripts
\scriptname1
\scriptname
...
```

After enabling this policy, click **Add** and enter the following information:

- ___Script:___The name of the script and an optional path, which are relative to \\domain\SYSVOL\domain\scripts\.

For example, if the domain name is ajax.org and you enter a script name of mlogin.sh, the script that gets executed on the domain controller is:

`\ajax.org\SYSVOL\ajax.org\Scripts\mlogin.sh``

You can specify additional relative directories in the path, if needed; for example, if you type submlogin.sh, the file that gets executed is:

```
\\ajax.org\SYSVOL\ajax.org\Scripts\sub\mlogin.sh
```

- **Parameters**: An optional set of arguments to pass to the script.

These arguments are interpreted the same way as in a UNIX shell; that is, space is a delimiter, and backslash is an escape character. You can also use $USER to represent the current user's name. For example:

```
arg1 arg2 arg3
arg1 'a r g 2' arg3
arg' $USER.
```

> **Note**: Be certain authenticated users have permission to read these files so the scripts can run when they log in.

Once this group policy is enabled, it takes effect when users log out and log back in.

Security & Privacy Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy

Description

Use the Security & Privacy group policies to control user security and privacy settings.

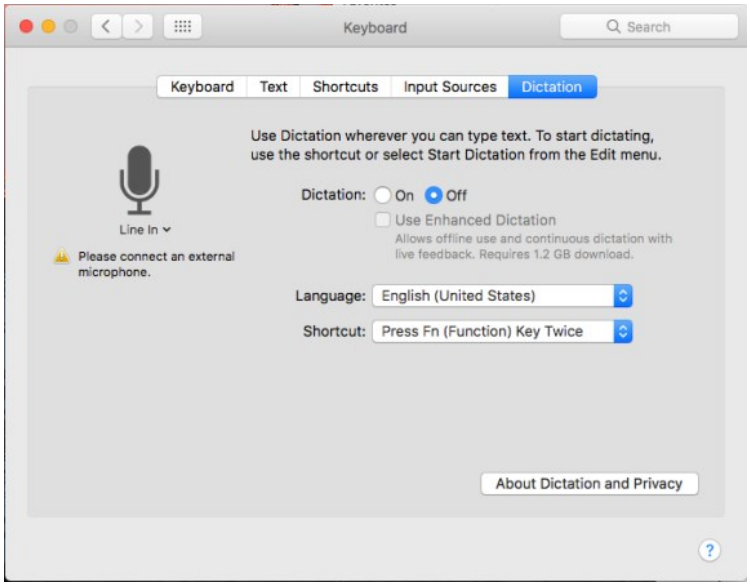
Disable Dictation

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › Disable Dictation

Description

Enable this policy to turn off Dictation in the System Preferences › Keyboard pane.



Once enabled, this group policy takes effect dynamically at the next group policy refresh interval.

Require a Password to Wake this Computer from Sleep or Screen Saver (Deprecated)

> **Note**: This group policy is deprecated, and will not work anymore. Please use the new same name group policy under "Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › Require a password to wake this computer from sleep or screen saver" instead.

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › Require a password to wake this computer from sleep or screen saver

Description

Lock the computer screen when the computer goes into sleep or screen saver mode and requires users to enter a user name and password to unlock the screen.

Enabling this group policy is the same as clicking the **Require a password to wake this computer from sleep or screen saver** option in the Security system preference.

After this group policy is enabled, it takes effect when the computer is rebooted.

Prohibit Authentication with Expired Password

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › Prohibit authentication with expired password

Description

Prohibit a user from unlocking the screen if a password change is required while the screen is locked. If a user logs in with a password that must be changed, and the computer goes into sleep or screen saver mode before the user updates the password, the user is locked out. Disabling this policy allows a user to

specify the old password to remove the screen lock.

Keychain Policies

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > Keychain Policies

Description

On OS X 10.11, you can create a keychain protected by a smart card token or a password. Once the Enable smart card protected keychain group policy takes effect, the token-protected keychain can only be unlocked with a PIN when the associated smart card is present. This group policy can be configured to allow users who lose or forget their smart card to continue to log in with a password. In this case, a new password-protected keychain is created to ensure users can continue to log in to their account; however, keychain items are not transferred from the token-protected keychain to the password-protected keychain.

This feature is not supported on OS X 10.10 and earlier.

Enable Protected Keychain

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > Keychain Policies > Enable protected keychain

Description

Create a new keychain protected by either an asymmetric token stored on a smart card or by a password, depending on the log in type. Enabling this policy requires users to have the smart card present to unlock the token-protected keychain.

When the smart card is renewed it will no longer unlock the protected keychain. There is no way to export a token-protected keychain; you will have to recreate the keychain items in the new token-protected keychain. In addition, if a smart card is lost, there is no way to recover items from the token-protected keychain.

The **Set as user default keychain** option is selected by default. This option is required to be able to log in with a password after this group policy takes effect. With this option set, the default keychain will be switched based on the login type (smart card login or password login). Deselect this option to leave the existing login keychain as the default keychain.

The **Delete the Password protected 'Login' Keychain after login** option is deselected by default. Select this option to delete the existing password-protected 'Login' Keychain after logging in with a smart card, leaving no keychains that can be unlocked without a smart card. This option is required to be able to log in with a password after this group policy takes effect without seeing keychain errors.

> **Note**: This feature is not supported on OS X 10.10 and earlier.

Lock Protected Keychain After Number of Minutes of Inactivity

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > Keychain Policies > Lock protected keychain after number of minutes of inactivity

Description

Lock the protected keychain after a period of inactivity that you specify in minutes.

This policy only works if you have enabled the Enable protected keychain group policy.

This policy takes effect at the next user login using smart card authentication.

Lock Protected Keychain When Sleeping

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > Keychain Policies > Lock protected keychain when sleeping

Description

Lock the protected keychain when the machine sleeps.

This policy only works if you have enabled the Enable protected keychain group policy.

This policy takes effect at the next user login using smart card authentication.

Allow All Applications to Access The Auto-Enrollment Private Key(S)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Public Key Policies > Allow all applications to access the auto-enrollment private key(s)

Description

Enabling this policy allows all applications to access the auto-enrollment private key(s) in the System keychain.

See Configuring Auto-Enrollment for more information about auto-enrollment keys.

> **Note**: This setting only applies to new auto-enrollment private key(s); it will not update already imported auto-enrollment private key(s) that are in the System keychain.

Allow Specific Applications to Access the Auto-Enrollment Private Key(S)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Public Key Policies > Allow specific applications to access the auto-enrollment private key(s)

Description

Enabling this policy allows specified applications to access the auto-enrollment private key(s) in System keychain.

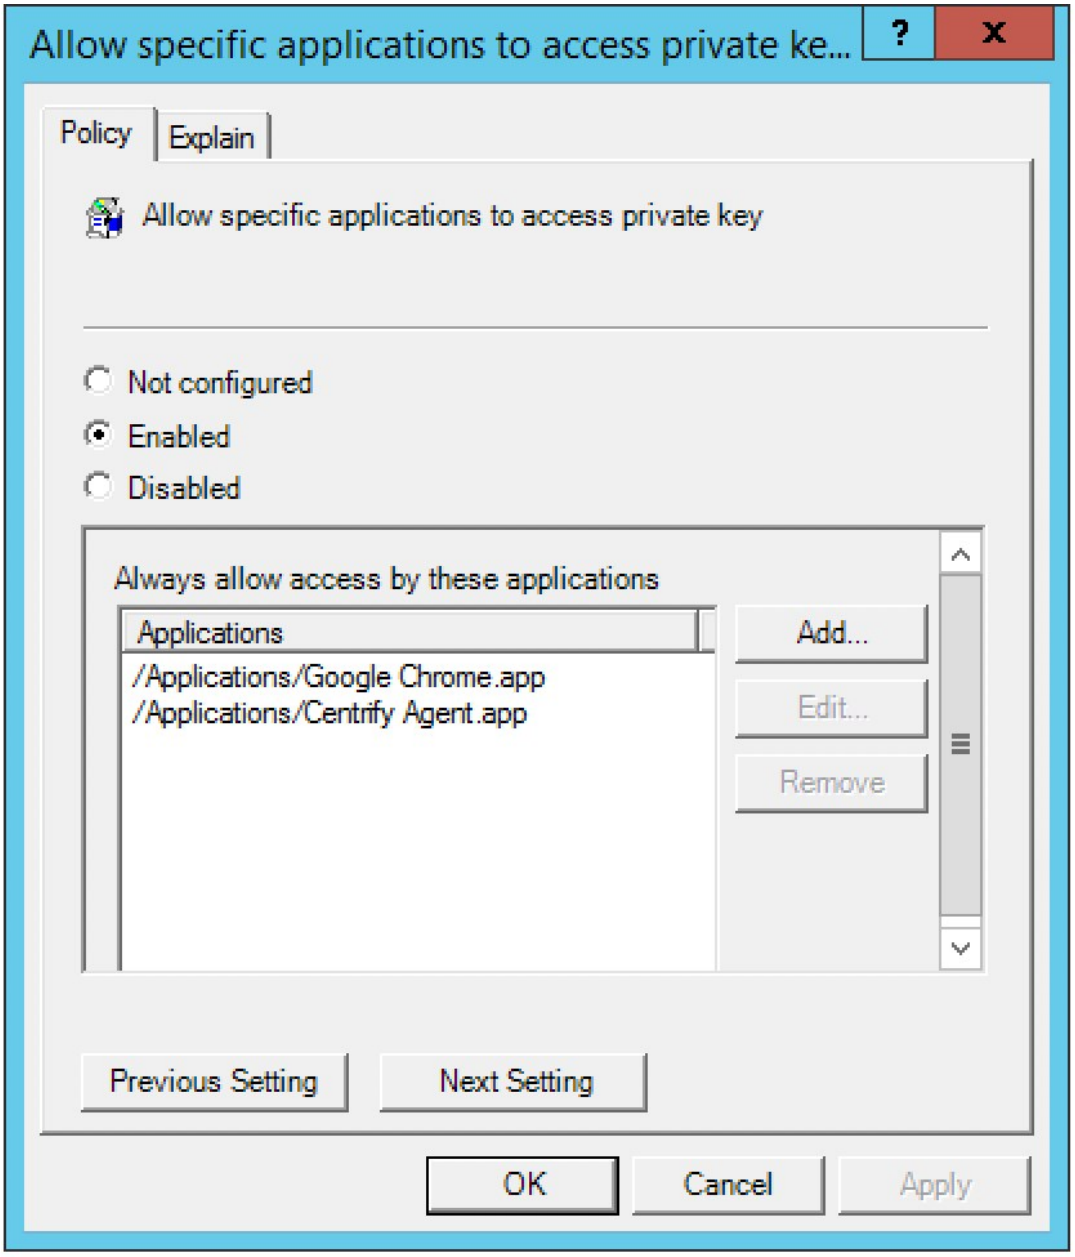
After you enable this policy, click **Add** to enter the path to the application you want to allow access to the auto-enrollment private key, then click **OK**. You can click **Add** again to add additional applications.

For example, to give Google Chrome and Delinea Agent access to the auto-enrollment private key, enter the application path for Google Chrome:

```
/Applications/Google Chrome.app
```

Click **OK**. Then click **Add** and enter the application path for Delinea Agent:

```
/Applications/Centrify Agent.app
```



After this group policy is enabled, the list of applications specified in the group policy are added to the access control list of the auto-enrollment private key in system keychain.

See Configuring Auto-Enrollment for more information about auto-enrollment keys.

> **Note**: This setting only applies to a new auto-enrollment private key. It does not change auto-enrolled private keys that are already in the keychain.

If the group policy above, **Allow All Applications to Access the Auto-enrollment Private Key(s)** is enabled, this group policy will be ignored.

Do Not Allow the Private Key(S) To Be Extractable

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy › Public Key Policies › Do not allow private key(s) to be extractable

Description

Enabling this policy prevents exporting the auto-enrollment private key(s).

> **Note**: This setting only applies to new auto-enrollment private key(s). It does not change auto-enrolled private keys that are already in the keychain.

System Preference Settings

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › System Preference Settings

Description

Use the **User Configuration › Policies › Centrify Settings › Mac OS X Settings › System Preference Settings** group policies to specify which preferences are enabled for use in System Preferences for Mac OS X users. Enabling a preference for use does not enable non-admin users to modify that preference. For example, some preferences, such as Startup Disk preferences, require an administrator name and password before a user can modify its settings. Displaying a preference does enable a user to view the preference's current settings.

By default, no system preference panes are displayed unless explicitly enabled. The group policies in this category correspond to System Preferences you can select for display in the Workgroup Manager. For example:

The user interface for System Preferences Settings differs significantly between different versions of Mac OS X. Therefore, there are separate System Preferences policies for each supported version of Mac OS X. In addition, to support existing installations that configured group policies by using a previous centrifydc_mac_settings template, the Centrify group policies provide a set of legacy preferences settings.

The **Use Version Specific Settings** group policy below determines whether to use legacy settings or platform-specific system preferences settings. By default (if you do not configure or disable this policy) legacy settings are used.

If you enable this policy, you can then enable platform-specific system preferences settings for each platform in your environment; see the following sections for information on each set of policies:

Use Version Specific Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Use version specific settings

Description

Enable the use of version-specific System Preferences settings.

If you enable this policy, you can then set platform-specific preferences settings for each platform in your environment. For example, if you have only 10.10 computers, you can enable this policy and then use Mac OS X 10.10 settings. If you have 10.9 and 10.10 computers, enable this policy, and then configure the version-specific policies as appropriate:

- Mac OS X 10.9 Settings
- Mac OS X 10.10 Settings

When a computer joins the domain, Delinea Management Services determines the OS version and applies the appropriate Preferences settings.

If this policy is disabled or not configured, Legacy Settings are used instead of version-specific settings. Likewise, Delinea versions prior to 4.4.2 always use Legacy Settings and ignore this policy setting.

If you configured System Preferences settings with a version of the product prior to 4.4.2, these settings are saved to Legacy Settings when you upgrade to the current version. You can keep or edit these settings as you wish.

> **Note**: The Legacy Settings may not match exactly the settings for each OS version; for example, some settings may be missing while others may be redundant for a particular OS version.

Legacy Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Legacy Settings

Description

When you upgrade from a version of Delinea prior to 4.4.2, your System Preferences settings are saved to Legacy Settings. You can keep or edit the individual legacy system preferences group policy settings as you wish.

> **Note**: The legacy settings may not match exactly the settings for each OS version; for example, some settings may be missing while others may be redundant for a particular OS version.

Showing items in the System pane of System Preferences	Select the items to display in the System pane of System Preferences.
Showing items in the Other pane of System Preferences	Select the items to display in the Other pane of System Preferences.

Limit items usage in System Preferences (deprecated)	Limit the usage of items in System Preferences. You must enable this group policy for any of the other group policy settings to take effect. Once this group policy is enabled, it takes effect when users log out and log back in.

Showing items in the Personal pane of System Preferences

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Enable System Preferences Pane: Personal

Description

Use the group policies in this category to choose which items to display in the Personal pane of System Preferences.

Enable Appearance

Enable usage of Appearance preferences in the Personal pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Dashboard & Expose

Enable usage of Dashboard & ExposE preferences in the Personal pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Desktop & Screen Saver

Enable usage of Desktop & Screen Saver preferences in the Personal pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Dock

Enable usage of Dock preferences in the Personal pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable International (Language & Text)

Enable usage of International preferences in the Personal pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Security

Enable usage of Security preferences in the Personal pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Spotlight

Enable usage of Spotlight preferences in the Personal pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Showing items in the Hardware System pane of Preferences

Use the group policies in this category to display items in the Hardware pane of System Preferences.

Enable Bluetooth

Enable usage of Bluetooth preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable CDs & DVDs

Enable usage of CDs & DVDs preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Displays

Enable usage of Displays preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Energy Saver

Enable usage of Energy Saver preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Ink

Enable usage of Ink preferences in the Hardware pane of System Preferences.

> **Note**: Ink preferences are only shown if a graphics tablet is connected to the Mac computer.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Keyboard & Mouse (Keyboard)

Enable usage of Keyboard & Mouse preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Mouse

Enable usage of Mouse preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Print & FAX

Enable usage of Print & FAX preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Sound

Enable usage of Sound preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Trackpad

Enable usage of Trackpad preferences in the Hardware pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Showing Items in the Internet & Network Pane of System Preferences

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Enable System Preferences Pane: Internet & Network

Description

Use the group policies in this category to display items in the Internet & Network pane of System Preferences.

Enable .Mac (MobileMe)

Enable usage of .Mac preferences in the Internet & Network pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Fibre Channel

Enable usage of Fibre Channel preferences in the Internet & Network pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Network

Enable usage of Network preferences in the Internet & Network pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable QuickTime

Enable usage of QuickTime preferences in the Internet & Network pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Sharing

Enable usage of Sharing preferences in the Internet & Network pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Showing items in the System pane of System Preferences

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Enable System Preferences Pane: System

Description

Use the group policies in this category to display items in the System pane of System Preferences.

Enable Accounts

Enable usage of Accounts preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Classic

Enable usage of Classic preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Date & Time

Enable usage of Date & Time preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Parental Controls

Enable usage of Parental Controls preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Software Update

Enable usage of Software Update preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Speech

Enable usage of Speech preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Startup Disk

Enable usage of Startup Disk preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Time Machine

Enable usage of Time Machine preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Enable Universal Access

Enable usage of Universal Access preferences in the System pane of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

Showing Items in the Other Pane of System Preferences

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Enable System Preferences Pane: Other

Description

Use the group policies in this category to display the items you specify in the Other pane of System Preferences.

Other Preferences Panes

Enable usage of additional preferences panes of System Preferences.

Once this group policy is enabled, it takes effect when users log out and log back in.

System Preferences Mac OS X 10.5 Settings (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.5 Settings

Description

If your environment does not contain Mac OS X 10.5 computers, you can ignore the group policies in this folder.

System Preferences Mac OS X 10.6 Settings (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.6 Settings

Description

If your environment does not contain Mac OS X 10.6 computers, you can ignore the group policies in this folder.

System Preferences Mac OS X 10.7 Settings (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.7 Settings

Description

The Mac OS X 10.7 Settings allow you to configure system preferences policies that apply specifically to Mac OS X 10.7 computers. Because the user interface varies between different versions of Mac OS X, separate policies are provided for each version. See **Legacy Settings**, above, for older versions of Mac OS X.

If your environment does not contain Mac OS X 10.7 computers, you can ignore these settings.

Limit Items Usage in System Preferences (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.7 Settings > Limit items usage in System Preferences

Description

Limit the usage of items in the System Preferences panel.

Once enabled, this group policy takes effect when users log out and log back in.

Enable System Preferences Panes 10.7 (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.7 Settings > Enable System Preferences Panes

Description

Use **Enable built-in System Preferences Panes**, below, to select the items to add to the standard System Preferences panes.

Use **Enable other System Preferences Panes**, below, to add preferences for third-party applications to the Other pane of the System Preferences.

Enable Built-in System Preferences Panes (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.7 Settings >

Enable System Preferences Panes > Enable built-in System Preferences Panes

Description

Select items to add to the System Preferences panel.

This policy is only effective if the **Limit items usage in System Preferences** group policy, above, is enabled. Otherwise this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

Enable Other System Preferences Panes (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.7 Settings > Enable System Preferences Panes > Enable other System Preferences panes

Description

Define a list of additional items to add to the Other pane of the System Preferences panel.

Preference pane applications are actually collections of files inside a directory (called bundles). Inside the Contents directory of every preference pane application is the info.plist file, and inside that file is the CFBundleIdentifier key that identifies the preference pane application. You need to use the value for this key when adding a preference pane application.

Generally, installed third party preference panes can be found in /System/Library/PreferencePanes, /Library/PreferencePanes or ~/Library/PreferencePanes.

You can find the CFBundleIdentifier key by using the defaults command. For example, to find the value for the QuickTime pane, use the following command in a terminal window:

```
defaults read /System/Library/PreferencePanes/QuickTime.prefPane   /Contents/info CFBundleIdentifier
```

which returns:

```
com.apple.preference.quicktime
```

To display the QuickTime icon in the **Other** pane of the System Preferences Panel, enable this policy, then click **Add** and enter com.apple.preference.quicktime.

This policy is effective only if the **Limit Items Usage on System Preferences** group policy, below, is enabled. Otherwise, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

System Preferences Mac OS X 10.8 Settings (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.8 Settings

Description

The Mac OS X 10.8 Settings allow you to configure system preferences policies that apply specifically to Mac OS X 10.8 computers. Because the user interface varies between different versions of Mac OS X, separate policies are provided for each version. See Legacy Settings for older versions of Mac OS X.

If your environment does not contain Mac OS X 10.8 computers, you can ignore these settings.

Limit Items Usage in System Preferences (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.8 Settings > Limit items usage in System Preferences

Description

Limit the usage of items in the System Preferences panel.

Once enabled, this group policy takes effect when users log out and log back in.

Enable System Preferences Panes 10.8 (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.8 Settings > Enable System Preferences Panes

Description

Use **Enable Built-in System Preferences Panes**, below, to select the items to add to the standard System Preferences panes.

Use **Enable Other System Preferences Panes**, below, to add preferences for third-party applications to the Other pane of the System Preferences.

Enable Built-in System Preferences Panes (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.8 Settings > Enable System Preferences Panes > Enable built-in System Preferences panes

Description

Select items to add to the System Preferences panel.

This policy is effective only if the Limit Items Usage on System Preferences group policy is enabled. Otherwise, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

Enable Other System Preferences Panes (deprecated)

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.8 Settings > Enable System Preferences Panes > Enable other System Preferences panes

Description

Define a list of additional items to add to the Other pane of the System Preferences panel.

Preference pane applications are actually collections of files inside a directory (called bundles). Inside the `Contents` directory of every preference pane application is the `info.plist` file, and inside that file is the `CFBundleIdentifier` key that identifies the preference pane application. You need to use the value for this key when adding a preference pane application.

Generally, installed third party preference panes can be found in `/System/Library/PreferencePanes`, `/Library/PreferencePanes`, or `~/Library/PreferencePanes`.

You can find the `CFBundleIdentifier` key by using the `defaults` command. For example, to find the value for the QuickTime pane, use the following command in a terminal window:

```
defaults read /System/Library/PreferencePanes/QuickTime.prefPane   /Contents/info CFBundleIdentifier
```

which returns:

```
com.apple.preference.quicktime
```

To display the QuickTime icon in the **Other** pane of the System Preferences Panel, enable this policy, then click **Add** and enter `com.apple.preference.quicktime`.

This policy is effective only if the **Limit Items Usage on System Preferences** group policy, below, is enabled. Otherwise, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

System Preferences Mac OS X 10.9 Settings (deprecated)

Path

Description

The Mac OS X 10.9 Settings allow you to configure system preferences policies that apply specifically to Mac OS X 10.9 computers. Because the user interface varies between different versions of Mac OS X, separate policies are provided for each version. See **Legacy Settings**, above, for older versions of Mac OS X.

If your environment does not contain Mac OS X 10.9 computers, you can ignore these settings.

Limit Items Usage in System Preferences (deprecated)

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › System Preference Settings › Mac OS X 10.9 Settings › Limit items usage in System Preferences

Description

Limit the usage of items in the System Preferences panel.

Once enabled, this group policy takes effect when users log out and log back in.

Enable Built-in System Preferences Panes (deprecated)

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › System Preference Settings › Mac OS X 10.9 Settings › Enable System Preferences Panes › Enable built-in System Preferences panes

Description

Select items to add to the System Preferences panel.

This policy is effective only if the **Limit Items Usage on System Preferences** group policy, below, is enabled. Otherwise, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

Enable Other System Preferences Panes (deprecated)

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › System Preference Settings › Mac OS X 10.9 Settings › Enable System Preferences Panes › Enable other System Preferences panes

Description

Define a list of additional items to add to the Other pane of the System Preferences panel.

Preference pane applications are actually collections of files inside a directory (called bundles). Inside the `Contents` directory of every preference pane application is the `info.plist` file, and inside that file is the `CFBundleIdentifier` key that identifies the preference pane application. You need to use the value for this key when adding a preference pane application.

Generally, installed third party preference panes can be found in `/System/Library/PreferencePanes`, `/Library/PreferencePanes` or `~/Library/PreferencePanes`.

You can find the `CFBundleIdentifier` key by using the `defaults` command. For example, to find the value for the QuickTime pane, use the following command in a terminal window:

```
defaults read /System/Library/PreferencePanes/QuickTime.prefPane  /Contents/info CFBundleIdentifier
```

which returns:

```
com.apple.preference.quicktime
```

To display the QuickTime icon in the **Other** pane of the System Preferences Panel, enable this policy, then click **Add** and enter

com.apple.preference.quicktime.

This policy is effective only if the **Limit Items Usage on System Preferences** group policy, below, is enabled. Otherwise, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

System Preferences Mac OS X 10.10 or Above Settings

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.10 Settings

Description

The Mac OS X 10. 10 or above Settings allow you to configure system preferences policies that apply specifically to Mac OS X 10.10 and above computers. Because the user interface varies between different versions of Mac OS X, separate policies are provided for each version. See **Legacy Settings**, above, for other versions of Mac OS X.

If your environment does not contain Mac OS X 10.10 or above computers, you can ignore these settings.

Limit Items Usage on System Preferences

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.10 Settings > Limit items usage on System Preferences

Description

Limit the usage of items in the System Preferences panel.

Once enabled, this group policy takes effect when users log out and log back in.

Enable System Preferences Panes 10.10

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.10 Settings > Enable System Preferences Panes

Description

Use **Enable other System Preferences Panes**, below, to add preferences for third-party applications to the Other pane of the System Preferences.

Enable Built-in System Preferences Panes

Path

User Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy Settings > System Preference Settings > Mac OS X 10.10 Settings > Enable System Preferences Panes > Enable built-in System Preferences panes

Description

Enable this group policy to enable the built-in System Preferences panes.

Enable or disable usage of items in the built-in System Preferences panes by checking or unchecking boxes corresponding to the items.

This policy is effective only if the **Limit Items Usage on System Preferences** group policy, above, is enabled. Otherwise, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

Enable Other System Preferences Panes

Path

User Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy Settings › System Preference Settings › Mac OS X 10.10 Settings › Enable System Preferences Panes › Enable other System Preferences panes

Description

Define a list of additional items to add to the Other pane of the System Preferences panel.

Preference pane applications are actually collections of files inside a directory (called bundles). Inside the Contents directory of every preference pane application is the info.plist file, and inside that file is the CFBundleIdentifier key that identifies the preference pane application. You need to use the value for this key when adding a preference pane application.

Generally, installed third party preference panes can be found in /System/Library/PreferencePanes, /Library/PreferencePanes or ~/Library/PreferencePanes.

You can find the CFBundleIdentifier key by using the defaults command. For example, to find the value for the QuickTime pane, use the following command in a terminal window:

```
defaults read /System/Library/PreferencePanes/QuickTime.prefPane   /Contents/info CFBundleIdentifier
```

which returns:

```
com.apple.preference.quicktime
```

To display the QuickTime icon in the **Other** pane of the System Preferences Panel, enable this policy, then click **Add** and enter com.apple.preference.quicktime.

This policy is effective only if the **Limit Items Usage on System Preferences** group policy, above, is enabled. Otherwise, this group policy is ignored.

Once enabled, this group policy takes effect when users log out and log back in.

This section explains how to set up smart card login for a Mac computer:

Understanding Smart Card Login

Smart cards provide an enhanced level of security authentication for logging into an Active Directory domain. To configure a smart card for use on a Mac computer that is running the DirectControl agent, requires that you have already set up a smart card for use in a Windows domain. You do not need to add any smart card infrastructure to the Mac computer, other than a smart card reader and a provisioned smart card.

If you have set up smart card login for Windows clients in a domain, you can use Access Manager to configure smart card login for Mac clients joined to the same domain. If you have provisioned a smart card for use on a Windows computer once you configure smart card support for a Mac computer, you can use the same smart card to log in to a Mac computer.

Supported Smart Card Types

Delinea Smart Card Support for MacOS is based on the MacOS modern native framework, CryptoTokenKit. TokenD is no longer supported.

For macOS 10.15 and later, Delinea supports personal identity verification (PIV) smart cards, USB CCID class-compliant readers, and hard tokens that support the PIV standard.

Configuring Smart Card Login

Delinea provides group policies, configuration options, and account options to perform the smart card configuration tasks desribed below.

> **Note**: Before configuring smart card login, refer to the next section, **Verifying Prerequisites for Configuring Smart Card Login** to ensure your environment meets all the prerequisites.

Verifying Prerequisites for Configuring Smart Card Login

- Make sure that your smart card is supported by MacOS.

  MacOS 10.15 and later supports personal identity verification (PIV) smart cards, USB CCID class-compliant readers, and hard tokens that support the PIV standard.

  - Provision a smart card with an NT principal name and PIN.
  - Verify that the Active Directory user's UPN matches the UPN on the smart card.
  - Make sure that there are at least two certificates in your smart card; these two certificates are for two different purposes: "Signature and smartcard logon" and "Encryption." MacOS will use the certificate which purpose is "Signature and smartcard logon" to logon, and use the certificate which purpose is "Encryption" to encrypt and decrypt the user's Keychain automatically. If there is no certificate which is for "Encryption", the user will need to input the Keychain password every time when that they log in.

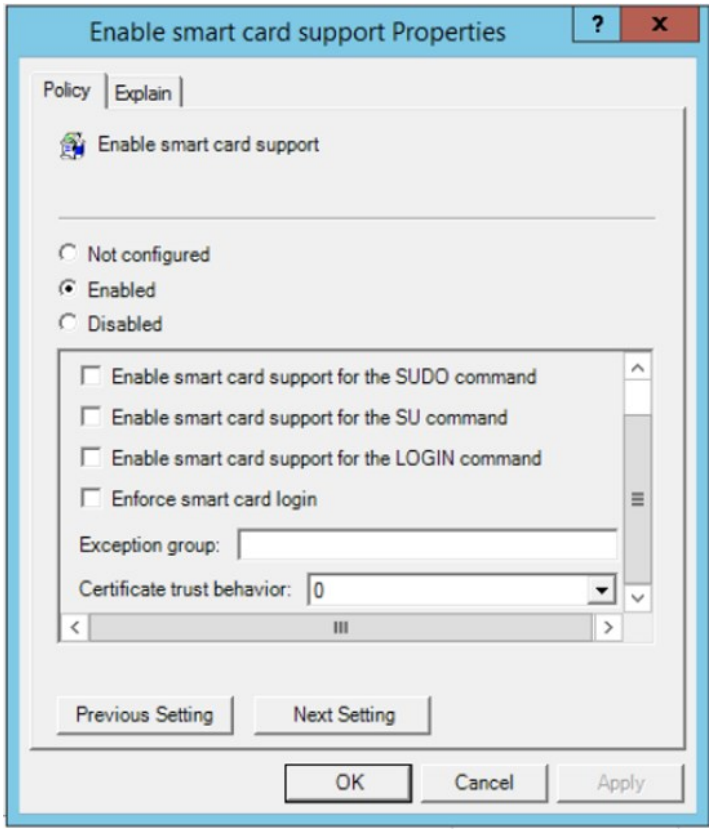
- Make sure that your smart card is able to log in to a Windows computer.

  If a user is able to log in to a Windows computer with a smart card, and you have a card reader and a fully-provisioned card for the Mac computer, the user should be able to log in to the Mac computer once you configure it for smart card support.

Enabling Smart Card Support

To enable smart card support for logging on

1. Make sure that you have configured the Delinea Agent to have full disk access.
2. Create or edit an existing Group Policy Object linked to a site, domain, or OU that includes Mac computers.
3. In the Group Policy Management Editor, expand **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy**, then double-click **Enable smart card support**.



4. Select **Enabled** to enable smart card support.
5. Select any of the following smart card options:
    - **Enable smart card support for the SUDO command**: When executing the SUDO command, the smart card user can authenticate by entering their smart card PIN.
    - **Enable smart card support for the SU command**: When executing the SU command, the smart card user can authenticate by entering their smart card PIN.
    - **Enable smart card support for the LOGIN command**: When executing the LOGIN command, the smart card user can authenticate by entering their smart card PIN.
    - **Enforce smart card login**: Users can only log in to the Mac computer by way of smart card login.
    - **Exception group**: Any users who belong to this group can always log in to the Mac computer with user name and password (no smart card required). In general, we recommend that you set an exception group, such as admins, when you select the option to enforce smart card login.
    - **Certificate trust behavior**: You can select one of these numbers to set smart card certificate behavior. The numbers mean the following:
        - 0: Smart card certificate trust isn't required.
        - 1: Smart card certificate and certificate chain must be trusted.
        - 2: Certificate and certificate chain must be trusted and not receive a revoked status.
        - 3: Certificate and certificate chain must be trusted and revocation status is returned valid.
6. Because smart card login is not password-based, **do not** enable the "Enable Keychain synchronization" group policy: Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy › Enable Keychain synchronization
7. If FileVault is enabled on your Mac, please enable the "Disable automatic login" group policy: Computer Configuration › Policies › Centrify Settings › Mac OS X Settings › Security & Privacy › FileVault2 › Disable automatic login.

   The policy takes effect dynamically at the next group policy refresh interval or after you run adgpupdate.

Verifying Smart Card Configuration

After enabling smart card support as described above in Configuring Smart Card Login, do the following to verify that a smart card is working:

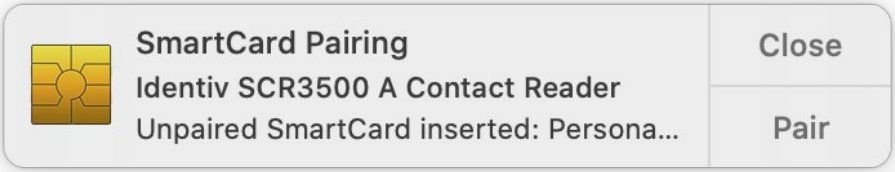
1. Insert the smart card into the reader.
2. Open the Terminal.app and run the following command:

   ```
   % sc_auth identities
   ```

   You should see that the smart card has paired to the Active Directory user. For example:

```
SmartCard: com.apple.pivtoken:00000000000000000000000000000000
Paired identities which are used for authentication:
9800A35AD2A41AEFB03CF431B76BA194E22F48EE    pivau1 - Certificate For PIV Authentication (PIV AU 1)
```

Note: You never need to pair your smart card manually. If you see the following SmartCard Pairing dialog, that means that the smart card support is not ready. Please re-check the smart card support GP and then excute the command adgpupdate.



Enabling the Sscreen Saver for Smart Card removal

Currently, we don't have a group policy to enable the screen saver when the smart card is removed. Please use the group policy entitled "Specify multiple login scripts" to deploy the following script:

```
#!/bin/bash
user_name=`ls -l /dev/console | cut -d " " -f 4`
defaults write /Users/$user_name/Library/Preferences/com.apple.screensaver tokenRemovalAction -int 1
chown $user_name:staff /Users/$user_name/Library/Preferences/com.apple.screensaver.plist
exit 0
```

The script sets the Mac to start the screen saver automatically when the smart card is removed.

Disabling Smart Card Support

To disable smart card support:

1. Edit the Group Policy Object linked to a site, domain, or OU that includes Mac computers, expand **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy**, then double-click **Enable smart card support**.
2. Select **Disabled** and click **OK**.

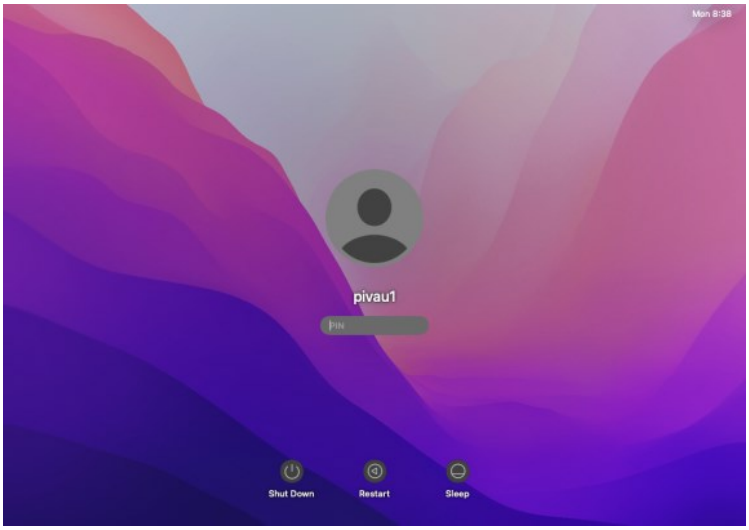
Using Smart Card Login

When a user inserts a smart card into the card reader attached to a Mac computer that is waiting for login, the login screen is replaced by a smart card enabled login screen.

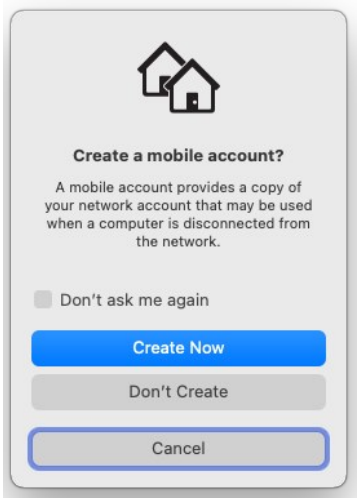
To log in with a smart card:

1. Insert the smart card into the smart card reader.

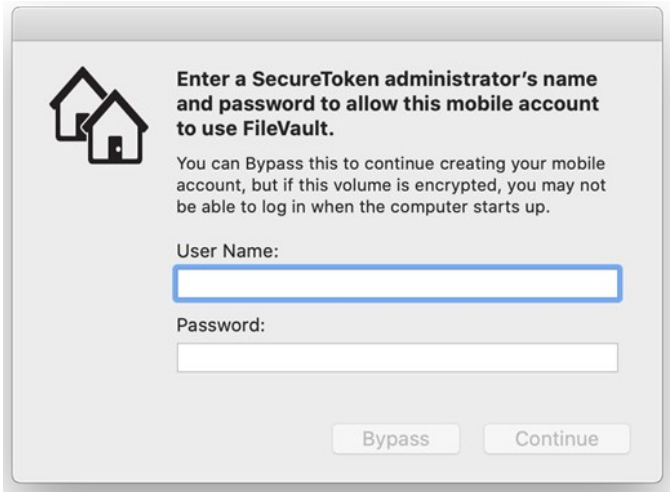
   A login screen displays, prompting you to enter your PIN.



2. If the "Configure mobile account creation" group policy is enabled, you are prompted to create a mobile account.



If the **Bypass the SecureToken dialog** is not enabled, after creating the mobile account, you are prompted to authenticate the SecureToken.



3. The system will then prompt you to set a password for Keychain.

   The password can be the same as or different than your Active Directory password. For security reasons, the password here should not be the same as your smart card PIN.

Troubleshooting Smart Card Login

If you have problems with smart card logon, Access Manager provides a command-line tool, sctool, which you can run to configure smart card logon, as well as to provide diagnostic information. See the sctool man page.

Additional smart card diagnostic procedures are provided in Diagnosing Smart Card Login Problems.

Other Functions of Smart Card Support on MacOS

MacOS 10.15 includes built-in support for the following capabilities:

- Authentication: LoginWindow, PKINIT, SSH, Screensaver, Safari, authorization dialogs, and in third-party apps supporting CTK
- Signing: Mail and third-party apps supporting CTK
- Encryption: Mail, Keychain Access, and third-party apps supporting CTK

For more information, please see https://support.apple.com/guide/deployment-reference-macos/intro-to-smart-card-integration-apd1fa5245b2/1/web/1.0.

Known Issues of Using Smart Cards with Macos

Due to a limitation of MacOS, a smart card user cannot get the User Group Policy automatically. The Computer Group Policy works normally. The workaround is to run the following commands after logging in with a smart card:

```
% sctool -k

% adgpupdate
```

After you run the above commands, log out and log back in. Most User Group Policy should work normally.

This section provides troubleshooting tips for administrators using the Delinea DirectControl Agent for Mac.

The following topics are covered:

Using Common Account Management Commands

Most UNIX-based platforms store account information in the local /etc/passwd file, and use commands such as getent command to query that information. On Mac computers, however, you would typically use the Directory Service application to manage local accounts and retrieve user information. For troubleshooting purposes, therefore, you should be familiar with the commands to use for retrieving information about Active Directory users and groups.

The following table describes several common Directory Service Command Line (dscl) commands that you may find useful.

dscl /Search –list /Users	List all of the users in the Directory Service and in Active Directory for the zone.
dscl /CentrifyDC –list /Users	List only the Active Directory users enabled for the zone.
dscl /CentrifyDC –read /Users/username	Display detailed information about the specified Active Directory *username*.
dscl /Search –list /Groups	List all of the groups in the Directory Service and in Active Directory for the zone.
dscl /CentrifyDC –list /Groups	List only the Active Directory groups enabled for the zone.
dscl /CentrifyDC –read /Groups/groupname	Display detailed information about the specified Active Directory *groupname*.

To get detailed information for all users or groups recognized on the Mac computer, you can use the following commands:

```
lookupd –q user –a name
```

```
lookupd –q group –a name
```

To get detailed information for a specific user or group, you can use the following commands:

```
lookupd –q user –a name username
```

```
lookupd –q group –a name groupname
```

To clear the Directory Service cache, you can use the following command:

```
lookupd -flushcache
```

To completely clear the cache of Active Directory login credentials, you should also run the `adflush command:

```
adflush
```

To retrieve Mac OS version and build information that `uname -a` does not provide, you can run the following command:

```
/usr/bin/sw_vers
```

Viewing the Agent Version on the Macs Joined to Active Directory

You can use the Active Directory module for Windows PowerShell to view the version of the Delinea DirectControl Agent for Mac on the Macs joined to your AD domain. This is useful to verify that all Macs joined to your AD have an appropriate version of the Delinea DirectControl Agent for Mac to avoid compatibility issues with OS updates.

Install the Active Directory Module for Windows PowerShell

The Active Directory module for Windows PowerShell is already installed on domain controllers. If you are using a member server, you will have to install it.

To install the Active Directory module for Windows PowerShell

Open an elevated PowerShell session on a Windows server in the domain and run the following command:

```
Add-WindowsFeature RSAT-AD-PowerShell
```

When the installation finishes it returns the following:

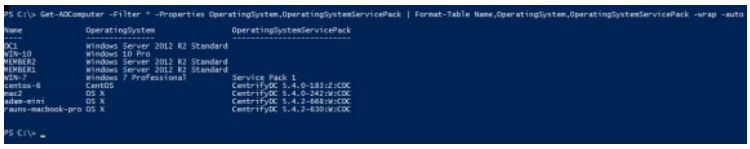
Once installed, on Windows Server 2012 and 2012 R2 the module automatically loads when you use one of its cmdlets; you do not need to import it.

Show PowerShell Output of Agent Versions for AD-joined computers

If you have a small environment, or just want to see a sample of the information that will be in the report, run the following from a Windows server with the AD PowerShell module installed:

```
Get-ADComputer -Filter * -Properties OperatingSystem,OperatingSystemServicePack | Format-Table Name,OperatingSystem,OperatingSystemServicePack -wrap -auto
```

For example:



The report includes all AD-joined computers in the domain. The example above shows a mix of Windows, Linux, and Mac computers. Where OperatingSystemServicePack is empty, it means there is no Service Pack installed (Windows computers), or there is no DirectControl agent installed (Mac or Linux/Unix).

In most cases there are too many computers for the PowerShell output to be easily readable. In these cases, refer to the next section, **Export the Report of Agent Versions to a CSV File**.

Export the Report of Agent Versions to a CSV file

You can export a report of Delinea DirectControl Agent for Mac versions on AD-joined computers to a CSV file for easier manipulation by running the following:

```
Get-ADComputer -Filter * -Properties OperatingSystem,OperatingSystemServicePack | Select-Object Name,OperatingSystem,OperatingSystemServicePack | Export-CSV CDCVersion.csv -NoTypeInformation -Encoding UTF8
```

In this example, PowerShell exports the data described above in **Show PowerShell Output of Agent Versions for AD-joined Computers** to a CSV file named CDCVersion.csv in the current directory. You can then open that CSV file using a spreadsheet application such as Excel to more easily analyze the data.

Enabling Logging for the Delinea DirectControl Agent for Mac

The Delinea DirectControl Agent for Mac installation includes some basic diagnostic tools and a logging mechanism to help you trace the source of problems if they occur. These diagnostic tools and log files allow you to periodically check your environment and view information about the agent operation, your Active Directory connections, and the configuration settings for individual computers.

In most cases, logging is not enabled by default for performance reasons. Once enabled, however, log files provide a detailed record of Delinea DirectControl Agent for Mac activity and can be used to analyze the behavior of Delinea Management Services and communication with Active Directory to locate points of failure.

For performance and security reasons, you should only enable agent logging when necessary, for example, when requested to do so by Delinea Corporation Technical Support, and for short periods of time to diagnose a problem. Keep in mind that sensitive information may be written to this file and you should evaluate the contents of the file before giving others access to it.

You can enable logging either by using the cdcdebug command or the Delinea for Mac Diagnostic Tool application.

To enable logging with the cdcdebug command:

1. Log in to the Mac as Local Admin and open the Terminal.
2. Run the following commands to clear and then enable the Delinea DirectControl Agent for Mac log file:

   ```
   % sudo /usr/local/share/centrifydc/bin/cdcdebug clear
   ```

   ```
   % sudo /usr/local/share/centrifydc/bin/cdcdebug on
   ```

3. Record the start time point:

   ```
   % date +%s
   ```

   For example: the output is 1610614011, please remember this output, it is the start time point.
4. Log out of the local admin user account.
5. Reproduce the issue: try to log in as the affected Active Directory user. Let it fail.
6. Log back in as Local Admin and open the Terminal again.
7. Record the end time point:

   ```
   % date +%s
   ```

   For example: the output is 1610614043, please remember this output, it is the end time point)
8. Enter the following commands to collect the Delinea DirectControl Agent for Mac log file:

   ```
   % sudo /usr/local/share/centrifydc/bin/cdcdebug -f pack [affected_AD_user_name] [start_time_point] [end_time_point]
   ```

   ```
   % adquery user -A [affected_AD_user_name] > /tmp/adquery.log
   ```

9. Send us the following files for analysis:

   ```
   /var/centrify/tmp/cdcdebug.tar.gz
   ```

   ```
   /tmp/adquery.log
   ```

10. Disable the Delinea DirectControl Agent for Mac log:

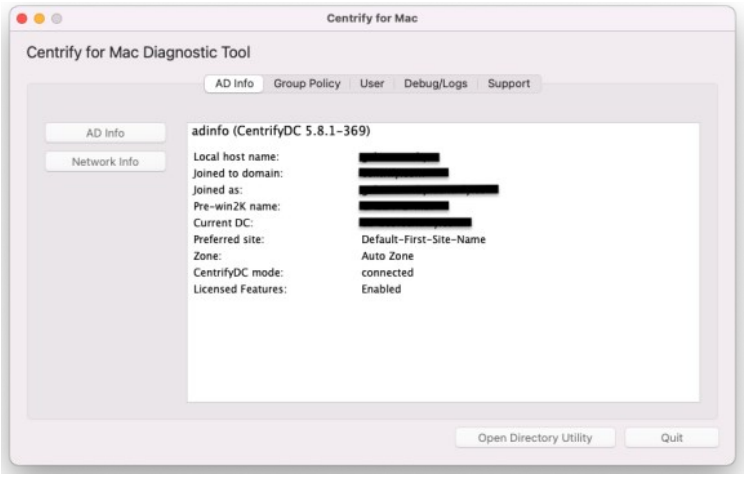
    ```
    % sudo /usr/local/share/centrifydc/bin/cdcdebug off
    ```

To enable logging with the Delinea for Mac Diagnostic Tool:

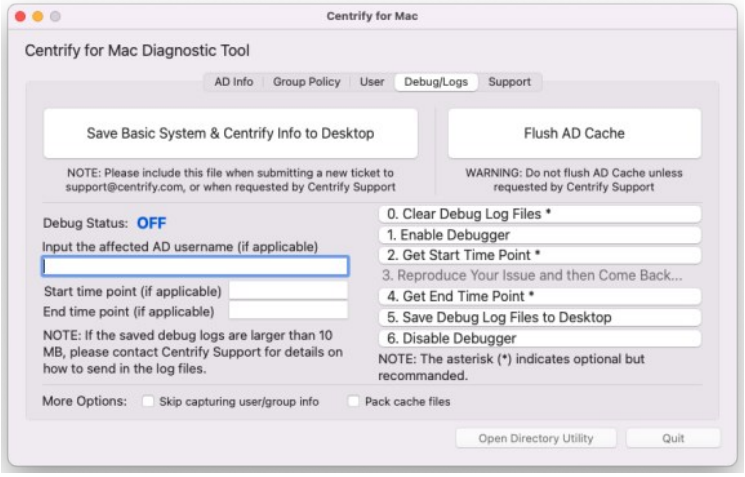
1. Log in to the Mac as Local Admin and open the application MacDiagnosticTool.app.

   The location of this app is "/Library/Application Support/Centrify/MacDiagnosticTool.app." You can run the following command to open it:

   ```
   % open /Library/Application Support/Centrify/MacDiagnosticTool.app
   ```

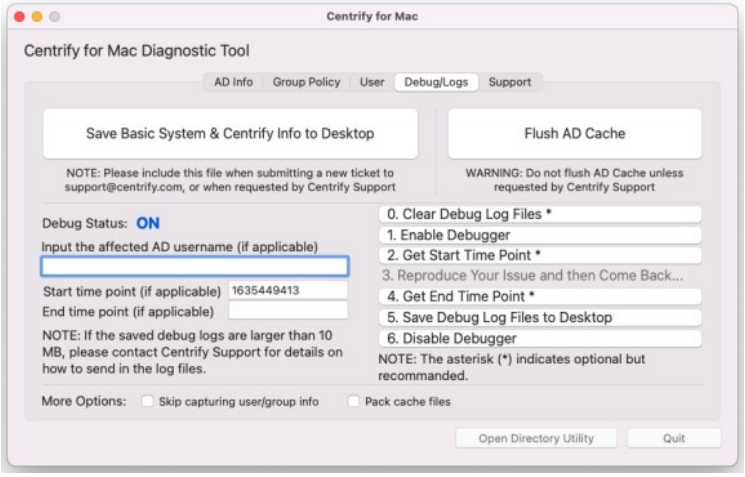


2. Click the **Debug/Logs** tab.

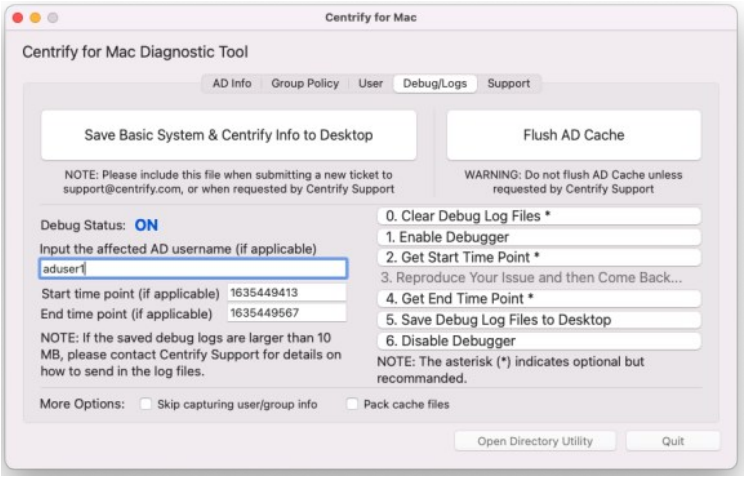


3. Click **0. Clear Debug Log Files**.
4. Click **1. Enable Debugger**.
5. Click **2. Get Start Time Point**.

   Note: You do not need to remember the start time point; it will be saved automatically.

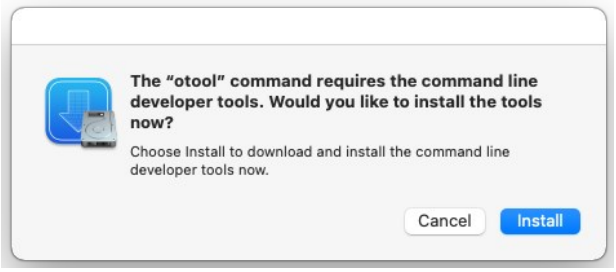


6. Click **Quit** to close the application.
7. Log out of the Local Admin account.
8. Reproduce the issue: try to log in as the affected Active Directory user. Let it fail.
9. Log back in as Local Admin and open the application MacDiagnosticTool.app again.
10. Click **4. Get End Time Point** and enter input the affected Active Directory user name.



11. Click **5. Save Debug Log Files to Desktop**, the tool will start to collect agent log files.

    Note: You might see a message display about installing the "otool" command; you can select **Cancel** or **Install**; either choice works.



The log file "CENTRIFY_FULL_LOG_PACK.zip" will be on the Desktop. Send the file to Delinea Technical Support for analysis.

12. Click **6. Disable Debugger**, then click **Quit** to close the application.

Enabling Logging for the Mac Directory Service

In addition to enabling logging for the agent, you may find it necessary to enable logging for the Open Directory Service.

To create a log file for the Open Directory Service:

1. Log in as or switch to the root or admin user.
2. Run the following command:

```
odutil set log debug
```

After running this command, you can find the resulting log files at: /var/log/opendirectoryd.log*. You can then provide both the agent log file and the Directory Service log file to Delinea Support if you need assistance troubleshooting issues.

Using the Agent on a Dual-boot System

If you are using a dual-boot system, and the computer name is the same for each version of the operating system, the Delinea DirectControl Agent for Mac(adclient) will not launch when you reboot and switch operating systems. The problem is that each operating system sets its own password for adclient and the password does not work for the other operating system.

The best way to avoid this problem is to provide a different computer name for each operating system. Because the computer names are different, the password for one operating system is not changed by the other operating system.

If you want to use the same computer name for both operating systems, you can work around the problem, as follows:

1. Leave the domain (adleave) before rebooting and switching operating systems.

   Note: You may leave and join the domain after rebooting and switching the operating system. However, you will experience some delay while adclient attempts to launch and fails.

2. Reboot with the other operating system.
3. Rejoin the domain (adjoin).

Using adgpupdate Appropriately

If adgpupdate is run multiple times in succession, it is possible that not all group policies will be applied correctly. To avoid this problem, do not run adgpupdate more than once per minute.

Understanding Delays when Logging on the First Time with a New User Account

Depending on the configuration of your startup services, you may find that new users are unable to log on to a computer immediately (within the first 15 to 30 seconds) after a computer is rebooted.

By default, the Mac login window only requires the DiskS and SecurityService startup services to start successfully to prompt for the user to log in. Authenticating users to Active Directory, however, requires the additional DirectoryServices startup service to be available. Starting the DirectoryServices startup service causes a 10 to 15 second delay before the LoginWindow can successfully authenticate new Active Directory users.

Configuring Single-sign on to Work with Non-Mac Computers

On a Mac computer, the ssh client does not forward (delegate) credentials to the server by default. Therefore, when attempting to use ssh from a Mac computer with DirectControl agent installed to a non-Mac computer with DirectControl agent installed, single sign-on (SSO) does not work. To fix this problem, set the configuration parameter, GSSAPIDelegateCredentials, to yes in the /etc/ssh_config file on the Mac computer.

Restricting Login Using FTP

In Active Directory, you can set properties to prevent a user from logging in to other Macintosh computers. However, this restriction will not prevent a user from logging in via FTP to Macintosh computers with the DirectControl agent installed. It does restrict logging in with telnet, ssh, rlogin, and rsh.

Logging on Using localhost

For many UNIX platforms, you can log on using localhost to refer to the local computer; for example:

```
root@localhost
```

This syntax does not work when logging on to a Macintosh computer, whether using the Macintosh UI, or remotely through ssh or FTP.

Changing the Password for Active Directory Users

In the Mac OS X, the passwd command authenticates the user only after you type the user password. Because of this, the passwd command does not recognize the user as an Active Directory user until after the password is entered and the password prompts defined for Active Directory users, which are typically set through group policy or by modifying the Delinea configuration file, are not displayed. You can still use the passwd or chpass command to change the Active Directory password for a user, but you will not see any visual indication that you are modifying an Active Directory account rather than a local user account.

Disabling the Apple Built-in Active Directory Plug-in

Apple provides a built-in Apple Directory plug-in that may interfere with the Delinea DirectControl Agent for Macinstallation and operation. Therefore, before installing the agent, disable Apple's built-in Active Directory plug-in. In addition, remove Active Directory from the Authentication and Contacts search paths. If this plug-in is enabled and the Delinea DirectControl Agent for Mac has been installed, disable the plug-in, then reboot the Macintosh computer for reliable operation.

To disable the Apple Directory plug-in and remove Apple Directory from the Authentication and Contacts search paths:

1. On a Mac computer, open the Directory Utility.

   You can find the Directory Utility in one of these folders depending on the operating system that you are running:

   - /System/Library/CoreServices
   - /Applications/Utilities

2. Click the lock icon and enter credentials to allow you to make changes.
3. Click the **Search Policy** icon.
4. Click the **Authentication** tab, then select Custom path in the **Search** box.

   If Active Directory was previously enabled, Active Directory appears in the Directory Domains box; for example:

   ```
   /Active Directory/All Domains
   ```

5. Select **/Active Directory/All Domains** and click **Remove** — or select the minus - sign). Then click **Apply**.
6. Click the **Contacts** tab, then select Custom path in the **Search** box. If Active Directory was previously enabled, Active Directory shows (in red font) in the Directory Domains box; for example:

   ```
   /Active Directory/All Domains
   ```

7. Select **/Active Directory/All Domains** and click **Remove**. Then click **Apply**.
8. Close the window.
9. If you have already installed the Delinea DirectControl Agent for Mac, reboot the computer.

Showing the Correct Status of the Delinea Plug-in

The Delinea plug-in is automatically added to the list of Apple Directory Utility plug-ins that are used for lookup and authentication. However, if the Apple Directory Utility tool is running when you install the Delinea DirectControl Agent for Mac, or when you join or leave a domain before updating to a new version of the agent, it will incorrectly display the status of the plug-in. For example, it will show the status as disabled, when in fact, the plug-in is enabled.

To avoid this problem, before launching the installer, be certain that the Apple Directory Utility tool is closed.

If the Directory Utility was open during installation, simply close and re-open Directory Utility, then make certain that the Delinea plug-in is enabled.

You may also restart the Delinea plug-in from the command line, as follows:

1. Close the Directory Utility.
2. Open a terminal.
3. Enter the following command:

   ```
   /usr/local/share/centrifydc/bin/dsconfig restart
   ```

4. Open the Directory Utility. The status of Delinea should be enabled.

Resolving VPN Access Issues with Mac OS X 10.7 and Later

Starting with Mac OS X 10.7, /etc/resolv.conf is no longer used for domain controller name resolution. Therefore, some VPN programs no longer update DNS server information in /etc/resolv.conf when signing on. On computers running Mac OS X 10.7 and later, this can result in the computer not being able to connect to a domain controller through a VPN.

To resolve this issue, explicitly specify in centrifydc.conf the location of DNS servers that are used to resolve domain controller names:

1. Open /etc/centrifydc/centrifydc.conf for editing.
2. Specify the IP addresses of DNS servers in the dns.servers parameter (if the parameter does not exist yet, create it now):
   ```
   dns.servers: x.x.x.x y.y.y.y
   ```

   where x.x.x.x y.y.y.y are the IP addresses of the DNS servers to use. This example shows two IP addresses; note that each IP address is separated by a space.
3. Save your changes to centrifydc.conf.
4. Restart the agent for the changes to take effect:

   ```
   sudo /usr/local/share/centrifydc/bin/centrifydcrestart
   ```

Diagnosing Smart Card Login Problems

Two general methods for diagnosing smart card log in problems are provided:

- By using the sctool utility as described in the sctool man page.
- By performing the diagnostic procedures described in this section.

The following procedures are intended to diagnose multiple causes of smart card log in failure. It is recommended that you retest smart card login at regular intervals (such as after each step) as you perform this procedure.

1. Ensure that macOS built-in PIV token is not disabled.

   ```
   % defaults read /Library/Preferences/com.apple.security.smartcard DisabledTokens
   ```

   It should not exist.
2. Ensure that smart card support is enabled.

   ```
   % sctool -s
   ```

   It should show that smart card support is enabled.
3. Ensure that the smart card can be recognized by MacOS.

   ```
   % sc_auth identities
   ```

   It should show your card and the card has been paired to the Active Directory user.
4. Collect support information.

```
% sctool -S
```

Send the file /tmp/sctool.support to Delinea Support.

Opening a Support Case Online

If you need assistance with troubleshooting an issue, you may need to open a case with Delinea Support. Before opening a new case, Delinea recommends searching the Delinea Support Portal to see if your problem is a known issue or something for which there is a recommended solution.

To search the Delinea Support Portal

1. Open https://www.delinea.com/support/ in a Web browser.
2. Click in the search field and type one or more key words to describe the issue, then click the search icon to view potential answers to your question.

If your issue is not covered in one of the search results, you should open a case with Delinea Support.

To open a new support case

1. Log in to the Delinea support portal.
2. Click **Manage Cases**, then click **Open a New Support Case**.

   The NEW CASE DETAIL page appears.
3. Enter your case details, then click **Next**.

   Provide as much information as possible about your case, including the operating environment where you encountered the issue, and the version of the Delinea product you are working with.

   A new page appears showing Suggest Knowledge Articles and Technical Resources. You can click **Show More** to see additional resources that might solve your problem.
4. Click **No Thanks, Submit a Case** to open a new case.

Collecting Information for Support Cases

To help ensure your issue gets resolved quickly and efficiently, gather as much information about your working environment as possible. See the information below in these two sections:

- Collecting general information about your environment
- Collecting information specific to login events

Collecting Information Specific to Smart Card Login Failure

Collect the following information prior to opening a support case related to smart card log in failure:

- The smart card type (for example, PIV, CAC, CACNG, and so on), manufacturer, and model.
- A screen image of the smart card and its certificates in Keychain Access.
- The following log files:

  /tmp/sctool_D.log

  /tmp/adquery.log

  /tmp/tokendfolder.log

  /var/Centrify/tmp/adinfo_support.tar.gz

To generate these logs, run the following commands while logged in as the local administrator:

```
sctool -D > /tmp/sctool_D.log

adquery user -A username_of_smartcard_user > /tmp/adquery.log

sudo ls -l /System/Library/Security/tokend/ > /tmp/tokendfolder.log

sudo adinfo -t
```

Collecting General Information about Your Environment

Take the following steps to gather information about your working environment before opening a support case.

1. Verify that the DirectControl agent is running on the computer where you have encountered a problem. For example, run the following command:

   ```
   ps aux | grep adclient
   ```

   If the adclient process is not running, check whether the watchdog process, cdcwatch, is running:

   ```
   ps aux | grep cdcwatch
   ```

   The cdcwatch process is used to restart adclient if it stops unexpectedly.

   > **Note**: The commands in the following three steps must be run as root or with the sudo command.

2. Enable logging for the DirectControl agent; for example:

   ```
   sudo /usr/local/share/centrifydc/bin/cdcdebug on
   ```

   > **Note**: Login events are captured in /var/log/centrifydc-login.log by default. Turning on cdcdebug captures login events in /var/log/centrifydc.log.

3. Create a log file for the Mac Directory Service. For example:

   - To enable logging for opendirectoryd:

   ```
   odutil set log debug
   ```

   - To disable logging for opendirectoryd when sufficient log information is collected:

   ```
   odutil set log default
   ```

4. Duplicate the steps that led to the problem you want to report. For example, if an Active Directory user can't log in to a managed system, attempt to log the user in and confirm that the attempt fails. Be sure to make note of key information such as the user name or group name being used, so that Delinea Support can identify problem accounts more quickly.

5. Verify that log file /var/log/centrifydc.log or /var/adm/syslog/centrifydc.log exists and contains data.

6. Run the cdcdebug command to generate logs that describe the domain and current environment; for example:

   ```
   sudo /usr/local/share/centrifydc/bin/cdcdebug -f pack username
   ```

   The following log files are created in /var/centrify/tmp when you execute the cdcdebug command:

   - adinfo_support.tar.gz
   - adinfo_support.txt
   - cdcdebug.tar.gz
   - dump_cache_error.log
   - stacktrace.txt

7. If there is a core dump during or related to the problem, save the core file and inform Delinea Support about it. Delinea Support may ask for the file to be uploaded for review.

   If the core dump is caused by a Delinea process or command, such as adclient or adinfo, open the /etc/centrifydc/centrifydc.conf file and change the adclient.dumpcore parameter from never to always and restart the agent:

   ```
   sudo /usr/local/share/centrifydc/bin/centrifydcrestart
   ```

   > **Note**: For more information about starting and stopping the agent, see the *Administrator's Guide for Linux and UNIX*.

8. If there is a cache-related issue, Delinea Support may want the contents of the /var/centrifydc directory. You should be able to create an archive of the directory, if needed.
9. If there is a DNS, LDAP, or other network issue, Delinea Support may require a network trace. You can use Ethereal to create the network trace from Windows or UNIX. You can also use Netmon on Windows computers.
10. Create an archive (for example, a .tar or .zip file) that contains all of the log files and diagnostic reports you have generated, and add the archive to your case or send it directly to Delinea Support.
11. Consult with Delinea Support to determine whether to turn off debug logging. If no more information is needed, run the following commands, which must be run as root or with sudo:

    ```
    odutil set log default

    sudo /usr/local/share/centrifydc/bin/cdcdebug off
    ```

Collecting Information Specific to Login Events

Login events are captured in /var/log/centrifydc-login.log by default. If you enable logging for the DirectControl agent by turning on cdcdebug, login events are then captured in /var/log/centrifydc.log.

The /var/log/centrifydc-login.log grows to a maximum size of 50M before it is compressed. When all compressed centrifydc-login.log files combined with the current log file exceed 250M, the oldest compressed log is replaced.

This section shows other methods of installing the agent besides the standard method using the package installer (DMG file); see Installing the Delinea DirectControl Agent for Mac. It also shows how to remove the agent and how to join and leave a domain.

The following topics are covered:

Installing Using the install.sh Script

Installing Silently on a Remote Computer

Uninstall from the Delinea System Preferences Pane

Run the uninstall.sh Script

Leaving an Active Directory Domain

Installing Using the install.sh Script

This section explains how to install using the install.sh script. This method is recommended for experienced UNIX administrators who are familiar with UNIX command-line installations. Otherwise, you should install by using the graphical user interface, which is described in Installing the Delinea DirectControl Agent for Mac.

To install using the install.sh command-line program:

> **Note**: Before launching the installer, be certain that Apple Directory Utility is closed. If it is open while running the installer, it causes the Delinea Directory Access plug-in to show the incorrect status, that is, it shows that the plug-in is disabled when in fact it is enabled.

1. Log on with a valid user account.

   > **Note**: You are not required to log on as the root user on, but you must know the password for the Administrator account to complete the installation.

2. Mount the CD-ROM device using the appropriate command for the local computer's operating environment, if it is not automatically mounted.
3. Change to the appropriate directory on the CD or on the network where the DirectControl agent package is located. For example, change to the Agent_Mac directory.
4. Run the install.sh script to start the installation of the Delinea software on the local computer's operating environment. For example:

   ```
   sudo ./install.sh
   ```

   Before beginning the installation, the install.sh script runs the ADCheck utility, which performs a set of operating system, network, and Active Directory checks to verify that the Mac computer meets the system requirements necessary to install the Delinea DirectControl Agent for Mac and join an Active Directory domain.

5. Review the results of the checks performed. If the target computer, DNS environment, and Active Directory configuration pass all checks with no warnings or errors, you should be able to perform a successful installation and join. If you receive errors or warnings, correct them before proceeding with the installation.
6. Follow the prompts displayed to select the services you want to install and the tasks you want to perform. For example, you can choose whether you want to join a domain or restart the local computer automatically at the conclusion of the installation.

When installation is complete, see **Understanding the Directory Structure** below for a description of the directories and files installed for Centrify.

Installing Silently on a Remote Computer

You can install the agent silently on a remote Mac computer in either of these ways:

- By using sudo commands from the command line. If you use this method, no user interaction on the target Mac computer is required. See the section below, **Installing Remotely on a Mac Computer Using sudo Commands**.
- By using Apple Remote Desktop. This method requires that you have Apple Remote Desktop 3 for remote software distribution. See the section below, **Installing Remotely on a Mac Computer Using Apple Remote Desktop**.

If you use this method to install version 5.1.0 of the agent, the Delinea Join Assistant launches on the target Mac computer after the installation completes, and a user must interact with the Delinea Join Assistant to complete the join process. This limitation exists only in version 5.1.0 of the agent. Earlier versions of the agent (that is, 5.0.x and lower) and later versions (5.1.1 and above) do not have this limitation, and can be installed using Apple Remote Desktop without any user interaction on the target Mac computer.

Installing Remotely on a Mac Computer Using Sudo Commands

Perform the following steps to use sudo commands to install the agent remotely on a target Mac computer without requiring any user interaction on the target Mac computer.

To install the agent remotely using sudo commands:

1. Ensure that you have administrator account credentials on the target Mac computer, and that SSH is installed on the target Mac computer.
2. On the computer where the Delinea packages were downloaded (that is, the source computer), use an appropriate file transfer method to push the CentrifyDC-x.x.x.pkg file to the target Mac computer.

   For example, perform these steps to transfer files from a PC source computer to the target Mac computer:

   1. On the source computer, ensure that file sharing is enabled, and that the folder containing the Delinea packages is a shared folder.
   2. On the target Mac computer:
      1. Open a new window in the Finder.
      2. In the sidebar under **Shared**, click **All**.
      3. Select the source computer.
      4. Click **Connect As**, type the user name and password for the source computer, and click **Connect**.
   3. The folder that you shared on the source computer appears in the Finder on the target Mac computer. Locate the CentrifyDC-x.x.x.pkg file on the source computer and drag it to the location of your choice on the target Mac computer.
3. On the source computer, use a program such as Putty to connect remotely to the target Mac computer through SSH. Log in to the target Mac computer using an account that has local administration privileges, such as the Local Admin account.
4. On the target Mac computer, navigate to the directory where the .pkg file was transferred and execute the following command:

   ```
   sudo /usr/sbin/installer –pkg CentrifyDC-x.x.x.pkg –target /
   ```

   When you execute this command, the agent is installed silently on the target Mac computer.

   - If an agent was already installed on the target Mac computer and this was an update of the existing agent, the target Mac computer was already joined to the domain, and you do not need to perform any additional steps.
   - If this was the first installation of the agent on the target Mac computer, you must enable licensed features and join the target Mac computer to a domain as described in Step 5 and Step 6.
5. Execute the following command on the target Mac computer to enable licensed features:

   ```
   sudo adlicense -l
   ```
6. When you join the target Mac computer to a domain, you can choose to join the auto zone or a specified hierarchical zone.

   - Execute the following command on the target Mac computer to join the target Mac computer to a domain and the Auto Zone:

     ```
     sudo /usr/local/sbin/adjoin --user Domain_Admin --container "domain.com/Path/To/OU"  --name computer_name --workstation domain_name.com
     ```

   - Alternatively, execute the following command on the target Mac computer to join the target Mac computer to a domain and a specified hierarchical zone:

     ```
     sudo /usr/local/sbin/adjoin --user Domain_Admin --container "domain.com/Path/To/OU"  --name computer_name --zone zone_namedomain_name.com
     ```

Installing Remotely on a Mac Computer Using Apple Remote Desktop

Perform the following steps to install the agent remotely on a target Mac computer without requiring any user interaction on the target Mac computer.

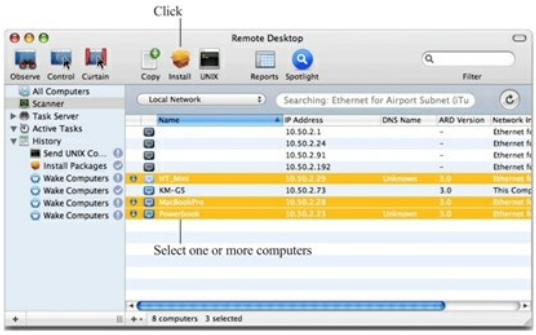
Note: If you use this method to install version 5.1.0 of the agent, the Delinea Join Assistant launches on the target Mac computer after the installation completes, and a user must interact with the Delinea Join Assistant to complete the join process. For all other versions of the agent, no user interaction on the target Mac computer is required.

To remotely install the DirectControl agent and join a computer to the domain using Apple Remote Desktop 3:

1. Verify that you have an Apple Remote Desktop 3 Admin station and one or more Apple Remote Desktop 3 Clients.
2. Verify that all of the Apple Remote Desktop 3 Client computers where you want to install the DirectControl agent are set to **Allow Remote Desktop** using the Service pane in the Sharing system preference. For example:

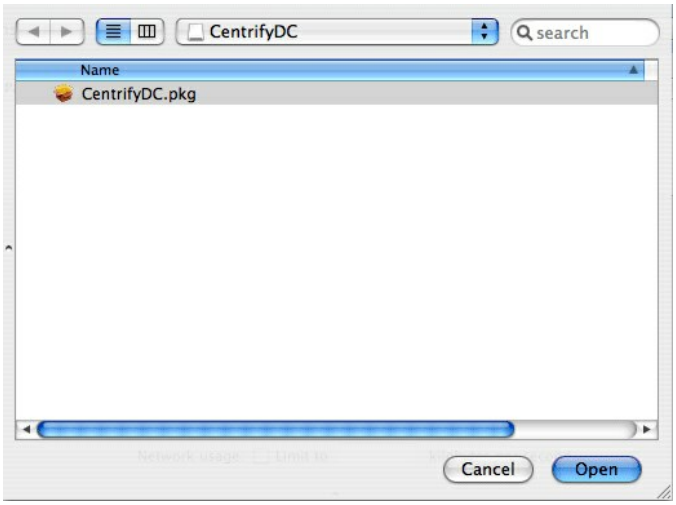
3. Copy the DirectControl agent package, for example centrifydc-release-macversion-i386.dmg, to the Apple Remote Desktop 3 Admin computer and verify that you can access the disk image.
4. Open Remote Desktop on the Admin Computer, then click **Scanner** and verify that the Mac computers on which you plan to install Delinea are listed and that ARD Version column displays 3.0 (or later). For example:

5. Select one or more computers from the list, then click **Install**. For example:

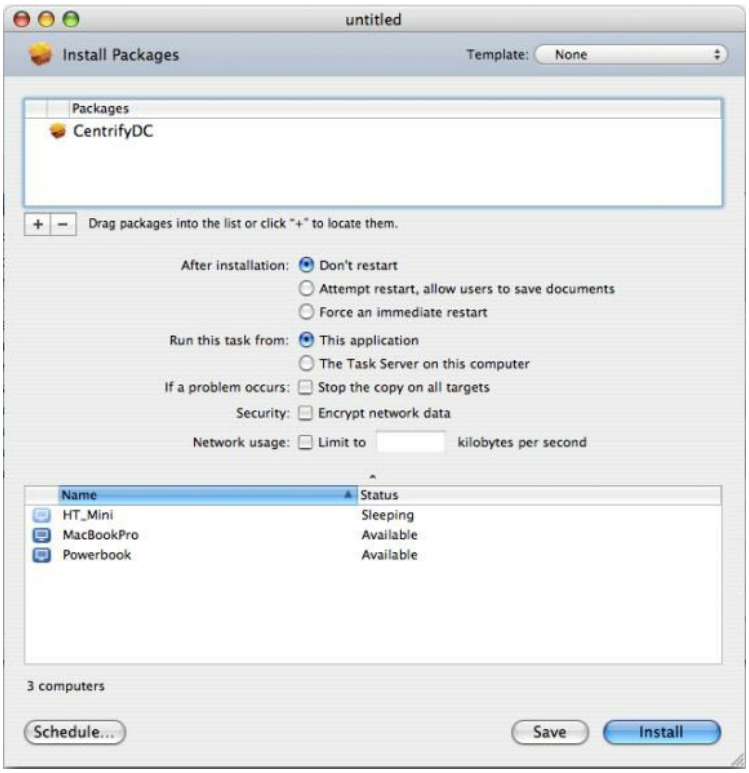


6. In the Install Packages window, click **+** to locate the CentrifyDC.pkg in the DirectControl agent disk image. For example:

7. In the DirectControl agent disk image, select the CentrifyDC.pkg file and click **Open** to add it to the Install Packages list. For example:



8. In the Install Packages window, click **Install** to install the listed packages, for example:



In most cases, you can use the default settings to install the Delinea DirectControl Agent for Mac. If you want to schedule the installation for another time rather than completing the installation now, click **Schedule**. For more information about the Apple Remote Desktop installation parameters, see Chapter 8 "Administering Client Computers," in the Apple Remote Desktop Manual.

If you click **Install** the Remote Desktop displays a progress bar and task status for each of the computers selected for the installation.

Understanding the Directory Structure

When you complete the installation, the local computer will be updated with the following directories and files:

/etc/centrifydc	The Delinea DirectControl Agent for Mac configuration file and the Kerberos configuration file.
/usr/local/share/centrifydc	Kerberos-related files and service library files used by the Delinea DirectControl Agent for Mac to enable group policy and authentication and authorization services.
/usr/local/sbin /usr/bin	Command line programs to perform Active Directory tasks, such as join the domain and change a user password.
/var/centrifydc	No files until you join the domain. After you join the domain, several files are created in this directory to record information about the Active Directory domain the computer is joined to, the Active Directory site the computer is part of, and other details.
/System/Library/Frameworks/ DirectoryService.framework/ Resources/Plugins	The Delinea Directory Service Plugin, CentrifyDC.dsplug, that enables you to join or leave the domain using the graphical user interface.

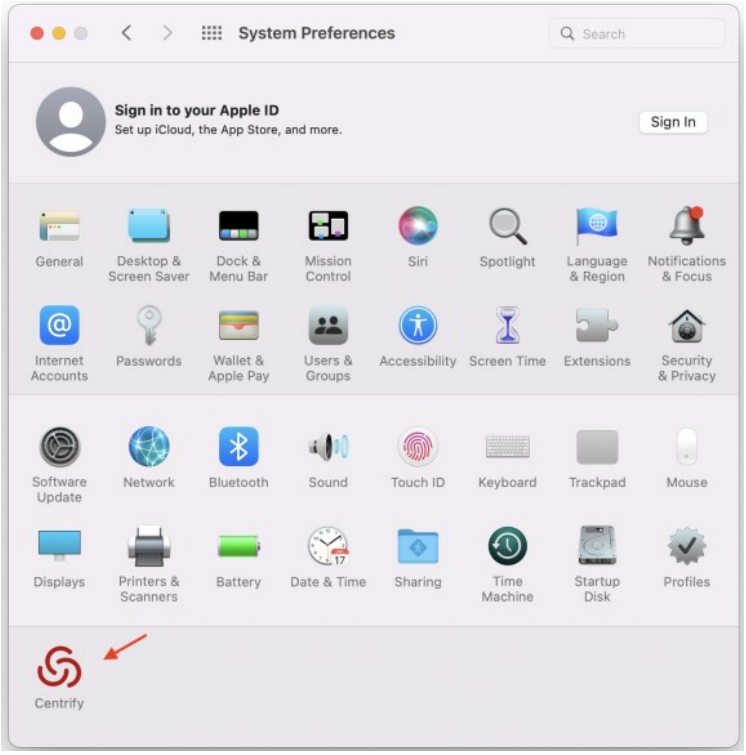
Uninstall from the Delinea System Preferences Pane

The Delinea System Preferences pane is created when you install the Delinea DirectControl Agent for Mac. You can use this pane to uninstall the Delinea

DirectControl Agent for Mac. Uninstalling the agent from the Delinea System Preferences pane also leaves the AD domain.

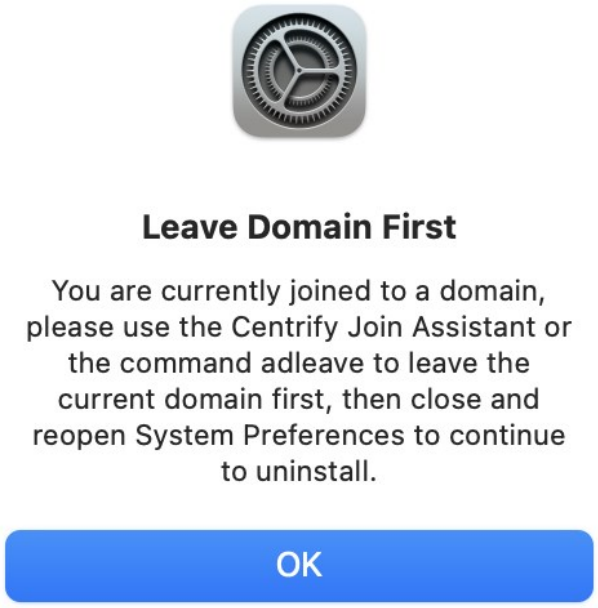
To uninstall the Delinea DirectControl Agent for Mac from the Delinea System Preferences pane

1. Open **System Preferences**, then click **Centrify**.



2. Click **Uninstall**, then click **OK** at the confirmation prompt.

   If you are currently joined to a domain, it will prompt the Leave Domain First dialog. For more information, see **Leaving an Active Directory Domain** below.



3. Enter administrator credentials and click **OK**.

   The uninstall process starts.

4. Click **OK** to quit when you see the window indicating that the Delinea DirectControl Agent for Mac was uninstalled.

Run the uninstall.sh Script

The uninstall.sh script is installed by default in the /usr/local/share/centrifydc/bin directory on each Centrify-managed system.

To remove the Delinea DirectControl Agent for Mac by running the uninstall.sh script

1. Open a Terminal window on the computer where the DirectControl agent is installed. For example, select **Applications > Utilities > Terminal**.
2. Switch to the root user or a user with superuser permissions. For example:

   ```
   su -
   ```

   Password: root_password

3. Run the uninstall.sh script. For example:

   ```
   /bin/sh /usr/local/share/centrifydc/bin/uninstall.sh
   ```

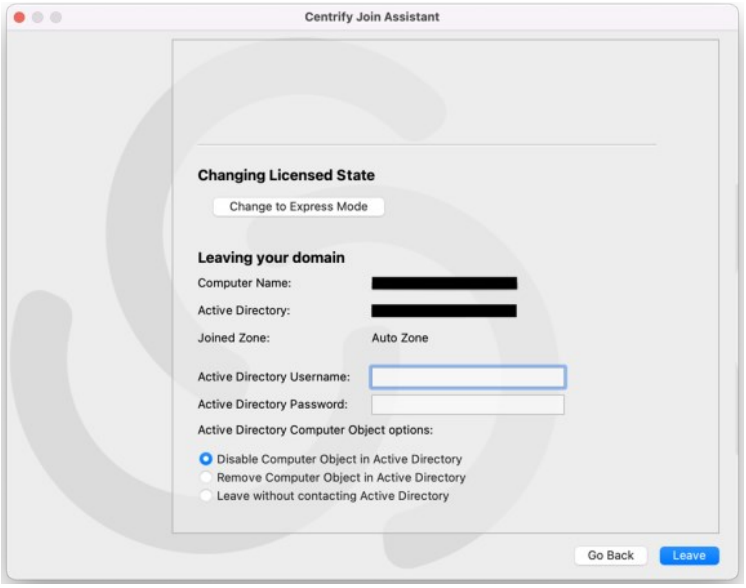
   The uninstall.sh script will detect whether the Delinea DirectControl Agent for Mac is currently installed on the local computer and whether the computer is currently joined to a domain. If the computer is not currently joined to a domain, the script will begin removing Delinea files from the local computer.

Leaving an Active Directory Domain

To start the Delinea program for joining or leaving a domain:

1. Click **Applications > Utilities > Delinea**, then double-click **Delinea Join Assistant** to open it.

   Click **Continue** on the Welcome page and the join assistant displays information about the domain to which the computer is connected:



2. Select whether to disable the computer object in Active Directory, remove the computer object from Active Directory, or leave without contacting Active Directory.

    - Disable: Disables the computer object in Active Directory.
    - Remove: Removes the computer object from Active Directory.
    - Leave without contacting Active Directory: This option forces the local computer's settings to their pre-join conditions without contacting Active Directory. The Computer Object will not be removed or disabled in Active Directory.

    Use this option if the Active Directory computer account has been modified or deleted so that the host computer can no longer work with it.

3. Click **Leave** to leave the domain.

The following topics are covered:

Server Suite is an IT management solution that provides three main services:

- Access control, provided through the Authentication Service.
- Privilege management, provided through the Privilege Elevation Service.
- Auditing, provided through Audit & Monitoring Service.

These services can be used together or independently, depending on the requirements of your organization.

Managing Windows Computers Using Delinea software

Server Suite is a security platform that includes multiple components for managing Windows computers. The components fall into two broad categories of features:

- Access-related components for managing access, including administrative privileges.
- Audit-related components for managing and analyzing audited activity.

Access-Related Features

Access-related features are provided by the Authentication Service and the Privilege Elevation Service. Together, these services enable you to manage access and administrative privileges for the computers in your organization. The primary tool for managing access-related features is Access Manager.

Access Manager provides a central console for defining and managing role-based access control rules and applying them to specific users, groups, or computers. For example, you can use Access Manager to delegate specific administrative tasks to a particular user or group. As an administrator, you can also use Access Manager to configure roles with start and expiration dates or limit the availability of a role to specific days of the week or hours of the day.

> **Note**: Server Suite treats gMSA accounts (group Managed Service Accounts) as Active Directory users.

Audit-Related Features

Audit-related features are provided by the Audit & Monitoring Service. This service enables you to collect and store audit trails that capture detailed information about user activity. The primary tool for managing audit-related features is Audit Manager.

Audit Manager provides a central console for configuring and managing audited computers, audit store databases, and the permissions granted to specific auditors. There is also a separate Audit Analyzer console for searching and replaying captured activity.

Choosing Access and Auditing Features

In addition to the management tools for access-related or auditing-related features, each computer you want to manage must have a Agent installed. After you install the agent, you choose whether to enable access features, auditing features, or both feature sets.

If you enable access features, the agent enforces the role-based privileges that enable users to run applications locally with administrative privileges without using the Administrator password and with their activity traceable to their own account credentials. You can also use role-based privileges to secure access to network services on remote computers.

If you enable auditing features, the agent captures detailed information about what users do when they access applications or network resources with administrative privileges.

You can use access features and components without auditing if you aren't interested in collecting and storing information about session activities. You can also deploy auditing features and components without access control and privilege elevation features if you are only interested in auditing activity on Windows computers. However, the real value of using Delinea software to manage Windows computers comes from using all of the services as an integrated solution for managing elevated privileges and ensuring accountability and regulatory compliance across all platforms in your organization.

Access Control for Windows Computers

By using Access Manager and deploying the Agent for Windows, you can develop fine-grained control over who has access to the Windows computers in your organization. You can also limit the use of administrative accounts and passwords. For example, you can restrict access to computers that host administrative applications or data center services and ensure that users accessing those computers can log on locally or connect remotely only when appropriate.

In a Windows environment without Delinea software, the primary way you secure access to Windows computers is by granting a limited number of users or groups local or domain administrator privileges. The main drawback of this approach is that the rights associated with group membership don't change. A user who has domain administrator rights has those rights on any computer in the domain at all times. In other cases, users who aren't administrators or members of an administrative group need administrative privileges to perform specific tasks that would require them to have an administrator and service account password. Shared passwords reduce accountability and are often flagged by auditors as a security issue.

Through the use of zones and roles, Delinea software provides granular control over **who** can do **what**, and over **where** and **when** those users should be granted elevated privileges.

One way trust environments

Windows agent supports one-way trust in the following scenarios:

- When the zone belongs to the resource forest.
- When the logon account belongs to the account forest.
- When the RunAs account or group belongs to the resource forest (RunAs group can be a built-in group).
- When the role assignment is at the zone, computer, or computer role level.

How Zones Organize Access Rights and Roles

One of the most important aspects of managing computers with Delinea software is the ability to organize computers, users, groups and other information about your organization into **zones**. A zone is a logical object created using Access Manager that is stored in Active Directory. You use zones to organize computers, rights, roles, security policies, and other information into logical groups. These logical groups can be based on any organizing principle you find useful. For example, you can use zones to describe natural administrative boundaries within your organization, such as different lines of business, functional departments, or geographic locations.

Zones provide the first level of refinement for access control, privilege management, and the delegation of administrative authority. For example, you can use zones to create logical groups of Windows computers to achieve these goals:

- Control who can log on to specific computers.
- Grant elevated rights or restrict what users can do on specific computers.
- Manage role definitions, including availability and auditing rules, and role assignments on specific computers.
- Delegate administrative tasks to implement "separation of duties" management policies.

You can also create zones in a hierarchical structure of parent and child zones to enable the inheritance of rights, roles, and role assignments from one zone to another or to restrict local or remote access to specific computers for specific users or groups.

Because zones enable you to grant specific rights to users in specific roles on specific computers, you can use zones as the first level of refinement for controlling who has access to which computers, where administrative privileges are granted, and time restrictions on when administrative privileges can be used.

You can also use zones to establish an appropriate separation of duties by delegating specific administrative tasks to specific users or groups on a zone-by-zone basis. With zones, administrators can be given the authority to manage a given set of computers and users without granting them permission to perform actions on computers in other zones or giving them access to other Active Directory objects.

How Role-Based Access Rights Can be Used

Role-based access rights are more flexible than Active Directory group membership because Active Directory groups provide static permissions. For example, if Jonah is a member the Active Directory Backup Operators group, he has all of the permissions defined for members of that group regardless of when or where he logs on to computers in the forest. In contrast, role assignments can be scheduled to start and end, apply only during specific hours, or only be available on specific computers. For example, Jonah may only be in the Backup Operators role on a specific computer or only on weekends.

Role-based access rights also prevent password sharing for privileged accounts, helping to ensure accountability. Users who need to be able to launch applications with elevated privileges can log on with their regular account credentials but run the application using an appropriate role without being prompted to provide the administrative password. For example, if Angela is assigned a role that enables her to run Disk Defragmenter using elevated privileges, she can log on with her normal credentials and select the role that enables her to run Disk Defragmenter without being prompted to provide an administrator user name and password.

Auditing User Activity on Windows Computers

Just as it is important to protect assets and resources from unauthorized access, it is equally important to track what users who have permission to access

those resources have done. For users who have privileged access to computers and applications with sensitive information, auditing helps ensure accountability and improve regulatory compliance. With the Audit and Monitoring service, you can capture detailed information about user activity and all of the events that occurred while a user was logged on to an audited computer.

If you choose to enable audit and monitoring service on Windows computers, the Agent starts recording user activity when a user selects a role or logs on to a computer. The agent continues recording until the user logs out or the computer is locked because of inactivity. The user activity captured includes an audit trail of the actions a user has taken and a video record of the applications opened, any text that was entered, and the results that were displayed on the screen. Because information about user activity, called a **session**, is collected as it happens, you can monitor computers for suspicious activity or troubleshoot problems immediately after they occur.

When users start a new session on an audited computer, they can be notified that their session is being audited and they cannot turn off auditing except by logging off. The information recorded is then transferred to a Microsoft SQL Server database so that it is available for querying and playback. You can search the stored user sessions to look for policy violations, user errors, or malicious activity that may have led to a service degradation or outage.

In addition to saving video record of user activity, sessions provide a summary of actions taken so that you can scan for potentially interesting or damaging actions without playing back a complete session. After you select a session of interest in the Audit Analyzer, the console displays an indexed list of actions taken in the order in which they occurred. You can then select any entry in the list to start viewing the session beginning with that action. For example, if a user opened an application that stores credit card information, you can scan the list of actions for the launch of that application and begin reviewing what happened in the session from that time until the user closed that application.

If users change their account permissions to take any action with elevated privileges, the change is recorded as an audit trail event. You can search for these events to find sessions of interest.

Using Access and Auditing Features Together

If you use the Access and Audit and Monitoring service features together, you can define role-based access rights, restrict when and where roles are available, identify roles that should be audited, trace activity when roles with elevated permissions are selected and used, and play back session activity based on the criteria you choose. However, audit and monitoring service requires database storage for the audited sessions and management of network communication for collecting and transferring audited sessions from computers being audited to one or more databases where the sessions are stored. You also need to decide which roles should require audit and monitoring service and the computers you want to audit.

This chapter provides an overview of the Delinea software architecture for identity management, privilege elevation, and auditing on Windows computers.

Identity and Privilege Management

In Server Suite, the authentication service and privilege elevation service provide role-based access control and privilege management for Windows computers. For administration, the services provide tools that help you define and manage access rights and roles for Active Directory users and groups. To enforce the rights and roles you define, you install an agent on each server or workstation to be managed.

Defining Rights and Roles Using Access Manager

When you install Server Suite, you choose the components you want to enable. For identity and privilege management, the key component for administration is the Access Manager console. Although there are other ways to define and manage access rights, roles, and role assignments, Access Manager is the primary tool for managing all of the Delinea software information stored in Active Directory. With Access Manager, you can:

- Create and manage zones to control access to all of the computers you support, including Windows, UNIX, Linux, and Mac OS X computers.
- Set and modify specific types of access right for users and groups.
- Add and customize the role definitions available in different zones, including any time restrictions on when roles are available or cannot be used.
- Assign and manage roles for individual Active Directory user or Active Directory groups.
- Associate groups of computers that share a common function or attribute with users who have a specific role assignment.
- Generate and view reports describing the users, groups, computers, and applications you are managing and which users and groups have access to which computers.
- View and manage licenses for servers and workstations.

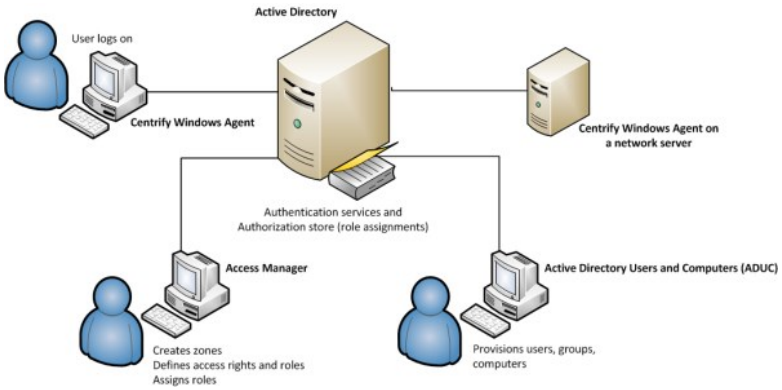
Enforcement of Rights and Roles by the Agent

For identity and privilege management, the key component for deployment is the Agent for Windows. After you install the agent on a server or workstation and identify a zone for the computer to join, the computer becomes a **Delinea-managed computer**. If you have enabled access management features for the agent, you can then define access rights and role-based policies to control what different sets of users can do on those computers in each zone.

After you deploy the Agent for Windows and select access management on a computer, the agent provides the following identity and privilege management features:

- Users logging on to the computer must be assigned to a role that allows them to log on.
- Users who are assigned to a role with **application rights** can run a specific application with elevated privileges.
- Users who are assigned to a role with **desktop rights** can create new Windows desktops that enables them to run all local applications with elevated privileges.
- Users who are assigned to a role with **network access rights** can connect to network resources with elevated privileges.

The following illustration provides a simplified view of the components for identity and privilege management.



In this illustration, an Agent is installed on an individual user's workstation and on a server accessed remotely. The administrative consoles that you use to manage zones, access rights, role definitions, and Active Directory accounts are installed on two separate computers. As shown in the illustration, all of these computers are part of an Active Directory domain and have access to an Active Directory domain controller. If you work with other platforms, the architecture

is the same but you would have additional platform-specific agents.

To ensure that you can centrally manage access to Windows computers with the privilege elevation service and the Agent for Windows, you should check that your network meets a few basic requirements:

- You have at least one Active Directory forest and domain controller.
- All of the computers you want to manage must be joined to an Active Directory domain and can communicate with an Active Directory domain controller over the network or through a firewall.
- You have a basic deployment plan in place that identifies your primary goals, team members and responsibilities, and a target set of computers.

The Audit and Monitoring Service Infrastructure

The Audit and Monitoring Service is part of Server Suite. The service captures detailed information about user activity on the computers you choose to audit.

Auditing Captures User Activity

After you deploy audit and monitoring service, the Agent for Windows captures all of the user activity on the computers you choose to audit. Depending on whether you enable identity and privilege management together with audit and monitoring service, or just audit and monitoring service on a computer, the agent starts recording user activity when a user selects a role or logs on to a computer and continues recording until the user logs out or the computer is locked because of inactivity. If you enable identity and privilege management together with audit and monitoring service on a computer, the agent records user activity when a role withaudit and monitoring service is used. If you only enable audit and monitoring service on a computer, all user activity is captured by default.

Each record of continuous user activity is called a **session**, and starts as soon as users log on, whether they log on locally, using a Windows Remote Desktop connection, through a virtual network connection such as Citrix or VNC, or using any other type of remote access software. A session ends when the user logs out, disconnects, or is inactive long enough to lock the desktop. If the user reconnects to a disconnected desktop or unlocks the desktop, the agent resumes recording the user's activity as a new session. Each session is a video record of everything that takes place on the user's desktop during a period of user activity.

Auditing Requires a Scalable Architecture

To ensure scalability for large organizations and fault tolerance, audit and monitoring service has a multi-tier architecture that consists of the following layers:

- **Audited computers** are the computers on which you want to monitor activity. To be audited, the computer must have an agent installed, audit features enabled, and be joined to an Active Directory domain.
- **Collectors** are intermediate services that receive and compress the captured activity from the agents on audited computers as it occurs. You should establish at least two collectors to ensure that audit and monitoring service is not interrupted. You can add collectors to your installation at any time, and it is common to have multiple collectors to provide load balancing and redundancy.
- **Audit stores** define a scope for audit and monitoring service and include the audit store databases that receive captured activity and audit trail records from the collectors and store it for querying and playback. Audit store databases also keep track of all the agents and collectors you deploy. For scalability and network efficiency, you can have multiple audit stores each with multiple databases.
- A **management database server** is a computer that hosts the Microsoft SQL Server instance with the audit management database. The management database stores information about the overall installation, such as the scope of each audit store, which audit store database is active, where there are attached databases, the audit roles you create, and the permissions you define. The management database enables centralized monitoring and reporting across all audit stores, collectors, and audited computers.
- **Audit Manager** and **Audit Analyzer consoles** are the graphical user interfaces which administrators can use to configure and manage the deployment of audit components, such as agents and collectors, or query and review captured user sessions.
- A **reporting database** collects data from audit stores and the management database and saves the data in a format that is optimized for reporting. With the reporting database, you can generate event notifications, such as when an audited system goes offline.

To ensure that audit data transferred over the network is secure, communication between components is authenticated and encrypted.

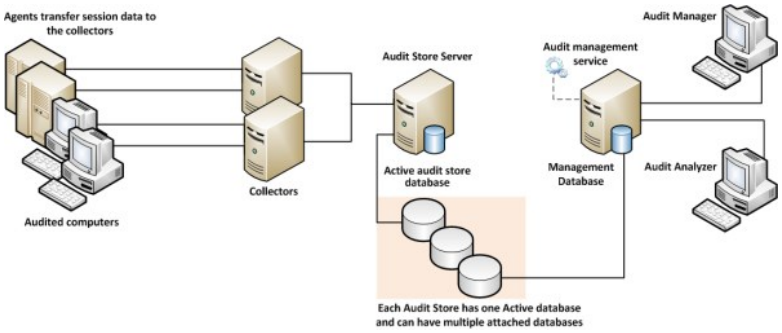
In addition to these core components of the audit and monitoring service infrastructure, there is a separate Windows service that is optional to collect audit trail events when there are audit store databases that are not accessible, for example, because of network issues or the database server is shut down. This audit management service spools the events on the management database, then sends them to the audit store database when the inaccessible database comes back online.

How Audited Sessions are Collected and Stored

The agent on each audited computer captures user activity and forwards it to a collector on a Windows computer. If the agent cannot connect to a collector—for example, because all of the computers hosting the collector service for the agent are shut down for maintenance—the agent spools the session data locally and transfers it to a collector later. The collector sends the data to an audit store server, where the audit data is stored in the Microsoft SQL Server database that you have designated as the **active audit store**. As you accumulate data, you can add more SQL Server databases to the audit store to hold historical information or to change the database designated as the active audit store database.

When an administrator or auditor uses the Audit Analyzer console to request session data, the audit management server retrieves it from the appropriate audit store.

The following figure illustrates the basic architecture and flow of data with a minimum number of audit and monitoring service components installed.



In the illustration, each agent connects to one collector. In a production environment, you can configure agents to allow connections to additional collectors for redundancy and load balancing or to prevent connections between specific agents and collectors. You can also add audit stores and configure which connections are allowed or restricted. The size and complexity of the auditing infrastructure depends on how you want to optimize your network topology, how many computers you are audit and monitoring service, how much audit data you want to collect and store, and how long you plan to retain audit records.

Deploying the Audit and Monitoring Service Infrastructure

The multi-tiered architecture of audit and monitoring service requires that you deploy an audit and monitoring service infrastructure to transfer and store the information captured by agents on the audited computers. This auditing infrastructure is referred to collectively as an **Auditing installation**. The audit and monitoring service installation represents a logical boundary similar to an Active Directory forest or site. It encompasses all of the audit and monitoring service components you have installed—agents, collectors, audit stores, management database, and consoles—regardless of how they are distributed on your network. The installation also defines the scope of audit data available. All queries and reports are against the audit data contained within the installation boundary.

The most common deployment scenario is to have a single audit and monitoring service installation for an entire organization so that all audit data and management of the audit data is centralized. Within a single audit and monitoring service installation, you can have components wherever they are needed, as long as you have the appropriate network connections that allow them to communicate with each other. The audit data for the entire installation is available to users who have permission to query and view it using a console. For most organizations, having a single audit and monitoring service installation is a scalable solution that allows a "separation of duties" security model through the use of audit roles. If you establish a single audit and monitoring service installation, there will be one Master Auditor role for the entire organization, and that Master Auditor can control the audit data that others users and groups can see or respond to by defining roles that limit access rights and privileges.

However, if you have different lines of business with different audit policies, in different geographic locations, or with different administrative groups, you can configure them as separate audit and monitoring service installations. For example, if you have offices in North America and Hong Kong managed by two different IT teams—IT-US and IT-HK—you might want to create two installations to maintain your existing separation of duties for the ITUS and IT-HK teams.

Planning Where to Install Audit and Monitoring Service Components

Before you install audit and monitoring service components, you should develop a basic deployment plan for how you will distribute and manage the components that make up an installation. For example, you should decide how many collectors and audit stores to create and where to put them. You should also consider the network connections required and how many computers you plan to audit. For example, you can have multiple agents using the same set of collectors, but you should keep the collectors within one hop of the agents they serve and within one hop of the audit stores to which they transfer data.

By planning where to install components initially, you can determine the number of collectors you should have for load balancing or redundancy. After the initial deployment, you can add collectors and audit stores whenever and wherever they are needed.

Using Multiple Databases in an Audit Store

Each audit store uses Microsoft SQL Server to provide database services to the installation. When you configure the first audit store, you identify the database instance to use for audit and monitoring service and that database becomes the active database for storing incoming audit data. A single audit store, however, can have several databases attached to it. Attached databases store historical information and respond to queries from the management database. You can use the Audit Manager console to control the databases that are attached and to designate which database is active. Only one database can be active in an audit store at any given time.

Although the audit store can use multiple databases, the presentation of session data is not affected. If a session spans two or more databases that are attached to the audit store, the Audit Analyzer console presents the data as a single, unbroken session. For example, if you change the active database during a session, some of the session data is stored in the attached database that is no longer active and some of it stored in the newly activated database, but the session data plays back as a single session to the auditor.

Using Multiple Consoles In an Installation

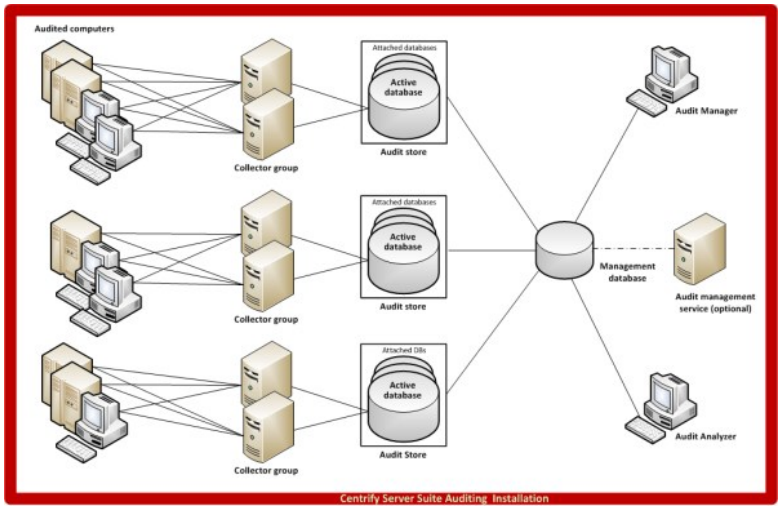
A single audit installation always has a single audit management server and database. In most cases, however, you use more than one console to request data from the audit management database. The two most important consoles in an installation are the Audit Manager console and the Audit Analyzer console.

- As an installation owner, you use the Audit Manager console to configure and manage the audit installation. In most organizations, there is only one Audit Manager console installed.
- Auditors and administrators use the Audit Analyzer console to search, retrieve, play back, and delete sessions. The auditor can use predefined queries to find sessions or define new queries. Auditors can also choose whether to share their queries with other auditors or keep them private. In most organizations, there are multiple Audit Analyzer consoles installed.

In addition to the Audit Manager and Audit Analyzer consoles, audit and monitoring service includes a settings control panel and a collector control panel.

- As an administrator, you can use the Audit & Monitoring Service Settings control panel to configure the agent on Windows. Normal users who log on and run applications on the audited computer cannot stop, pause, restart, or configure the agent.
- You can use the collector control panel to configure a collector.

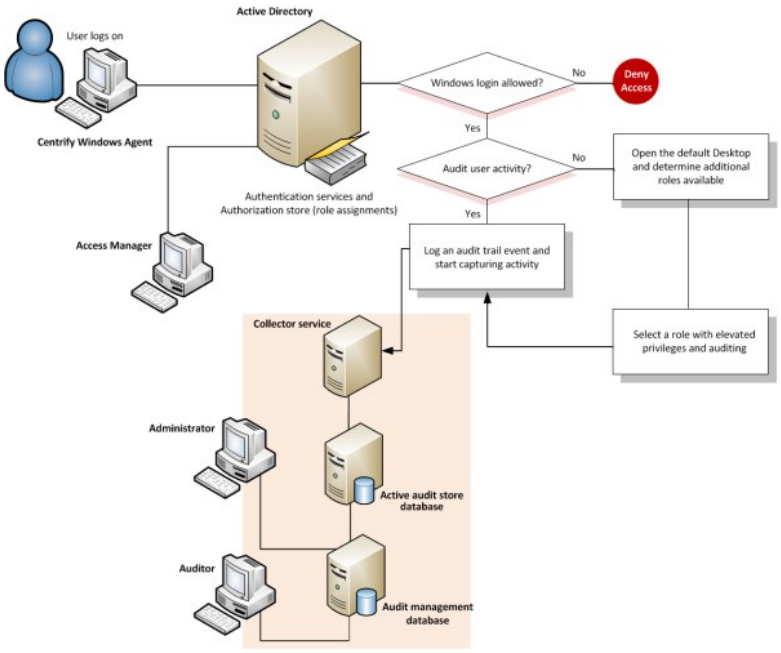
The following illustration is an example of the architecture of a medium-size installation.



Basic Operation with Identity and Privilege Management, and Auditing

When you combine identity and privilege management together with auditing on the same computer, you have an audit trail and video record of actions performed with elevated privileges. For example, when you deploy identity and privilege management features, users must be assigned to a role with permission to log on. If they are allowed to log on and audit and monitoring service is deployed, the agent begins auditing their activity. If a user creates a new desktop, opens a protected application, or connects to services on a remote network server with administrative or service account privileges, the action is recorded and can be traced back to the account used to log on.

The following illustration provides a simplified view of the architecture and flow of data when you deploy components for identity management, privilege management, and auditing.



Although it is not depicted in the illustration, the audit trail records every successful or failed attempt to use a role, including the login role. You do not have to enable audit and monitoring service for a role to record this information. Every computer that has the Agent for Windows records the use of elevated privileges by default. If you do enable audit and monitoring service for a role, however, you can record all of the user activity after the user switches to the audited role. With audit and monitoring service enabled, the audit trail and the user activity are stored in the database and available for display and analysis anywhere you install the Audit Analyzer console. Without audit and monitoring service, the audit trail is only available in the Windows event log on the local computer where the activity took place.

Planning a Deployment

This chapter describes the decisions you need to make during the planning phase of a deployment and summarizes what's involved in deploying identity management, privilege management, audit and monitoring service, and Agents. It includes simplified diagrams that highlight the steps involved.

Because of its multi-tier architecture and storage requirements, most of the information in this chapter applies to planning a deployment of audit and monitoring service. If you are only interested in deploying identity and privilege management without auditing, you should scan What's involved in the deployment process for relevant topics and continue to Installing Server Suite and updating Active Directory.

Why Planning is Important

Deploying Delinea software on Windows affects how users access local applications and remote services. These changes will become a critical part of your IT infrastructure and the management of your organization's resources. Therefore, it is important that you plan and test your deployment strategy and validate the results before placing Delinea software components into a production environment.

After you deploy Delinea software in a production environment, the rights and roles you define will control whether users can log on and what they can do on specific computers if they are allowed to log on. Because preventing users from accessing critical resources or services can affect business operations, you should analyze the requirements of your environment as thoroughly as possible before moving from a pilot deployment into production.

Identify Identity, Privilege Management, and Auditing Goals

As discussed in Managing Windows computers using Delinea software, you have the option of focusing your deployment on identity and privilege management, or on audit and monitoring service, or on a combination of the two. If you plan to install components for identity and privilege management together with audit and monitoring service, you can use roles and role assignments to control which users and groups are audited and under what circumstances auditing takes place. You can also capture detailed information about what happened after a user selected a role with domain administrator privileges or started an application using a service account.

During the planning phase, you should decide on the goals of your deployment—identity and privilege management, audit and monitoring service, or both—because that decision affects all of the other decisions you need to make. If you plan to include audit and monitoring service, you should also start to identify who and what you want to audit, any roles where no auditing should be done, and any roles that will require auditing.

Decide on the Scope of the Installation

Before you deploy any of the audit and monitoring service infrastructure, you should decide on the scope of the installation and whether you want to use a single installation for your entire Active Directory site, or separate installations for different geographical areas or functional groups.

The most common deployment is a single audit and monitoring service installation for each Active Directory forest, so that auditors can query and review information for the entire organization. However, if your Active Directory site has more than one forest, you might want to use more than one audit and monitoring service installation. If you want to use more than one audit and monitoring service installation, you should determine the subnetwork segments that will define the scope of each installation.

In Active Directory, a site represents the collection of Internet Protocol (IP) addresses that describe the physical structure of your network. If you are not familiar with how Active Directory sites are defined, you should consult Microsoft documentation for more information.

Decide Where to Install the Management Database

Each installation has a single audit management server and database. The management database is a Microsoft SQL Server database that stores information about the installation such as the Active Directory sites or subnets associated with each audit store.

The computer you use for the audit management database should have reliable, high-speed network connectivity. The management database does not store the captured sessions, and is, therefore, much smaller than the audit store databases. There are no specific sizing requirements or recommendations for the management database.

You can use the following guideline as the recommended hardware configuration for the computer you use as the management database:

Management database	Any	1 to 2	2.33 GHz	8 GB

Decide Where to Install Collectors and Audit Stores

Although a collector and an audit store database can be installed on the same computer for evaluation, you should avoid doing so in a production environment. As part of the planning process, therefore, you need to decide where to install collectors and audit store databases. In designing the network topology for the audit and monitoring service installation, there are several factors to consider. For example, you should consider the following:

- Database load and capacity
- Network connectivity
- Port requirements
- Active Directory requirements

The next sections provide guidelines and recommendations to help you decide where to install the collectors and audit store databases required to support the number of computers you plan to audit.

Use Separate Computers for Collectors and Audit Store Databases

To avoid overloading the computers that host collectors and audit store databases, you should install collectors and audit store SQL Server databases on separate computers. Because SQL Server uses physical memory to store database information for fast query results, you should use a dedicated computer for the audit store database, and allocate up to 80% of the computer's memory to SQL Server. In most installations, you also need to plan for more than one audit store database and to periodically rotate from one database to another to prevent any one database from getting too large. For more information about managing audit store databases, see Managing audit store databases.

Plan for Network Traffic and Data Storage

You should minimize the distance network packets have to travel between an agent and its collector. You should also minimize the distance between collectors and their audit stores. If possible, you should not have more than one gateway or router hop between an agent and its collector.

Default Ports for Network Traffic and Communication

To help you plan for network traffic, the following provides an overview of the network communications and ports used when a user logs on and the ports used in the initial set of network transactions.

When a user logs on, the Agent for Windows connects to Active Directory to begin the lookup process, then the agent and the domain controller exchange messages as follows:

- Directory Service - Global Catalog lookup request on port 3268.
- Authentication Services - LDAP sealed request on port 389.
- Kerberos – Ticket Granting Ticket (TGT) request on port 88.
- Network Time Protocol (NTP) Server – Time synchronized for Kerberos on port 123.
- Domain Name Service (DNS) – Host (A), Pointer (PTR), Service Location (SRV) records on port 53.
- RPC over TCP - For inbound RPC endpoint mapper connections to support network discovery or if password management and validation uses RPC over TCP on port 135.

Depending on the specific components you deploy and operations performed, you might need to open additional ports. The following table summarizes the ports used for different editions of Delinea software.

22	Encrypted TCP communication for OpenSSH connections	Authentication service and privilege elevation service for secure shell connections on remote clients.
23	TCP communication for Telnet connections	Delinea authentication service, privilege elevation service, and audit and monitoring service. By default, telnet connections are not allowed because passwords are transferred over the network as plain text.
53	TCP/UDP communication	Authentication service and privilege elevation service, clients use the Active Directory DNS server for DNS lookup requests.

88	Encrypted UDP communication	Authentication service and privilege elevation service, Kerberos ticket validation and authentication, agents, Delinea PuTTY
123	UDP communication for simple network time protocol (NTP)	Authentication service and privilege elevation service, keeps time synchronized between clients and Active Directory for Kerberos ticketing.
389	Encrypted TCP/UDP communication	authentication service and privilege elevation service, Active Directory authentication and client LDAP service.
443	Cloud proxy server to Delinea cloud service	Delinea software for mobile device management.
445	Encrypted TCP/UDP communication for delivery of group policies	Authentication service and privilege elevation service, adclient and adgpupdate use Samba (SMB) and Windows file sharing to download and update group policies, if applicable.
464	Encrypted TCP/UDP communication for Kerberos password changes	Authentication service and privilege elevation service, Kerberos ticket validation and authentication for agents,Delinea PuTTY, adpasswd, and passwd.
1433	Encrypted TCP communication for the collector connection to Microsoft SQL Server	Authentication service, privilege elevation service, and audit and monitoring service; collector service sends audited activity to the database.
3268	Encrypted TCP communication	Authentication service and privilege elevation service, Active Directory authentication and LDAP global catalog updates.
5063	Encrypted TCP/RPC communication for the agent connection to collectors	Authentication service, privilege elevation service, and audit and monitoring service; auditing service records user activity on an audited computer.
none	ICMP (ping) connections	Authentication service and privilege elevation service, to determine whether if a remote computer is reachable.

Auditing Requires Database Management

If you are planning a deployment with just audit and monitoring service or with identity management, privilege management, and auditing, you must plan how you will create and manage the databases that receive and store audit data. You should also consider your data archiving and retention policies, who should be given auditor permissions, and other details because these decisions affect your storage and maintenance requirements. For more information about managing an installation for auditing, see Managing auditing for an installation.

For audit and monitoring service, you should plan a pilot deployment of 20 to 25 agents to determine how much audit data your organization would generate and how fast the database can increase in size as you add agents. For more information about monitoring a pilot deployment for audit and monitoring service and guidelines for sizing the database, see Estimating database requirements based on the data you collect.

Identify an Active Directory Site or Subnets

Depending on the size and distribution of your Active Directory site, an audit store might cover an entire site or specific subnet segments. If you have a large, widely distributed site, you should consider network connectivity and latency issues in determining which subnets each audit store should serve. In addition, you should always place collectors in the same site as the agents from which they receive data. Collectors and agents must always be in the same Active Directory forest. If possible, you should put collectors and agents in the same domain.

> **Note**: If you deploy agents in a perimeter network, such as a demilitarized zone (DMZ), that is separated from your main network by a firewall, put the collectors in the same Active Directory domain as the audited computers. The collectors can communicate with the audit store database through a firewall.

Determine How Many Collectors and Audit Stores to Install

Although you can add collectors and audit stores to your audit and monitoring service installation after the initial deployment, you might want to calculate how many you will need before you begin deploying components. You should always have at least two collectors to provide redundancy. As you increase the number of agents deployed, you should consider adding collectors.

Estimate the Number of Agents and Sessions Audited

If you plan to use more than the minimum number of collectors, the most important factor to consider is the number of concurrent sessions you expect to monitor on audited computers. The number of concurrent sessions represents the number of interactive users that the agent is actively capturing for at the same time.

You can use the following guidelines as a starting point and adjust after you have observed how much audit data you are collecting and storing for Windows computers:

up to 100 agents	2	1
more than 100 agents	2 for every 100 agents	1 for every 100 agents

Determine the Recommended Hardware Configuration

The hardware requirements for collectors and audit store servers depend on the size of the installation and where the components are installed on the network. For example, the requirements for a computer that hosts the collector service are determined by the number of audited computers the collector supports, the level of user activity being captured and transferred, and the speed of the network connection between the agents and the collector and between the collector and its audit store.

You can use the following guidelines as the recommended hardware configuration for the computers you use as collectors and audit store servers when auditing Windows computers:

Collectors	Up to 100 active agents	2	2.33 GHz	8 GB
Audit store	Up to 200 active agents	2	2.33 GHz	8 GB
	200 to 500 active agent	4	2.33 GHz	32 GB

Guidelines for Storage

Because audit and monitoring service collectors send captured user sessions to the active SQL Server database, you should optimize SQL Server storage for fast data logging, if possible. For the active database, you get the most benefit from improvements to disk write performance. Read performance is secondary. Fibre Attached Storage (FAS) and Storage Area Network (SAN) solutions can provide 2 to 10 times better performance than Direct Attached Storage (DAS), but at a higher cost. For attached databases that are only used to store information for queries, you can use lower cost storage options.

Guidelines for Disk Layout

The following table outlines the recommended disk arrays:

Operating system	C: RAID 1	Operating system files, page file, and SQL Server binaries.
Microsoft SQL Server	D: RAID 10 (1+0)	Audit store database.
	E: RAID 10 (1+0)	Audit database log files.
	F: RAID 1 or 10 (1+0)	Temporary database space (tempdb) for large queries for reports.

G: RAID 1	Database dump files.	

The size of disk needed depends on the number, length, and types of sessions recorded each day, the selected recovery model, and your data retention policies. For more information about managing audit store databases, see Managing audit store databases.

Decide Where to Install Agents

The Agent for Windows must be installed on all of the computers you want to audit. Therefore, as part of your planning process, you should decide whether you want to audit every computer on the network or specific computers, such as the computers used as servers or used to run administrative software.

Before installing the agent, verify the following:

- The computer is joined to Active Directory.
- The computer has Windows security update KB3033929 installed if it is running Windows 7 with Service Pack 1 or Windows Server 2008 R2 with Service Pack 1.
- The computer has .NET 4.6.2 or later installed.
- The computer has Windows Installer version 4.5 or newer.
- Agents can communicate with a collector only if the agents and collector are in the same Active Directory forest.

Decide Where to Install Consoles

You can install and run the Audit Manager console and the Audit Analyzer console on the same computer or on different computers. The computers where you install the consoles must be joined to the Active Directory domain and be able to access the management server and the database that serves the installation.

You can also use the Audit Analyzer console to run queries from any additional computers with network access to the management database. Therefore, you should decide where it would be convenient to have this capability.

Check SQL Server Logins for Auditing

An audit installation requires at least two Microsoft SQL Server databases: one for the management database and at least one for the first audit store database. To successfully connect to these databases, you must ensure that the appropriate users and computers have permission to read or to read and write for the databases that store audit-related information.

The simplest way to manage SQL logins for auditors and administrators is to do the following:

- Ensure you have a SQL login account for the NT Authority\System built-in account.
- Add the NT Authority\System account to the system administrator role.
- Use Audit Manager to grant Manage SQL Logins permissions to the Active Directory users and groups that require them.

If you use Audit Manager to manage SQL logins, you can use Active Directory membership to automatically add and remove the permissions required for auditing activity. There is no requirement to use the SQL Server Management Studio to manage logins or permissions. Because it is recommended that you have a dedicated SQL Server instance for auditing, giving the NT Authority\System account a SQL login and system administrator role is an acceptable solution for most organizations.

Create Security Groups for Auditing

Depending on whether you configure Microsoft SQL Server to use Windows only authentication or Windows or SQL Server authentication, your SQL Server login credentials might be a Windows account or a SQL Server login account that is not associated with a Windows account.

To facilitate communication and the management of SQL logins, you can create Active Directory security groups for the following users and computers:

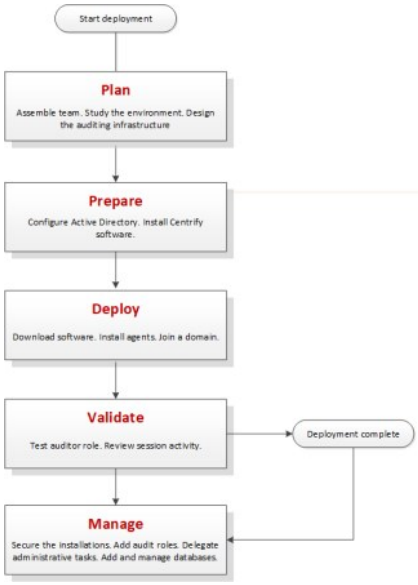
- **Admins** for the user accounts that perform administrative tasks using Audit Manager.
- **Auditors** for the user accounts that user Audit Analyzer.
- **TrustedCollectors** for the computers accounts that host the collector service.

If you create these Active Directory security groups, you can then use Audit Manager to grant Manage SQL Login permissions for each group to allow its members to connect to the appropriate SQL Server database. Creating Active Directory security groups with SQL Server logins enables you to manage access to the databases required for auditing through Active Directory group membership without the help of the database administrator.

Any time you want to add an administrator, auditor, or collector computer to the installation, you simply add that user account or computer object to the appropriate Active Directory group. If an administrator or auditor leaves or if you want to stop using the collector on a particular computer, you can remove that user or computer from its Active Directory security group to prevent it from accessing the database.

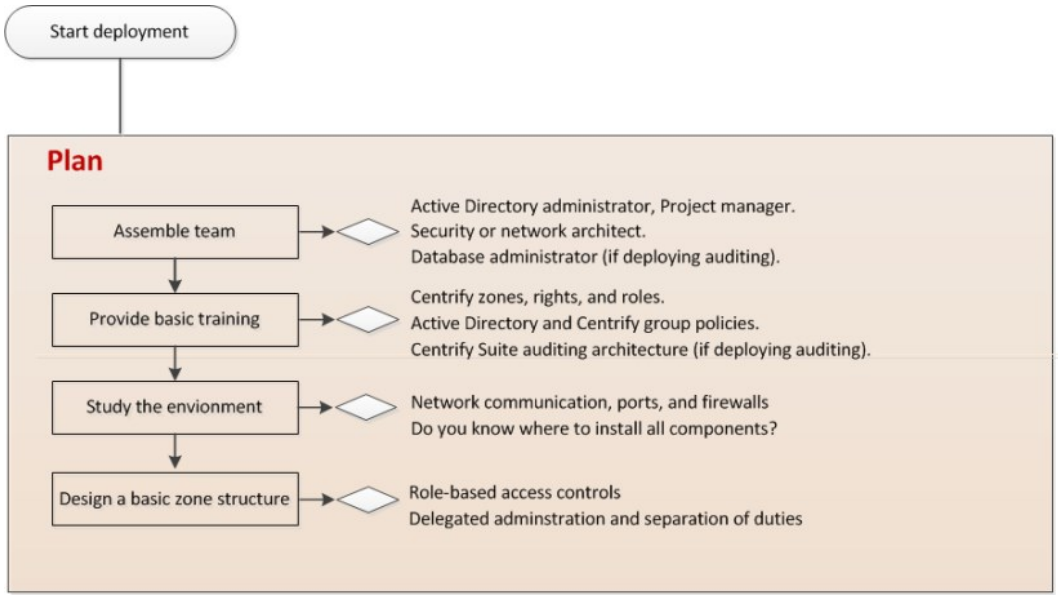
What's Involved in the Deployment Process

Most of the planning in this chapter has focused on designing the audit and monitoring service infrastructure and deciding where to install components. The following illustration provides a visual summary of the complete deployment process and highlights the keys to success. The sections after the flowchart provide additional details about what's involved in each phase or the decisions you will need to make, such as who should be part of the deployment team, where to install the software, and who has permission to do what.



Plan

During the first phase of the deployment, you collect and analyze details about your organization's requirements and goals. You can then also make preliminary decisions about sizing, network communication, where to install components, and what your zone structure should look like.



Here are the key steps involved:

- Identify the goals of the deployment.

  - Is identity and privilege management or audit and monitoring service a primary goal?
  - Are identity and privilege management and audit and monitoring service equally important to the organization?
  - Is audit and monitoring service important for specific computers?
  - Is audit and monitoring service important for computers used to perform administrative tasks?
  - Is audit and monitoring service important for computers that host specific applications or sensitive information?
  - Should audit and monitoring service be required for users in specific groups or with specific roles?

    For example, if audit and monitoring service is important, are you primarily interested in auditing Windows servers, such as SQL Server, Exchange, and IIS, administrative workstations, or computers that host specific applications or sensitive information?

- Assemble a deployment team with Active Directory and other expertise.
  - People with specific knowledge, such as Exchange, IIS, or Sharepoint administrators.
  - If auditing, at least one Microsoft SQL Server database administrator.
- Provide basic training on Delinea software architecture, concepts, and terminology.
- Study the existing environment to identify target computers where you plan to install Delinea software components.
  - Plan for permissions and the appropriate separation of duties for your organization.
  - Review network connections, port requirements, firewall configuration.

    For more information about network communication and the ports used, see Plan for network traffic and data storage.

  - Identify computers for administration.
    - **Basic deployment** — Access Manager
    - **Auditing** — Audit Manager and Audit Analyzer consoles
  - Identify computers to be used as collectors, audit stores, and the management database.
    - Verify that you have reliable, high-speed network connections between components that collect and transfer audit data.
    - Verify you have sufficient disk storage for the first audit store database.
  - Identify the initial target group of computers to be managed and audited.
- Design a basic zone structure that suits your organization.
  - Single or multiple top-level parents.
  - Initial child zones, for example, separate zones for different functional departments or administrative groups.

Prepare

After you have analyzed the environment, you should prepare the Active Directory organizational units and groups to use. You can then install administrative consoles and the audit and monitoring service infrastructure, and prepare initial zones.

Here are the key steps involved:

- (Optional) Create organizational units or containers to define a scope of authority.

  The deployment team should consult with the Active Directory enterprise administrator to determine whether any additional containers or organizational units would be useful, who should be responsible for creating Licenses and Zones container objects, and who will manage the objects in those containers.

- (Optional) Create the additional Active Directory security groups for your organization.

  Groups can simplify permission management and the separation of duties.

- Install Access Manager on at least one administrative Windows computer.
- Open Access Manager for the first time to run the Setup Wizard for the Active Directory domain.
- Create a parent zone and the appropriate child zones as identified in your basic zone design.

  The hierarchical zone structure you use depends primarily on how you want to use inheritance and roles.
- Prepare Windows computer accounts in the appropriate zones and assign the default Windows Login role to the appropriate Active Directory users and groups.
- Install Audit Manager and Audit Analyzer together or separately.
- Create an installation and a management database on one computer.
- Create an audit store and audit store database on at least one computer.
- Install a collector on at least two computers.

Deploy

After you have prepared Active Directory, installed administrative consoles on at least one computer, created at least one zone, and prepared the audit and monitoring service infrastructure, you are ready to deploy on the computers to be managed.

Here are the key steps involved:

- Create Desktop, Application, and Network Access rights.
- Add Desktop, Application, and Network Access rights to custom role definitions.
- Assign custom roles to the appropriate Active Directory users and groups.
- Install the Agent for Windows on a target set of computers.
- Join the appropriate zones.
- Prepare a Group Policy Object for deploying agents remotely using a group policy.
- Assign the appropriate permissions to the users and groups who should have access to audit data.

Validate

After you have deployed agents on target computers, you should test and verify operations before deploying on additional computers.

Here are the key steps involved:

- Log on locally to a target computer using an Active Directory user account and password to verify Active Directory authentication and Windows Login role assignment.
- Open a Remote Desktop Connection to a target computer to verify Active Directory authentication and Windows Login role assignment on a remote computer.
- Create a new desktop that gives you administrative rights and verify that you can start and stop Windows services or perform other administrative tasks.
- Right-click an application, select Run using selected roles, then select an available role for running the application.
- Open Audit Analyzer and query for your user session if audit and monitoring service is enabled.

Manage

After you have tested and verified identity management, privilege management, and audit and monitoring service operations, you are ready to begin managing the installation and refining on-going operations.

Here are the key steps involved if you deploying identity management, privilege management, and auditing for Windows computers:

- Secure the installation.
- Add roles and assign roles and permissions to the appropriate users, groups, and computers.
- Delegate administrative tasks to the appropriate users and groups for each zone.
- Deploy additional group policies on the appropriate organizational units.
- Create new databases and rotate the active database.
- Archive and delete old audit data.

- Automate key administrative tasks using Delinea-defined Powershell-based cmdlets and scripts.

Delinea

Authentication and Privilege Elevation Services Deployment Checklist

The following checklist provides an overview of each of the main steps that are involved when you deploy the Authentication Service and Privilege Elevation Service. For any tasks related to Delinea software, there are links to more information and procedures.

For auditing deployment steps, please see the Audit & Monitoring Service deployment checklist.

	PREPARATION AND PLANNING		
1	Analyze your network topology to determine where to install components and services and any hardware or software updates required.		Planning a Deployment
2	Create a list of the computers where you plan to install different components.		Planning a Deployment
3	Determine how you plan to install the software onto your computers.		Planning a Deployment
	PRE-INSTALL TASKS		
4	Prepare a domain account that has permissions to create Active Directory containers and child objects.	You'll need this account to create the OU using the Installation wizard.	
5	Prepare an Active Directory group to be zone administrators.		
6	Create the Zone Provisioning Agent (ZPA) service account.	Requires Active Directory domain admin privileges	
7	Apply group policy to allow the ZPA to run as a service.	Requires Active Directory domain admin privileges	
	INSTALL TASKS		
8	Install the Access Manager console, ZPA, group policies, create the OU in Active Directory, and so forth.		Installing Server Suite
9	(Optional) Configure ZPA – this is only needed if you plan on automatically provisioning users.		
10	Run adcheck on any UNIX computer that you want to manage and fix any issues until adcheck produces no issues.		
11	Install a Agent for Windows on each Windows computer that you want to manage.		Installing the Agent for Windows
12	Install a Agent for *NIX on each UNIX or Linux computer that you want to manage.		
13	Install additional Access Manager consoles on any Windows computer that you want to use for the Authentication and Privilege Management services.		Installing Additional Consoles
14	Verify that agents are working correctly. Run adinfo on managed UNIX computers.		Troubleshooting and Common Questions
	POST-INSTALL HOUSEKEEPING		

15	Identify UNIX users who do not have an Active Directory account.	Automatically done by adimport	adimport man page
16	Identify service accounts.		
17	Collect and analyze sudoers files.		
18	Create a list of roles in sudoers that will be migrated to Privilege Elevation Service.		
19	Create a list of users and groups to be migrated to Active Directory.		
20	Create missing Active Directory user accounts.		
	SETUP AND CONFIGURATION		
21	Create list of computers that will be joined to each zone.		
22	Create parent and child zones.		Creating a New Parent Zone Creating Child Zones
23	Delegate control to zones.		Delegating Control of Administrative Tasks
24	Import UNIX users and groups into Active Directory.		
25	Create Zone Provisioning groups and add users and groups to them.		
26	Pre-create computer objects in zones.		
27	Create role groups .		
28	Assign roles and users to role groups.		
29	Create ComputerRoles and ComputerRole groups.		Create a New Computer Role
30	Assign roles, users, and computers to ComputerRole groups.		Add Role Assignments to the Computer Role
31	Use “Show Effective Users” to check that profiles and roles are correct.		
32	Start the ZPA agent.	You configured ZPA in a previous step.	
33	Configure the ZPA provisioning rules for the parent zone.		
34	Join UNIX servers to Zones.		

35	Change the UID/GID of files for those users who have been assigned a new UID/GID in the Zone. Run adfixid on servers.	* Critical task that must be carefully coordinated with the users. Can be done at time of join to Active Directory with a script.	
	FINAL TASKS		
36	Check the status of the join and roles on the servers.	Run adflush, adinfo and dzinfo	
37	Back up passwd, shadow, and group files.		
38	Remove the users and groups (that have been migrated to Active Directory) from the local files.	Run adrmlocal on servers	

Accounts and Permissions for Installation and Deployment

Below is a summary of the account permissions that you need to install and deploy Server Suite.

Authentication and Privilege Elevation Services permissions

Access Manager Account Permissions

n/a	Domain administrator (when running Access Manager for the first time)	domain admin (in most cases)	Because the Setup Wizard creates container objects, you might need to use a domain administrator account. This requirement depends on the specific permissions your organization has configured for different classes of users. For example, if your organization only permits Domain Admins to create parent and child objects in Active Directory, you need to use an account with those permissions to run the Setup Wizard.

For more information, see:

- "Running Access Manager for the First Time" and "Permissions Required to use the Setup Wizard" in the Unexpected Link Text

Zone Provisioning Agent Account Permissions

Cfy_SVC_ZPA	Active Directory account	**Log on as a service**	The Zone Provisioning Agent requires permission to create UNIX profiles-- that is, the service connection points in each zone where it needs to perform provisioning operations. The service account that runs the Zone Provisioning Agent requires the **Log on as a service** right set as a local computer security policy, or in the default domain policy.

For more information, see:

- "About Zone Provisioning Agent and its Requirements" in the Unexpected Link Text

Report Services Account Permissions

report service account to run the Reporting Service	For domain-based reporting: Replicating directory changes at the domain level (ADUC) and replicate directory changes in ADSI For zone-based reporting: Read permission	Log on as a service		
SQL Server service account to run SQL Server	n/a	Log on as a service		member of the securityadmin role
PostgreSQL service				the account must have permission to connect to

account				PostgreSQL and create a database
report admin to run the Report Configuration wizard or the Upgrade & Deployment wizard and deploy reports to an existing SQL Server instance	needs to be a member of the domain	n/a	Folder Settings > Content Manager role	member of the securityadmin role (At the very least, the user needs permission to connect to SQL Server and create a database.)
report admin to modify the Reports Control Panel	Read permission to the domain root object of the selected domain. Read permission to all computer objects in the selected domain.	n/a		
Report viewer to view reports from SSRS/Internet Explorer			Site settings > System user role Folder settings > browser (assign SSRS roles to Active Directory group or users)	
Report writer read, write, edit access for reports, in addition to the permissions needed to view reports			Site settings > System user role Folder settings > Content Manager role (assign SSRS roles to Active Directory group or users)	

SQL Server Permissions Set by the Report Services Configuration Wizard

report services account to run the SQL Server Reporting Service	Snapshot Service (predefined role)
SQL Server service account to run SQL Server	If you deploy to an existing SQL Server instance, the configuration wizard makes no changes to the SQL Server service account. If you deploy to a new SQL Server instance: --If the operating system is Windows 2008 and you're using a SQL Server version later than 2012, virtual accounts are used for various SQL Server components, as follows: SQL Server engine: NT SERVICE\MSSQL$<InstanceName> SQL Server Agent: NT SERVICE\SQLAgent$<InstanceName> Full text search: NT SERVICE\MSSQLFDLauncher$<InstanceName>

	SSRS: NT SERVICE\ReportServer$<InstanceName> --Otherwise, the SQL Server service accounts are configured as follows: SQL Server engine: NT Authority\Network Service SQL Server Agent: NT Authority\Network Service Full text search: NT Authority\Local Service SSRS: NT Authority\Local Service
report admin to run the Report Configuration Wizard and deploy reports to an existing SQL Server instance	Connect SQL (cannot be revoked after setup) Create Database, Create any database, or Alter any database member of securityadmin role, or Alter any login permission
report admin to modify the Reports Control Panel	SnapshotAdmin (predefined role)
Report viewer to view reports from SSRS/Internet Explorer	Login permission SnapshotViewer (predefined role)
Report writer read, write, edit access for reports, in addition to the permissions needed to view reports	Login permission SnapshotViewer (predefined role)

> **Note**: Microsoft SQL Server Reporting System (SSRS) affords only role-based security in their reports. Be sure to grant appropriate access to reports. For example, if a user has access to only some data in the specified domain but all reports, they will be able to view all reports on all data from Active Directory.

For more information, see:

- "Required User Permissions for Report Services" and "SQL Server Permissions that are Set by the Configuration Wizard" in the Unexpected Link Text

Audit & Monitoring Permissions

Auditing permissions for SQL Server

NT Authority\System	machine account	SQL Server Roles: sysadmin role

Auditing security groups

Admins for the user accounts that perform administrative tasks using Audit Manager.	Active Directory	no explicit SQL Server permissions needed — Audit Manager handles the SQL Server permissions	Creating Active Directory security groups with SQL Server logins enables you to manage access to the databases required for auditing through Active Directory group membership without the help of the database administrator.
Auditors for the user accounts that use Audit Analyzer.			
Collectors for the computer accounts that host the			

collector service.

For more information, see Checking SQL Server Logins for Auditing.

This chapter describes how to install Server Suite software on Windows computers in a production environment. It includes instructions for installing all identity and privilege management, audit and monitoring service, and multi-factor authentication components. It also describes how to install the Agent for Windows, and how to enable services on agent-managed Windows computers.

If your deployment plan includes identity and privilege management, as well as audit and monitoring service, you should review the details in Planning a deployment before installing any components.

In a production environment, you should use separate computers for different components to ensure scalability and performance. For information about setting up an evaluation environment on a single computer for testing, see the *Evaluation Guide for Windows*.

Installation Checklist

As a preview of what's involved in the installation process, the following steps summarize what you need to do and the information you should have on hand for a successful deployment of Server Suite.

To prepare for installation:

1. Analyze your network topology to determine where to install components and services and any hardware or software updates required.

   For a review of the decisions to make and recommended hardware configuration, see Planning a deployment.

2. Create a list of the computers where you plan to install different components.

   For example, list the computers where you plan to install agents, collectors, audit store databases, consoles, and group policy extensions.

   If you are installing the audit and monitoring service infrastructure, you should use a dedicated computer for each component, so that the audit collector service, audit store database, and audit management database are on separate computers with high-speed and reliable network connectivity.

   For a review of the requirements associated with each component, see Planning a deployment.

3. Determine the scope of the audit installation.

   The most common deployment scenario is a single installation for an Active Directory site, but you can have more than one installation, if needed, and use subnets to limit the scope of the installation. If you are only implementing access management, you can skip this step, Step 4, and Step 7 through Step 10.

   For a review of what constitutes an installation, see Deploying the audit and monitoring service infrastructure and Decide on the scope of the installation.

4. Create Active Directory security groups for managing the permissions required for the audit and monitoring service infrastructure.

   For a review of the Active Directory security groups to create, see Create security groups for auditing. If you are only implementing identity and privilege management, you can skip this step.

5. Install Access Manager on at least one computer that can connect to the Active Directory forest.

6. Open Access Manager and add containers for licenses and zones to the Active Directory forest.

7. Install Microsoft SQL Server.

   If you are not a database administrator in your organization, you should submit a service request or contact an administrator who has permission to create databases for assistance. For more information about preparing a SQL Server database engine for auditing, see Installing and configuring Microsoft SQL Server for auditing. If you are only implementing access management, you can skip this step.

8. Install Audit Manager and Audit Analyzer.

   For more information about installing these products, see Installing the Audit Manager and Audit Analyzer consoles. If you are only implementing identity and privilege management, you can skip this step.

9. Open Audit Manager to create a new installation for auditing.

   For more information about using Audit Manager to create a new installation and audit store, see Creating a new installation. If you are only

implementing identity and privilege management, you can skip this step.

10. Install the audit collector service on at least two Windows computers.

    You can add collectors to the installation at any time. For more information about installing and configuring collectors, see Installing and configuring audit collectors. If you are only implementing identity and privilege management, you can skip this step.

11. Install an Agent for Windows on each Windows computer that you want to manage or audit.

    For more information about installing and configuring Agent for Windows, see Installing the Agent for Windows.

12. Install additional consoles on any Windows computer that you want to use for identity and privilege management, or audit and monitoring service.

After the initial deployment, you can add new agents, collectors, audit stores, and audit store databases to the audit installation or create additional installations at any time.

Installing Server Suite and Updating Active Directory

When you install Server Suite, components for the following features are installed:

- The Identity Platform, which enables MFA login, endpoints, and other platform services.
- The Privilege Elevation Service, which enables users and zone-joined computers to have elevated privileges.
- The Audit & Monitoring Service, which enables audit and monitoring service data to be collected and stored.
- The Agent for Windows, which enables each computer where the agent is installed to be managed by Server Suite software.
- The Licensing Service, which works together with Server Suite components to monitor and report usage and activity for all types of licenses. For more information about the licensing service, see the *License Management Administrator's Guide*

You can select which features to install from the Delinea software setup program.

After Server Suite are installed, you must enable some or all of them on each agent-managed computer. The enablement step lets you decide which services are available on each agent-managed computer.

Things to remember

- At least one zone must be created before an agent-managed computer can be enabled to use the identity and privilege management features that you install. If no zones are available, the agent-managed computer will not have the option of being joined to the authentication and privilege elevation services.
- When the Agent is upgraded or when it adds the Identity Platform, a corporate endpoint enrollment is performed in the Privileged Access Service. The endpoint device moves into the endpoint category and the device is marked as corporate owned.

Running the Setup Program on a Windows Computer

You can install components for all Server Suite from the Server SuiteCD or a downloaded ISO or ZIP file. After you access the distribution media, the setup or autorun program copies the necessary files to the local Windows computer. There are no special permissions required to run the setup or autorun program other than permission to install files on the local computer.

To install Delinea software on Windows:

1. Log on to the computer you have selected for administrative tasks and browse to the location where you have saved downloaded Delinea software files.

   If you have a physical CD, the Getting Started page is displayed automatically. If the page is not displayed, open the autorun.exe file to start the installation of Delinea software.

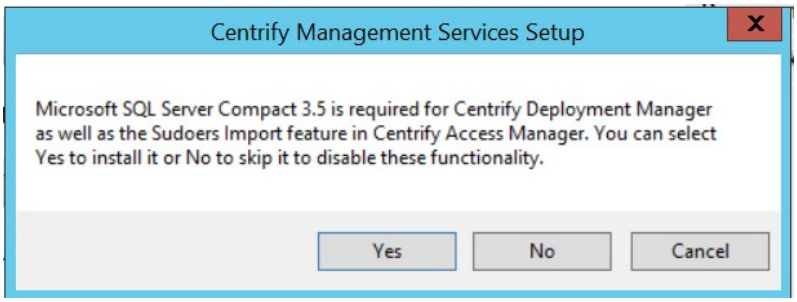
2. On the Getting Started page, click **Authentication & Privilege** to start the setup program for authentication and privilege elevation services.

   Note: {/b}The **Authentication & Privilege** components are the recommended first components to install so that Access Manager is available for you to use to create zones. At least one zone must be created before you can enable the authentication and privilege elevation services on an agent-managed computer.

   If any programs must be updated before installing, the setup program displays the updates required and allows you to install them. After updates are complete, you can restart the setup program.

3. At the following screen, select **Yes** to install Microsoft SQL Server Compact. The Access Manager console uses the Microsoft SQL Server Compact for

storage.



If you select No, Microsoft SQL Server Compact is not installed and some features of Access Manager are not available.

4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I agree to these terms**, then click **Next**.
6. Type your name and company name, then click **Next**.
7. Expand and select the Administration and Utilities components you want to install, then click **Next**.

   If you are only managing identity and privileges for Windows computers, you can install a subset of the components. For a Windows-only deployment, select the following components:

   - **ADUC property page extension** if you want to include profiles when displaying properties in Active Directory Users and Computers.
   - **Access Manager console (all)** if you want to use an administrative console to manage zones and roles.
   - **Group Policy Management Editor extension** if you want to deploy group policies.

     Installing Report Services is optional. If you select this option, see Installing and configuring Microsoft SQL Server for auditing for additional details.

     For a Windows-only deployment, you can deselect Utilities to skip the installation of those components.
8. Accept the default location for installing components, or click **Browse** to select a different location, then click **Next**.
9. Review the components you have selected, then click **Next**.

   The setup program begins installing the selected components.
10. Click **Finish** to complete installation.
11. Optionally install additional Server Suite components as follows:

    - **Licensing Service.** This service is installed by default when you install the Authentication & Privilege components, and usually does not need to be installed separately. For more information about the licensing service, see the *License Management Administrator's Guide*.
    - **Audit & Monitor.** The Auditing and Monitoring Service is not installed automatically with any other components, and must be installed separately if you intend to use auditing and monitoring features. For installation details, see Installing the Audit Manager and Audit Analyzer consoles.
    - **Agent for Windows.** To install the agent on client Windows computers so that those computers can be managed by Server Suite, see Installing the Agent for Windows.

Opening Access Manager to Update Active Directory

The first time you start Access Manager, a Setup Wizard prepares the Active Directory forest with parent containers for licenses and zones. The Setup Wizard also sets the appropriate permissions for the objects automatically. For more information about using the Setup Wizard to update Active Directory, see Starting Access Manager for the first time.

Installing and Configuring Microsoft SQL Server for Auditing

If you want to audit user activity on Windows, you must have at least one Microsoft SQL Server database instance for the audit management database and audit store databases. We recommend that you use a dedicated instance of SQL Server for the audit management database. A dedicated SQL Server instance is an instance that does not share resources with other applications. The audit store databases can use the same dedicated instance of SQL Server or their own dedicated instances.

There are three database deployment scenarios for your installation:

- **Evaluation**—Use the SQL Server Express with Advanced Services setup program (SQLEXPRADV_x64_ENU.exe) to create a new instance of Microsoft SQL Server Express. *You should only use Microsoft SQL Server Express for evaluation or for limited use in a test environment*. You should not use SQL Server Express databases in a production environment.

  If you choose to install a different version of Microsoft SQL Server Express for an evaluation and the version requires .NET version 3.5 SP1, you will need to manually install the .NET files yourself (the installer doesn't include these files).

- **Manual installation with system administrator privileges**—Install a Microsoft SQL Server database instance for which you are a system administrator or have been added to the system administrator role.

- **Manual installation without system administrator privileges**—Have the database administrator (DBA) install an instance of Microsoft SQL Server and provide you with system administrator credentials or information about the database instance so that you can create the management database and audit store databases.

Downloading and Installing SQL Server Manually

You can use an existing Microsoft SQL Server database engine or install a new instance. You can download Microsoft SQL Server software from the Microsoft website or through the Support Portal](https://www.delinea.com/login/?portal=support). In selecting a version of Microsoft SQL Server to download, you should be sure it includes Advanced Services. Advanced Services are required to support querying using SQL Server full-text search.

After downloading an appropriate software package, run the setup program using your Active Directory domain account and follow the prompts displayed to complete the installation of the SQL Server database engine.

Configuring SQL Server to Prepare for Audit and Monitoring Service

After you install the SQL Server database engine and management tools, you should configure the SQL Server instance for audit and monitoring service by doing the following:

- Depending on the version of SQL Server you install, you might need to manually enable full text search. For example, use SQL Server Surface Area Configuration for Services and Connections to start the full-text search service.
- Use SQL Server Configuration Manager to enable remote connections for TCP/IP.
- Use SQL Server Configuration Manager to restart the SQL Server and SQL Server Browser services.
- Verify whether SQL Server is using the default TCP port 1433 for network communications. If you use a different port, you should note the port number because you will need to specify in the server name when you create the management and audit store databases.

Installing the Audit Manager and Audit Analyzer Consoles

You can install Audit Manager and Audit Analyzer on the same computer or on different computers. The computers where you install the consoles must be joined to the Active Directory domain and be able to access the audit management database.

In most cases, the consoles are installed together on at least one computer.

To install Audit Manager and Audit Analyzer on the same computer:

1. Log on to the computer you have selected for administrative tasks and browse to the location where you have saved downloaded Delinea files.

   If you have a physical CD that you made from the ISO image file, the Getting Started page is displayed automatically. If the page is not displayed, open the autorun.exe file to start the installation of Delinea software.

2. On the Getting Started page, click **Audit & Monitor** to start the setup program for audit and monitoring service service components.

   In the rare case where the administrator should not have access to the Audit Analyzer, select Audit Manager, then click **Next**.

After you install Audit Manager, you are prompted to create a new installation. If you want to create the installation at a later time, you can run the setup program again to create a new installation.

Creating a New Installation

Before you can begin audit and monitoring service, you must create at least one installation and a management database. Creating the management database, however, requires SQL Server system administrator privileges on the computer that hosts the SQL Server instance. If possible, you should have a database administrator add your Active Directory domain account to the SQL Server system administrators role.

If you have not been added to the system administrators role, you should contact a database administrator to assist you. For more information about creating a new installation when you don't have system administrator privileges, see How to create an installation without system administrator privileges.

To create a new installation and management database as a system administrator:

1. Log on using an Active Directory account with permission to install software on the local computer.
2. Open the Audit Manager console to display the New Installation wizard.

   The New Installation wizard displays automatically the first time you start Audit Manager. You can also start it by clicking **Action > New Installation** or from the right-click menu when you select the Audit Manager node.
3. Type a name for the new installation, then click **Next**.

   Tip: {/b}Name the installation to reflect its administrative scope. For example, if you are using one installation for your entire organization, you might include the organization name and All or Global in the installation name, such as AcmeAll. If you plan to use separate installations for different regions or divisions, you might include that information in the name, for example AcmeBrazil for a regional installation or AcmeFinance for an installation that audits computers in the Finance department.
4. Select the option to create a new management database and verify the SQL Server computer name, instance name, and database name are correct, then click **Next**.

   If the server does not use the default TCP port (1433), you must provide the server and instance names separated by a backslash, then type a comma and the appropriate port number. For example, if the server name is ACME, the instance name is BOSTON, and the port number is 1234, the server name would be ACME\BOSTON,1234.

   If you're connecting to a SQL Server availability group listener, click Options (next to the Server Name) and enter the following connection string parameters:

   MultiSubnetFailover=Yes
5. Type the license key you received, then click **Add** or click **Import** to import the keys directly from a file, then click **Next**.
6. Accept the default location or click **Browse** to select a different Active Directory container to which you want to publish audit-related information, then click **Next**.
7. Select **Enable video capture recording of user activity** if you want to capture a full video record of desktop activity on Windows computers when users are audited, then click **Next**.

Selecting this option enables you to review everything displayed during an audited user session, but will increase the audit store database storage requirements for the installation. You can deselect this option if you are only interested in a summary of user activity in the form of audit trail events. Audit trail events are recorded when users log on, open applications, and select and use role assignments with elevated rights.

8. Review details about the installation and management database, then click **Next**.

   If you have SQL Server system administrator (sa) privileges and can connect to the SQL Server instance, the wizard automatically creates the management database.

9. Select the **Launch Add Audit Store Wizard** option if you want to start the Add Audit Store wizard, then click **Finish**.

   If you want to create the first audit store database at a later time, you should deselect the **Launch Add Audit Store Wizard** option and click **Finish**.

   For more information about adding the first audit store database, see Create the first audit store.

How to Create an Installation without System Administrator Privileges

If you do not have the appropriate permission to create SQL Server databases, you cannot use the New Installation wizard to create the management database without the assistance of a database administrator.

If you do not have system administrator privileges, the wizard prompts you to specify another set of credentials or generate SQL scripts to give to a database administrator. For example:

If you don't have a database administrator immediately available who can enter the credentials for you, you cannot continue with the installation.

To create an installation when you don't have system administrator privileges:

1. Select the option to generate the SQL scripts, then click **Next**.
2. Select the folder location for the scripts, then click **Next**.
3. Review details about the installation and management database you want created, then click **Next**.

   The wizard generates two scripts: Script1 prepares the SQL Server instance for the management database and Script2 creates the database.

4. Click **Finish** to exit the New Installation wizard.
5. Send the scripts to a database administrator with a service or change control request.

   Note: {/b}You should notify the database administrator that the scripts must be run in the proper sequence and not modified in any way. Changes to the scripts could render the database unusable.

6. After the database administrator creates the database using the scripts, open the Audit Manager console to run the New Installation wizard again.
7. Type the name of the installation, then click **Next**.

8. Select **Use an existing database** and verify the database server and instance name, then click the Database name list to browse for the database name that the database administrator created for you.

   If the server does not use the default TCP port, specify the port number as part of the server name. For example, if the port number is 1234, the server name would be similar to ACME\BOSTON,1234.

9. Select the database name from the list of available databases, click **OK**, then click **Next**.
10. You should only select an existing database if the database was created using scripts provided by Delinea.
11. Type a license key or import licenses from a file, then click **Next**.
12. Review details about the audit management database to be installed, then click **Next**.
13. Select the **Launch Add Audit Store Wizard** option if you want to start the Add Audit Store wizard, then click **Finish**.

Create the First Audit Store

If you selected the Launch Add Audit Store Wizard at the end of the New Installation Wizard, the Add Audit Store Wizard opens automatically. You can also open the wizard at any time by right-clicking the Audit Stores node in the Audit Manager console and choosing Add Audit Store.

To create the first audit store:

1. Type a display name for the audit store, then click **Next**.

   Tip: {/b}If your plan specifies multiple audit stores, use the name to reflect the sites or subnets serviced by this audit store. Note that an audit store is actually a record in the management database. It is not a separate process running on any computer. You use a separate wizard to create the databases for an audit store.

2. Click **Add Site** or **Add Subnet** to specify the sites or subnets in this audit store.
   - If you select Add Site, you are prompted to select an Active Directory site.
   - If you select Add Subnet, you are prompted to type the network address and subnet mask.

     After you make a selection or type the address, click **OK**. You can then add more sites or subnets to the audit store. When you are finished adding sites or subnets, click **Next** to continue.

     The computer you use to host the audit store database should be no more than one gateway or router away from the computers being audited. If your Active Directory sites are too broad, you can use standard network subnets to limit the scope of the audit store.

3. Review information about the audit store display name and sites or subnets, then click **Next**.
4. Select the **Launch Add Audit Store Database Wizard** option if you want to create the first audit store database, then click **Finish**.

Create the Audit Store Database

If you selected the Launch Add Audit Store Database Wizard check box at the end of the Launch Add Audit Store Wizard, the Add Audit Store Database Wizard opens automatically. You can also open the wizard at any time from the Audit Manager console by expanding an audit store, right-clicking the Databases node, and choosing Add Audit Store Database.

To create the first audit store database:

1. Type a display name for the audit store database, then click **Next**.

   The default name is based on the name of the audit store and the date the database is created.

2. Select the option to create a new database and verify that the SQL Server computer name, instance name, and database name are correct.

   The default database name is the same as the display name. You can change the database name to be different from the display name, if you want to use another name.

   If the server does not use the default TCP port, specify the port number as part of the server name. For example, if the port number is 1234, the server name would be similar to ACME\BOSTON,1234.

When entering the SQL Server host computer name, note that you can enter either the server short name (which is automatically resolved to its fully qualified domain name, or FQDN) or the actual server FQDN or the CNAME alias for the server.

If the database is an Amazon RDS SQL Server:

1. Select the **This is an Amazon RDS SQL Server** option.
2. In the Server Name field, enter the RDS SQL Server database instance endpoint name used for Kerberos authentication.

   For example, if the database host name is northwest1 and the domain name is sales.acme.com, then the endpoint name would be northwest1.sales.acme.com.

   Click **Options** to enter additional connection string parameters or to enable data integrity checking.

- You can enable or disable data integrity checking once, when you create the audit store database. To change the state, you must rotate to a new audit store database.

Connecting to SQL Server on a Remote Computer

To create an audit store database on a remote computer, there must be a one-way or two-way trust between the domain of the computer on which you are running the Add Audit Database wizard and the domain of the computer hosting SQL Server. The Active Directory user account that you used to log on to the computer where the Audit Manager is installed must be in a domain trusted by the computer running SQL Server. If there is no trust relationship, you must log on using an account in the same domain as the computer running SQL Server. If you are accessing the computer running SQL Server remotely, you can use the Run As command to change your credentials on the computer from which you are running the wizard.

Verify Network Connectivity

The computer hosting the SQL Server database for the active audit store server be online and accessible from the Audit Manager console and from the clients in the Active Directory site or the subnet segments you have defined for the audit store. You should verify that there are no network connectivity issues between the computers that will host collectors and those hosting the SQL Server databases.

How to Create the Database without System Administrator Privileges

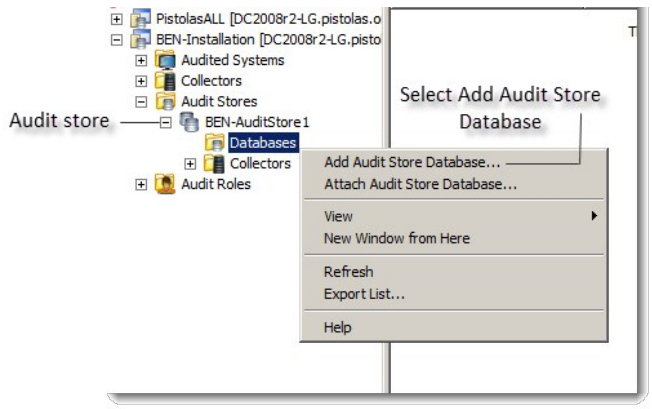
If you do not have system administrator privileges, the wizard prompts you to specify another set of credentials or generate SQL scripts to give to a database administrator. If you don't have database administrator credentials or a database administrator immediately available who can enter the credentials for you, you should generate the scripts, then follow the prompts displayed to exit the wizard.

To add the database to the audit store after you have generated the scripts:

1. Send the scripts to a database administrator with a service or change control request.

   Note: {/b}You should notify the database administrator that the scripts must be run in the proper sequence and not modified in any way. Changes to the scripts could render the database unusable.

2. After the database administrator creates the database using the scripts, open the Audit Manager console.
3. Expand the installation node, then expand Audit Stores and the specific audit store you for which you want a new database.
4. Select **Databases**, right-click, then click **Add Audit Store Database**. For example:



5. Type a display name for the audit store database, then click **Next**.
6. Select **Use an existing database** and select the database that the database administrator created for you.

   Because this is the first audit store database, you also want to make it the active database. This option is selected by default. If you are creating the database for future use and don't want to use it immediately, you can deselect the **Set as active database** option.

   If the server does not use the default TCP port, specify the port number as part of the server name. For example, if the port number is 1234, the server name would be similar to ACME\BOSTON,1234.

The installation, management database, and first audit store database are now ready to start receiving user session activity. Next, you should install the collectors and, finally, the agents to complete the deployment of the audit and monitoring service infrastructure.

Installing and Configuring Audit Collectors

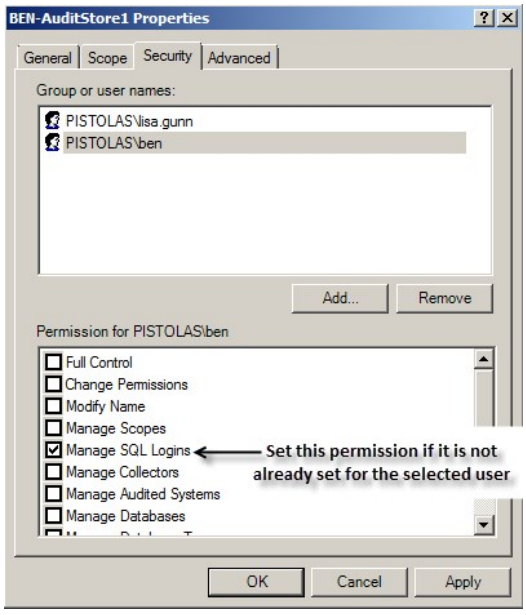
After you have created a new installation, with an audit management database and at least one audit store and audit store database, you must add the collectors that will receive audit records from the agents and forward those records to the audit store. For redundancy and scalability, you should have at least two collectors. For more information about planning how many collectors to use and the recommended hardware and network configuration for the collector computers, see Decide where to install collectors and audit stores.

Set the Required Permission

Before you configure a collector, you should check whether your user account has sufficient permissions to add new collector accounts to the audit store database. If you are a database administrator or logged on with an account that has system administrator privileges, you should be able to configure the collector without modifying your account permissions. If you have administrative rights on the computer hosting Audit Manager but are not a database administrator, you can set the appropriate permission before continuing.

To set the permission required to add accounts to the audit store database:

1. Open Audit Manager.
2. Expand the installation, then expand Audit Stores.
3. Select the audit store that the collector will connect to, right-click, then click **Properties**.
4. Click the **Security** tab.
5. Click **Add** to search for and select the user who will configure the collector.
6. Select the **Manage SQL Logins** right, then click **OK**.



Install the Collector Service Using the Setup Program

If your user account has sufficient permissions to add new collector accounts to the audit store database, you can install a collector by running the setup program on a selected computer. When prompted to select components, select Audit Collector and deselect all of the other components, then click **Next**. Follow the instructions in the wizard to select the location for installing files and to confirm your selections, then click **Finish** to complete the installation.

Configure the Audit Collector Service

By default, when you click **Finish**, the setup program opens the Collector Configuration Wizard. Alternatively, you can start the configuration wizard at any time by clicking Configure in the Collector Control Panel.

To configure the collector service:

1. Type the port number to use, then click **Next**.

   The default port is 5063 for communication from agents to the collector. If you want to use a different port, the wizard checks whether the port is open in the Windows firewall.

   If you're running another firewall product, open the port with the tools provided by that product. If there's an upstream firewall—such as a dedicated firewall appliance—between the Collector and the computers to be audited, contact the appropriate personnel to open the port on that firewall.

2. Select the installation of which this collector will be a part, then click **Next**.

   The configuration wizard verifies that the installation has an audit store that services the site that the collector is in and that the collector and its audit store database are compatible.

3. Select whether you want to use Windows authentication or SQL Server authentication when the collector authenticates to the audit store database, then click **Next**.

   In most cases, you should choose Windows authentication to add the computer account to the audit store database as a trusted, incoming user.

   If Microsoft SQL server is in a different forest or in an untrusted forest, you should use SQL Server Management Studio to set up one or more SQL Server login accounts for the collector. After you create the SQL Server login account for the collector to use, you can select SQL Server authentication, then type the SQL Server login name and password in the wizard.

4. Choose the maximum number of connections you want for the SQL Server Connection Pool, then click **Next**.

5. Review your settings for the collector, then click **Next**.

6. Click **Finish** to start the collector service and close the wizard.

Installing the Agent for Windows

You must install an agent on every Windows computer that you want to manage or audit. You can install the agent in the following ways:

- Interactively, by running the setup program on each computer.

  When the installation finishes, the agent configuration panel launches automatically. You can configure the agent to enable Delinea services right away, or exit the configuration panel and configure the agent later. See Installing the Agent for Windows interactively using the setup program for details about this installation method.

- Silently, by executing appropriate commands in a terminal window on each computer. This method also requires you to configure the agent registry settings on each computer. See Installing the Agent for Windows silently on remote Windows computers for details about this installation method.

  A variation of this method is to use a third-party software distribution product, such as Microsoft System Center Configuration Manager (SCCM), to execute the appropriate command line remotely, so that the software is deployed on remote computers. Using a third-party software distribution product is not covered in this guide.

- Silently and centrally, by using a Windows group policy to execute installation and registry configuration commands remotely on each computer that is joined to the domain. See Installing the Agent for Windows silently on all domain computers by using group policy for details about this installation method.

Regardless of the deployment method you choose, you should first make sure that the computers where you plan to deploy meet all of the installation prerequisites.

Verifying Prerequisites

Before installing the Agent for Windows, verify the computer on which you plan to install meets the following requirements:

- The computer is running a supported Windows operating system version.
- The computer is joined to Active Directory.
- The computer has sufficient processing power, memory, and disk space for the agent to use.
- The computer has Windows security update KB3033929 installed if it is running Windows 7 with Service Pack 1 or Windows Server 2008 R2 with Service Pack 1.
- The computer has .NET 4.6.2 or later installed.
- The computer has Windows Installer version 4.5 or newer.

If you are installing interactively using the setup program, the setup program can check that the local computer meets these requirements and install any missing software required. if you are installing silently or from a Group Policy Object, you should verify the computers where you plan to install meet these requirements.

Installing the Agent Interactively Using the Setup Program

The procedure in this section describes how to use the agent installation wizard to install the agent on a Windows computer. After the agent is installed, you will enable the agent to use one or more services that you installed earlier on the main administrative computer as described in Installing Server Suite and updating Active Directory.

To install the agent on Windows using the setup program:

1. Insert the distribution CD into the computer on which you wish to install the agent or browse to the location where you have saved downloaded files.
2. On the Getting Started page, click **Agent** to start the setup program for the agent.

   If the Getting Started page is not displayed, open the autorun.exe file to start the installation of Delinea software.
3. If a previous version of the agent is installed, click **Yes** when prompted to upgrade the Agent for Windows.
4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I accept the terms in the License Agreement**, then click **Next**.
6. Accept the default location for installing components, or click **Change** to select a different location, then click **Next**.

7. In the Ready to install Agent for Windows page, click **Install**.
8. Click **Finish** to complete the installation and start the agent configuration panel.

   Go to Configuring the agent for details about using the agent configuration panel to enable Delinea services and configure how the agent interacts with those services.

Configuring the Agent

By default, when you click **Finish**, the setup program opens the agent configuration panel. In the agent configuration panel, you can enable the agent to connect to Delinea services that are installed on the main administrative computer as described in Installing Server Suite and updating Active Directory. After a service is enabled, you can use the agent configuration panel to configure settings that define how the agent will interact with each service.

The first time the agent configuration panel opens, it does not display any services for you to enable. Services display in the agent configuration panel only after you manually instruct the configuration panel to check for services and display those that are eligible to be enabled.

Only services that are installed and configured as required are eligible to be enabled. For example, if you installed the Privilege Elevation Service earlier (as described in Running the setup program on a Windows computer) but did not create a zone, the Privilege Elevation Service does not display on the list of services that you can enable.

To enable services using the agent configuration panel:

1. If the agent configuration panel is not open, open it by clicking **Agent Configuration** in the list of applications in the Windows Start menu.
2. In the agent configuration control panel, click **Add service**.

   All Delinea services that are available to be enabled are displayed.
3. In the list of Delinea services, highlight a service and click **OK**.
4. Provide additional information about the service that you are enabling:
   - **Audit & Monitoring Service**:

     In the Select an Audit Installation page, select an audit store from the list of available audit stores. Click **Next**, and the computer is connected to the audit store.
   - **Identity Platform Settings**:
     1. In the Connect to Identity Platform page, type the URL of the identity platform instance to connect to, or select an instance from the list of registered platform instances in the forest. Click **Next**.
     2. In the Multi-factor authentication for Windows Login page, ensure that the check box to enable multi-factor authentication is selected. Next, use the **All Active Directory accounts** button or **Accounts below** button to specify which Active Directory accounts are enabled for multi-factor authentication login. If you select **Account below**, use the **Add** and **Remove** buttons to select accounts. Click **Next** when you are finished.
   - **Privilege Elevation Service**:
     1. In the Join to a zone page, type a zone or select a zone from the list of available zones. You can also choose to select the option to retrieve the zone data before the computer restarts. This option can be helpful in situations where you might lose connection to the domain after restarting, such as when you're using a VPN connection.

        Click **Next**, and the computer is joined to the zone.
     2. After the computer is joined to a zone, you must reboot the computer to activate all privilege elevation service features on the computer.

        If the zone that you select is already configured with a Privileged Access Service tenant, the message **Identity Platform enabled** displays after the computer joins the zone. In this situation, the instance is managed by the zone, and is shown as read-only.
5. To add additional services, click **Add service** and repeat the preceding steps.

   When you are done, the services that you enabled are shown in the **Enabled services** section of the agent configuration panel.
6. If necessary, continue to configure Delinea services after their initial configuration during enablement as described in these sections:

- Configuring agent settings for the audit and monitoring service
- Configuring agent settings for offline audit and monitoring service storage
- Configuring agent settings for the Identity Platform
- Configuring agent settings for privilege elevation

Configuring Agent Settings for the Audit and Monitoring Service

If you want to reconfigure agent settings for auditing on a Windows computer after initially configuring them during enablement (or if you did not use the agent configuration panel when you enabled the service), you can open the agent configuration panel manually and configure the agent as described in this section.

To configure agent settings for audit and monitoring service:

1. In the Windows Start menu, click **Agent Configuration** in the list of applications.

   The agent configuration panel opens, and displays the Delinea services that are currently enabled. You can configure any service listed in the **Enabled services** section.

2. Click **Audit & Monitoring Service**, and then click **Settings**.
3. In the General tab, click **Configure**.
4. Select the maximum color quality for recorded sessions, then click **Next**.

   See Selecting the maximum color quality for recorded sessions for more information on the configuration of this setting.

5. Specify the offline data location and the maximum percentage of disk that the offline data file should be allowed to occupy, then click **Next**.

   See Configuring agent settings for offline audit and monitoring service storage for more information on the configuration of this setting.

6. Select the installation that the agent belongs to, then click **Next**.
7. Review your settings, then click **Next**.
8. Click **Finish**.
9. Click **Close** in the General tab to save your changes.

For information about using the Troubleshooting tab, see Monitoring collector status locally.

Selecting the Maximum Color Quality for Recorded Sessions

Because auditing Windows computers captures user activity as video, you can configure the color depth of the sessions to control the size of data that must be transferred over the network and stored in the database. A higher color depth increases the CPU overhead on audited computers but improves resolution when the session is played back. A lower color depth decreases network traffic and database storage requirements, but reduces the resolution of recorded sessions.

The default color quality is low (8-bit).

Configuring Agent Settings for Offline Audit and Monitoring Service Storage

The “Maximum size of the offline data file” setting defines the minimum percentage of disk space that should be available, if needed, for audit and monitoring service. It is intended to prevent audited computers from running out of disk space if the agent is sending data to its offline data storage location because no collectors are available.

For example, if you set the threshold to 10%, auditing will continue while spooling data to the offline file location as long as there is a least 10% of available disk space on the spool partition. When the available disk space reaches the threshold, auditing will stop until a collector is available.

The agent checks the spool disk space by periodically running a background process. By default, the background process runs every 15 seconds. Because of the delay between background checks, it is possible for the actual disk space available to fall below the threshold setting. If this were to occur, auditing would stop at the next interval. You can configure the interval for the background process to run by editing the

HKLM\Software\Centrify\DirectAudit\Agent\DiskCheckInterval registry setting.

Configuring Agent Settings for the Identity Platform

If you want to reconfigure agent settings for the Identity Platform on a Windows computer after initially configuring them during enablement (or if you did not use the agent configuration panel when you enabled the service), you can open the agent configuration panel manually and configure the agent as described in this section.

To configure agent settings for the Identity Platform:

1. In the Windows Start menu, click **Agent Configuration** in the list of applications.

   The agent configuration panel opens, and displays the Delinea services that are currently enabled. You can configure any service listed in the **Enabled services** section.

2. Click **Identity Platform**, and then click **Settings**.

3. In the General tab, review the authentication options in the Features area:

   - **Multi-factor authentication:**

     - If the status is **Enabled**, the computer is not joined to a zone, and you can configure all Identity Platform settings that are shown in the General tab.

     - If the status is **Enabled per zone settings**, the computer is joined to a zone, and most Identity Platform settings are based on the zone configuration.

       In this situation, the **Browse** and **Details** buttons in the General tab are disabled, because those features are controlled by the zone configuration. The only configuration that you can perform in the General tab is to change the proxy server settings.

       Multi-factor authentication displays in the Authentication Source drop-down once the status is Enabled per zone settings.

   - **RADIUS authentication:**

     - If the status is **Enabled**, you can select this option to use as the authentication option for privilege elevation. You can enable this option either by group policy or a local configuration setting.

     - If the status is **Disabled**, click **Details** to configure and enable the RADIUS server connection.

       
       RADIUS authentication displays in the Authentication Source drop-down once the status is Enabled.

4. To change proxy server settings:
    1. Click **Change**.
    2. Specify a new proxy server address.
    3. Click **OK**.
5. To change to a different Identity Platform instance (only configurable if the computer is not joined to a zone):
    1. Click **Browse**.
    2. Select an instance from the list of registered platform instances in the forest.
    3. Click **OK**.
6. To specify which Active Directory accounts require multi-factor authentication (only configurable if the computer is not joined to a zone):
    1. Click Details.
    2. Use the **All Active Directory accounts** button or **Accounts below** button to specify which Active Directory accounts are enabled for multi-factor authentication login. If you select **Account below**, use the **Add** and **Remove** buttons to select accounts.
    3. Click **OK**.
7. Click **Close** in the General tab to save your changes.

For information about using the Troubleshooting tab, see the *Multi-factor Authentication Quick Start Guide*.

Configuring Agent Settings for Privilege Elevation

If you want to reconfigure agent settings for privilege elevation on a Windows computer after initially configuring them during enablement (or if you did not use the agent configuration panel when you enabled the service), you can open the agent configuration panel manually and configure the agent as described in this section.

If you haven't yet configured the agent settings for privilege elevation, see Configuring the agent for details.

To configure existing agent settings for privilege elevation:

1. In the Windows Start menu, click **Agent Configuration** in the list of applications.

    The agent configuration control panel opens, and displays the services that are currently enabled. You can configure any service listed in the **Enabled services** section.
2. Click **Privilege Elevation Service**, and then click **Settings**.
3. In the General tab, click **Change**.
4. In **Change the zone for this computer**, click **Browse**.
5. Click **Find Now** to search for an appropriate zone for the agent.
6. Select a zone from the list of search results, then click **OK**.
7. Click **OK** to use the zone you selected.
8. Click **Close** in the General tab to save your changes.

For information about using the Troubleshooting tab, see Running diagnostics and viewing logs for the agent.

Installing the Agent without MFA Login

If desired, you can install the Agent for Windows without the MFA login feature. This can be useful in situations where either you don't want to enforce multi-factor authentication or you don't use Privileged Access Service.

To install the Agent for Windows without the MFA login feature:

- Run the following command:

msiexec /i "Agent for Windows64.msi" /qn PRIVILEGEONLY=1

Installing the Agent for Windows Silently on Remote Windows Computers

If you want to perform a "silent" (also called *unattended*) installation of the Agent for Windows, you can do so by specifying the appropriate command line options and Microsoft Windows Installer (MSI) file to deploy. You must execute the commands on every Windows computer that you want to manage or audit.

Note: {/b}You can also use a silent installation to automate the installation or upgrade of the agent on remote computers if you use a software distribution product, such as Microsoft System Center Configuration Manager (SCCM), to deploy software packages. However, installing remotely in this way is not covered in this topic.

Deciding to Install with or without Joining the Computer to a Zone

Before you begin a silent installation, you should decide whether you will wait until later to join the computer to a zone, or join the computer to a zone as part of the installation procedure.

If you install without joining a zone during installation:

- See Configuring registry settings for details about the registry settings that you can configure manually after the installation finishes.
- See Installing silently without joining a zone for details about performing the installation.

If you install and join a zone during installation:

- You use a transform (MST) file that is provided with Server Suite to configure a default set of agent-specific registry keys during the silent installation.
- You can optionally edit the MST file before performing the installation to customize agent-specific registry settings for your environment.
- You can optionally use the registry editor to configure registry settings after the installation finishes.
- See Configuring registry settings for details about the registry settings that you can configure by editing the MST file.
- See Editing the default transform (MST) file for details about how to edit the MST file before you perform the installation.
- See Installing and joining a zone silently for details about performing the installation.

Configuring Registry Settings

When you perform a silent installation, several registry settings specific to the agent are configured by the default MSI file. In addition, a default transform (MST) file is provided for you to use if you join the computer to a zone as part of the installation procedure. When executed together, the default MSI and MST files ensure that the computer is joined to a zone, and that a default set of agent-specific registry keys is configured.

If your environment requires different or additional registry settings, you can edit the MST file before performing an installation. Then, when you execute the MSI and MST files to perform an installation, your customized registry settings are implemented. For details about how to edit the MST file, see Editing the default transform (MST) file.

> **Note**: If you do not join the computer to a zone during installation, you do not use the MST file. In this situation, you can create or edit registry keys manually after the installation finishes by using the registry editor.

The following table describes the agent-specific registry settings that are available for you to configure during installation (by using the MST file) or after installation (by using the or the registry editor). Use the information in this table if you need to configure registry settings differently than how they are configured by the default MSI and MST files. Keep the following in mind as you review the information in the table:

- The default MSI file is named Agent for Windows64.msi, and is located in the **Agent** folder in the Delinea download location.
- The default MST file is named Group Policy Deployment.mst, and is located in the **Agent** folder in the Delinea download location.
- If you want to install the agent without the MFA login feature, use the Group Policy Deployment-PrivilegeOnly.mst, and is located in the **Agent** folder in the Delinea download location.
- All of the settings in the following table are optional, although some are included in the default MSI and MST files so that they are configured when the MSI and MST files execute during an installation.
- Settings that are included in the default MSI and MST files are noted in the table.
- Some settings are environment-specific, and therefore do not have a default value. Others are not environment-specific, and do have a default value.
- The settings described in the table are located in the MSI file's Property table.
- The **Setting** column shows both the property name in the MSI file, and the name (in parentheses) of the registry key in the Windows registry.

	Specifies the color depth of sessions recorded by the agent. The color depth affects the resolution of the activity recorded and the size of the records stored in the audit store database when you have video

Auditing and Monitoring	REG_MAX_FORMAT (MaxFormat)	capture auditing enabled. You can set the color depth to one of the following values: 0 to use the native color depth on an audited computer. 1 for a low resolution with an 8-bit color depth 2 for medium resolution with a 16-bit color depth (default) 4 for highest resolution with a 32-bit color **This setting is included in the default MSI file.** In the registry, this setting is specified by a numeral (for example, 1). In the MSI file Property table, it is specified by the # character and a numeral (such as #1). The default value is 1.
Auditing and Monitoring	REG_DISK_CHECK_THRESHOLD (DiskCheckThreshold)	Specifies the minimum amount of disk space that must be available on the disk volume that contains the offline data storage file. You can change the percentage required to be available by modifying this registry key value. **This setting is included in the default MSI file.** In the registry, this setting is specified by a numeral (for example, 1). In the MSI file Property table, it is specified by the # character and a numeral (such as #10). The default value is 10, meaning that at least 10% of the disk space on the volume that contains the offline data storage file must be available. If this threshold is reached and there are no collectors available, the agent stops spooling data and audit data is lost.
Auditing and Monitoring	REG_SPOOL_DIR (SpoolDir)	Specifies the offline data storage location. The folder location you specify will be where the agent saves ("spools") data when it cannot connect to a collector. **This setting is not included in the default MSI file.** To use it, you must edit the default transform (MST) file so that it is processed together with the MSI file during installation, or create it manually in the registry after the installation finishes.
Auditing and Monitoring	REG_INSTALLATION_ID (InstallationId)	Specifies the unique global identifier (GUID) associated with the installation service connection point. **This setting is not included in the default MSI file.** To use it, you must edit the default transform (MST) file so that it is processed together with the MSI file during installation, or create it manually in the registry after the installation finishes.
Auditing and Monitoring	REG_LOG_LEVEL_DA (LogLevel)	Specifies what level of information, if any, is logged. Possible values are: off information warning error verbose **This setting is included in the default MSI file.** The default value is information.
Authentication & Privilege	REG_RESCUEUSERSIDS (RescueUserSids)	Specifies which users have rescue rights. Type user SID strings in a comma separated list. For example: *user1SID,user2SID,usernSID* **This setting is not included in the default MSI file.** To use it, you must edit the default transform (MST) file so that the setting is processed together with the MSI file during installation, or create it manually in the registry after the installation finishes.
Authentication & Privilege	REG_LOG_LEVEL_DZ (LoggingLevel)	Specifies what level of information, if any, is logged. Possible values are: off information warning error verbose **This setting is included in the default MSI file.** The default value is information.
Authentication & Privilege	GPDeployment	Specifies whether the computer is joined to the zone where the computer was pre-created. This setting is used only during installation and does not have a corresponding registry key. Possible values are: 0 - The computer is not joined to the zone. 1 - The computer is joined to the zone. **This setting is included in the default transform (MST) file.** To use it, you must execute the MST file when you execute the default MSI file. The default value is 1, meaning that the pre-created computer is joined to the zone.
Authentication & Privilege	ZONEDATA	Specifies the option to retrieve the zone data before the computer restarts. This option can be helpful in situations where you might lose connection to the domain after restarting, such as when you're using a VPN connection. Possible values are: YES NO The default value is NO in the default MSI file.

Editing the Default Transform (MST) File

This section describes how to edit the default transform (MST) file Group Policy Deployment.mst. You execute the MST file together with the installation (MSI) file during a silent installation if you want to join the computer to a zone as part of the installation.

The MST file specifies registry key settings that are different from those specified in the MSI file. You use the MST file to customize a silent installation for a specific environment. Using an MST file makes it unnecessary to edit registry keys manually after a silent installation.

Note: {/b}By default, auditing features are installed when you install the Agent for Windows. The service is not enabled by default, but the service item in the configuration panel appears if the feature is enabled through group policy.

See Installing and joining a zone silently for instructions about how and when to execute the MST file.

To edit the default MST file:

1. You will use the Orca MSI editor to edit the MST file. Orca is one of the tools available in the Windows SDK. If the Windows SDK (or Orca) is not installed on your computer, download and install it now from this location:

   https://msdn.microsoft.com/en-us/library/aa370557(v=vs.85).aspx

2. Execute Orca.exe to launch Orca.
3. In the **Agent** folder in the Delinea download location, copy Group Policy Deployment.mst so that you have a backup.
4. In Orca, select **File > Open** and open the Agent for Windows64.msi file located in the **Agent** folder in the Delinea download location.
5. In Orca, select **Transform > Apply Transform**.
6. In Orca, navigate to the **Agent** folder in the Delinea download location and open Group Policy Deployment.mst.

   The file is now in transform edit mode, and you can modify data rows in it.

7. In the Orca left pane, select the Property table.

   Notice that a green bar displays to the left of "Property" in the left pane. This indicates that the Property table will be modified by the MST file.

   The right pane displays the properties that configure registry keys when the MSI file executes. Notice that the last property in the table, GPDeployment, is highlighted in a green box. This indicates that the GPDeployment property will be added to the MSI file by the MST file.

   Note: {/b}In order for the computer to join a zone during installation, the Group Policy Deployment.mst file *must* specify the GPDeployment property with a value of 1.

8. In the right pane, edit or add properties as necessary to configure registry keys for your environment. See the table in Configuring registry settings for details about agent-specific properties that are typically set.

   - To edit an existing property, double click its value in the **Value** column and type a new value.
   - To add a new property, right-click anywhere in the property table and select **Add Row**.

9. After you have made all necessary modifications, select **Transform > Generate Transform** to save your modifications to the default MST file.

   Be sure to save the MST file in the same folder as the MSI file. If the MST and MSI files are in different folders, the MST file will not execute when you execute the MSI file.

   The MST file is now ready to be used as described in Installing and joining a zone silently.

Installing Silently without Joining a Zone

This section describes how to install the agent silently without joining the computer to a zone. This procedure includes configuring registry settings manually using the registry editor or a third-party tool.

Note: {/b}To install the agent and join the computer to a zone during installation, see Installing and joining a zone silently for more information.

Check prerequisites:

1. Verify that the computers where you plan to install meet the prerequisites described in Verifying prerequisites. If prerequisites are not met, the silent installation will fail.
2. If you are installing audit and monitoring service, verify that the following tasks have been completed:
   1. Installed and configured the SQL Server management database and the SQL Server audit store database.
   2. Installed and configured one or more collectors.
   3. Configured and applied the DirectAudit Settings group policy that specifies the installation name.

To install the Agent for Windows silently without joining the computer to a zone:

1. Open a Command Prompt window or prepare a software distribution package for deployment on remote computers.

   For information about preparing to deploy software on remote computers, see the documentation for the specific software distribution product you are using. For example, if you are using Microsoft System Center Configuration Manager (SCCM), see the Configuration Manager documentation.

2. Run the installer for the Agent for Windows package. For example:

   msiexec /qn /i "Agent for Windows64.msi"

   By default, none of the services are enabled.

3. Use the registry editor or a configuration management product to configure the registry settings for each agent. See the table in Configuring registry settings for details about agent-specific registry keys that you can set.

   For example, under

   HKEY_LOCAL_MACHINE\Software\Centrify\DirectAudit\Agent, you could set the DiskCheckThreshold key to a value other than the default value of 10%.

Installing and Joining a Zone Silently

This section describes how to install the agent and join the computer to a zone at the same time. The procedure described here includes the following steps in addition to executing the MSI file:

- You first prepare (pre-create) the Windows computer account in the appropriate zone.
- You execute an MST file together with the MSI file to join the computer to a zone and configure registry settings during the installation.

  Note: {/b}Joining the computer to a domain is applicable only when you are enabling Authentication & Privilege features.
  To install the agent without joining the computer to a zone during installation, see Installing silently without joining a zone for more information.

Check prerequisites:

1. Verify that the computers where you plan to install meet the prerequisites described in Verifying prerequisites. If prerequisites are not met, the silent installation will fail.
2. If you are enabling audit and monitoring service in addition to Authentication & Privilege, verify that the following tasks have been completed:
   1. Installed and configured the SQL Server management database and the SQL Server audit store database.
   2. Installed and configured one or more collectors.
   3. Configured and applied the DirectAudit Settings group policy that specifies the installation name.

To install the Agent for Windows and add a computer to a zone during installation:

1. Prepare a computer account in the appropriate zone using Access Manager or the PowerShell command New-CdmManagedComputer. See Preparing Windows computer accounts for more information.

2. You will use the default transform file Group Policy Deployment.mst in Step 3 to update the MSI installation file so that the computer is joined to the zone in which it was pre-created in Step 1. You can optionally modify Group Policy Deployment.mst to change or add additional registry settings during installation.

   If you want to edit Group Policy Deployment.mst to change or add additional registry settings and have not yet done so, edit it now as described in Editing the default transform (MST) file.

   In order for the computer to join the zone from Step 1, the Group Policy Deployment.mst file *must* specify the GPDeployment property with a value of 1.

3. Run the following command:

   msiexec /i "Agent for Windows64.msi" /qn TRANSFORMS="Group Policy Deployment.mst"

   By default, Privilege Elevation Service is enabled by joining a zone. If the zone is also configured with a platform instance (tenant), Identity Services Platform will also be enabled. If you want to enable auditing, configure the corresponding registry value in the Property page of the MST file: REG_CURRENT_INSTALLATION or via Group Policy.

   You can also choose to install the specify the option to retrieve the zone data before the computer restarts. This option can be helpful in situations where you might lose connection to the domain after restarting, such as when you're using a VPN connection. To specify that the agent retrieves zone

data before the computer restarts, run the following command:

msiexec /i "Agent for Windows64.msi" /qn TRANSFORMS="Group Policy Deployment.mst" ZONEDATA="YES"

The computer will be restarted automatically to complete the deployment and start the agent.

Installing the Agent for Windows Silently on All Domain Computers by Using Group Policy

You can use a group policy object (GPO) to automate the deployment of the Agent for Windows. Because automated installation fails if all the prerequisites are not met, be sure that all the computers on which you intend to install meet the requirements described in Verifying prerequisites.

> **Note**: If you install the Common Component before you install the agent, information about the installation of the agent can be captured in a log file for troubleshooting purposes.

To create a new group policy object for the deployment of the Agent for Windows:

1. Prepare computer accounts in the appropriate zones using Access Manager or the PowerShell command New-CdmManagedComputer. See Preparing Windows computer accounts for more information.
2. Copy the Agent for Windows64.msi and Group Policy Deployment.mst installer files to a shared folder on the domain controller or another location accessible from the domain controller.

   When you select a folder for the agent installer files, right-click and select **Share with > Specific people** to verify that the folder is shared with Everyone or with appropriate users and groups.
3. Right-click on the Agent for Windows64.msi file, then select **Edit with Orca**.
4. Select **Transform > Apply Transform**, then select Group Policy Deployment.mst from the same location as the Agent for Windows64.msi file.
5. Select the Property table on the left hand side and add the following:

REG_ZONELESS_MFA_TENANT	Tenant URL	(Ex: https://aaa1111.my.delinea.net:443/) Note: You must include “https://” and “:443/”.
REG_ZONELESS_MFA_ENABLED	true	Default Value = false
REG_EFFECTIVE_ZONELESS_MFA_USERS	Comma-Separated user or group names, or enter * for All AD users	
REG_CONNECTOR_BRANDING	Delinea	

1. Close Orca and save the changes as a new mst file.

   Make sure you save it in the same location as the msi file.
2. On the domain controller, click **Start > Administrative Tools > Group Policy Management**.
3. Select the domain or organizational unit that has the Windows computers where you want to deploy the Agent, right-click, then select **Create a GPO in this domain, and Link it here**.
4. For example, you might have an organizational unit specifically for Delinea-managed Windows computers. You can create a group policy object and link it to that specific organizational unit.
5. Type a name for the new group policy object, for example, Agent Deployment, and click **OK**.
6. Right-click the new group policy object and click **Edit**.
7. Expand **Computer Configuration > Policies > Software Settings**.
8. Select **Software installation**, right-click, and select **New > Package**.

9. Navigate to the folder you selected previously, then select the Agent for Windows64.msi file, and click **Open**.
10. Select **Advanced** and click **OK**.
11. Click the **Modifications** tab and click **Add**.
12. Select the .mst file created previously, then click **Open**, and click **OK**.
13. Close the Group Policy Management Editor, right-click the Agent Deployment group policy object, and verify that **Link Enabled** is selected.

    By default, when computers in the selected domain or organizational unit receive the next group policy update or are restarted, the agent will be deployed and the computer will be automatically rebooted to complete the deployment of the agent.

If you want to test deployment, you can open a Command Prompt window to log on to a Windows client as a domain administrator and force group policies to be updated immediately by running the following command:

gpupdate /force

After installation, all of the registry settings that were specified in the MSI and MST files are configured. If you need to further configure registry settings, use the registry editor to do so as described in Installing the Agent for Windows silently on remote Windows computers.

Installing the Agent on a Computer Running Server Core

You cannot use the autorun.exe or the setup.exe program to install components on a computer that is configured to run as a Server Core environment. Instead, you must install from Microsoft Installer (.msi) files using the msiexec command-line program.

To install the Agent for Windows on Server Core:

1. Use the Deployment Image Servicing and Management (DISM) or another command-line tool to enable the .NET Framework.

   For example, if the .NET Framework is located on the installation media in the D:\sources\sxs folder, use the following command:

   DISM /Online /Enable-Feature /FeatureName:NetFx3 /All /LimitAccess /Source:D:\sources\sxs

2. Copy the Agent for Windows files to the Server Core computer.

   For example:

   copy D:\Common\Centrify* C:\Centrify Agent

   copy D:\Agent* C:\Centrify Agent

3. Install the Common Component service using the .msi file.

   For example, to install the Common Component on a computer with 64-bit architecture, you might use the following command:

   msiexec /i Centrify Common Component64.msi" /qn

4. Install the Agent for Windows using the .msi file.

   For example, to install the Agent for Windows with identity management, privilege elevation, auditing, and monitoring features enabled on a computer with 64-bit architecture, you might run the following command:

   msiexec /qn /i "Agent for Windows64.msi" ADDLOCAL=ALL

   You can also choose to install the specify the option to retrieve the zone data before the computer restarts. This option can be helpful in situations where you might lose connection to the domain after restarting, such as when you're using a VPN connection. To specify that the agent retrieves zone data before the computer restarts, run the following command:

   msiexec /i "Agent for Windows64.msi" /qn TRANSFORMS="Group Policy Deployment.mst" ZONEDATA="YES"

5. Restart the computer with the appropriate shutdown options to complete the installation and start agent services.

   For example, you might run the following command:

   shutdown /r

Installing Additional Consoles

You can install additional consoles on any domain computers you want to use for managing access using zones or roles, or for managing the audit and monitoring service infrastructure. You also might want to install additional consoles on the computers to be used by auditors. You can install additional consoles from the Management Services setup program or from individual component-specific setup programs. For example, you can use the Audit Analyzer Console.exe setup program to install Audit Analyzer on a computer.

Installing Group Policy Extensions Separately from Access Manager

Group policy extensions are packaged separately from Access Manager, enabling the following installation options:

- You can install group policy extensions on any Windows domain computer without also installing Access Manager on the computer.
- You can install Access Manager on any Windows domain computer without also installing group policy extensions on the computer.

The group policy extension package has its own .exe and .msi installer files, so that you can install group policy extensions interactively through an installation wizard (by executing the .exe file) or silently from the command line (by executing the .msi file). Additionally, you can select or de-select the group policy extensions for installation when you run the Access Manager installation wizard.

Note: {/b}At the start of an installation, the group policy extension installer checks for previously installed versions of group policy extensions. If it detects a newer version than the version you are trying to install, the installation stops.

To install standalone group policy extensions interactively with the group policy installer:

1. On the Windows domain computer where you will install group policy extensions, navigate to the Delinea ISO bundle containing the group policy extension installer file.

   The installer file is named <!---TODO update filename---> CentrifyDC_GP_Extension-*#.#.#-architecture.*exe.

   For example: <!---TODO update filename--->

   CentrifyDC_GP_Extension-5.2.3-win64.exe

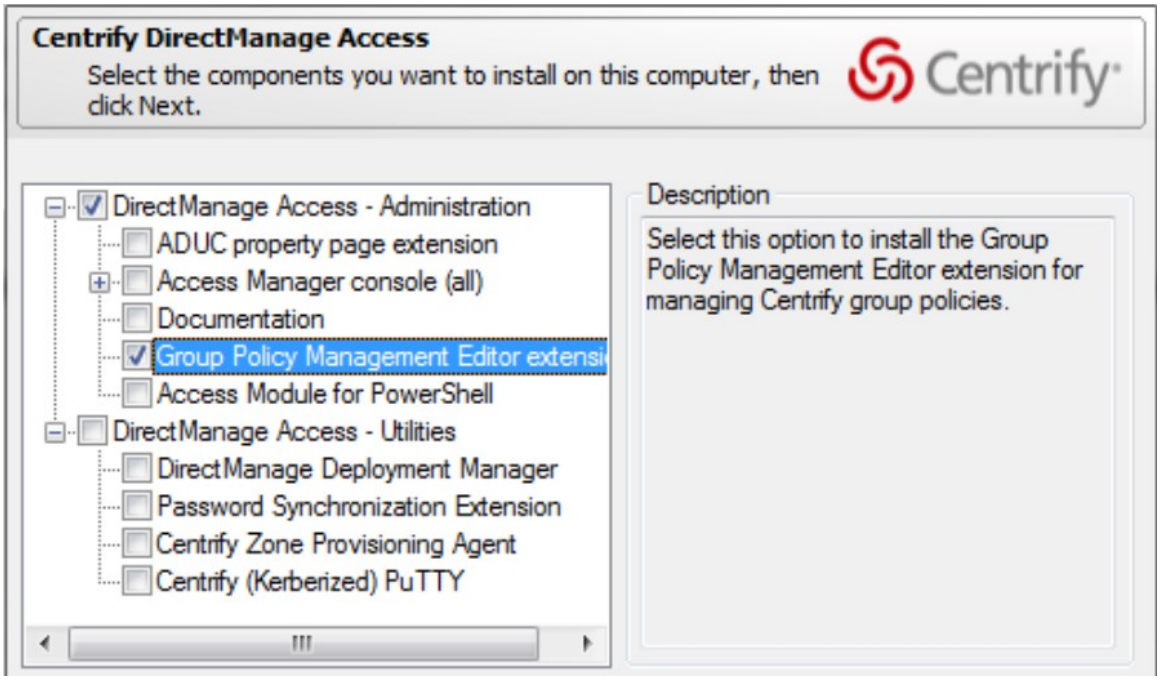
   In most distributions, the installer file is located in the following folder in the ISO bundle:

   DirectManage\Group Policy Management Editor Extension

2. Double-click the installer file to launch the Group Policy Management Editor Extension Setup Wizard.
3. Follow the wizard installation instructions to install the group policy extensions.

To install standalone group policy extensions interactively with the Management Services installer:

1. On the Windows domain computer where you will install group policy extensions, launch the setup program for Management Services components as described in Installing Server Suite and updating Active Directory.
2. Proceed through the setup program until you reach the wizard page in which to select individual components to install.
3. De-select every component except for **Group Policy Management Editor extension for managing group policies**:



4. Continue to follow the wizard installation instructions as described in Installing Server Suite and updating Active Directory until you are finished with the installation.

To install standalone group policy extensions silently without installing Access Manager:

1. Open a Command Prompt window.
2. Execute the group policy extension .msi installer file from the command line.

   The installer file is named <!---TODO update filename---> CentrifyDC_GP_Extension-*#.#.#-architecture.*msi.

   For example: <!---TODO update filename--->

   CentrifyDC_GP_Extension-5.2.3-win64.msi

   In most distributions, the installer file is located in the following folder in the ISO bundle:

   DirectManage\Group Policy Management Editor Extension

   The following is a typical command to run the 64-bit .msi installer file: <!---TODO update filename--->

   msiexec /qn /i "CentrifyDC_GP_Extension-5.2.3-win64.msi"

   For more information about installing with a .msi file, see Installing the Agent for Windows silently on remote Windows computers.

To install Access Manager interactively without installing group policies:

1. On the Windows domain computer where you will install group policy extensions, launch the Management Services setup program and select Authentication & Privilege as described in Installing Server Suite and updating Active Directory.
2. Proceed through the setup program until you reach the wizard page in which to select individual components to install.
3. De-select the **Group Policy Management Editor extension** component.
4. Continue to follow the wizard installation instructions as described in Installing Server Suite and updating Active Directory until you are finished with the installation.

Zones are the key component for organizing access rights and role assignments for Windows computers. This chapter describes how to use Access Manager to create zones, manage zone properties, add Windows computers to selected zones, and move and rename zone objects.

Starting Access Manager for the First Time

The first time you start Access Manager, a Setup Wizard prepares the Active Directory forest with parent containers for licenses and zones. The Setup Wizard also sets the appropriate permissions for the objects. For example, all authenticated users are granted read access of the Licenses container by default. These steps are typically performed once by a domain administrator. If you choose to, you can create the container objects manually.

What to do Before Updating Active Directory

Before you use Access Manager the first time, you should contact the Active Directory administrator to determine the appropriate location for the Licenses and Zones parent containers and whether you have the appropriate rights for completing this task. The specific administrative rights required for this task depend on the policies of your organization and who has permission to create classStore and parent and child container objects in Active Directory.

Rights Required for this Task

If you don't have administrative rights to create container objects in Active Directory, a domain administrator in the forest root domain can manually create the container objects and set the rights on those objects to allow other users to complete the initial configuration without being members of an administrative group.

The following table describes the minimum rights that must be granted on manually created container objects for other users to successfully complete the configuration with the Setup Wizard.

Licenses container	Read all properties Create classStore objects Modify permissions	This object only
	Write Description property Write displayName property	This object and all child objects
	By default, all Authenticated Users have read and list contents permission for the Licenses container and all of its child objects.	
Zones container	Read all properties Create classStore objects Create Container objects	This object only
	Write displayName property	This object and all child objects

If you are a domain administrator and use the Setup Wizard to create the container objects, you should add a security group for Zone Administrators to Active Directory. Set the following permissions on the parent Zones container to allow other users to manage zones.

Zones container	Read all properties Create Container objects Delete Container objects	This object only
	Write displayName property	This object and all child objects

Who Should Perform this Task

A Windows Active Directory administrator performs this task, depending on your organization's policies, by running the Setup Wizard or by manually creating container objects and notifying another user of the location of the container objects. The user who runs the Setup Wizard must be granted the rights required to create classStore objects.

How Often You Should Perform this Task

In most organizations, you only do this once for an Active Directory forest. However, if you want to create more than one administrative boundary, you can create additional parent containers as needed.

Steps for Completing this Task

The following instructions illustrate how to run the Setup Wizard from Access Manager.

To update Active Directory using Access Manager:

1. Open Access Manager.
2. At the Welcome page, click **Next**.
3. Select **Use currently connected user credentials** to use your current log on account or select **Specify alternate user credentials** and type a user name and password, then click **Next**.
4. Select a location for installing license keys in Active Directory, then click **Next**.

   The default container for license keys is <!---TODO update path ---> *domain_name*/Program Data/Centrify/Licenses. To create or select a container object in a different location, click **Browse**. If an Active Directory administrator has created the Licenses container for you, click Browse and navigate to the appropriate location. The Setup Wizard will create a classStore object in the location you specify.

   You can create additional containers in other locations later using the Manage Licenses dialog box.
5. Review the permission requirements for the container, then click **Yes** to confirm your selection.
6. Type or copy and paste the license key you received, then click **Add**.

   If you received multiple license keys, add each key to the list of installed licenses, then click **Next**. If you received license keys in a text file, click **Import** to import the keys directly from the file instead of adding the keys individually, then click **Next**.
7. Select **Create default zone container** and specify a location for the Zones container, then click **Next**.

   The default container location for zones is <!---TODO update ---> *domain_name*/Program Data/Centrify/Zones. To create or select a container object in a different location, click **Browse**. If an Active Directory administrator has created the Zones container for you, click Browse and navigate to the appropriate location. The Setup Wizard will create a classStore object in the location you specify.

   Any zones you create are placed in this container location by default.

   The next three pages only apply if you are managing multiple platforms. For a Windows-only deployment, you can click **Next** to leave the following options unselected:

   - Grant computer accounts in the Computers container permission to update their own account information.
   - Register administrative notification handler for Microsoft Active Directory Users and Computers snap-in.
   - Activate profile property pages.
8. Review and confirm your configuration settings, click **Next**, then click **Finish**.

After you click Finish, the Access Manager console is displayed.

What to Do Next

Create at least one parent zone.

Where you can find additional information

If you want to learn more about the importance and benefits of using zones, see the following topics for additional information:

- Access control for Windows computers
- How zones organize access rights and roles
- Identity and privilege management

Preparing to Use Zones

One of the most important aspects of managing computers with Delinea software is the ability to organize computers, users, and groups into **zones**. You use zones to create logical groupings for:

- Managing access rights, role definitions, and role assignments.
- Delegating administrative tasks based on a separation of duties.
- Associating groups of computers and groups of users with specific role assignments.

Controlling Access through Hierarchical Zones

Server Suite for Windows only supports **hierarchical zones**. Hierarchical zones enable you to establish parent-child zone relationships, allowing rights, role definitions, and role assignments to be inherited down the zone hierarchy. One of the first decisions you need to make is how you can use the zone hierarchy most effectively.

With hierarchical zones, you define rights and roles in a parent zone so that those definitions are available in one or more child zones, as needed. Child zones can also inherit user and group role assignments. At any point in the zone hierarchy, you can choose to use or override information from a parent zone.

There are no predefined limits to the number of zones that can be used in a zone hierarchy or the number of levels deep zones can be nested in the hierarchy you define. For practical purposes, keep the hierarchy similar to the following:

- One or more top-level **parent** zones that includes all users and groups.
- One to three levels of intermediate **child** zones based on natural access control or administrative boundaries.

There are many different approaches you can take to defining the scope of a zone, including organizing by platform, department, manager, application, geographical location, or how a computer is used. The factors that are most likely to affect the zone design, however, will involve managing access rights and roles and delegating administrative tasks to the appropriate users and groups.

Managing Access Rights and Roles Using Zones

Zones enable you to grant specific rights to users in specific roles on specific computers. By assigning roles, you can control the scope of resources any particular group of users can access and what those users can do. For example, all of the computers in the finance department could be grouped into a single zone called “finance” and the members of that zone could be restricted to finance employees and senior managers, each with specific rights, such as permission to log on locally, access a database, update certain files, or generate reports.

Rights represent specific operations users are allowed to perform. A **role** is a collection of rights that can be defined in a parent or child zone and inherited. For example, a role defined in a parent zone can be used in a child zone, in a computer role, or at the computer level.

System and Predefined Rights

There are specialized login rights, called system rights. The system rights for Windows computers are:

- **Console login is allowed**: Specifies that users are allowed to log on locally using their Active Directory account credentials.
- **Remote login is allowed**: Specifies that users are allowed to log on remotely using their Active Directory account credentials.
- **PowerShell remote access is allowed**: Specifies that users are allowed to log on remotely to PowerShell.

There are additional predefined rights that allow access to specific applications. For example, there are predefined rights that allow users to run Performance Monitor or Server Manager without having an administrator’s password. You grant users permission to access computers by assigning them to a role that includes at least one login right. You can then give them access to specific applications or privileges using additional predefined or custom access rights.

Granting Permission to Log On

By default, zones always provide the **Windows Login** role to allow users to log on locally or remotely to computers in the zone. Users must have at least one role assignment that grants console or remote login access or they will not be allowed to access any of the computers in the zone.

> **Note**: The Windows Login role grants users the permission to log on whether they are authenticated by specifying a user name and password or by using a smart card and personal identification number (PIN).

Because the Windows Login role only allows users to log on, it is often assigned to users in a parent zone and inherited in child zones. However, the Window Login role does not override any native Windows security policies. For example, most domain users are not allowed to log on to domain controllers. Assigning

users the Windows Login role does not grant them permission to log on to the domain controllers. Similarly, if users are required to be members of a specific Windows security group, such as Server Operators or Remote Desktop Users, to log on to specific computers, the native Windows security policies take precedence.

There are additional predefined roles that grant specific rights, such as the **Rescue always permit login** role that grants users the "rescue" right to log on if audit and monitoring service is required but not available. In general, at least one user should be assigned this role to ensure an administrator can log on if the audit and monitoring service service fails or a computer becomes unstable.

Delegating Administrative Tasks in Hierarchical Zones

You can use zones to delegate administrative tasks to specific users or groups. Using hierarchical zones, you can give separate groups of administrators the authority to manage a different sets of computers and users without granting them permission to perform actions on other computers, in other zones, or on other Active Directory objects. You can also use zones to establish a separation of duties so that only specific groups or users can perform certain tasks. For example, you can create a child zone for software-development and give the dev_mgrs group authority to manage rights and roles and manage role assignments on the computers in that zone.

By creating child zones and delegating administrative tasks within those zones, you can group computers that form a natural administrative set or that should be managed by different administrative teams. For example, you might want to group computers that are managed by a local support organization in one zone and computers that are managed by a corporate IT group in another zone. You can also control what different groups of users can do within each child zone. For example, you can set up regional zones to provide a separation of duties, authorizing users in San Francisco to manage computers in their local office while a team in Barcelona has authority to join computers to the zone and manage role assignments for offices located in Spain but does not have the authority to add users or groups.

Associating Computers and Role Assignments

You can use zones to associate a set of users with a particular role assignment to a particular set of computers. This association of a group of computers with a particular role assignment is called a **computer role**. For example, you might have several computers that are dedicated to a specific function, such as hosting Oracle databases, or to a functional area, such as payroll. Some groups of users who access these computers might require a specific set of rights. For example, the database administrators who access the computers hosting Oracle databases need different rights than users who are updating payroll records in the databases being hosted.

A computer role enables you to link the privileges associated with the database administrator role assignment, such as permission to backup and restore or create new tables, with the computers that host the Oracle databases. You can configure a separate computer role for the rights required by the users processing payroll on the same set of computers. The computer role creates the link between users with a specific role assignment, database administrator or payroll department, and the computers where that role assignment applies.

If you add an Oracle database server, you add it to the computer group. If new users are assigned the database administrator role, they automatically receive the appropriate access rights on the computers hosting Oracle databases.

You can also use computer roles to specify whether you want session-level auditing for a group of computers.

Creating a New Parent Zone

In most cases, you design a basic zone structure as part of the deployment process. After the initial deployment, you can create new hierarchical zones any time you have new administrative boundaries. For example, if you acquire another organization, add offices that are managed by a different group, or restructure the organization along different functional lines, you are likely to need new zones.

What to Do Before Creating a New Parent Zone

Before you can create parent zones, you must have installed Access Manager and run the Setup Wizard. You should also have a basic zone design that describes how you are organizing information, for example, whether you are using one top-level parent zone or more than one parent zone. There are no other prerequisites for performing this task.

Rights Required for this Task

Only the user who creates a zone has full control over the zone and can delegate administrative tasks to other users and groups through the Zone Delegation Wizard. To create new zones, your user account must be a domain user with the following permissions:

Parent container for new zones, for example: *domain*/Delinea/Zones	On the **Object** tab, select **Allow** to apply the following permission to this object and all child objects: Create Container Objects Create Organizational Unit Objects. **Note**: Both permissions are required if you want to allow zones to be created as either container objects or organizational unit objects.
Parent container for Computers in the zone	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create group objects Write Description property

> **Note**: If the Active Directory administrator manually sets the permissions required to create zones, you should verify that the account also has permission to add an authorization store, define rights and roles, and manage role assignments.

Who Should Perform this Task

A Windows domain administrator performs this task, depending on your organization's policies. The user who creates the zone is responsible for delegating administrative tasks to other users or groups, if necessary. In most organizations, this task is done using an account with domain administrator privileges.

How Often You Should Perform this Task

After you are fully deployed, you create new zones infrequently to address changes to your organization.

Steps for Completing this Task

The following instructions illustrate how to create a new parent zone using Access Manager. Examples of script that uses the Windows API are included in the *Software Developer's Kit* or may be available in community forums on the Delinea website. For code examples using ADEdit, see the *ADEdit Command Reference and Scripting Guide*.

To create a new parent zone using Access Manager:

1. Open the Access Manager console.
2. In the console tree, select **Zones** and right-click, then click **Create New Zone**.
3. Type the zone name and, optionally, a longer description of the zone.

   In most cases, you should use the default parent container and container type that you created when you configured the Active Directory forest, then click **Next**.

   For zones that include Windows computers, you should always use the **default zone type**, which creates the new zone as a hierarchical zone. For Windows computers, only hierarchical zones are supported. The only reasons for changing the default other settings would be if you want to:

   - Create a zone in a new location to separate administrative activity for different groups of administrators.
   - Create a zone as an organizational unit because you want to assign a Group Policy Object to the zone.
4. In most cases, you'll want to leave the **Skip permission delegation** option deselected. If you select this option, the service does not set the security descriptor for the zone; you'll need to go in and set that attribute yourself. Some organizations prefer to set security descriptors manually. Security descriptors include security information such as the object owner, who has access rights to the object, and so forth.
5. Review information about the zone you are creating, then click **Finish**.

What to Do Next

After you create a new parent zone, you might want to create its child zones.

Where you can find additional information

If you want to learn more about the importance and benefits of using zones, see the following topics for additional information:

- How zones organize access rights and roles
- Preparing to use zones

Creating Child Zones

For Windows, the primary reason for creating child zones is to inherit role definitions and role assignments from a parent zone. Less often, you might want to use a child zone to override role definitions and assignments that you have made in a parent zone. For example, if you have created a role definitions that allows a user to run a specific application with administrative privileges in a parent zone, you can use child zones to limit the scope of that right to specific subsets of computers.

What to Do Before Creating Child Zones

Before you create child zones, you must have installed Access Manager, run the Setup Wizard to create the Zones container, and created at least one parent zone. You should also have a basic zone design that describes the zone hierarchy for the child zone. There are no other prerequisites for performing this task.

Rights Required for this Task

Only the user who creates a zone has full control over the zone and can delegate administrative tasks to other users and groups through the Zone Delegation Wizard. To create new child zones, your user account must be a domain user with the following permissions:

Container for the parent zones, for example if the parent zone is berlin: *domain*/MyOU/Zones/berlin	On the **Object** tab, select **Allow** to apply the following permission to this object and all child objects: Create Container Objects Create Organizational Unit Objects. **Note**: Both permissions are required if you want to allow zones to be created as either container objects or organizational unit objects.
Parent container for Computers in the zone	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create group objects Write Description property These permissions are only needed if you are supporting "agentless" authentication in the new zone.

> **Note**: If the Active Directory administrator manually sets the permissions required to create zones, you should verify that the account also has permission to add an authorization store, define rights and roles, and manage role assignments.

Who Should Perform this Task

A Windows administrator performs this task, depending on your organization's policies. The user who creates the zone is responsible for delegating administrative tasks to other users or groups, if necessary. In most organizations, this task is done using an account with domain administrator privileges.

How Often You Should Perform this Task

After you are fully deployed, you create new child zones infrequently to address changes to the scope of ownership and administrative tasks.

Steps for Completing this Task

The following instructions illustrate how to create a new child zone using Access Manager.

To create a new child zone using Access Manager:

1. Open the Access Manager console.
2. In the console tree, expand **Zones** and individual zones to select the parent zone for the new child zone.
3. Right-click, then click **Create Child Zone**.
4. Type the zone name and, optionally, a longer description of the zone.

   Because this is a child zone, you should use the default parent container and container type, then click **Next**.
5. In most cases, you'll want to leave the **Skip permission delegation** option deselected. If you select this option, the service does not set the security descriptor for the zone; you'll need to go in and set that attribute yourself. Some organizations prefer to set security descriptors manually. Security descriptors include security information such as the object owner, who has access rights to the object, and so forth.
6. Review information about the child zone, then click **Finish**.

Opening and Closing Zones

Because properties and objects are organized into zones, you must open a zone to work with its contents. If you open a parent zone, its child zones are also available for you to use by default. If you open a child zone, you can choose whether to open its parent zone. Once you open a zone, it stays open until you close it and you can have multiple zones and zone levels open at the same time. If you have a large number of zones, you should close any zones you aren't actively working with for better performance.

As an alternative to opening individual or parent and child zones manually, you can automatically load all zones in a forest or all zones in a specific container at startup time. If you choose to load all zones, you cannot manually close zones.

To open an individual parent or child zone:

1. Open Access Manager.
2. In the console tree, select **Zones** and right-click, then click **Open Zone**.
3. Type all or part of the name of the zone you want to open, then click **Find Now**.
4. Select the zone to open from the list of results, then click **OK**. You can use the CTRL and SHIFT keys to select multiple zones.

After you open the zones you want to work with, you should save your changes when you exit the Access Manager console, so that the open zones are displayed by default the next time you start the console.

To close an open zone:

1. Open Access Manager.
2. Expand the zone hierarchy until you can select the specific zone name you want to close
3. Right-click, then click **Close**.
4. Click **Yes** to confirm that you want to close the zone.

To load all zones automatically:

1. Open Access Manager.
2. In the console tree, select Access Manager, right-click, then click **Options**.
3. On the **Filter Settings** tab, select **Load all zones**, then select **connected forest** to automatically load all zones in the forest or click **Browse** to navigate to specific container.

   Selecting this option prevents you from opening or closing any zones manually. You should not select the Load all zones option if you want to manually open and close individual zones for performance reasons.

Changing Zone Properties

After you create a zone, you can change its zone properties at any time. For example, if you want to change the parent zone for a child zone, you can do so by modifying the child zone's properties.

To change the properties for a zone:

1. Open Access Manager.
2. Expand **Zones** to display the list of zones, then expand the zone hierarchy until you see the zone you want to modify.
3. Select the zone, right-click, then click **Properties**.
4. On the General tab, you can view the location of the zone in Active Directory and the zone type.

   From the General tab, you can make the following changes:

   - Change the parent zone for a child zone.
   - Modify the zone description.
   - Select a specific Licenses container for the zone to use.
   - Configure the access control list of permissions for the zone.

For example, click **Browse** to find and select a new zone to use as the parent of a child zone, then click **OK** to save the new zone properties. For Windows computers, only the properties on the General tab are applicable.

Moving a Child Zone to a New Parent Zone

You can make an existing zone a child of another zone by dragging and dropping it from one zone to another or by changing the Parent zone field on the zone's Properties General tab.

If a child zone inherits role assignments from its parent zone, the console displays a warning message and prevents you from moving the zone until you have removed the role assignments. If moving the zone creates a circular hierarchy, the console prevents you from moving the zone.

Delegating Control of Administrative Tasks

If you are the creator of a parent or child zone, you can use the Access Manager console to give other users and groups permission to perform specific types of administrative tasks within each zone you create. For example, assume you have created a zone called Finance. Certain users or groups who access computers in that zone must be able to perform administrative tasks on their own without your help. You want to give them the permissions they require to accomplish specific tasks without turning over full control to anyone except your most trusted administrative staff. Using Access Manager and the Zone Delegation Wizard, you select the appropriate groups and users for the Finance zone and specify exactly what each do. For example:

- Members of the group Finance-ITStaff are allowed to perform All administrative tasks within the Finance zone. They can change zone properties, join and remove computers from the zone, define rights and roles, and assign roles to users and groups. Only your most trusted administrative staff are members of this group.
- Members of the group FinanceManagers are allowed to join and remove computers from the zone and assign roles to users and groups.
- Members of the group FinanceUsers are allowed to add users, add groups, and join computers to the zone, but perform no other tasks.
- The users jason.ellison and noah.stone have permission to remove computers from the zone.

In most cases, each zone should have at least one Active Directory group that can be delegated to perform all administrative tasks, so that members of that group can manage their own zone. You are not required to create or use a zone administrator group for every zone. However, assigning the management of each zone to a specific user or group creates a natural separation of duties for administrative tasks.

If you delegate control for individual tasks—for example, by assigning only the join computers task to one group and only the add and remove users tasks to another—you should ensure the members of each group know the tasks they are assigned.

You can delegate administrative tasks for parent zones, for child zones, and for individual computers. Because computer-level overrides are essentially single computer zones, you can assign administrative tasks to users and groups at the computer level.

To delegate which users and groups have control over the objects in a zone:

1. Open Access Manager.
2. Expand **Zones** to display the list of zones, then expand the zone hierarchy until you see the specific zone you want to modify.
3. Select the zone, right-click, then click **Delegate Zone Control**.
4. Click **Add** to find the users, groups, or computer accounts to which you want to delegate specific tasks.
5. Select the type of account—**User**, **Group**, or **Computer**—to search for, type all or part of the account name, then click **Find Now**.
6. Select one or more accounts from the list of results, then click **OK**.
7. Repeat Step 4 through Step 6 until you are finished adding users and groups to which you want to assign the same administrative tasks, then click **Next**.
8. Select the tasks you want to delegate to the user or group, then click **Next**.

   For example, if you want all of the members of the group you selected in the previous steps to be able perform all administrative tasks for a zone, select **All**.
9. If you are delegating the task of joining computers to a zone, you can specify the scope of computers you can join to the zone; you pick a container in Active Directory to grant access to.

   If you leave the scope blank, the scope is the domain root. Be aware that the postalAddress field is used for information about joining computers to a zone; if you lookup the permissions for people you've delegated the task of joining computers to a zone, they'll have permissions to the postalAddress field for the affected computers.

10. Review your delegation settings, then click **Finish** to close the wizard.

Granting the Authority to Perform All Administrative Tasks

Only the administrator who creates a zone has full control over the zone's properties and only that administrator can delegate administrative tasks to other users. For each zone you create, you should identify at least one user or group that can be delegated to perform all administrative tasks. For example, if you have a Finance zone, you may want to create a Finance Admins group in Active Directory and then delegate **All** tasks to that group so that members of that group can manage the zone.

Although you are not required to create or use a zone administrator group for every zone, assigning the management of each zone to a specific user or group simplifies the delegation of administrative tasks.

If members of the designated administrative group must be able to create parent or child zones, they should be assigned the rights described in Creating a new parent zone and Creating child zones.

Restricting Authority to Specific Administrative Tasks

You can use the Zone Delegation Wizard to set up fine-grain control over the specific administrative tasks different sets of users or groups can perform. For example, you can choose to grant the Join Operators group permission to join computers to the zone and no other tasks. You can then specify another group is only allowed add and remove users. If you choose to use fine-grain control over specific administrative tasks, you should ensure the members of those groups know their restricted authority.

> **Note**: If you delegate administrative tasks to one or more groups that have members logged on, you should inform the group members that they should log out and log back on so that they can perform the administrative tasks assigned to the group.

Adding Windows Computers to a Zone

To use identity and privilege management features, a Windows computer must have the Agent for Windows installed, be joined to an Active Directory domain, and joined to a zone. Depending on your organization's policies, you can either allow any authenticated user with a valid domain account to join a zone or require a domain administrator account to join a zone.

If you want to have individual users deploy the Agent for Windows on their own computers and join a zone without administrative rights, you can prepare the zone in advance and let users know which zone to join. If only domain administrators are allowed to join computers to zones, you should log on to computers with the Agent for Windows installed using an account that has appropriate administrative rights and provide a password.

Preparing Windows Computer Accounts

If joining a zone is restricted to privileged users, you may want to prepare a computer account in the zone before joining. By preparing the computer account before joining, users can add their computers to the zone without any special rights or permissions in Active Directory.

To prepare a Windows computer account using Access Manager:

1. Open Access Manager.
2. Expand **Zones** to display the list of zones, then expand the parent and child zone hierarchy until you see the specific zone to which you want to add the computer account.
3. Right-click, then click **Prepare Windows Computer**.
4. Click **Find Now** to search for and select the computer account to add to the selected zone.
5. Click **OK** to add the computer account to the Access Manager console in the zone's Computers container.
6. A dialog box displays that asks if you want to skip permission delegation when creating the computer. In most cases, click **No**.

   If you click Yes, the service does not set the security descriptor for the zone; you'll need to go in and set that attribute yourself. Some organizations prefer to set security descriptors manually. Security descriptors include security information such as the object owner, who has access rights to the object, and so forth.

Changing the Zone for the Computer

You can move computer accounts from one zone to another at any time, if needed. Users who have administrative privileges can change the current zone on

their local computer using the agent configuration panel. You can also change the zone information for a computer from Access Manager by changing its Active Directory properties or by dragging and dropping the computer from its current to a new zone.

To change the zone for a computer using Access Manager and Active Directory properties:

1. Open Access Manager.
2. Expand **Zones** to display the list of zones, then expand the zone hierarchy until you see the specific zone you want to modify.
3. Expand **Computers** to display the list of computers in the zone.
4. Select the computer that you want to modify, then right-click and select **AD Properties**.
5. Click the **Windows Profile** tab.
6. Click **Browse** and type all or part of the zone name, then click **Find Now**.
7. Select the new zone for the computer from the list of results, then click **OK**.
8. If the computer has role assignments defined, Access Manager prevents you from moving the computer until you remove the role assignments.

Leaving a Zone

You can remove a computer from a zone at any time. Users who have administrative privileges can leave the current zone on their local computer using the agent configuration panel. You can also remove the zone information for a computer from Access Manager by deleting the computer from its current zone. Leaving the zone does not remove the computer object from Active Directory.

To remove a computer from a zone using Access Manager:

- Open Access Manager.
- Expand **Zones** to display the list of zones, then expand the zone hierarchy until you see the specific zone you want to modify.
- Expand **Computers** to display the list of computers in the zone.
- Select the computer that you want to remove from the zone, right-click, then select **Delete**.
- Click **Yes** to confirm the removal of the computer from the zone.

Renaming a Zone

You can rename a zone at any time. For example, if your organization changes how business units are aligned, moves to a new location, or merges with another organization, you might want to update zone names and descriptions to reflect these changes. You might also want to rename zones if your initial deployment did not use a naming convention for new zones, and you want to implement one after you have agents deployed.

What to Do Before Renaming a Zone

Before you rename zones, you might want to define and document a naming convention to use for future zones or the reasons for changing the zone name. You should also identify the computers in the zone to be renamed. You do not need to restart the agent on Windows computers for the new zone name to be recognized. However, you might need to perform other administrative tasks—such as changing role assignments—after renaming a zone. There are no other prerequisites for performing this task.

Rights Required for this Task

To rename a zone, your user account must be set with the following permissions:

Parent container for an individual zone For example, a ZoneName container object, such as: *domain*/Zones/arcade	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Write Description Write name Write Name These are the minimum permissions required to rename a zone and not allow a user or group to modify any other zone properties. You can set permissions manually, or automatically grant these and other permissions to specific users or groups by selecting the **Change zone properties** task in the Zone Delegation Wizard.

Who Should Perform this Task

A Windows administrator performs this task, depending on your organization's policies. The user who creates the zone is responsible for delegating administrative tasks to other users or groups, if necessary. In most organizations, this task is done using an account with domain administrator privileges.

How Often You Should Perform this Task

After you are deployed, you rename zones only when you need to address organizational changes or to implement or improve the naming conventions you use.

Steps for Completing this Task

The following instructions illustrate how to rename a zone using Access Manager.

To rename a zone using Access Manager:

1. Open Access Manager.
2. Expand **Zones** to display the list of zones, then expand any child zones in the zone hierarchy until you see the specific zone you want to modify.
3. Select the zone to change, right-click, then click **Rename**.
4. Type the new name and, if needed, any changes to the zone description.

   You do not have to restart any Agents on the computers in the zone you have renamed. Computers will remain joined to the zone even after changing the zone name.
5. Users who have administrative privileges can verify the updated zone name on their local computer using the agent configuration panel.

Working Directly with Managed Computers

When you deploy a Agent on a computer, that computer has tools installed locally to allow you to manage access, troubleshoot agent operations, and view information about roles and role assignments, and auditing status.

Depending on the rights associated with the role you are using, you can use the tools on the managed computer to open new desktops, run individual applications with elevated privileges, connect to services on remote computers, join or change the zone for a computer, set the level of detail to record in log files, generate diagnostic information for the agent, and view detailed information about your own or other users' effective rights and roles.

Using the Agent Configuration

The Agent for Windows provides an agent configuration panel from which you can configure agent settings for the Privileged Access Service, Privilege Elevation Service, and Audit & Monitoring Service. If you have the appropriate privileges, you can use the agent configuration panel to select the zone for a computer to join, change the current zone, or remove a computer from a zone.

To use the agent configuration panel to select the zone for a local computer:

1. Log on to a computer where the Agent is deployed.
2. From the Windows Start menu, select **Agent Configuration**.
3. Click **Privilege Elevation Service**.
4. Click **Settings**.
5. On the General tab, click **Change**.
6. Click **Browse**, type all or part of the zone name, and click **Find Now** to search for the zone.
7. Select the new zone in the search results, click **OK**, then click **OK** to return General tab.
8. Click **Close** to return to the agent configuration panel.

You can also use the agent configuration panel to set logging level, view logs, and get diagnostic information about agent operations. For more information about using the agent configuration panel to configure logging and get diagnostic information, see Troubleshooting and common questions.

If you allow users to join their own computers to a zone, you should notify them of the zone to use and see that they have access to the User's Guide for Windows.

Working with Zone Role Workflow

You can enable zone role workflow in the Admin Portal so that your users can request access to systems in particular zones. Enabling zone role workflow requires having a Connector installed in the domain. For improved performance, you can also install the Client with the CSS Extension on the affected systems.

For details about how to enable zone role workflow, see Working with zone role workflow

Using Zone Role Workflow with the Connector

If you set up zone role workflow with just the Connector, be aware that there will be a delay between when the approver approves the request and when the user can access the affected systems. Although the Connector updates Active Directory immediately after the approver approves the request, a delay occurs because it can take some time to replicate the Active Directory information and also because the Agent reloads authorization information from Active Directory at specified intervals.

Using Zone Role Workflow with the Client

If you set up zone role workflow and also install the Client (so that you'll have installed both the Agent and the Client) and enable the CSS Extension on the Client, then there is no delay. Once the designated approvers approve the request, the user can access the specified system(s) immediately. The Client uses the client channel in the background to securely communicate with the Agent.

> **Note**: For deployments that have zone role workflow enabled for use with the Client, the affected systems must have Python 3.4 or later installed.

This chapter describes how to establish role-based access controls for the computers that have the Agent for Windows installed and identity and privilege management features enabled.

Basics of Authorization and Access Rights

You can use Access Manager to centrally manage what users can do on computers that have the Agent for Windows installed. For example, you can control who can log on or connect remotely for each computer in a zone through the assignment of roles. As discussed in Managing access rights and roles using zones, a **right** represents a specific operation that a user is allowed to perform.

System Rights Allow Users to Log On

For Windows computers, the most basic rights are the system rights that determine whether a user can log on locally, log on remotely, or both. The rights that grant users local and remote access are defined by default in the Windows Login role so that you can grant users access simply by assigning the Windows Login role and without defining any custom roles or any additional access rights. You can enable or disable these system rights in any custom role definition, but you cannot add, modify, or delete them.

In most cases, you can assign the Windows Login role to all local Windows users, all Active Directory users, or both, to allow users to log on locally or remotely. However, the system rights in the Windows Login role do not override any native Windows security policies. For example, most domain users are not allowed to log on locally on domain controllers. Depending on how your organization has configured native Windows security policies, users might need to be members of a specific Windows security group, such as Server Operators or Remote Desktop Users, to log on to specific computers locally or remotely.

If you would like to require multi-factor authentication for users or groups that use Delinea-managed Windows computers, you must assign them the **require MFA for login** role in addition to the Windows Login role as there is no system right to enable multi-factor authentication within the Windows Login role.

If you enable multi-factor authentication, users will be required to type their password and provide a second form of authentication before being able to log on. For example, you can configure an authentication profile that requires users to answer a phone call, click a link in an email message, respond to a text message, provide a one-time password (OTP) token, or answer a security question. Before defining this system right, however, you should be aware that multi-factor authentication for Delinea-managed Windows computers relies on the infrastructure provided by the Privileged Access Service.

For more information about preparing to use multi-factor authentication, see the Multi-factor Authentication Quick Start Guide.

In addition to the system rights that specify whether a user can log on locally or remotely, you can use the **Rescue rights** setting to specify that users in a particular role should always be allowed to log on to a computer. This option is intended as a "safety net" for "emergency" situations when users would normally be locked out. For example, if auditing is required for a role, but the agent is not running or has been removed, users are not allowed to log on. You can use the rescue rights option to allow selected administrative users access to computers when they would otherwise be locked out and prevented from logging on. Because this option allows unaudited activity, you should strictly limit its use.

> **Note**: If you do not explicitly set the Rescue rights option for any users, only the local administrator and the domain administrator accounts will have rescue rights. Those accounts are always allowed to log on by default.

Windows-specific Rights Can Grant Users Privileged Access

In general, you use the default Windows Login role for most users during the initial deployment to prevent disruptions in user access. You can then define custom roles to add specialized access rights to grant users additional privileges in a controlled manner.

For Windows computers, these specialized access rights are:

- **Desktop** access rights enable users to create additional working environments and run applications in that desktop with their own credentials but as a member of an Active Directory or built-in group. Users who are assigned to a role with desktop rights can switch from their default desktop to a desktop with administrator privileges without having to enter an Administrator password. With a desktop right, users can also run any application from their default desktop using a selected role and credentials without opening a new desktop.
- **Application** access rights enable users to run specific local applications as another user or as a member of an Active Directory or built-in group. Users who are assigned to a role with application rights can log on with their normal Active Directory credentials and run a specific application using a role with elevated privileges without having to enter the service account or Administrator password.
- **Network** access rights enable users to connect to a remote computer as another user or as a member of an Active Directory or built-in group to perform operations, such as start and stop services, that require administrative privileges on the remote computer. Users who are assigned to a role with network access rights can perform administrative operations on a remote server using a role with elevated privileges that only applies to the operations performed on the network computer without having to enter the service account or Administrator password. You can use zones to control who can connect and perform tasks on remote computers and what their elevated privileges allow them to do.

Combining Rights into Roles and Role Assignments

You can combine the system rights and specialized Windows rights into **role definitions** that reflect the needs of a specific job function, such as database administrator or web services administrator, or a particular task, such as troubleshooting application failures. You can then assign those roles to specific users and groups.

You can configure rights, role definitions, and role assignments in any parent or child zone. In most cases, you define rights and roles in a parent zone and make role assignments in a child zone.

Roles can be assigned to individual Active Directory users or to Active Directory groups. Therefore, you can manage how roles are applied to users completely through Active Directory group membership.

The rights from multiple role assignments accumulate, which provides great flexibility and granularity in how you define and assign rights and roles. For example, you can use the Windows Login role to control console and remote access, and define a second role with desktop access rights so that a user assigned to both roles could log in and create another desktop for accessing applications with administrative privileges. By separating login and desktop access rights into separate roles, not every user who is allowed to log on can create a desktop with administrative privileges.

Deciding Where to Define and Assign Roles

Because access rights are additive, it is important to consider where you define and assign roles to control who has administrative privileges on which computers. For example, it might seem reasonable to assign the predefined Windows Login role to all Active Directory users. Doing so, however, could grant broad permission to log on locally or remotely on computers to which you want to restrict access. If you assign that role in a parent zone, it is inherited along with any additional rights granted in child zones.

In most cases, it is appropriate to define roles in parent zones, but assign roles carefully in child zones to avoid granting access rights on computers that host administrative applications or sensitive information.

Adding Predefined Rights to a Zone

There are many predefined rights available that grant access to specific Windows applications. For example, there is a predefined Performance Monitor right that allows users to run Performance Monitor on a computer without being a local administrator or knowing an administrative password.

You can add any or all of these predefined rights to any zone so they are available to include in role definitions. Alternatively, you can add predefined rights to individual role definitions without adding them to zones. In either case, you create the predefined rights in the context of a role definition.

To create predefined rights in a zone:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to define a predefined right.
3. Expand **Authorization > Role Definitions**.
4. Select a role definition, right-click, then select **Add Right**.
5. Select a type of right if you want to filter the list of rights displayed.

   For example, select Any Windows Rights or Any Windows Applications to list only Windows-specific rights.
6. Click **Create Predefined Rights**.
7. Select the specific predefined rights you want created in the zone you selected in Step 2 from the list of available rights, then click **OK**.

   By default, all of the selected predefined rights are added to the role definition in the zone. You can deselect any of the rights you don't want added to the role definition.
8. If you have selected at least one of the predefined rights as applicable for the role definition, click **OK**.

   If none of the predefined rights is applicable for the role definition, you can click **Cancel** to add the rights to the zone without adding them to the role definition.

You can click **Refresh** in Access Manager to see the predefined rights listed as Windows application rights.

Enabling Multi-factor Authentication for Windows Rights

In addition to the **require MFA for login** role, which requires users to provide both their password and a second form of authentication to log on to a Delinea-managed Windows computer, you can enable multi-factor authentication for a predefined right. When you define a desktop, application, or network access right, you can choose to enable multi-factor authentication for that right. For example, if you want to require multi-factor authentication before a user can open a privileged desktop, you would issue that user a role with a predefined desktop right that has multi-factor authentication enabled.

To enable multi-factor authentication for a right definition:

1. Right-click the predefined right after adding it to a role definition.
2. Select **Properties**.
3. Click the **Run As** tab and select **Re-authenticate current user** and **Require multifactor authentication**.

   Note: Before defining this right, you should be aware that multi-factor authentication for Delinea-managed Windows computers relies on the infrastructure provided by the Privileged Access Service.
4. Click **OK**.

Using Multi-factor Authentication When There are Selective Cross-forest Trusts

If you have domains in different forests that have a two-way selective trust relationship, any computer or user accounts that are used to log on to the remote forest must be granted the "Allowed to authenticate" right on the domain controllers in both forests to get role information.

In addition to granting the "Allowed to authenticate" right to users and to computers with the Agent for Windows installed, the right must also be granted to computers that host your connectors.

After you grant these computers and users the "Allowed to authenticate" right for the domains in both forests, users that are assigned a role with a multi-factor authentication right for privilege elevation will be able to authenticate using any of the authentication mechanisms that you have assigned to them.

If a connector is not allowed to authenticate on the remote domain controller, some multi-factor authentication mechanisms may fail to authenticate users.

For more information about preparing to use multi-factor authentication, see the Multi-factor Authentication Quick Start Guide.

Defining Desktop Access Rights

When users log on with their normal Active Directory credentials, Windows brings up the **default desktop** for the user logging on. You can define desktop rights to enable users to create additional working environments—new desktops—that run using their own credentials but with the privileges of an Active Directory or built-in group.

Users who are assigned to a role with desktop rights can switch from their default desktop to a desktop with elevated privileges to perform administrative tasks. For example, if assigned to a role that has a desktop right, a user can create a new desktop and switch to it when he needs perform administrative tasks such as install new software or stop running services on the local computer account. The user can perform these tasks without having to enter the service account or Administrator password.

Users who are assigned a role with desktop rights can also select any application on the computer, right-click, and run the application using a selected role. The difference between the desktop right and an application right is that the desktop right allows the user to run any applications using the privileged account defined in the desktop right. An application right restricts access to a specific application using the privileged account explicitly defined for that application.

Desktop rights are useful for users who frequently perform tasks that require the privileges associated with the Administrator account.

To define a desktop right:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to define a desktop right.
3. Expand **Authorization > Windows Right Definitions**.
4. Select **Desktops**, right-click, then click **New Windows Desktop**.
5. On the General tab, type a name and a description for the desktop right.

Name	Type the name you want to use for this desktop right. For example, if the desktop allows a user to create a desktop using the privileges associated with a service account, you might include the security group in the name.
Description	Type a description for this desktop right. The description is optional. You can use it to provide a more detailed explanation of the privileges associated with the desktop.
Priority	Set the priority for this desktop right.

1. Click the **Run As** tab.

   You can browse for and select a specific group that will allow you to log on with your own credentials but with the elevated privileges of the specified group.

   Click **Add AD Groups** or **Add Built-in Groups** to search for and select a previously-defined or built-in group with the privileges you want to add to the logged in user's account.

   Select **No re-authentication required** to allow users to use the desktop right without any additional authentication.

   Select **Re-authenticate current user** if you want to prevent the desktop right and its privileges from being used by anyone not authorized to do so. Selecting this option also allows you to enable multi-factor authentication for the right. For more information, see Enabling multi-factor authentication for Windows rights.

   If you select the Re-authenticate current user option, users are prompted to re-enter their password to verify their identity before they are allowed to create a new desktop or switch between desktops. Forcing users to re-authenticate ensures the privileges associated with the desktop are only granted to users who have been assigned those privileges.

   If you select this Re-authenticate current user option for users who are authenticated using a smart card, users must enter a personal identification number (PIN) or a password to resume working with the desktop.

2. Click **OK** to save the desktop right.

Where Desktop Rights Apply

Desktop rights can be used on Windows servers and workstations that have a traditional Windows desktop. If the computer you are using is running Windows 8 or 8.1, or Windows Server 2012 or 2012 R2, Windows does not provide access to applications natively when you switch from the default desktop to a privileged desktop due to changes to the underlying interfaces and supported features within the operating system. To enable access to applications on computers running these versions of Windows, the Agent for Windows provides a custom start menu. The start menu allows you to open and run applications as you would on Windows 7 or Windows Server 2008 R2. The start menu is installed on the left side of the taskbar and displays the Delinea logo. This start menu is only available if you are using a role with Delinea desktop rights and cannot be modified.

Defining Application Rights

Application rights allow users to run specific applications using either another user account or using their own credentials but with the privileges of an Active Directory or built-in group.

When you create an application right, you specify one or more application executable files to which you want to control access. The capability to specify more than one executable file in a single application right takes into account situations in which one application might reside in different locations on different computers. For example, the executable file for SQL Server Management Studio resides in different locations in Windows 2005, Windows 2008, and Windows 2012. By specifying all instances of the executable file in one application right, you can use that application right to control access to SQL Server Management Studio on computers running any of those operating systems.

You can also use Delinea application utilities to allow access to common administrative tasks such as software installation, network, and Windows feature management. For more information on using these utilities, see Using Delinea application utility rights

> **Note**: Although it is possible to define different applications (for example, SQL Server Management Studio and Internet Explorer) in one application right, this is not a recommended practice. Instead, it is recommended that you create separate application rights for different applications.

How to Specify Which Applications are in an Application Right

You can specify which application executable files are in an application right in these ways:

- You can specify the path and file name of an application executable file. You can perform this operation in two ways:
  - Manually, by typing or pasting the path and file name into an application right definition form. Specifying files manually is recommended only if you need to include a small number of files in the definition—typically just one or two. See Defining an application right manually for more information.
  - By navigating to the executable file or a running process that was launched by the executable file. After locating the executable file, you can import the path and file name into the application right definition form. See Using an installed application or running process to create application rights for more information.
- You can specify search criteria for application executable files, and then include all application executable files that match those criteria in the application right. You can perform this operation in two ways:
  - Manually, by typing or pasting values into search criteria fields. See Defining an application right manually for more information.
  - By importing values into search criteria fields from an executable file or from a running process that was launched by the executable file. See Using an installed application or running process to create application rights for more information.

See Examples of application right definitions for examples of defining application rights in all of these ways.

Defining an Application Right Manually

This section describes how to create an application right by manually typing or pasting information into several application right definition forms.

> **Note**: Alternatively, you can import information into application right definition forms from an executable file or from a running process that was launched by the executable file. See Using an installed application or running process to create application rights for more information.

To define an application right manually:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to define an application right.
3. Expand **Authorization > Windows Right Definitions**.
4. Select **Applications**, right-click, then click **New Windows Application**.
5. On the General tab, type a name and a description for the application right, and specify a priority for the application right.

Name	Type the name you want to use for this application right. For example, if the right allows a user to run SQL Server Configuration Manager using the privileges associated with a security group, you might include the service account in the name. For example, you might use a name like SQL Config Manager.
Description	Type a description for this application right. The description is optional. You can use it to provide a more detailed explanation of the privileges associated with running the application.
	Set the priority for this application right. If more than one application right is added to the same role definition, the priority value determines the application right to use when users assigned to that role open that application. The lower the value, the higher the priority. For example, a right with the priority of 1 takes precedence over a priority value of 2. If the application rights have the same priority value, the application right listed first under the role definition is used.

1. Click the **Match Criteria** tab and use it to create or edit application definitions. Each application definition specifies one application or a group of applications. The set of application definitions displayed in the **Match Criteria** tab defines the set of applications that can be run by this application right.

   In the **Match Criteria** tab, click **Add** to create a new application definition.

   The Definition Settings dialog appears.

2. In the upper portion of the Definition Settings dialog, provide this information about the application definition.

	Type a description for this application definition. For example, if the definition specifies one executable file (such as SQL Server Management

Description	Studio for Windows 2005), you might type **Windows 2005 SQL Server Management Studio** here. Or, if the definition specifies more general criteria so that multiple executable files (such as SQL Server Management Studio for all versions of Window) can run, you might type a more general description such as **SQL Server Management Studio**.
File Type	Select the type of executable file for this definition. If you are constructing the definition so that it specifies multiple executable files, all files must all be of the type that you specify here. Supported file types are: .bat .cmd .com .cpl .exe .msc .msi .msp .ps1 .vbs .wsf

1. To specify executable files in this definition by typing or pasting the file name and location, select the **Path** option. Go to Step 9 and continue from there.

   Specifying files in this way is recommended only if you need to include a small number of files in the definition—typically just one or two.

   To specify a larger number of executable files in this definition, it is recommended that you select file parameters that are common to the set of files. Files that match the parameters are then included in the definition. To do this, go to Step 10 and continue from there.

2. Perform this step to specify a small number of executable files in this definition. In this step, you type or paste information about the executable file name, location(s), and arguments. When you are done with this step, go to Step 11 and continue from there.

Name	Type the name of the application executable file. If this field is defined, you must also select a path option (standard system path or a specified path). For example, to specify the SQL Server Management Studio executable, type Ssms.exe.
Standard system path	Select **Standard system path** to use the directories where the user would normally find the application specified. For example, to use the application executable in its default directory, select **Standard system path**.
Specify path	Select **Specify path** if you want to define the location of the application specified. If you select this option, you can specify one or more paths, separated by a semicolon (;). Supported path variables are %systemroot%, %system32%, %syswow64%, %program files%, %winagentinstall%, and %program files(x86)% (note that a space between "program" and "files" is required). For example, to specify the location of the SQL Server Management Studio executable file in Windows 2008, type C:\Program Files (x86)\Microsoft SQL Server\100\Tools\Binn\VSShell\Common7\IDE.
Arguments	If you selected a file type of .msc in Step 7, the **Arguments** option is required. The **Arguments** option is optional for all other file types. Select the **Arguments** option and leave the argument field blank to specify that the application cannot accept any arguments. To specify that the application can run using any argument, leave the Arguments option deselected. For example, if you specified the SQL Server Management Studio executable and left the **Arguments** option deselected, users can run SQL Server Management Studio with any option on a local computer with elevated privileges. If you want to restrict the arguments allowed, in the argument field type the list of arguments to allow. Valid arguments be must enclosed by quotation marks and separated by a space. For example, to allow users to run the specified application using argument1, argument2, or argument3, you would specify the list of arguments like this: "argument1" "argument2" "argument3" By default, arguments that you specify do not need to be a case-sensitive match, but do need to be an exact match (that is, a match is returned if the actual argument is a partial match of the argument string that you specify). If arguments must be a case-sensitive match for a particular application, select the **Keep arguments case sensitive** option. If arguments can be a partial match for a particular application, deselect the **Match whole string only** option.

1. Perform this step to specify a larger number of executable files in this definition. In this step, you use the **File details** area to specify characteristics that are used to search for applications to include in this definition. All of the characteristics that you specify must be met in order for an application to be a match. For example, if you specify a product name of Microsoft SQL Server and a company name of Microsoft Corporation, all executable files that meet both of those criteria are included in this definition.

   Note: This step describes how to manually fill in each field in the **File details** area. You can select any combination of these fields to specify the file characteristics for which to search. Alternatively, you can populate fields in the Definition Settings dialog by importing values from an installed executable file or from a running process. Filling in fields by importing is faster and more accurate than filling in fields manually one at a time. For details about filling in fields by importing, see Using an installed application or running process to create application rights.

Product Name	Select an operator (is or contains) from the drop-down list and in the provided field type the product name for which to search. If you select is, matches are returned for product names that exactly match the string that you type here. If you select contains, matches are returned for product names that contain the string that you type here anywhere in the product name.
Company	Select an operator (is or contains) from the drop-down list and in the provided field type a company name for which to search.
File Description	Select an operator (is or contains) from the drop-down list and in the provided field type a file description for which to search.
Volume Serial #	Select an operator (is, contains, starts with, or ends with) from the drop-down list and in the provided field type a serial number for which to search. The supported format is 8-character hex string (FFFFFFFF). This criterion is matched only if the executable file was from CD/DVD media.
Publisher	Select an operator (is, contains, starts with, or ends with) from the drop-down list and in the provided field type publisher information for which to search. For example, publisher information could look similar to: CN=Acme Corporation, OU=Digital ID Class 3 - Microsoft Software Validation v2, O=Acme Corporation, L=Sunnyvale
Product Version	Select an operator (equal, earlier or equal, or later or equal) from the drop-down list and in the provided field type product version information for which to search. For example, the product version could look similar to: 3.1
File Version	Select an operator (equal, earlier or equal, or later or equal) from the drop-down list and in the provided field type file version information for which to search. For example, the file version could look similar to: 3.1.2
File Hash	Select this option to match applications using the encrypted file hash for the application. The file hash for the application is generated using the SHA-1 encryption algorithm, which is FIPScompliant. You can click **Import Process** or **Import File** and select an application to populate the File Hash field for which to search. Only applications with a hash string that is exactly the same as the string generated by the MD5 algorithm are matched. You can only use file hash matching to identify an application for files that are less than 500MB to limit the CPU and memory used to calculate the file hash. If the file with matching hash information is larger than 500MB, an empty value is returned for the file hash field.
Owner	In the provided field, type owner information for which to search. Matches are returned for owner information that exactly matches the string that you type here. Owner information can be: AD user/group/builtin (SID) local user (user name) local group (group name) For example, the owner could look similar to: NT AUTHORITY\SYSTEM DEMO\Ed.Admin (this is an AD user account) Amy Adams (this is a local user account)

1. Optionally select the **Application requires administrative user** option to specify that applications in this definition run only if RequestedExecutionLevel is set to requireAdministrator in the application manifest. If you select this option, the applications in this definition run only for administrators and require that the applications be launched with the full access token of an administrator. This option applies only to .exe files.
2. Click **OK** to save the definition. You are returned to the **Match Criteria** tab, and the new or modified definition appears in the **Match Criteria** list of definitions.
3. Click the **Run As** tab and select the account that has the privileges you want to enable for this application right.

   You can browse for and select a specific user account or have the application run using the logged in user's account credentials but with the elevated privileges of a specified group. Click **Add AD Groups** or **Add Built-in Groups** to search for and select a previously-defined or Built-in group with the privileges you want to add to the logged in user's account.

   In most cases, you select a specific user account only if the application should run as a service account. However, some applications require a specific privileged user account to be used. For example, Microsoft System Center Operations Manager (SCOM) and Exchange require a user account. If you are defining an application right for an application that requires a privileged user account rather than membership in a privileged group, you should create a service account and use that account for the run-as account.

   Select **Re-authenticate current user** if you want to prevent the application right and its privileges from being used by anyone not authorized to do so. Selecting this option also allows you to enable multi-factor authentication for the right. For more information see Enabling multi-factor authentication for Windows rights.

   If you select this option, users are prompted to re-enter their password to verify their identity before they are allowed to select a role for running a local application. Forcing users to reauthenticate ensures the privileges associated with the application right are only granted to users who have been assigned those privileges.

If you select this option for users who are authenticated using a smart card, users must enter a personal identification number (PIN) or a password to resume working with the application.

4. Click **OK** to save the application right.

Using Application Utility Rights

This section describes how you can manage user access to Windows programs and features using application utility rights.

There are many common administrative tasks such as managing software installations, changing network settings, and adding or removing Windows features that require access to the explorer.exe application on Windows systems. Because granting users privileged access to explorer.exe can allow the user to perform many other tasks that you may want to remain restricted, you can use the Delinea application utilities, **Application Manager**, **Network Manager** and **Windows Feature Manager**, to grant access to these tasks using the corresponding predefined rights.

When you create a new zone, the Delinea utility rights are automatically added to the list of Windows Right Definitions. However, in zones that existed before the addition of these utility rights, you may need to add them by following the procedure below.

To add the Delinea Utilities to the list of Windows Right Definitions

1. Right click **Windows Right Definitions** and select **Add predefined rights**.

   Windows Right Definitions can be found in the following location:

   The application rights can be found in the following location:

   Access Manager > Zones > Zone Name > Authorization > Windows Right Definitions

2. Select the rights you would like to add and click **OK**.

   The rights will now appear under **Applications**.

It is important to note that if you do not install the Agent for Windows in the default location during the installation or upgrade process, users who are assigned these rights may not be able to access the corresponding applications. If you have installed the agent in a location other than the default location, you can specify a variable in the application right settings to allow them to be used by assigned users by doing the following:

To specify the application right path

1. Right click on the application right and select **Properties**.

   The application rights can be found in the following location:

   Access Manager > Zones > Zone Name > Authorization > Windows Right Definitions > Applications.

2. Click the **Match Criteria tab**, and then click **Edit.**
3. Check the **Path** box in the **Commands components** section, and select **Specific path**.
4. In the **Specific path** field, enter the following variable: %winagentinstall%

Do this for each of the Utility application rights.

Application Manager

Application Manager is a utility that allows a user to manage installed software. Application Manager is similar to the Windows utility Programs and Features. It can allow users who are assigned a role with the **Utility - Application Manager** right to Refresh, Uninstall, Change, or Repair installed software.

Windows Feature Manager

When you assign workstation users a role with the predefined right **Utility - Windows Feature Manager**, they will be able to access the normal Windows Feature Manager, where they can choose what Windows features to add or remove.

When you assign server users a role with this right, the Windows Feature Manager will launch. This utility is similar to the normal Windows utility, with a few notable differences.

Opening the utility will launch a wizard. When you select whether to add or remove roles and features on the first screen of the wizard, you can only perform one action at a time. For example, if you choose **Add roles and features**, you will not be able remove any installed features until you go back to the initial screen and choose **Remove roles and features**.

Additionally, when you attempt to install features that require the installation of dependent components, you will be prompted to add those features. All features with one or more components installed will appear with a check mark next to the name.

Network Manager

When you assign users a role with the predefined right Utility - Network Manager, they will be able to access the Delinea version of Network Manager that is similar to the Windows version.

Users assigned a role with this right can view a list of network adapters for Ethernet and wireless connections and configure their IP and DNS settings.

Using an Installed Application or Running Process to Create Application Rights

This section describes how to create an application right by importing values from an installed executable file or from a running process. After values are imported into the application right definition form, you can select which fields to use as search criteria for matching applications. Applications that match the search criteria are included in the application definition.

For more information about filling in fields by importing, see Examples of application right definitions.

To define an application right based on an installed application:

1. Follow the procedure for creating a new application right manually to the point where the Definition Settings dialog opens (see Defining an application right manually).
2. In the Definition Settings dialog, click **Import File**.
3. Navigate to an application executable file, highlight the file, and click **Open**.

   Fields in the Definition Settings dialog fill in with all of the information that is available for the file that you selected. For example, if you navigated to C:\Program Files\Centrify\Access Manage and selected the Mmc_config.exe file, the Definition Settings dialog would look similar to this:

   Notice that:

- The **File Type** field is set to .exe.
- The **Path** option is selected, and the file name and path name are filled in.
- Most fields in the **File details** section are filled in, but none are selected.

  The settings shown in this example specify that only the Mmc_config.exe <!---TODO update path ---> file located in C:\Program Files\Centrify\Access Manage is included in the application right. The information in the **File details** section is not used because no options in that section have been selected.

4. Choose whether to expand the definition to include other executable files, or to save the definition as it is currently defined (so that it specifies only the Mmc_config.exe file shown here).

   To expand the definition to include other executable files, go to Step 5 and continue from there.

   To save the definition as it is currently defined:

   - In the **Description** field, type a description for this application definition. This is the string that displays in the list of application definitions on the **Match Criteria** tab.
   - Click **OK**.
   - Continue to define the application right as described in Defining an application right manually.

5. To expand the definition to include other executable files, use the **File details** area to specify characteristics that are used to search for executable files. All of the characteristics that you specify must be met in order for an executable file to be a match. See Defining an application right manually for details about operators and syntax for each option in the **File details** area.

   - Deselect the **Path** option.

     This step is necessary because all of the search options that you select use the AND operator when the search executes. If you leave the **Path** option selected, the search is constrained to this location and the definition will include only the file that is specified in the **Name** field.

   - In the **File details** area, select options to define search criteria for executable files.

     Selecting criteria that are more general will usually result in a greater number of executable files being included in the definition. In the example shown in Step 3, you would select only the **Company** option if you wanted to allow this definition to run all .exe files having a company name tag of Acme Corporation. Select additional options to limit the scope of the search so that fewer executable files are included in the definition.

   - In the **Description** field, type a description for this application definition. This is the string that displays in the list of application definitions on the **Match Criteria** tab.
   - Click **OK**.
   - Continue to define the application right as described in Defining an application right manually. When you are done, the application right is available to use.

To define an application right based on a running process:

1. Follow the procedure for creating a new application right manually to the point where the Definition Settings dialog opens (see Defining an application right manually).
2. In the Definition Settings dialog, click **Import Process**.

   A list of running processes displays. By default, the list does not include these processes:

   Processes having an owner of SYSTEM, Local Service, or Network Service

   - conhost.exe
   - dllhost.exe
   - dwm.exe
   - explorer.exe

- svchost.exe
- taskhost.exe

  To display these processes, select the **Show all processes** option.

  Note: System Idle Process and processes having unsupported file extensions (for example, .scr) are never shown.

3. Highlight a process and click **OK**.

   Fields in the Definition Settings dialog fill in with information from the executable file that launched the process that you selected.

4. Select executable files to include in this definition as described in Step 4 on page 149 through Step 5 on page 150. When you are done, the application right is available to use.

Examples of Application Right Definitions

This section contains these examples of how to use the Definition Settings dialog to specify an application right definition:

- Example 1: Manually specify one application path and file name—Describes how to define an application right to run the Access Manager console by manually entering the path name and application name.
- Example 2: Manually specify one application residing in two locations—Describes how to define an application right to run SQL Server Management Studio on Windows 2008 and Windows 2012 systems by manually entering the application name and the path names to the application on both systems.
- Example 3: Specify one application by importing its location—Describes how to define an application right to run the Access Manager console by <!---TODO update filename---> navigating to the centrifydc.msc file and importing its information.
- Example 4: Specify several applications by importing and specifying search criteria—Describes how to define an application right to run SQL Server Management Studio on several versions of the Windows operating system by navigating to the Ssms.exe file on Windows 2008, importing its information, and constructing application search criteria based on that information.

Example 1: Manually specify one application path and file name

In this example, it is assumed that you want to create an application right to run the Access Manager console application, and you know the path and file name of the application executable file.

1. Open the Definition Settings dialog and fill it in as follows:

   Description—Type a name of your choice (for example, **Default Access Manager Console Application**).

   Path—Select this check box.

   Name—Type the application name; in this case <!---TODO update filename---> centrifydc.msc.

   Arguments—Select this check box and specify which arguments can be executed through this application right.

   Specific path—Select this option and type the full path name to the <!---TODO update filename---> **centrifydc.msc** executable file: <!---TODO update path--->

   C:\Program Files\Centrify\Access Manager

2. Click **OK** to save the application right definition setting.

Example 2: Manually specify one application residing in two locations

In this example, it is assumed that you want to create an application right to run SQL Server Management Studio on Windows 2008 and Windows 2012 systems. The SQL Server Management Studio executable file resides in different locations in those operating systems, and you know the paths those locations.

1. Open the Definition Settings dialog and fill it in as follows:

   Description—Type a name of your choice (for example, **SQL Server Management Studio 2008/2012**).

   Path—Select this check box.

   Name—Type the application name; in this case Ssms.exe.

Arguments—Optionally select this check box and specify which arguments can be executed through this application right.

Specific path—Select this option and type the full path names to the **Ssms.exe** executable file in Windows 2008 and Windows 2012. Separate the path names with a semicolon(;)

C:\Program Files (x86)\Microsoft SQL Server\100\Tools\Binn\VSShell\Common7\IDE;C:\Program Files\Microsoft SQL Server\110\Tools\Binn\ManagementStudio

2. Click **OK** to save the application right definition setting.

Example 3: Specify one application by importing its location

This example is similar to Example 1; it is assumed that you want to create an application right to run the Access Manager console application. Unlike in Example 1, you are not sure of the path name to the application executable file and you will navigate to it rather than type it in the form.

1. Open the Definition Settings dialog.
2. Click **Import File**.
3. Navigate to the <!---TODO update filename---> centrifydc.msc executable file, highlight it, and click **Open**.
4. Verify that the Definition Settings dialog fills in with application information.
5. In the Description field, type a name of your choice (for example, Default Access Manager Console Application).
6. Click **OK** to save the application right definition setting.

Example 4: Specify several applications by importing and specifying search criteria

This example is similar to Example 2; it is assumed that you want to create an application right to run SQL Server Management Studio on more than one version of the Windows operating system, starting with Windows 2008. Unlike in Example 2, you do not want to constrain the latest version of Windows to Windows 2012. Instead, you want to account for future versions of Windows and provide the capability to run SQL Server Management Studio on future Windows releases.

1. Open the Definition Settings dialog on a Windows 2008 system.
2. Click **Import File**.
3. Navigate to the Ssms.exe executable file, highlight it, and click **Open**.

   The Definition Settings dialog fills in with information from the Windows 2008 version of Ssms.exe.
4. Deselect the **Path** option so that the definition is not constrained just to that location.
5. Select the **File Description** option and keep the default operator and string.
6. Select the **Product Version** option and change the operator from **equal** to **later or equal**.

   The definition is now configured to include all .exe files having a file description tag of **SSMS - SQL Server Management Studio** and a product version later than or equal to the version that is installed on this Windows 2008 system.
7. In the Description field, either keep the string that was imported with the Ssms.exe file or type a description of your choice.
8. Click **OK** to save the application right definition setting.

Defining Network Access Rights

Network access rights allow users to access services on remote computers using another user account on the remote computer. Users who are assigned to a role with network access rights are only granted the elevated privileges when accessing the remote computer.

To define a network access right:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to define an application right.
3. Expand **Authorization > Windows Right Definitions**.
4. Select **Network Access**, right-click, then click **New Network Access**.
5. On the General tab, type a name and a description for the network access right.

Name	Type the name you want to use for this network access right. For example, if the right allows a user to connect remotely to a Microsoft SQL Server instance using the privileges associated with a database system administrator account, you might include the SQL login name. For example, you might use a name like sysadmin.
Description	Type a description for this network access right. The description is optional. You can use it to provide a more detailed explanation of the privileges associated with this right.
Priority	Set the priority for this application right. If more than one network access right is included in the roles selected, the priority value determines which network access right to use. The lower the value, the higher the priority. For example, a right with the priority of 1 takes precedence over a priority value of 2. If users have multiple roles selected, the priority value of the network access right determines which network access right takes precedence over the access rights in other roles. For more information about selecting multiple roles for connecting to remote servers, see Scenario: Using multiple roles for network resources.

1. Click the **Access** tab to select the account that has the privileges you want to enable for accessing the remote computer.

   You can browse for and select a specific user account, create a new account, or access the remote computer using the logged-in user's account credentials but with the elevated privileges of a specified group account. Click **Add AD Groups** or **Add Built-in Groups** to search for and select a previously-defined or Built-in group with the privileges you want to add to the logged in user's account.

   In most cases, you select a specific user account only if accessing the remote computer using a service account.

   Select **Re-authenticate current user** if you want to prevent the network access right and its privileges from being used by anyone not authorized to do so. Selecting this option also allows you to enable multi-factor authentication for the right. For more information see Enabling multi-factor authentication for Windows rights.

   If you select this option, users are prompted to re-enter their password to verify their identity before they are allowed to select a role for accessing applications on a remote computer. Forcing users to reauthenticate ensures the privileges associated with the network access right are only granted to users who have been assigned those privileges.

   If you select this option for users who are authenticated using a smart card, users must enter a personal identification number (PIN) or a password to resume working with the remote server.

2. Click **OK** to save the network access right.

Using Network Access Rights When There are Two-way Selective Cross-forest Trusts

If you have domains in different forests that have a selective two-way trust relationship, any computer or user accounts that are used to log on to the remote forest must be granted the "Allowed to authenticate" right on the domain controllers in both forests to get role information. After you grant the computer used to access the remote server the "Allowed to authenticate" right for the domains in both forests, you can select roles that grant network access rights from either forest.

If an account is not allowed to authenticate on the remote domain controller, you cannot view or select roles that would otherwise allow you to perform tasks on the remote server.

Defining Custom Roles with Specific Rights

Rights can be combined or used independently of each other to create role definitions. Role definitions describe job functions that require a specific set of rights, including the specific days and times the role should be available for performing the operations allowed. If you have created desktop, application, or network access rights, you must create at least one role definition to use these rights.

To create a new role definition for a job function, you need to do the following:

- Create a new role and specify when the role is available.
- Specify how users in the role are allowed to log on.
- Add specialized Windows access rights to the role, as applicable.
- Specify whether the role requires multi-factor authentication before it can be selected.

In most cases, creating a separate role definition for each access right gives you the most granular control over what users assigned to a role can do. For example, if you create separate role definitions for desktop, application, and network access rights, you can choose which apply to specific users and groups

through role assignments.

Creating a Role Definition with Desktop Rights

Before you can make the desktop rights you have defined available to users or groups, you must create one or more role definitions that include those rights. Desktop rights are especially useful to include in roles for users who frequently perform tasks that require the privileges associated with the Administrator group.

To create a new role definition with desktop rights:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to define a new role that includes a desktop right.
3. Expand the **Authorization** node.
4. Select **Role Definitions**, right-click, then click **Add Role**.
5. Type a role name and optional description for the role.

   The description can include details about time restrictions for the role and whether the role is audited or not.
6. Select **Allow local accounts to be assigned to this role** if you want to be able to assign local users or groups to the role you are creating.

   If you do not select this option, only Active Directory domain users can be assigned to the role.
7. Click **Available Times** and use the grid to specify when to allow or deny access for this role definition if you want to restrict when this role is available.
8. Click the **System Rights** tab and select **Console login is allowed** to allow users in the role to log on locally.

   To use the desktop right, the user must be able to log on locally on the computer. If you want to allow users to log on using a remote desktop connection, you can also select **Remote login is allowed**.

   > **Note**: Remote computers must be configured to allow remote desktop connections for the "Remote login is allowed" right to be valid. You can configure a computer to allow remote desktop connections by right-clicking Computer and selecting Properties or from the System Control Panel, then clicking **Remote settings**.

   Users must be assigned to at least one role with either console login or remote login rights to access any computers where the Agent for Windows is installed. You can grant access using the Windows Login role definition or the system rights in any custom role definition.

   The Windows right **PowerShell remote access is allowed** allows you to log on remotely to PowerShell.

   If you want to allow users to log on even when the Windows agent isn't running or when audit and monitoring service is required but not available, you can select the rescue right. Because this right allows users to log on without having their activity audited, you should only assign roles with this right to trusted administrators or under controlled conditions. For example, assume you have a computer with sensitive information that normally requires all user activity to be audited. If that computer has application or operating system issues that require you to disable auditing temporarily, you can use a role with the rescue right to log on to that computer to diagnosis and fix the issue.
9. In the **Authentication** tab, you can add multi-factor authentication. If you want to require multi-factor authentication for users to access the role, select **Require multi-factor authentication for login**. You can also require multi-factor authentication for access to individual rights when you define the rights to add to roles. For more information see Enabling multi-factor authentication for Windows rights.
10. Click the **Audit** tab and select an option.

    If you select **Audit not requested/required**, users can log on to audited computers without having their session activity recorded. An audit trail event is recorded in the Windows event log when users open a desktop with this role, but the detailed record of what took place during the session is not captured.

    If you select **Audit if possible**, session activity is recorded when users open a desktop with elevated privileges on audited computers and not recorded when they log on to computers where audit and monitoring service is not enabled or audited computers when auditing is not currently running.

    If you select **Audit required**, users can only open a desktop with elevated privileges when auditing is running. If audit and monitoring service is not available or not currently running, the role is not available and users cannot use the elevated privileges.

11. Click **OK** to save the role definition.
12. Select the role definition, right-click, then click **Add Right** to add a desktop right to the role definition.
13. Select the desktop right from the list of rights from the current zone and from any parent zones, then click **OK** to add the right to the role definition.

Creating a Role Definition with Application Rights

Before you can make the application rights you have defined available to users or groups, you must create one or more role definitions that include those rights. Application rights are especially useful to include in roles for users who infrequently require access to specific applications with the privileges associated with the Administrator account or a service account on a local computer.

To create a new role definition with application rights:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to define a new role that includes an application right.
3. Expand the **Authorization** node.
4. Select **Role Definitions**, right-click, then click **Add Role**.
5. Type a role name and optional description for the role.

   The description can include details about time restrictions for the role and whether the role is audited or not.
6. Click **Available Times** and use the grid to specify when to allow or deny access for this role definition if you want to restrict when this role is available.
7. Click the **System Rights** tab and select **Console login is allowed** to allow users in the role to log on locally.

   To use the Run as selected role utility and an application right, the user must be able to log on locally on the computer where the application runs. If you want to allow users to log on using a remote desktop connection, you can also select **Remote login is allowed**.

   Users must be assigned to at least one role with either console login or remote login rights to access any computers where the Agent for Windows is installed. You can grant access using the Windows Login role definition or the system rights in any custom role definition.

   If you want to require multi-factor authentication for users to access the role, select **Require multi-factor authentication**. You can also require multi-factor authentication for access to individual rights when you define the rights to add to roles. For more information see Enabling multi-factor authentication for Windows rights.
8. Click the **Audit** tab and select an audit and monitoring service option.
   - If you select **Audit not requested/required**, users can log on to audited computers without having their session activity recorded. An audit trail event is recorded in the Windows event log when users select this role to run the application, but the detailed record of what took place during the session is not captured.
   - If you select **Audit if possible**, session activity is recorded when users select this role to run the application and not recorded when they use the application on computers where audit and monitoring service is not enabled or audited computers when audit and monitoring service is not currently running.
   - If you select **Audit required**, users can only select this role to run the application when audit and monitoring service is running. If audit and monitoring service is not available or not currently running, the role is not available and users cannot use their elevated privileges.
9. Click **OK** to save the role definition.
10. Select the role definition, right-click, then click **Add Right** to add the application right to the role definition.
11. Select the application right from the list of rights from the current zone and from any parent zones, then click **OK** to add the right to the role definition.

Creating a Role Definition for Network Access Rights

Before you can make the network access rights you have defined available to users or groups, you must create one or more role definitions that include those rights. Network access rights are especially useful to include in roles for users who require remote access to network services with the privileges associated with the domain Administrator account or a service account on the remote computer.

1. Open the Access Manager console.

2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to define a new role that includes a network access right.
3. Expand the **Authorization** node.
4. Select **Role Definitions**, right-click, then click **Add Role**.
5. Type a role name and optional description for the role.

   The description can include details about time restrictions for the role and whether the role is audited or not.
6. Click **Available Times** and use the grid to specify when to allow or deny access for this role definition if you want to restrict when this role is available.
7. Click the **System Rights** tab and select **Remote login is allowed** to allow users in the role to connect to services on the remote computer.

   The user must be able to connect to the computer remotely to perform administrative tasks on that computer. If you want to allow users to log on locally, you can also select **Console login is allowed**.

   Users must be assigned to at least one role with either console login or remote login rights to access any computers where the Agent for Windows is installed. You can grant access using the Windows Login role definition or the system rights in any custom role definition.

   If you want to require multi-factor authentication for users to access the role, select **Require multi-factor authentication**. You can also require multi-factor authentication for access to individual rights when you define the rights to add to roles. For more information see Enabling multi-factor authentication for Windows rights.
8. Click the **Audit** tab and select an auditing option.

   If you select **Audit not requested/required**, users can connect to remote audited computers without having their session activity recorded. An audit trail event is recorded in the Windows event log when users select this role to connect to remote servers, but the detailed record of what took place during the session is not captured.

   If you select **Audit if possible**, session activity recorded when users log on to audited computers and not recorded when they log on to computers where audit and monitoring service is not enabled or audited computers when audit and monitoring service is not currently running.

   If you select **Audit required**, users can only log on to audited computers when audit and monitoring service is running. If audit and monitoring service is not available or not currently running, the role is not available and users cannot use their elevated privileges.
9. Click **OK** to save the role definition.
10. Select the role definition, right-click, then click **Add Right** to add a network access right to the role definition.
11. Select the network access right from the list of rights from the current zone and from any parent zones, then click **OK** to add the right to the role definition.

Combining Rights in the Same Role Definition

The previous sections illustrate how to create custom role definitions specifically for desktop, application, or network access rights. You can also combine multiple rights in the same role definition. For example, you can create a role definition that allows a user to open a specific application on the local computer using a service account with elevated privileges. The same role definition can also include a network access right that enables the user to modify information on a remote server.

Assigning Users and Groups to a Role

You can assign a role to an Active Directory user or to an Active Directory group. You can assign a role that is defined in the current zone or in a parent zone. You can also specify optional start and end times for the role assignment.

To assign users and groups to a role in a zone:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to make role assignments.
3. Expand **Authorization**.
4. Select **Role Assignments**, right-click, then click **Assign Role**.

5. Select the role definition from the list of roles, then click **OK**.

   By default, the role is set to start immediately and never expire. You can set a **Start time**, **End time**, or both start and end times for the role assignment. For example, if the role applies to a contractor who will be hired for a specific amount of time and you want to automatically disable the role after they finish the job and leave the organization, you can specify the start and end times when you assign the role.

6. Select whether the role assignment applies to all Active Directory accounts, all local accounts, or specific Active Directory and local accounts.

   To assign the role to specific accounts, click **Add AD Account** to search for and select the Active Directory groups or users to assign to the role, then click **OK**.

Rights and Role Assignments for Local Users

The rights you assign to users and group in a particular role apply to Active Directory users and groups. They can also apply to locally-defined users and groups if you configure the role definition to allow local accounts to be assigned to the role. All Windows users, including local users, must be assigned at least one role that allows them log on locally, remotely, or both.

Restricting Roles that Include Network Access Rights

Because role definitions can include a combination of rights and you can assign roles to local users, Active Directory users, or both, it is possible for you to assign roles that include network access rights to local accounts. Access Manager does not prevent you from configuring role definitions or role assignments in this way. However, users who log on with a local account will not be allowed to select the Advanced View or those network access rights for the remote computer. Therefore, you should avoid configuring role definitions that include network access rights and allow local accounts. Instead, you should keep role definitions that include network access rights separate from role definitions that allow local accounts to be assigned.

Making Rights and Roles Available in Other Zones

The access rights and role definitions that you create are specific to the zone where you configure them, and to any child zones of that zone. Once configured, though, you can copy and paste or drag and drop the definitions from one zone to another. After you import the information into a new zone, you can modify any of the details you have previously defined. For example, you can choose to export all the rights you have defined in one zone but create a completely new set of role definitions for those rights in the import zone.

Rights, roles, and role assignments are all inherited from parent to child zones, so generally there is no need to import or export roles within a zone hierarchy, but you may want to do so across zones. For example, if you have set up separate parent zones for different lines of business or different functional groups in your organization, you might want to import rights and roles from one business unit or functional group to another.

Exporting a Zone's Rights and Role Definitions

You can export right and role definitions to an xml file that you can then use to import these definitions into another zone.

To export rights and role definitions:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone that has the rights and roles you want to export.
3. Expand Select the **Authorization** node, right-click, then click **Export Roles and Rights**.
4. Select the information you want to export, then click **Next**.
5. Click **Browse** to specify a location and file name for the export file, then click **Next**.
6. Review the information to be exported, then click **Finish**.

Importing Rights and Role Definitions into a New Zone

You can import rights and role definitions that you have previously saved from a different zone. You can also copy a paste or drag and drop rights and roles to a different zone.

To import rights, role definitions, and role assignments:

Before you begin, be certain you have saved rights and role definitions from a different zone and know the location of the xml file in which they are saved.

1. Open Access Manager.
2. Expand **Zones** and the parent zone or child zones until you see the zone into which you want to import rights and roles.
3. Select the **Authorization** node, right-click, then click **Import Roles and Rights**.

4. Click **Browse** to navigate to the file that contains the authorization information you want to import, then click **Next**.
5. Select the information you want to import, then click **Next**.
6. Review the information to be imported, then click **Finish**.

Copying Rights and Role Definitions into a New Zone

Exporting and importing information from one zone to another is the best solution if you want to include most or all information about rights and roles in a new zone. If you want to limit the information copied from one zone to another, you can copy and paste or drag and drop the information instead. With copy and paste, you can select specific right definitions, role definitions, or role assignments that you want to include in a new zone.

To copy role assignments from one zone to another, however, you should verify that the role definition associated with the role assignment exists in the new zone or is included in the information you are copying to the new zone.

To copy rights, role definitions, or role assignments:

1. Open the Access Manager.
2. Expand **Zones** and the parent zone or child zones until you see the zone that has the rights, role definitions, or role assignments you want to copy.
3. Expand the **Authorization** node.
4. Expand **Window Right Definitions**, **Role Definitions**, or **Role Assignments** until you see the specific right, role, or role assignment you want to copy.
5. Select the specific right, role definition, or role assignment to copy, right-click, then click **Copy**.
6. Open a different zone and expand **Authorization > Windows Right Definitions**, **Role Definitions,** or **Role Assignments**, right-click, then click **Paste**.

Alternatively, you can select a specific right, role definition, or role assignment and drag it to the appropriate node in a new zone.

Viewing Rights and Roles

You can view the status and effective rights for any user in a zone, whether they have been assigned a role or not. You can view detailed information about the rights and role assignments for users by selecting **Show Effective Windows User Rights** in the Access Manager console.

Displaying Rights for an Individual User in the Console

To view role assignments and Windows access rights for a user in the Access Manager console:

1. Open Access Manager.
2. Expand **Zones** and the parent zone or child zones until you see the zone that has the user of interest.
3. Right-click, then click **Show Effective Windows User Rights**.
4. Select a user to see information for the user in the selected zone or click **Browse** to select a specific computer in the zone if you only want to view user rights for a particular computer in the selected zone.
5. Click a tab to see the user's role assignments, desktop rights, application rights, or network access rights.
    - **Role Assignments** lists the user's role assignments, including where the assignment was made. For example, the Object Assigned column indicates whether the assignment for a user is explicit (*user*@*domain*), from a group (*group*@*domain*), or inherited from another setting (All AD Accounts). The Start Time and End Time are only displayed for roles that have time constraints.
    - **Windows Desktops** lists the user's desktop rights granted by the roles to which the user is assigned. The tab identifies the account that can be used to open a new desktop or run an application, the zone where the desktop right is defined, and the role definition that includes the right.
    - **Windows Applications** lists the user's application rights granted by the roles to which the user is assigned. The tab identifies the specific application and the account that can be used to run the application, the zone where the application right is defined, and the role definition that includes the right.
    - **Network Access** lists the user's network access rights granted by the roles to which the user is assigned. The tab identifies the account that can be used to connect to services on a remote computer, the zone where the network access right is defined, and the role definition that includes the right.
6. Click **Close** when you are finished reviewing user rights in a zone or on particular computers.

Scenario: Using a Network Access Role to Edit Group Policies

The steps in this section illustrate a specific scenario of how to configure and use a desktop right and a network access right that allows the user Josh.Adams to log on with his normal Active Directory credentials, open an application that enables him to edit group policies, then connect to a domain controller with administrative privileges so that he can edit a Group Policy Object.

1. Install the Agent for Windows on the domain controller.
2. Install the Agent for Windows on a Windows computer that hosts the Group Policy Management console that the Josh.Adams uses to access the domain controller remotely.
3. Assign Josh.Adams the predefined Windows Login role and the custom role definition gpedit that includes a desktop right and a network access right.
4. Josh Adams logs on to his Windows computer using his Active Directory user name and password.

   To use a role with network access rights, you cannot log on using a local user account. You must use a domain user account authenticated using Active Directory.
5. On his local computer, Josh right-clicks the Delinea icon in the system tray section of the task bar, then selects New Desktop.
6. In his list of available roles, Josh selects his gpedit role, then clicks OK.
7. Josh opens the Group Policy Management console on his local computer, connects to the domain controller in the console, then selects the default domain policy Group Policy Object.
8. Josh right-clicks the default domain policy, then selects Edit to modify the group policy.
9. When he is done working with the group policies, he switches back to his default desktop.

Scenario: Using Multiple Roles for Network Resources

For the local computer, users can select only one role at a time for their desktop or running an application. However, users can select more than one role to access network resources. By selecting multiple roles on the client, users can run applications that connect to multiple remote servers to perform administrative tasks.

In this scenario, Maya.Santiago uses a privileged account to open SQL Server Management Studio on her local computer. From this application, she wants to add accounts that require domain administrator privileges on a remote domain controller and modify database settings on a remote SQL Server instance. To do her work, she needs elevated privileges to run SQL Server Management Studio on her local computer and network access rights to contact the domain controller and the database server.

As the administrator, you have prepared the environment:

- You have put computers in appropriate zones and configured appropriate rights.
- You have configured a role definition, SideBet-DC-Admin, that grants network access to the domain controller using elevated privileges.
- You have also configured a role definition, SQL-DB-Default, that grants network access to SQL Server instances using elevated privileges.
- You have assigned Maya.Santiago to the roles.

To use an application that connects to multiple remote servers:

1. Install the Agent for Windows on the domain controller, the computer that hosts the SQL Server instance, and the computer Maya.Santiago uses to manage the SQL Server instance.
2. Assign Maya.Santiago the custom roles definition SideBet-DC-Admin that includes a desktop right and a network access right.
3. Maya.Santiago logs on to her Windows computer using her Active Directory user name and password.
4. On her local computer, Maya right-clicks SQL Server Management Studio, selects **Run with Privilege**.
5. Maya clicks **Advanced View** to see the list of available roles and selects SideBetDCAdmin as the local role that enables her to run local applications with administrator privileges.
6. Maya then clicks the **Select one or more network roles** option and selects the SideBetDC-Admin role for remote access to the domain controller and the SQLDBDefault role for remote access to the database server, then clicks **OK**.

   After she clicks OK, SQL Server Management Studio starts and she connects to the remote SQL Server instance using Windows authentication. The change to a role with privileges is recorded in the local Windows Application event log.
7. Maya uses SQL Server Management Studio to add and modify information on the domain controller and the SQL Server database.
8. When she is done working, she closes the application and returns to her default desktop and her login account privileges.

Defining Rights for Windows Applications that Encrypt Passwords

Microsoft provides a data protection application-programming interface (DPAPI) to enable applications to secure sensitive information, such as passwords, using encryption. The Data Protection API is the most common way to secure personal information on Windows computers because the information that is encrypted for one user cannot be decrypted by another user. Many applications and system services, including Microsoft Encrypting File System (EFS), Microsoft Internet Explorer, and Google Chrome for example, use the Data Protection API to encrypt passwords.

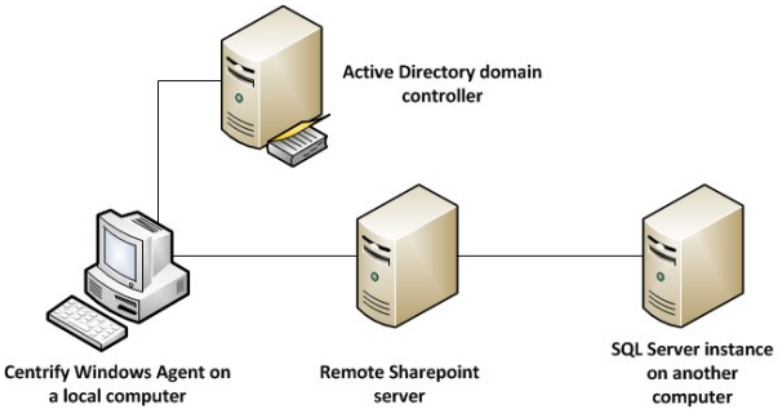
To use a desktop or application right with an application that uses the Data Protection API, you should select the **Self with added group privileges** option for the Run-as account. If you select this option when defining a right, you can install the Agent for Windows on the computer where the application using the Data Protection API is installed to allow users to run the application with administrative privileges.

If you want to use a specific user account for an application that uses the Data Protection API, you must install the Agent for Windows on both the domain controller and the computer where the application using DPAPI is installed. You must also make sure the domain controller is in a zone where users who are going to use the application are granted network access rights. In this scenario, the domain controller must be able to confirm the identity of the specific user account to allow protected information to be decrypted.

For example, assume you define an application right for running Access Manager using the Windows AM-Owner account and assign the user Steve to a role that has this application right. When Steve logs on to the computer where Access Manager is installed and opens the application using the role he is assigned, the Agent for Windows on the domain controller identifies him as the user AM-Owner and provides Jess with the master key for encryption and decryption, enabling him to use Access Manager to add computers, deploy agents, and perform other tasks.

Enabling Access Across Multi-tiered Application Layers

The traditional client/server scenario involves using a Windows client computer to connect to a Windows server to perform some operation. However, it is increasingly common that privileged access must cross multiple application layers. For example, you might have users who log on with their normal credentials who perform administrative tasks on a remote Sharepoint server and those tasks further require access to a SQL Server instance on yet another computer.

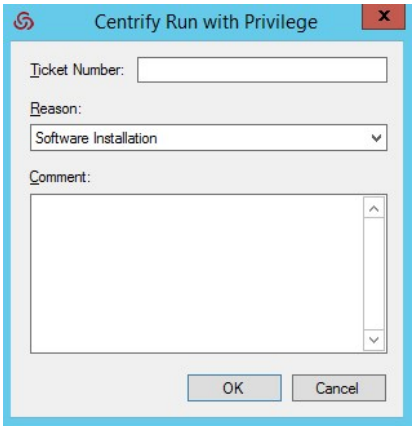


One way to ensure access across multiple applications tiers is to have all of the remote computers involved be in the same zone. At a minimum, the client computer and the computer in the first tier must have the Agent for Windows installed. If the client computer and the computer in the first tier are in different zones, which is the most common scenario, you should place computers in any additional tiers in the same zone as the computer in the first tier.

Requiring Users to Justify Privilege Elevation

You can assign some group policies that force your users to provide a reason when they choose to run an application with privilege. There are two group policies that you can use:

You can use just one of these policies or both. With either of these policies, when a user goes to run an application with privilege, they're prompted with an additional dialog box where they can enter a ticket number, a reason category, and any comments.



The above dialog box prompts users to enter the following information:

- **Ticket number**: If you have enabled the privilege elevation validator policy and subsequent script, you can validate the ticket number that a user enters against a ticketing system such as ServiceNow. If you haven't enabled the privilege elevation validator policy, users can enter any text string here.
- **Reason**: The user selects the reason category that best fits their situation. Their choices are:
  - Software Installation
  - Remote System Administration
  - Local System Administration
  - Windows Feature Management
  - System Networking Change
  - Maintenance (Shutdown, Reboot, Power Off)
  - PowerShell or Other CLI
  - Operation (Services, Zone Operations, etc.)
  - Other
- **Comment**: The user enters any comments about their need to run with privilege. You can view these comments in the audit trail event.

For more details about these policies, see the Group Policy Guide and the group policies' explain text.

Working with Computer Roles

A computer role associates a group of computers in a zone with a set of role assignments to users or groups. For example, you might have a set of computers dedicated to a specific function, such as hosting Oracle databases or payroll processing application. Users who are database administrators for those computers require different privileges than users who update payroll records on those computers.

Using a computer role, you can associate the group of computers that host an Oracle database with a specific role assignment, for example, users who are assigned the oracle dba role. The oracle-dba role definition might include desktop and network access rights because the users assigned to the oracle-dba role require administrative privileges.

You could also create a second computer role that associates the group of computers that host the payroll processing application with a group of users who are allowed to log on and update payroll records without granting any other administrative privileges. For example, if some of the computers that host an Oracle database are used for payroll processing, you can define another computer role—payroll-west—that associates just those computers with the role assignment payroll_mgmt. The payroll_mgmt role definition might have the console login right and an application right specifically for the payroll application. When users are assigned the payroll_mgmt role, they can log on locally and run the payroll application with elevated privileges only on the group of computers defined in the computer role payroll-west.

To use computer roles, you must do the following:

- Decide on the attribute the computers in a particular group share. For example, you can use a computer role to identify computers in the web farm, that host specific applications, or serve a specific department.
- Identify the sets of users that share common access rights and create Active Directory groups for them. For example, if you are creating a computer role for Oracle database servers, you might have different access rights for application users, database administrators, and backup operators.
- Identify the role definitions each set of users should be assigned. For example, application users role might use the default Windows Login role, while administrators might require a custom role definition with desktop and network access rights, and backup operators might require a custom role

definition with an application right.

Using Computer Roles to Simplify the Management of Access Rights

Deciding how best to use computer roles requires some planning and configuration that may not be part of your initial deployment plan. To make effective use of computer roles, you also prepare appropriate role definitions for different sets of users. However, computer roles provide a powerful and flexible option for managing access to computers using your existing processes and procedures for managing Active Directory group membership.

After you create a computer role, it is easy to manage even as your organization changes and grows. For example, if another Oracle database server comes online, you add it to the computer group you created for Oracle database servers in Active Directory. If other DBAs join your organization, you add them to the Active Directory group you created for Oracle administrators. The computer role links the computer group to the role assignment and no additional updates are needed to accommodate these kinds of organizational changes. If you need to modify the access rights, you can change the role definition and have the changes apply to all members of the group.

Create an Active Directory Group for a Set of Computers

Computer roles create links between objects in Active Directory and access rights defined in Access Manager. After you have identified a group of computers that share a common attribute, you should create an Active Directory group for those computers if one does not already exist.

You can also create the computer group and add its members directly from Access Manager when you create the computer role. If you are not preparing the Active Directory group before creating the computer role, you can skip this section and go directly to Create a new computer role.

To create an Active Directory group for computers in a computer role:

1. Open Active Directory Users and Computers to create a new Active Directory group.
2. For example, create a new Active Directory group for Oracle Database Servers.
3. Select the new computer group, right-click, then click **Properties**.
4. Click the **Members** tab, then click **Add**.
5. Click **Object Types**, select **Computers**, then click **OK**.
6. Search for and select the computers that you have identified as Oracle database servers as members of the new group, then click **OK**.
7. Click **OK** to save the group.

Create an Active Directory Group for Each Set of Access Rights

In addition to the Active Directory group for the computers in a computer role, you should have an Active Directory group for each set of users that should have different access rights. By mapping Active Directory groups to role definitions, you can manage group membership and access rights at the same time using your current procedures.

To create an Active Directory group for each set of users linked to a computer role:

1. Open Active Directory Users and Computers to create a new Active Directory group for each set of users to link to the computer role.

   For example, create separate Active Directory groups for application users, database administrators, and backup operators using a naming convention similar to *ComputerAttribute*_Role_*UserSet*. For example, create the following Active Directory groups:

   - OracleServers_Role_AppUsers
   - OracleServers_Role_DBAs
   - OracleServers_Role_Backup

2. Select each new group, right-click, then click **Properties**.
3. Click the **Members** tab, then click **Add**.
4. Search for and select the users that you have identified as members of the each group, then click **OK**.
5. Click **OK** to save the group membership.

Create a Role Definition for Each Set of Users with Different Access Rights

Before you create a new role definition, identify the specific rights associated with each role and define those rights if they do not already exist. For this sample scenario, you might create role definitions similar to the following:

- Oracle_AppUsers with Windows Login access and an application right for a specific database application.
- Oracle_DBAs with Windows Login access and desktop and network access rights on computers in a specific zone.
- Oracle_Backup with console login allowed right and an application right that allow members of the group to run backup utilities with the privileges of the built-in Backup Operators group.

Create a New Computer Role

After you have prepared the appropriate Active Directory groups and role definitions for different sets of users, you can create one or more computer roles.

To create a new computer role:

1. Open Access Manager.
2. Expand **Zones** and the parent zone or child zones until you see the zone that has the computer for which you want to define a computer role.
3. Expand the **Authorization** node.
4. Select **Computer Roles**, right-click and click **Create Computer Role**.
5. Type a name and description for the computer role.

   For example, type OracleServers, and an optional description, such as Oracle database servers in the San Francisco data center.
6. In **Computers group** list, select **<...>** to search for the Active Directory group of computers you created in Create an Active Directory group for a set of computers.

   Select **<Create group >** if you want to create a new Active Directory group of computers and add members now. If you are creating a new group, click **Browse** to select a container to use, type a group name, and select the scope of the group, then click **OK**.
7. Click **OK** to save the computer role.
8. If you selected an existing computer group, expand **Computer Roles > Members** to see the computers that are members of this computer role.

   If you created a new computer group at Step 6, select the new computer role, right-click **Members**, then select **Add Computer** to search for and select one or more computers to add to the group.

Add Role Assignments to the Computer Role

If you have created the appropriate Active Directory groups and role definitions that you want to assign, you can now assign the roles to set of users as required.

To add role assignments to users in Active Directory groups:

1. Expand the computer role you just created, for example, expand **OracleServers**.
2. Select **Role Assignments**, right-click, then click **Assign Role**.
3. Select the role definition from the list of roles, then click **OK**.

   For example, select the Oracle_DBAs role definition. By default, the role is set to start immediately and never expire. You can set a **Start time**, **End time**, or both start and end times for the role assignment. For example, if the role applies to a contractor who will be hired for a specific amount of time and you want to automatically disable the role after they finish the job and leave the organization, you can specify the start and end times when you assign the role.
4. Select whether the role assignment applies to all Active Directory accounts, all local accounts, or specific Active Directory and local accounts, then click **OK** to complete the role assignment.

   For example, to assign the Oracle_DBAs role to the Active Directory OracleServers_Role_DBAs security group, click **Add AD Account**. You can then select **Group** to search for the group, select it from the results, then click **OK**.
5. Repeat Step 1 through Step 4 for each group that you want to add to this computer role. For example, repeat the steps to assign the Oracle_AppUsers role to the OracleServers_Role_AppUsers security group and the Oracle_Backup role to the OracleServers_Role_Backup security group.
6. Select the **Role Assignments** node to see all of the role assignments you have defined for groups associated with the computer role.

7. Select the **Members** node to see the computers or groups of computers to which the role assignments apply.

Assigning Roles on Multiple Computers at Once

To simplify the process of assigning Active Directory users or groups to a role, you can perform a bulk role assignment. With a bulk role assignment, you can assign a role to multiple Active Directory users and groups on multiple computers at the same time. For example, if you have two groups of SQL Server administrators and three computers where the members of those groups need access to their SQLServerAdmin role, you can select those two groups and those three computers to be assigned the SQLServerAdmin role in the same process. You can also specify optional start and end times for the role assignment and have those settings apply for all of the users, groups, and computers you have selected for bulk assignment.

To assign users and groups to a role in a zone:

1. Open the Access Manager console.
2. Expand **Zones** and the parent zone or child zones until you see the zone where you want to make role assignments.
3. Right-click, then select **Assign Roles to Computers**.
4. Type the user and group names you want to be included in the role assignment, then click **OK**.

   You can specify multiple names separated by a semi-colon (;). You can also search for user and group names by typing part of the name and clicking Check Names or by clicking Advanced and entering search criteria.
5. Type the computer names you want to be included in the role assignment, then click **OK**.

   You can specify multiple names separated by a semi-colon (;). You can also search for the computer names by typing part of the name and clicking Check Names or by clicking Advanced and entering search criteria.
6. Select a role for the list of roles available, then click **OK**.
7. Review the role assignment start and end time and the user and group accounts that are being assigned the role, then click **OK**.

   You can make changes to the start and end times if you want those changes applied for all of the users, groups, and computers that are part of this bulk role assignment.

After you click **OK**, the selected users and groups are then automatically assigned the selected role on the selected computers.

Using the Authorization Center Directly on Managed Computers

The Authorization Center is available on managed computers where you have deployed the Agent for Windows and enabled the privilege elevation service. From the Authorization Center, you can view details about the rights, role definitions, role assignments, and auditing status for any users. Individual users can see details about their own login rights, effective roles, role assignments, role definitions, and auditing status. Administrators can select any user of interest to view the details for that user.

To use the Authorization Center on a local computer:

1. Log on to a computer where the Agent for Windows and privilege elevation features are deployed.
2. Click the arrow next to the notifications area in the taskbar.
3. Right-click the Delinea icon, then select **Open Authorization Center**.
4. Click a tab to see details about the current user's roles.
   - **Effective Login Rights** displays the current user's local, remote, and PowerShell login rights and whether auditing is requested, required, or not applicable.
   - **Effective Roles** lists the roles that have been assigned to the current user and the status of each role names to which the user is assigned. You can right-click a role, then select Role Properties to view additional details, such as any time constraints defined for the role and the specific rights granted by the role.
   - **Role Assignments** lists details about the user's role assignments, including where the assignment was made. For example, the Object Assigned column indicates whether the assignment for a user is explicit, from a group, or inherited from another setting, for example, from the selection of All Active Directory Accounts. You can right-click a role, then select Assignment Properties or Role Properties to view additional details, such as any time constraints defined for the role and the specific rights granted by the role.

- **Role Definitions** lists detailed information about the selected user's login rights and the audit requirements that have been defined for the roles the user has been assigned. You can right-click a role definition, then select Properties to view additional details.
- **Auditing** lists the desktops used and auditing status for each desktop started in a session.

5. Click **Browse** to view information for another user.
6. Type all or part of the user name, then click **OK**.

   If more than one user name is found, select the appropriate user from the results, then click **OK**.
7. Click **Close** when you are finished viewing detailed authorization information for the selected user.

Working with the Authorization Cache on Managed Computers

Authorization information—such as your rights, role definitions, and assignments—is cached locally on each computer where you have deployed the Agent for Windows. The cache saves access privilege information to improve performance and also to persist elevated privilege capabilities for users and groups when the computer is not connected to Active Directory.

The following sections describe:

- Which Server Suite capabilities are and are not persisted by the cache when a computer is disconnected from a domain controller.
- Where the cache resides.
- How and when to perform cache operations such as refreshing, flushing, and dumping.

Persisted and Non-persisted Capabilities

The Server Suite cache persists several role-based capabilities when a computer is not connected to Active Directory. A computer is considered to be *not connected* when the Windows agent is unable to reach one or more of the following entities:

- The domain to which the computer is joined.
- The domain of any zone in the *zone hierarchy*. The zone hierarchy is the domain of the zone that the machine is joined to, or any parent zones of that joined zone.
- An Active Directory global catalog (GC) associated with any of these domains.

If the Windows agent can reach all of these entities, it is considered to be *connected.*

Persisted Capabilities

These capabilities are supported when a computer is not connected:

- Users can log in based on role.
- Users can run applications based on role.
- Users can create desktops based on role.
- Computers can be removed from zones.
- Delinea software can be installed (but the computer cannot be joined to a zone).
- Delinea software can be upgraded, but this practice is not recommended because there will be no authorization data in the cache after the upgrade.

Non-persisted capabilities

These limitations exist when a computer is not connected:

- You cannot join a zone or change a computer's zone.
- The use of Network rights is not supported.

Cache Location

The cache resides in <!---TODO update path ---> *SYSTEMDRIVE*\ProgramData\Centrify\DirectAuthorize\Cache.

Performing Cache Operations

You must have administrator privileges to perform the cache operations described here. Available cache operations include:

- Refreshing the cache (perform this operation from the user interface or the command line)
- Flushing the cache (performed from the command line)
- Dumping the cache (performed from the command line)

Refreshing the Cache

As administrator, you can refresh the cache from the user interface or from the command line. Refreshing the cache updates the cache with fresh information from Active Directory, ensuring that the agent has the most up-to-date information about users' current rights and roles.

Refreshing the cache is useful if you change authorization information with the management console, and you want to see the updated information on the Windows agent right away.

> **Note**: In domains containing multiple domain controllers, you might not see the updated information even after you refresh the cache. In cases such as this, wait for Active Directory replication (typically a few minutes), and then refresh the cache again. Alternatively, wait another 10 minutes and the agent will refresh the data on its own.

You can refresh and flush the cache only on computers that are connected to a domain controller.

To refresh the cache from the user interface:

1. Open the agent configuration panel by clicking **Agent Configuration** in the list of applications on the Windows Start menu.
2. Click **Privilege Elevation Service**.
3. Click **Settings**.
4. Click the **Troubleshooting** tab.
5. Click **Refresh**, then click **OK** to acknowledge the successful operation.

> **Note**: Alternatively, you can execute the dzrefresh command line utility to refresh the cache as described in the next section.

To refresh the cache from the command line:

Execute the dzrefresh command line utility to refresh the cache. Executing dzrefresh performs the same operation as clicking the **Refresh** button in the agent configuration panel **Troubleshooting** tab.

The syntax for running the dzrefresh utility is:

dzrefresh

Flushing the Cache

Execute the dzflush command line utility to flush (clear) the cache. Flushing the cache removes all cache data and reloads it from Active Directory. You should flush the cache only when directed to do so by Support. Under most circumstances, you should refresh the cache rather than flush the cache.

The syntax for running the dzflush utility is:

dzflush

Dumping the Cache

Execute the dzdump command line utility to dump the cache to standard output or to a redirect file that you specify on the command line. You can also use the options shown here to display only specific types of cache data, such as zone hierarchy, role definitions, right definitions, and other data.

You should execute the dzdump utility only when directed to do so by Support.

The syntax for running the dzdump utility is:

dzdump [/d [*directory-path*]] [/w=*screen-width*] [/s] [/n] [/g] [/l] [/a] [/r] [/i] [/t] [/z] [/u] [/h]

If you execute dzdump with no options, all dzagent in-memory cache is dumped.

Setting valid options

You can use the following options with dzdump:

/d	Dump cache files from the default location.
/d=*directory-path*	Dump cache files from the specified location.
/w=*screen-width*	Use the specified width rather than the default of 80 for word-wrap. Set /w=0 to disable word-wrap.
/s	Display SID mappings.
/n	Display name mappings.
/g	Display assignee mappings.
/l	Display assignments in the joined zone hierarchy.
/a	Display assignments for SIDs.
/r	Display role definitions.
/i	Display right definitions.
/t	Display access token information.
/z	Display zone hierarchy.
/u	Display recent user log-ins.
/h	Display help information.

Configuring PowerShell Remote Access

You can run PowerShell commands on remote computers and have the agent handle the authentication and privilege elevation for you. In order to run remote PowerShell commands, the following requirements apply:

- The target computer needs to have the Agent for Windows installed with the Privilege Elevation Service enabled.
- Assign the user to a role with the "PowerShell remote access is allowed" system right granted.

If you're using the Audit & Monitoring Service, when a user attempts to run PowerShell remotely on a computer, the system triggers an audit trail event. Audit & Monitoring Service is an optional service.

To assign PowerShell remote access to a user:

1. In the **Access Manager** console, open the zone that the Windows system to be managed belongs to (Access Manager is not necessary installed on the machine with the Windows agent).
2. Under **Role Definitions**, right-click a role that you'd like to assign PowerShell remote access permission to and select **Properties**.
3. Under **System Rights** > **Windows rights**, select **PowerShell remote access is allowed**.
4. Right-click **Role >Assignment** and select **Assign Role**.
5. Select the role as defined above and assign the Windows account to it.

What Gets Audited for Remote PowerShell Commands and Scripts

For cases where someone runs individual PowerShell cmdlets, the audit trail event captures the following details:

- Specific cmdlets that were run
- Arguments
- Return codes

- User who ran the cmdlets
- The timestamp when the user ran the cmdlets

For cases where someone runs a PowerShell script, the audit trail event captures the name of the script as well, and if the script was run remotely the audit trail event captures the contents of the script. If the script is very long, the audit trail will truncate it and add an ellipsis (...).

> **Note**: If the user runs a PowerShell script on the target system from that same system, the audit trail event does NOT capture the contents of the script. This is due to a limitation in Windows Remote Management. Basically, the thing to remember is that if you send over script text to a remote system, the audit trail captures the script text; if you send over just a script filename, that's what the audit trail captures.

Examples of Remote PowerShell Commands

For example, if a user runs individual PowerShell commands on a remote system, they would start the session with a command similar to the following:

Enter-PSSession -ComputerName **targetcomputername**

The audit trail event captures details about any commands that the user enters during the above PowerShell session.

As another example, if a user runs a script without first creating the remote session and runs the script against a remote, target system from another system, the user might run a command similar to the following:

Invoke-Command -ComputerName **targetcomputername** -FilePath {c:**script**.ps1}

In this second example, you'll know that the user ran a script because there'll be a isscript=true parameter in the audit trail.

As a final example, if a user runs a script without first creating the remote session and runs the script from the target system, the user might run a command similar to the following:

Invoke-Command -ComputerName **targetcomputername** -Command{c:**script**.ps1}

Hiding the Remote PowerShell Script Text

There may be situations where your users have scripts to run on remote systems but you don't want or need the script text to appear in the audit log. To hide the script text from the audit log, change the following registry to 1 (the default value is 0): <!---TODO update path --->

SOFTWARE\Policies\Centrify\DirectAuthorize\Agent\HideRemotePsScript (REG_DWORD)

You can set the HideRemotePsScript option by group policy.

Authentication Service Enforcement

Any time you open the Access Manager console, a background process determines the availability of licenses.

As you increase the number of licenses in use, license enforcement is progressive. If the number of computers is less than 90% of the number of licenses you have purchased, there's no affect on any auditing features. If the number of computers is more than 90% of the licenses purchased, enforcement depends on the number of licenses in use:

- 90-100% of the licensing limit displays a warning message that you are close to over deployment, but you can continue to use all authentication and privilege elevation features.
- 100-120% of the licensing limit displays a warning message that you must acknowledge by clicking **OK** when you open the console, after which you can resume using the console.
- Over 120% of the licensing limit displays a warning message for 60 seconds when you open the console. If you see the 60 second warning message, use the License dialog box to add license keys to continue using features.

You can contact Delinea to purchase additional licenses or remove some computers to bring the number of licenses used into compliance.

Configuring MFA with RADIUS for Privilege Elevation Service for Windows Checklist

This document provides a configuration checklist for 3rd party multi-factor authentication providers such as Duo, Okta, SecurID (or any other vendor that provides a RADIUS service) to provide identity validation with the Privilege Elevation Service in the Microsoft Windows platform.

If you have an identity service provider (such as Duo, Okta, SecureID, and so forth) that you use for MFA logins, you can integrate authentication and privilege

elevation with your identity provider and the RADIUS protocol to require MFA for privilege elevation tasks, such as Run with Privilege and New Desktop.

Make sure that you work with your RADIUS expert along with your network and directory services lead administrators during the design and configuration tasks.

The checklist below includes links to documented procedures.

> **Note**: If you use Privileged Access Service, although you can enable MFA with RADIUS, the recommended practice is that you use the native integration.

	RADIUS requirements	
1	Gather the following settings for your RADIUS service: IP address or fully qualified domain name Port Timeout settings Pre-shared secret	
2	Verify that you can generate a RADIUS one-time password successfully.	
3	Verify that identity authentication is working correctly with your RADIUS system.	
4	Have access to someone who is knowledgeable about your RADIUS system and can answer questions or help troubleshoot issues, if needed.	
	Windows and Active Directory requirements for RADIUS configuration	
5	A Windows computer to use as a RADIUS client for initial testing, including: Client name Client IP address	
6	Make sure that client systems can reach the RADIUS server over the network (check your firewall settings). You may need help also from your network team if your RADIUS cluster has a load-balancer in the front end.	
7	You have administrative access to the designated Windows computer so that	

	you can install software and do configurations.	
8	You have Active Directory account access so that you can modify group policies that apply to the target computer.	
9	You have access to the Group Policy Management Console.	
10	Your Active Directory expert must decide how the group policy layout and scope will be designed so that the group policies are applied to the clients based on their RADIUS service availability.	
	Authentication and Privilege Elevation Services Requirements for RADIUS configuration	
11	Access Manager console is installed on the client computer.	For details, see Running the setup program on a Windows computer.
12	The Agent for Windows is installed on the client system, you've configured the system to work with Privilege Elevation Service, including joining the computer to a zone.	For details, see Installing the Agent for Windows.
13	You have administrative access to Access Manager so that you can manage roles and rights.	
14	The group policy templates from release 19.6 or later are installed. For RADIUS configuration, you need at least the Delinea Windows settings group policies.	For details, see Installing group policy extensions separately from Access Manager.
15	If you want to capture the RADIUS events in your SIEM system, make sure the Audit trail is configured to go to the local log file.	In GPME, go to computer Configuration > Policies > Audit Trail Settings > Global Settings > Send audit trail to log file (this is not configured by default). For details, see "Send audit trail to log file" in the *Group Policy Guide*.

16	You have a role and user to test with. Make sure the role has rights for privilege elevation, such as New Desktop rights or Run as Role.	Make sure that you can elevate privileges successfully for that user and role before you try to configure RADIUS authentication.
	Configure a system to use RADIUS for privilege elevation (using group policies)	
17	Enable and configure the RADIUS group policies.	Configure the following group policies: Windows › MFA Settings › Specify the authentication source for privilege elevation : set this policy to RADIUS Authentication. Windows › MFA Settings › Remote Authentication Dial-In User Service (RADIUS) Settings › Enable Remote Authentication Dial-In User Service (RADIUS): enable this policy. Specify the RADIUS connection timeout: Configure to match your RADIUS timeout setting. Specify the RADIUS server IP address: enter your RADIUS IP address. Specify the RADIUS server port number: enter your RADIUS port number (the default is 1812). For details, see "Remote Authentication Dial-In User Service (RADIUS) Service Settings" in the *Group Policy Guide*. After you update the policies, do a group policy update on the Windows client computer.
18	Configure the role to require re-authentication using multi-factor authentication.	For example: Right-click your test role and choose Properties. The Role Properties dialog box opens. Click the Run As tab. Select Re-authenticate current user and then select Require multi-factor authentication. Click OK to apply the changes.
19	Run dzflush to make sure that the agent has the changes from Access Manager.	For details, see Using dzflush.
20	Set the RADIUS shared secret.	The RADIUS secret is unique to each system and will match the secret that the RADIUS server has. You can set the pre-shared secret by either of the following methods on the client computer: Run the Set-CdmRadiusSecret cmdlet to set the RADIUS shared client secret. For details, see the DirectAuthorize PowerShell cmdlet help. Use the Agent Configuration settings dialog box to configure the RADIUS server, including the pre-shared secret. For details, see Configuring agent settings for the Identity Platform.
	TEST AND VERIFY	
21	Verify that a user can elevate privileges by entering the RADIUS one-time password.	For example, if your role has New Desktop rights: Right-click the System Tray and select New Desktop. In the dialog box that appears, select your test role and click OK. If the RADIUS authentication has been configured successfully, you are prompted to enter a password for RADIUS authentication. Enter the password and click Next to continue. You can also view the audit trails for the successful authentication in the system's event log.
22	Verify that a user cannot elevate privileges after entering an incorrect RADIUS one-time password.	

Adding Remote Users Automatically

If desired, you can configure your deployment so that members of the Windows Login group or the Windows Remote Login group are also automatically added to the Remote Desktop Users group and the ConsoleLogonUser group.

To make this change, add the following registry entry on each computer where you have installed the Agent for Windows: <!---TODO update path --->

HKEY_LOCAL_MACHINE\SOFTWARE\Centrify\DirectAuthorize\Agent\EnableAddUsersToRdpAndConsoleLogOn = 1

If you later uninstall the agent, the uninstall process removes the affected user accounts from the Remote Desktop Users group and the ConsoleLogonUser group. Only the user accounts that the agent added to those groups are affected.

Enabling Users to Run Applications with Alternate Accounts

Alternate accounts are typically a privileged or administrator account in Active Directory that's associated with an owner account. You can log in to the alternate account using your main account.

For example, system administrators typically have several accounts, a user account for general log-ins and an administrative account to access specific systems and services.

Here are the things you need to do in order to enable the ability to run with alternate accounts:

1. Set up alternate accounts for users in Privileged Access Service
2. Install a cloud connector in your domain and the Web Server (IWA) service is enabled.
3. Enable the policy entitled "Enable run with alternate account."
4. (Optional but recommended) Configure the following policies to set up a grace period after which time users running applications with alternate accounts must re-authenticate:
    - "Require re-authentication to run application with alternate account"
    - "Configure Windows authentication grace period for run with alternate account"
5. Install the Agent for Windows and enable the Identity Platform service on each computer where you want users to be able to run with alternate accounts.

If you don't enable the run with alternate account feature, your users can still run applications with these alternate accounts by logging in to Privileged Access Service and checking out the password.

You can manage your local Windows users and groups, if desired. This way, you can centrally manage the accounts.

Overall, to manage local users and groups on Windows systems, you'll need to

- Install the Agent for Windows on each Windows system where you want to manage local accounts.
- Enable local account management on those Windows systems in the Privilege Elevation settings for the agent. For details, see Enabling Windows local account management.
- In Access Manager, you can then add, edit, or remove local users and groups. For details, Adding local Windows accounts and Removing local Windows accounts
- Manage the passwords for local Windows accounts. For details, see Creating and managing local Windows user passwords.
- Use group policies to manage local Windows accounts. .

Adding Local Windows Accounts

Before you enable local account management on your Windows computers, add the local users and groups in Access Manager.

Note: {/b}If you first enable local account management with the enforce option and if you have any existing local accounts on that system but not defined in a zone, then the service will remove those local users during the next synchronization. Built-in local Windows accounts are not removed.

To add a local Windows user:

1. In Access Manager, navigate to either a zone or a Windows computer and go to **Windows Data**
2. Right -click **Local Users** and select **Add User to Zone** or **Add User**, depending on where you're adding the user.
3. Enter the user name and click **OK**.
4. Specify the attributes for the local Windows user:
    - **Full name**: The first and last name of the new local Windows user.
    - **Description**: A description of the user.
    - **State**: Specify one of the following:
        - **Enable**: Set the state to Enable for a local Windows account that is in use.
        - **Disable**: Set the state to Disable for a local Windows account that is not in use.
        - **Remove**: If you've chosen not to enforce local account management, mark the user as Remove and the service will remove the user at the next synchronization interval.

          Note: {/b}The service will not remove any built-in local Windows accounts, even if you mark it as Remove in Access Manager.
    - **Password options**: If desired, select any of the following:
        - **User must change password at next logon**: The service will force the local Windows user to change the account password the next time that the user logs in to the computer. Note that this option applies only to new accounts.
        - **User cannot change password**: The user won't be able to change the password.
        - **Password never expires**: The user's password will never expire.
5. Click **OK** to save your changes.

   The new user will be available on the affected systems after the next local account synchronization.

To add a local Windows group:

1. In Access Manager, navigate to either a zone or a Windows computer and go to **Windows Data**
    1. Right -click **Local Groups** and select **Add Group to Zone** or **Add Group**, depending on where you're adding the group.
    2. Enter the group name and click **OK**.

2. Specify the attributes for the local Windows group:
    - **Description:** Enter a description of your choice.
    - **Members:** Click **Add** to launch the Add Members dialog. In a comma-separated list, type the names of the users who will be in the group.

      Note that Access Manager does not check the validity of the user names that you provide. You should ensure that all of the names that you provide are local Windows user names that currently exist.
    - **State:** Specify either **Enable** or **Remove**.
        - **Enable**: Set the state to **Enable** for a local Windows account that is in use.
        - **Remove**: If you've chosen not to enforce local account management, mark the group as **Remove** and the service will remove the group at the next synchronization interval.
3. Click **OK** to save your changes.

   The new group will be available on the affected systems after the next local account synchronization.

Enabling Windows Local Account Management

You can have Delinea manage your local Windows user and group accounts; to do so, you need to enable and configure a few settings. Install the agent and enable local account management on each Windows system where you want to manage local accounts.

Be aware that if you enable local account management, the service does not delete any built-in Windows users or groups, even if you mark one of those accounts for remove.

Note: {/b}Windows local account management is not supported on domain controllers.

To configure local account management for Windows:

1. From the Privilege Elevation Service Settings dialog box Local Account Management tab, click **Configure**.

   The Local Account Management Configuration dialog box opens.
2. Select the **Enable local account management** option.
3. Select **Yes** to enforce local account management or **No** to not enforce local account management.

   Enforcing local account management means that after you remove a local Windows user or group from Access Manager, the service will remove the local user or group from the computer after the next synchronization.

   If you choose not to enforce local account management, in order to remove a user you mark it as removed rather than explicitly removing the account from Access Manager.
4. Specify a script that will run when the service synchronizes local account information with Access Manager and the affected computers. The script can set the passwords for the local accounts and also display a list of enabled, disabled, or removed users.

   For details, see Creating and managing local Windows user passwords.

   There is a sample script provided that you can use as a starting point:

   C:\Program Files\Centrify\Agent for Windows\SampleNotification.ps1

   The script will run after each synchronization of local accounts when the any of the following have occurred:
    - New local users are added
    - Local users are enabled
    - Local users are disabled
    - Local users are removed
5. Specify a synchronization interval.

   This interval controls how often the service synchronizes local account information between Access Manager and the affected computers. The default is 60 minutes.

6. Click **OK** to save your changes and close the dialog box.

Creating and Managing Local Windows User Passwords

After you create local Windows users, you still need to assign a password to each user. Instead of manually setting the passwords in Local Users and Groups, you'll set up the initial passwords for your local user accounts by way of a PowerShell script.

There is a sample script provided that you can use as a starting point:

C:\Program Files\Centrify\Agent for Windows\SampleNotification.ps1

In general, the script should both set passwords and notify you of changes in local accounts. The script will run after each synchronization of local accounts when the any of the following have occurred:

- New local users are added
- Local users are enabled
- Local users are disabled
- Local users are removed

Typically, the script should perform the following user account tasks:

- Assign a random password to newly provisioned local users.
- Provide the user account information, including the generated passwords, to your password management solution.

After you have the script set up, you can use group policy to automatically run it. .

How you set up the passwords and the script depends on if you're using a password management system or not. Below are the ways you can set up local user passwords.

Use Privileged Access Service to manage local Windows account passwords:

1. Register for Privileged Access Service.
2. Download the Client for Windows software package.
3. On each Windows computer where you will assign passwords to local users, run the cenroll command to register the computer as a managed resource.
4. Create a PowerShell notification script that runs on each of these Windows computers, gives each user a random password, and sends the password to Privileged Access Service.

   In the script, you can set it to run the csetaccount command to send the password to Privileged Access Service.
5. Using one of the following two methods, configure the notification script to run after the agent synchronizes local account information:
   - In the local account management settings for the agent

     Agent settings > Local Account Management tab > Configure > Local Account Management Configuration dialog box
   - In the group policy

     (Settings > Windows Settings > Local Account Management > Notification Command Line)

Use a third-party system to manage local Windows account passwords:

1. Create a PowerShell script that runs on each of these Windows computers and gives each user a random password.
2. Include a section in the script that submits the passwords to the password management product for storage and maintenance.
3. Using one of the following two methods, configure the notification script to run after the agent synchronizes local account information:
   - In the local account management settings for the agent

     Agent settings > Local Account Management tab > Configure > Local Account Management Configuration dialog box
   - In the group policy

(Settings > Windows Settings > Local Account Management > Notification Command Line)

Removing Local Windows Accounts

If you have enabled local account management on a Windows system, there are two different ways to remove users. Your approach depends on if you've configured to enforce local account management or not.

Be aware that if you enable local account management, the service does not delete any built-in Windows users or groups, even if you mark one of those accounts for remove.

To remove a local Windows user or group if local account management is enforced:

- In Access Manager, right-click the user or group and select **Delete**.

  The account is removed from Access Manager immediately. When the service next synchronizes local account information, the service removes the user or group from the affected Windows systems too.

To remove a local Windows user or group if local account management is not enforced:

- In Access Manager, right-click the desired user or group and select **Change Profile State**, then select **Remove**.

  The account is marked as "Remove" and remains visible in Access Manager. When the service next synchronizes local account information, the service removes the user or group from the affected Windows systems too.

This chapter describes how to use the Master Auditor role and group policies to control who is audited and who can search and play back captured user sessions for an installation.

Configuring Selective Auditing

If you are using identity and privilege management features, you can control audit and monitoring service by using Access Manager to configure role definitions with different audit requirements, and then assigning those role definitions to different sets of Active Directory users. For more information about using role definitions to control auditing, see Defining custom roles with specific rights.

If you are using audit and monitoring service without also using identity and privilege management features, you can use group policies to control which Windows users to audit, or to capture activity for all Windows users.

To control audit and monitoring service using group policies:

1. Open the Group Policy Management console.
2. Expand the forest and domains to select the Default Domain Policy object.
3. Right-click, then click **Edit** to open Group Policy Management Editor.
4. Expand Computer Configuration > Policies, then select **DirectAudit Settings**.
5. Select the Audited user list to identify specific users to audit.

   When you enable this group policy, only the users you specify in the policy are audited. If this policy is not configured, all users are audited.
6. Select the Non-audited user list to identify specific users that should not be audited.

   When you enable this group policy, only the users you specify are not audited. If this policy is not configured, all users are audited. If you enable both the Audited user list and the Non-audited user list policies, the users you include in the Non-audited user list take precedence over the Audited user list.

The following table details the effect of configuring and enabling the Audited user list and Non-audited user list group policies, and including or not including Windows users in those lists.

Not configured	Not configured	No users are defined for either policy, so all users accessing audited computers are audited.
Not configured	Enabled	Only the users you specify in the Audited user list policy are audited. If no users are specified when the policy is enabled, no users are audited.
Not configured	Enabled	Only AUL is enabled, but user is not listed in it.
Enabled	Not configured	If no users are specified in the Non-audited user list and the policy is enabled, no users are exempt from auditing. All users are audited.
Enabled	Enabled	If both policies are enabled, the non-audited user takes precedence over the audited list of users. If a user is specified in the audited list, that user is explicitly audited. If a user is specified in the non-audited list, that user is explicitly not audited. If the same user is specified in both lists, the user is not audited because the non-audited user takes precedence. If no users are specified for either policy, all users are audited because the non-audited user takes precedence.

Enabling Audit Notification

If you enable audit notification, users see a message informing them that their actions are being auditing when they log on. fter you enable notification, the

message is always displayed on audited computers if the session activity is being recorded.

To enable audit notification for an installation:

1. In the Audit Manager console, right-click the installation name, then select **Properties**.
2. Click the **Notification** tab.
3. Select **Enable notification**.

   Deselect this option to turn off notification.
4. Click the browse button to locate and select a text file that contains the message you want to display.

   A notification message is required if you select the Enable notification option. The contents of the file you select are displayed below the file location. The maximum text file size is 30 KB.
5. Click the browse button to locate and select an image to appear as a banner across the top of the audit notification.

   Displaying a banner image is optional when you enable notification. The maximum image file size is 15 KB. For the best image display, use an image that is 468 pixels wide by 60 pixels high.

   Note: {/b}Animated GIF files are not supported for use as audit notifications. If you do specify an animated GIF, the image displays as a static image.
6. Click **OK** or **Apply**.

   Users will see the notification message the next time they log in.
7. If you enable notification after you have deployed agents, update the local policy on the audited computers by running the following command:

   gpupdate /FORCE

Managing Audit Roles and Auditors

Audit roles grant access to auditors to search, replay, and delete specific audited sessions using the Audit Analyzer console. Each audit role identifies a set of audited sessions, the list of auditors who have access to those sessions, and what the auditors in a specific role are allowed to do.

You identify a set of sessions by specifying criteria you want to use, for example, all sessions from a particular audited computer, associated with a specific application, or recorded during a specific period of time.

You identify the auditors for a set of sessions by specifying individual Active Directory users or Active Directory groups of auditors. If you use Active Directory groups, you can manage the privileges for all of the members of the group using your existing procedures for managing Active Directory groups. You can also configure the type of access granted to each member of the audit role.

You create and assign users and groups to audit roles using the Audit Manager console. You create the audit roles by rightclicking on the Audit Roles node. You add users and groups to an audit role by right-clicking on the specific role name.

Every installation automatically has a Master Auditor role. The Master Auditor has access to all audit data and permission to read, replay, update the review status, and delete sessions for the entire installation. The Master Auditor can also create roles, assign users, set permissions, and delegate administrative tasks for all of the audit stores in the installation. You cannot rename, delete, or modify permissions for the Master Auditor, but you can assign other users and groups to the Master Auditor role.

Granting Permission to Manage Audit Roles

The Master Auditor can grant the Manage Audit Role permission for an installation to one or more audit team leaders. The Manage Audit Role permission grants full control over all of the audit roles in the installation. An audit team leader can then create new roles, change the permissions specific audit roles grant, add or remove members, and remove roles.

When creating an audit role, an audit team leader defines the following:

- Target session type and optional other criteria.
- A collection of rights on the target sessions: Read, Update Status, Replay, and Delete.

For example, an audit team leader might define the following audit roles to control what different team members can do:

- A role named Windows Session Viewer for first level reviewers with a target of Windows sessions and only the right to Read session information. The members of the First Review group who are assigned to the Windows Session Viewer audit role can read, but not delete, replay or update the status of Windows sessions in the installation.
- A role named Incident Escalation for security managers with a target of Windows sessions from the last 72 hours, and permission to Read, Replay, and Update Status for the targeted session. The members of the Security group who are assigned to the Incident Escalation audit role can read, replay, and update the review status of Windows sessions from the previous 72 hours, but not delete any of the sessions they have reviewed.

Creating a New Audit Role

If you are the Master Auditor or have been granted the Manage Audit Role right, you can create new audit roles for your organization.

To create a new audit role:

1. Open Audit Manager.
2. Select Audit Roles, right-click, then click **Add Audit Role**.
3. Type a name and description for the new audit role, then click **Next**.
4. Select the type of session.

   For example, select Windows session to limit this audit role to sessions captured by the Agent for Windows.
5. Click **Add** to select additional criteria, such as time constraints, review status, or application used.

   After you click Add, select an attribute and the appropriate criteria, then click **OK**. For example, if you select Time, you can then select specific date range or a period of time, such as the past 24 hours or this year.
6. Click **Execute Query** to test the criteria you have selected by examining the results the query returns.
7. Click **Close** to close the query results, then click **Next**.
8. Select the rights to allow for this role, then click **Next**.
9. Review your settings for this role, then click **Next**.

   By default, the Assign Users and Groups to the Audit Role option is selected so that you can immediately begin populating the new audit role.
10. Click **Finish** to begin adding users and groups to the role.

Assigning Users and Groups to an Audit Role

If you selected the Assign Users and Groups to the Audit Role option at the end of the Add Audit Role wizard, the Assign Users and Groups to the Audit Role wizard opens automatically. You can also open the wizard at any time by right-clicking a specific audit role name in the Audit Manager console and choosing Assign Users and Groups.

To assign users and groups to an audit role:

1. Open Audit Manager.
2. Expand Audit Roles, and select a specific audit role name.
3. Right-click, then click **Assign Users and Groups**.
4. Type all or part of a name and click **OK**.

   If there is more than one name that matches the criteria you specify, select the appropriate name from the names found, then click **OK**. A user or group can be a member of more than one audit role.

Delegating Audit-related Permissions

As the Master Auditor, you can delegate administrative tasks to other Active Directory users or groups. When you grant administrative rights to designated users and groups, you make them “trustees” with permission to perform specific operations. Because delegating administrative tasks to other users is a key part of managing an installation, it is covered in the next chapter.

However, one of the permissions you can delegate to other users and groups is the Manage Audit Role permission. With this permission, selected trustees can create, modify, and delete audit roles. For more information about delegating administrative tasks, see Setting administrative permissions.

Modifying an Audit Role's Properties

The Master Auditor and the audit roles you define are listed under Audit Roles in the Audit Manager console. Selecting a specific audit role name displays a list of members in the right pane. If you are the Master Auditor or been granted the Manage Audit Role permission, you can modify the properties for an audit role after you have created it by selecting the role in Audit Manager, right-clicking, then selecting Properties. For example, you can change the name or description of an audit role, specify the type of sessions members of the role can access, the privileges the audit role grants, and the users and groups who are assigned to the audit role.

How Access Roles and Audit Roles Differ

Depending on whether you have enabled audit and monitoring service together with identity and privilege manager on an agent-managed computer, you might have two sets of roles or just one set of roles and the information captured and the activity allowed depends on the type of role being used.

Identity and Privilege Management Only

If you have only enabled identity and privilege management on a computer and defined access roles:

- Users will not be able to log on if they are assigned to a role where is audit and monitoring service required.
- Users will be able to log on if they are assigned to a role where the audit if possible option is set. In this case, only identity and privilege management audit trail events are captured. For example, the agent records successful and failed logons and when users change from one role to another. Because audit and monitoring service is not enabled, the agent does not capture a video record of all user activity. You also are not able to define audit roles to control who can read or delete audit trail records.
- Users will be able to log on if they are assigned to a role that does not require audit and monitoring service. In this case, only identity and privilege management audit trail events are captured.
- Auditors will not be able to review user activity on these computers. You also are not able to define audit roles to control who can read or delete audit trail records.

If no audit and monitoring service components are installed, you must use the Windows Event Viewer to search for and review audit trail events.

Auditing Only

If you have enabled only audit and monitoring service on a computer and defined access roles:

- Users will be able to log on if they are assigned to a role where audit and monitoring service is required as long as the agent is running.
- Users will be able to log on if they are assigned to a role where the audit if possible option is set. In this case, logging on starts a video record of all user activity on the computer. Because identity and privilege management are not enabled, the user cannot select any access roles that provide desktop, application, or network access rights. The user cannot change roles so only the audit trail records successful and failed logons events.
- Users will be able to log on if they are assigned to a role that does not require audit and monitoring service. In this case, audit trail events are recorded, but no session activity is captured.
- Auditors will be able to review all or selected user activity on these computers, and you can define audit roles to control who has access to the captured user sessions based on the criteria you specify.

Identity and Privilege Management and Auditing on the Same Computer

If you have enabled audit and monitoring service together with identity and privilege management on the same computer and defined access and audit roles:

- Users will be able to log on if they are assigned to a role where audit and monitoring service is required as long as the agent is running. If the agent is stopped for any reason, the user will be allowed to log on only if also assigned a role with a rescue system right.
- Users will be able to log on if they are assigned to a role where the audit if possible option is set. If the audit and monitoring service service is active and you have enabled video capture auditing, both audit trail events and user activity are captured. For example, the agent records successful and failed logons and user activity when users change from one role to another. If the audit and monitoring service service is not enabled or not currently active, the agent does not capture a video record of all user activity.
- Users will be able to log on if they are assigned to a role that does not require audit and monitoring service. In this case, only audit trail events are captured.
- Auditors will be able to review user activity associated with specific roles on these computers, and you can define audit roles to control who has access to the captured user sessions based on the criteria you specify.

This chapter describes how to secure and manage the audit and monitoring service infrastructure after the initial deployment of Delinea software on Windows computers. It includes tasks that are done by users assigned the Master Auditor role for an installation and users who are Microsoft SQL Server database administrators.

Securing an Installation

For production deployments, you can take the following steps to secure an audit and monitoring service installation:

- Use the Installation group policy to specify which installation agents and collectors are part of. By enabling the Installation group policy you can prevent local administrators from configuring a computer to be part of an unauthorized installation.
- Configure a trusted group of collectors to prevent a hacker from creating a rogue collector to collect data from agents.
- Configure a trusted group of agents to prevent a hacker from performing a Denial of Service attack on the collector and database by flooding a collector with false audit data.
- Encrypt all data sent from the collector to the database.

Before you can follow these steps to secure an installation, you must have access to an Active Directory user account with permission to create Active Directory security groups, enable group policies, and edit Group Policy Objects.

To secure an installation using Windows group policy:

1. Open the Group Policy Management console.
2. Expand the forest and domain to select the Default Domain Policy object.
3. Right-click, then click **Edit** to open Group Policy Management Editor.
4. Expand **Computer Configuration** › **Policies** › **CentrifyDirectAudit <!---TODO update filename---> Settings**, then select **Common Settings**.
5. Double-click the **Installation** policy in the right pane.
6. On the Policy tab, select **Enabled**.
7. Click **Browse** to select the installation you want to secure, then click **OK**.
8. Click **OK** to close the Installation properties.

Securing an Audit Store with Trusted Collectors and Agents

By default, audit stores are configured to trust all audited computers and collectors in the installation. Trusting all computers by default makes it easier to deploy and test audit and monitoring service in an evaluation or demonstration environment. For a production environment, however, you should secure the audit store by explicitly defining the computers the audit store can trust.

You can define two lists of trusted computers:

- Audited computers that can be trusted.
- Collector computers that can be trusted.

To secure an audit store:

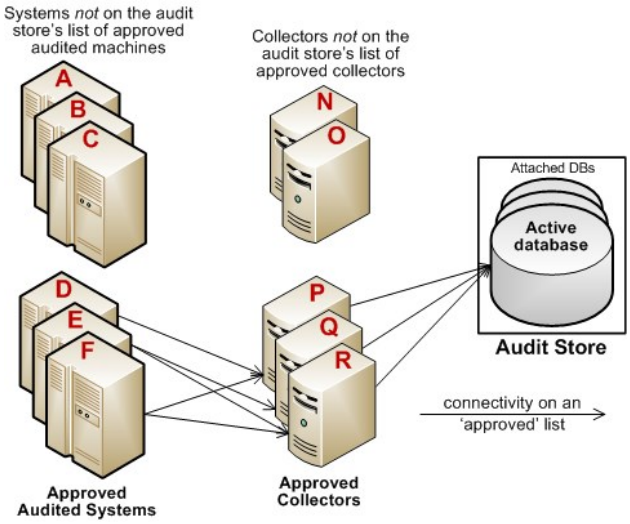
1. Open the Audit Manager console.
2. Expand the installation and Audit Stores nodes.
3. Select the audit store you want to secure, right-click, then select **Properties**.
4. Click the **Advanced** tab.
5. Select **Define trusted Collector list**, then click **Add**.
6. Select a domain, click **OK**, then search for and select the collectors to trust and click **OK** to add the selected computers to the list.

   Only the collectors you add to the trusted list are allowed to connect to the audit store database. All other collectors are considered untrusted and cannot write to the audit store database.
7. Select **Define trusted Audited System list**, then click **Add**.
8. Select a domain, click **OK**, then search for and select the audited computers to trust and click **OK** to add the selected computers to the list.

Only the audited computers you add to the trusted list are allowed to connect to the trusted collectors. All other computers are considered untrusted and cannot send audit data to trusted collectors.

9. Click **OK** to close the audit store properties dialog box.

The following example illustrates the configuration of trusted collectors and trusted audited computers.



In this example, the audit store trusts the computers represented by P, Q, and R.Those are the only computers that have been identified as trusted collectors in the audit store Properties list. The audit store has been configured to trust the audited computers represented by D, E, and F. As a result of this configuration:

- Audited computers D, E, and F only send audit data to the trusted collectors P, Q, and R.
- Trusted collectors P, Q, and R only accept audit data from the trusted audited computers D, E, and F.
- The audit store database only accepts data for its trusted collectors P, Q, and R, and therefore only stores audit data that originated on the trusted audited computers D, E, and F.

Disabling a trusted list

After you have added trusted collectors and audited computers to these lists, you can disable either one or both lists at any time to remove the security restrictions. For example, if you decide to allow audit and monitoring service data from all audited computers, you can open the audit store properties, click the Advanced tab, and deselect the **Define trusted Audited System list** option. You don't have to remove any computers from the list. The audit store continues to only accept data from trusted collectors.

Using security groups to define trusted computers

You can use Active Directory security groups to manage trusted computer accounts. For example, if you create a group for trusted audited computers and a group for trusted collectors, you can use those groups to define the list of trusted collectors and audited computers for the audit store. Any time you add a new computer to one of those groups, thereafter, it is automatically trusted, without requiring any update to the audit store properties.

Securing Network Traffic with Encryption

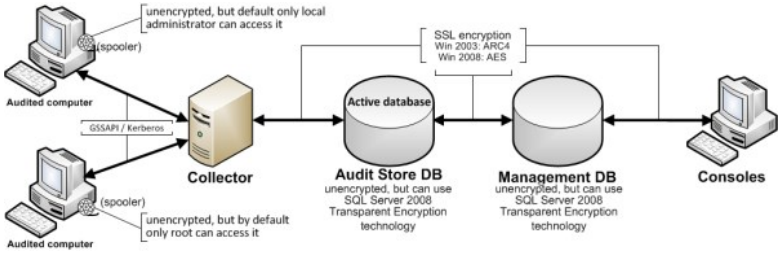
The last step in securing an installation is to secure the data collected and stored through encryption. The following summarizes how data is secured as it moves from component to component:

- Between an audited computer and the spooler that stores the data locally when no collectors are available, audit data is not encrypted. Only the local Administrator account can access the data by default.
- Between the audited computer's data collection service (wdad) and the collector, data is secured using Generic Security Services Application Program Interface (GSSAPI) with Kerberos encryption.
- Between the collector and the audit store database, data can be secured using Secure Socket Layer (SSL) connections and ARC4 (Windows 2003) or AES (Windows 2008) encryption if the database is configured to use SSL connections.
- Between the audit store and management databases, data can be secured using Secure Socket Layer (SSL) connections and ARC4 (Windows 2003) or

AES (Windows 2008) encryption if the database is configured to use SSL connections.

- Between the management database and the Audit Manager console, data can be secured using Secure Socket Layer (SSL) connections and ARC4 (Windows 2003) or AES (Windows 2008) encryption if the database is configured to use SSL connections.

The following illustration summarizes the flow of data and how network traffic is secured from one component to the next.



Enabling Secure Socket Layer (SSL) communication

Although the database connections can be secured using SSL, you must configure SSL support for Microsoft SQL Server as part of SQL Server administration. You must also have valid certificates installed on clients and the database server. If you are not the database administrator, you should contact the database administrator to determine whether encryption has been enabled and appropriate certificates have been installed. For more information about enabling SSL encryption for SQL Server and installing the required certificates, see the following Microsoft support article:

http://support.microsoft.com/kb/316898

Enabling encryption for Microsoft SQL Server Express

If you use Microsoft SQL Server Express, encryption is turned off by default. To secure the data transferred to the database server, you should turn encryption on.

To enable encryption for each audit store and management database:

1. Log on to the computer hosting an audit store or management database with an account that has database administrator authority.
2. Open **SQL Server Configuration Manager**.
3. Select the SQL Server Network Configuration node, right-click **Protocols for** *DBINSTANCE*, then select **Properties**.
4. On the **Flags** tab, select **Yes** for the **Force Encryption** option, then click **OK** to save the setting.

Using a service account for Microsoft SQL Server

When you install Microsoft SQL Server, you specify whether to use Windows authentication or a mix of Windows and SQL Server authentication. You also specify the accounts that the database services should use. By default, system accounts are used. If SQL Server uses a domain user account instead of a system account, you should ensure that the account has permission to update the SQL Server computer object in Active Directory. If the account has permission to update the computer where SQL Server is running, SQL Server can publish its service principal name (SPN) automatically. Getting the correct service principal name is important because Windows authentication relies on the SPN to find services and DirectManage Audit uses Windows authentication for console-to-audit management database connections. If the SPN is not found, the connection between the console and audit management database fails.

The audit management database-to-audit store connection and the collector-to-audit store connection can use either Windows authentication or SQL Server authentication. If SQL Server authentication is used, it does not matter whether the SQL Server instance uses a system account or a service account. If you have configured SQL Server to use Windows authentication only, be sure that the Windows account is allowed to connect to the audit management database and to the audit store database.

Setting Administrative Permissions

When you create a new installation, you become the primary administrator for that installation. As the primary administrator and Master Auditor, you have full control over the entire installation and the ability to delegate administrative tasks to any other Active Directory user or group. When you grant administrative rights to designated users and groups, you make them "trustees" with permission to perform specific operations. You can set granular permissions to tightly control what specific users can do or grant broad authority over operations in an installation.

If you have a large or widely-distributed installation, you can also install additional Audit Manager and Audit Analyzer consoles for the users who have been delegated administrative tasks to use.

To delegate administrative tasks to other users:

1. Open Audit Manager.
2. Select the installation name, right-click, then click **Properties**.
3. Click the **Security** tab to delegate administrative tasks for the entire installation.
4. Click **Add** to add Active Directory users or groups to the list of trustees who granted any type of rights on this installation.
5. Select a user or group listed, then select the appropriate rights for that trustee, then click **OK**.

   The following table lists the rights available.

Full Control	All operations on the selected installation.
Change Permissions	Add or remove users and groups as trustees for the installation. Modify permissions for trustees on the selected installation.
Modify Name	Modify display name for the selected installation.
Manage Management Database List	Add or remove management databases for the selected installation.
Manage Audit Store List	Add or remove audit stores for the selected installation.
Manage Collectors	Enable a trusted group of collectors for this audit store. Add a collector to the trusted group of collector in this audit store. Remove collector from the trusted collectors in this audit store. Remove disconnected collector records from this audit store.
Manage Audited Systems	Enable trusted group of audited computers for this audit store. Add a computer to the trusted group of audited computers in this audit store. Remove a computer from the trusted group of audited computers in this audit store. Remove disconnected audited computer records from this audit store.
Manage Audit Role	Add, modify, or remove audit roles in the selected installation. Assign users and groups to audit roles. Remove users and groups from roles.
Manage Queries	Add, modify, or remove queries in the selected installation.
Manage Publications	Add or remove publication locations for the selected installation.
Manage Licenses	Add or remove license keys for the selected installation.
Modify Notification	Enable or disable audit notification in the selected installation. Select the notification message. Select a banner image.
Modify Audit Options	Enable or disable the option to capture video of all user activity on audited computers. Control whether users are allowed to update the review status of their own sessions. Control whether users are allowed to delete their own sessions.
View	Enable to view audited computers and sessions.

1. Click **OK** to complete the delegation of administrative rights for the selected installation.

You can also delegate administrative tasks for individual audit stores and management databases, and set permissions on audit roles. For information about delegating administrative tasks for audit stores, see Configuring permissions for an audit store. For information about delegating administrative tasks for management databases, see Configuring permissions for the management database.

For information about setting permissions on audit roles, see Managing audit roles and auditors.

Managing Audit Stores

An audit store defines a set of Active Directory sites or subnets and a collection of databases that contain audit data. Typically, an installation has one audit store with multiple databases. However, you can add audit stores if you are auditing computers in a large and widely distributed network or have multiple Active Directory sites with computers you want to audit.

Configuring the Scope of an Audit Store

In most organizations, a single audit store is used to map to an Active Directory site. However, there are situations where you might want to define the scope of an audit store based on subnets. For example:

- If you have a subnet that Active Directory considers part of a site that is connected over a slow link you might want to configure a separate audit store and collectors that service audited computers in the remote subnet.
- If you have very large Active Directory site, you might require multiple audit stores for load distribution. You can accomplish this by partitioning an Active Directory site into multiple audit stores based on subnets. Each subnet has its own audit store, set of collectors, and audited computers.

You can configure the scope of an audit store by adding or removing Active Directory sites or subnets.

To configure the scope for an audit store:

1. Open Audit Manager.
2. Expand the installation node, then expand Audit Stores and select a specific audit store name.
3. Right-click, then select **Properties**.
4. Click the **Scope** tab.
5. Click **Add Site** to select an Active Directory site from the list of sites found or click **Add Subnet** to type a specific subnet address and mask.

Configuring Permissions for an Audit Store

If you are the Master Auditor or have Change Permission rights, you can modify the rights granted to Active Directory users or groups. When you enable rights for designated users and groups, you make them "trustees" with permission to perform specific operations.

To configure permissions for managing the audit store:

1. Open Audit Manager.
2. Expand the installation node, then expand Audit Stores and select a specific audit store name.
3. Right-click, then select **Properties**.
4. Click the **Security** tab.
5. Click **Add** to add Active Directory users or groups to the list of trustees who granted any type of rights on this audit store.
6. Select a user or group listed, then select the appropriate rights for that trustee, then click **OK**.

   The following table lists the rights available.

Full Control	All operations on the audit store.
Change Permissions	Modify permissions on this audit store.

Modify Name	Modify display name for this audit store.
Manage Scopes	Add a subnet or Active Directory site to the audit store. Remove a subnet or Active Directory site from the audit store.
Manage SQL Logins	Set the allowed incoming collectors for this audit store's databases. Set the allowed incoming management databases for this audit store's databases.
Manage Collectors	Enable a trusted group of collectors for this audit store. Add a collector to the trusted group of collector in this audit store. Remove collector from the trusted collectors in this audit store. Remove disconnected collector records from this audit store.
Manage Audited Systems	Enable trusted group of audited computers for this audit store. Add a computer to the trusted group of audited computers in this audit store. Remove a computer from the trusted group of audited computers in this audit store. Remove disconnected audited computer records from this audit store.
Manage Databases	Add audit store databases to this audit store. Attach audit store databases to this audit store. Detach an audit store database from this audit store. Change the active database in this audit store. Modify the display name of an audit store database.
Manage Database Trace	Enable or disable database trace. Export database trace.

Managing Audit Store Databases

During the initial deployment, your installation only has one audit store database. As you begin collecting audit data, however, that database can quickly increase in size and degrade performance. Over time, an installation typically requires several Microsoft SQL Server databases to store the data being captured and historical records of session activity, login and role change events, and other information. As part of managing an installation, you must manage these databases to prevent overloading any one database and to avoid corrupting or losing data that you want to keep.

One of the biggest challenges in preparing and managing Microsoft SQL Server databases for storing audit data is that it is difficult to estimate the level of activity and how much data will need to be stored. There are several factors to consider that affect how you configure Microsoft SQL Server databases for auditing data, including the recovery method, memory allocation, and your backup and archiving policies.

For more complete information about managing and configuring SQL Server, however, you should refer to your Microsoft SQL Server documentation.

Selecting a Recovery Model

Standard backup and restore procedures come in three recovery models:

- **Simple**—The simple recovery model allows high-performance bulk copy operations, minimizes the disk space required, and requires the least administration. The simple recovery model does not provide transaction log backups, so you can only recover data to the point of the most recent full or differential backup. The default recovery model is simple, but is not appropriate in cases where the loss of recent changes is not acceptable.
- **Full**—The full recovery model has no work-loss exposure, limits log loss to changes since the most recent log backup, and provides recovery to an arbitrary time point. However, the full recovery model uses much more disk space.
- **Bulk-logged**—The bulk-logged recovery model provides higher performance and minimizes the log space used by disk-intensive operations, such as create index or bulk copy. With the bulk-logged recovery model, you can only recover data to the point of the most recent full or differential backup. However, because most databases undergo periods of bulk loading or index creation, you can switch between bulk-logged and full recovery models to minimize the disk space used to log bulk operations.

When a database is created, it has the same recovery model as the **model** database. Although the simple recovery model is the default, the full and bulk-logged recovery models provide the greatest protection for data, and the full recovery model provides the most flexibility for recovering databases to an earlier point in time. To change the recovery model for a database, use the ALTER DATABASE statement with a RECOVERY clause.

Regardless of the recovery model you choose, you should keep in mind that backup, restore, and archive operations involve heavy disk I/O activity. You should schedule these operations to take place in off-peak hours. If you use the simple recovery model, you should set the backup schedule long enough to prevent

backup operations from affecting production work, but short enough to prevent the loss of significant amounts of data.

Configuring the Maximum Memory for Audit Store Databases

Because Microsoft SQL Server uses physical memory to hold database information for fast query results, you should use a dedicated instance to store auditing data. Because SQL Server dynamically acquires memory whenever it needs it until it reaches the maximum server memory you have configured, you should set constraints on how much physical memory it should be allowed to consume.

The maximum server memory (max server memory) setting controls the maximum amount of physical memory that can be consumed by the Microsoft SQL Server buffer pool. The default value for this setting is such a high number that the default maximum server memory is virtually unlimited. Because of this default value, SQL Server will try to consume as much memory as possible to improve query performance by caching data in memory.

Processes that run outside SQL Server, such as operating system processes, thread stacks, socket connections and Common Language Runtime (CLR) stored procedures are not allowed to use the memory allocated to the Microsoft SQL Server buffer pool. Because those other processes can only use the remaining available memory, they might not have enough physical memory to perform their operations. In most casts, the lack of physical memory forces the operating system to read and write to disk frequently and reduces overall performance.

To prevent Microsoft SQL Server from consuming too much memory, you can use the following formula to determine the recommended maximum server memory:

- Reserve 4GB from the first 16GB of RAM and then 1GB from each additional 8GB of RAM for the operating system and other applications.
- Configure the remaining memory as the maximum server memory allocated for the Microsoft SQL Server buffer pool.

For example, if the computer hosting the Microsoft SQL Server instance has 32GB of total physical memory, you would reserve 4 GB (from first 16 GB) + 1GB (from next 8 GB) + 1 GB (from next 8 GB) for the operating system, then set the Maximum server memory for Microsoft SQL server to 26 GB (32 GB – 4 GB – 1 GB – 1 GB = 26).

For more information about how to configure Microsoft SQL Server maximum memory setting and other memory options, see the following Microsoft article: https://docs.microsoft.com/en-us/previous-versions/sql/sql-server-2008-r2/ms178067(v=sql.105)

You should configure the maximum memory allowed for the Microsoft SQL Server instances hosting audit store databases and the management database. However, this setting is especially important to configure on the Microsoft SQL Server instance hosting the active audit store database.

Using Transact-SQL to Configure Minimum and Maximum Memory

You can control the minimum and maximum memory that the SQL Server buffer manager uses by issuing Transact-SQL commands. For example:

```
sp_configure 'show advanced options', 1
reconfigure
go
sp_configure 'min server memory', 60
reconfigure
go
sp_configure 'max server memory', 100
reconfigure
go
```

For more information about configuring SQL Server and setting minimum and maximum server memory using T-SQL, see https://docs.microsoft.com/en-us/sql/database-engine/configure-windows/server-memory-server-configuration-options?view=sql-server-2017

Estimating Database Requirements Based on the Data you Collect

To determine how audit and monitoring service will affect database capacity, you should monitor a pilot deployment of 20 to 25 agents with representative activity to see how much data is produced daily. For example, some audited computers might have few interactive user sessions or only short periods of activity. Other audited computers might have many interactive user sessions or long sessions of activity on average.

During the pilot deployment, you want to the following information:

- How many interactive user sessions occur daily on each computer?
- How long do sessions last on average?
- What are the activities being captured, and what is the average size of each session being captured?
- How long do you need to store the captured data to balance performance and storage?

- What is the data retention period for audited data?

From the information you collect in the pilot deployment and the data retention policy for your organization, you can estimate the database size using the following guideline:

(number of agents) x (number of sessions per agent) x (average data size per session) x (retention days)

Results in the estimated size of the Microsoft SQL Server database for the number of days in the retention policy

For example, if an average session generated 100 KB in the database and the installation had 250 agents, 10 sessions per agent, and a six-month retention period (about 130 working days), the storage requirement for the audit store database would be 36.9 GB:

250 agents x 10 sessions/agent each day x 100 KB/session x 130 days = 32,500,000 KB

The following table shows examples of the data storage requirement in an installation with Windows agents, typical levels of activity with an average of one session per day on each audited computer, and the recovery mode set to Simple:

100	20 minutes	806 KB - low activity	79 MB	394 MB	10 GB
50	25 minutes	11.56 MB - high activity	578 MB	2.81 GB	73.36 GB
100	20 minutes	9.05 MB - high activity	905 MB	4.42 GB	115 GB

In this example, an installation with 100 Windows agents with low activity would require approximately 10 GB for the audit store database to keep audit data for 6 months. An increase in the number of interactive sessions, session length, or average session size would increase the database storage required.

If SQL Server requires more space to accommodate the new data, it expands the database file immediately, which can cause degraded performance. To reduce the effect of database expansion on performance, allocate sufficient space to support database growth. In addition, monitor database space and when space is low, schedule a database expand operation for an off-peak time.

Adding New Audit Store Databases to an Installation

When you first set up an installation, you also create the first audit store and audit store database. By default, that first database is the active database. As you begin collecting audit data, you might want to add databases to the audit store to support a rolling data retention policy and to prevent any one database from becoming a bottleneck and degrading performance.

Only one database can be the active database in an audit store at any given time. The computer hosting the active database should be optimized for read/write performance. As you add databases, you can change the older database from active to attached. Attached databases are only used for querying stored information and can use lower cost storage options.

Note: {/b}A single instance of Microsoft SQL Server can host multiple databases.

Audit store databases have the following characteristics:

- A database can be active, attached, or detached.
- Only one database can be actively receiving audit data from collectors.
- A database cannot be detached while it is the active database.
- A database that was previously the active database cannot again be the active database.
- If a detached database contains parts of sessions presented to the Audit Analyzer, a warning is displayed when the auditor replays those sessions.

Rotating the Active Database

Database rotation is a management policy to help you control the size of the audit store database and the performance of database operations. There are several reasons to do database rotation:

- It is more difficult to manage one large database than multiple small databases.
- Performance is better with multiple small databases.
- Backing up, restoring, archiving, and deleting data all take significantly more time if you work with one large database.

- Database operations take very little time when you work with multiple small databases.

For audit and monitoring service, you can implement a database rotation policy by having the collector write data to a new database after a certain period of time. For example, the collector in site A writes data to the database siteA-2014-11 in November, then write data to database siteA-2014-12 in December and to the database siteA-2015-01 in January. By rotating from one active database to another, each database stays more compact and manageable.

Creating a New Database for Rotation

You can rotate from one active database to another at any time using the Audit Manager console.

To create a new database for rotation:

1. Open Audit Manager.
2. Expand the installation node, then expand Audit Stores and a specific audit store name.
3. Select Databases, right-click, then select **Add Audit Store Database** to create a new database.
4. Select the **Set as Active database** option so collectors start writing to the newly created database.

It is possible to write a script to automate the database rotation process. For details, see the SDK documentation.

Database Archiving

To implement periodic archiving, add a new active database, leave one or more previous databases attached, and take the oldest database off-line for archiving.

Queries During Rotation and Archiving

If the database backup program supports online backup, the Audit Analyzer can still query the database while the backup is in progress. However, the backup program may block updates to the session review status. If the backup program does not support online backup, the database will be offline until the backup is complete.

Database Backups

You can back up a database whether it is attached to the audit store or detached from the audit store.

Allowed Incoming Accounts

You can specify the accounts that are allowed to access the audit store database. By configuring these accounts, you can control which collector computers can connect to the audit store database and which management databases have access to the data stored in the audit store database.

Your account must have Manage SQL Login permission to configure the incoming accounts.

To configure allowed accounts:

1. Open Audit Manager.
2. Expand the installation node, then expand Audit Stores and select a specific audit store name.
3. Select a database under the audit store, right-click, then select **Properties**.
4. Click the **Advanced** tab.
5. Click **Add** to add a collector or management database account. For example:

   ![alt](images/8d96b4edb390e2b9de495a3a7399d708.png "Add Collector or Management Database Account)

6. Select an authentication type.
   - If you select Windows authentication, you can browse to select a computer, user, or group to add.
   - If you select SQL Server authentication, you can select an existing SQL Server login or create a new login.

Connections should use Windows authentication whenever possible. However, computers in an untrusted forest cannot connect to an audit management database using Windows authentication. To allow connections from an untrusted forest, add a SQL Server login account as the incoming account for the management database.

Managing the Management Database

The audit management database keeps track of where components are installed and information about the installation. To connect to the database or manage its properties, select a specific installation name in Audit Manager, right-click, then select **Management Databases**.

Configuring the Scope of the Management Database

The audit management database stores information about the set of Active Directory sites or subnets it supports. You can modify the scope of the management database if you are auditing computers in a large and widely distributed network or have multiple Active Directory sites with computers you want to audit.

To configure the scope for a management database:

1. Open Audit Manager.
2. Select the installation name, right-click, then select **Management Database**.
3. Click **Properties**, then click the **Scope** tab.
4. Click **Add Site** to select an Active Directory site from the list of sites found or click **Add Subnet** to type a specific subnet address and mask.

Configuring Permissions for the Management Database

If you are the Master Auditor or have Change Permission rights, you can modify the rights granted to Active Directory users or groups. When you enable rights for designated users and groups, you make them "trustees" with permission to perform specific operations.

To configure audit store security:

1. Open Audit Manager.
2. Select the installation name, right-click, then select **Management Database**.
3. Click **Properties**.
4. Click the **Security** tab.
5. Click **Add** to add Active Directory users or groups to the list of trustees who granted any type of rights on this management database.
6. Select a user or group listed, then select the appropriate rights for that trustee, then click **OK**.

   The following table lists the rights available.

Full Control	All operations on the management database.
Change Permissions	Modify permissions on the management database.
Modify Name	Modify display name for this management database.
Manage Scopes	Add a subnet or Active Directory site to the management database. Remove a subnet or Active Directory site from the management database.
Manage SQL Logins	Set the allowed incoming accounts for the management database. *Database owner is by definition an allowed user.* Set the outgoing account for the management database.
Remove Database	Remove this audit management database from the installation.
Manage Database Trace	Enable or disable database trace. Export database trace.

Managing Collectors

You can view information about the collectors you have deployed in the Audit Manager console. For example, for each collector, you can see the location of the collector on the network, whether the collector is connected to or disconnected from the audit store, and how long a connected collector has been running since it was last restarted, the audit store to which the collector is assigned, and the active database to which the collector is currently sending audit data. You can also see the audited computers that currently connected to each collector and the audited computers that are not currently connected to this collector.

If you install the collector service on a computer but it has never connected to any agents or audit stores, it is not included in collector list on the Audit Manager console.

Monitoring Collector Status Locally

In addition to the information available in the Audit Manager console, the Windows computers on which you have installed a collector provide a local Collector Control Panel applet. The Collector Control Panel displays information about current connectivity and status for the local collector. You can use the control panel to configure the collector port number, installation, and authentication type if you want to make changes after the initial deployment. You can also use the control panel to start, stop, or restart the collector service, and to generate diagnostic information about the collector.

1. Log on to the computer on which you have installed a collector.
2. In the list of applications on the Windows Start menu, click **Audit Collector Control Panel** to open the audit collector control panel.
3. On the General tab, click **Configure** to change the port number, installation, or type of authentication to use when connecting to the audit store.

   The General tab also displays current configuration and status for the local collector service. If you make changes, the new information is displayed after a short period of time.
4. Click **Stop** if you want to temporarily stop a running service, or **Restart** if you want to stop and immediately restart a running collector service.
5. Click the Troubleshooting tab, then click **Diagnostics** to generate diagnostic information about the installation the collector is part of, the Active Directory site or subnets associated with the audit store the collector connects to, the collector status, and other information. For example:

   After you generate diagnostic information, you can right-click to select all of the text. With the text selected, right-click, and select Copy to copy and paste the diagnostic report into a text file.
6. Click **Options** to specify the level of detail to include in the log file or to turn off logging.

   The default log level reports informational messages, warnings, and errors. You can click **View Log** to see information in the current log file.
7. Click **Close** to return to the agent configuration panel.

Removing Collectors

If you want to remove a collector, you can use the Programs and Features > **Uninstall a program** control panel or the setup program you used to install the collector.

If you run the setup program, select the collector from the list of components, then click Next. Because a collector is installed, the wizard prompts you the Change, Repair or Remove the collector. Click **Remove**.

Managing Audited Computers and Agents

You can see information about audited computers and the audit and monitoring service status of Agents for Windows using the Audit Manager console. For example, for each audited computer, you can see the computer name and IP address, whether the audited agent is currently connected or disconnected, and how long the agent has been running since it was last restarted. You can also see the collector to which the agent is sending data and the audit store and audit store database where the audit data is stored.

Monitoring Agent Status Locally

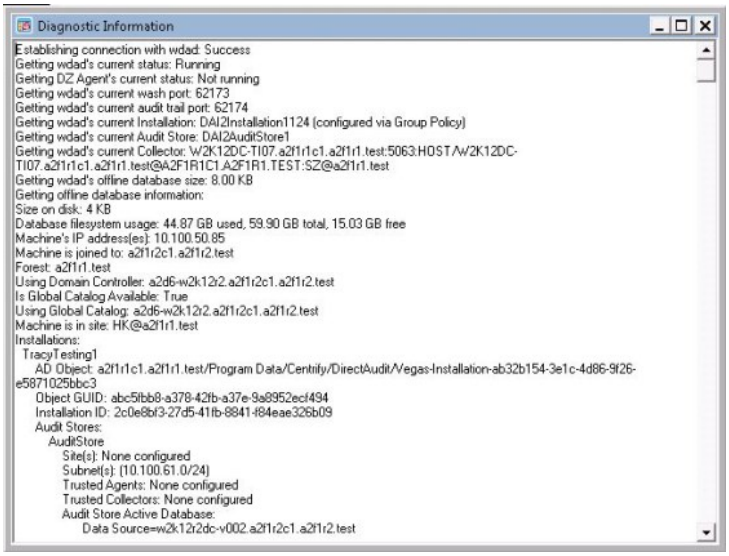
In addition to the information available in the Audit Manager console, the Windows computers on which you have installed a Agent for Windows with audit and monitoring service enabled include a local agent configuration panel applet. The agent configuration panel displays information about current connectivity and status for the local agent. You can use the agent configuration panel to configure the color depth, offline storage, or installation if you want to make changes after the initial deployment. You can also use the agent configuration panel to generate diagnostic information about the agent.

To use the agent configuration panel:

1. Log on to the computer on which you have installed a Agent for Windows with audit and monitoring service enabled.
2. In the list of applications on the Windows Start menu, click **Agent Configuration** to open the agent configuration panel.
3. Click **Auditing and Monitoring Service**.
4. Click **Settings**.
5. On the General tab, click **Configure** to change the color depth, offline storage file location and maximum size, and the installation to use for the local agent.

   > **Note**: The offline storage location should be an empty folder. If you select a folder that contains any files other than the spooled audit data, those files may be moved or lost.

   The General tab also displays current configuration and status for the local agent. If you make changes to the configuration, the new information is displayed after a short period of time. If the agent cannot connect to any collector, it spools audit data to the offline data location. When it finds a collector, the agent sends the spooled data to it. The offline storage space is not reclaimed until all of the spooled data has been sent to a collector.
6. Click the Troubleshooting tab, then click **Diagnostics** to generate diagnostic information about the installation the agent is part of, the collector the agent sends data to, the size of offline storage, and other information. For example:



After you generate diagnostic information, you can right-click to select all of the text. With the text selected, right-click, and select Copy to copy and paste the diagnostic report into a text file.

7. Click **Options** to specify the level of detail to include in the log file or to turn off logging.

   The default log level reports informational messages, warnings, and errors. You can click **View Log** to see information in the current log file.

8. Click **Close** to return to the agent configuration panel.

Setting the Color Depth for Captured Sessions

Because audit and monitoring service captures user activity as video, you can configure the color depth of the sessions to control the size of data that must be transferred over the network and stored in the database. A higher color depth also increases the CPU overhead on audited computers but improves resolution when the session is played back. A lower color depth decreases the amount of data sent across the network and stored in the database. In most cases, the recommended color depth is medium (16 bit). The CPU and storage estimates in this guide are based on a medium (16 bit) color depth.

To change the color depth for captured sessions:

1. Log on to the computer where the Agent for Windows is installed.
2. In the list of applications on the Windows Start menu, click **Agent Configuration** to open the agent configuration panel.
3. Click **Auditing and Monitoring Service**.
4. Click **Settings**.
5. On the General tab, click **Configure**
6. Select the maximum color quality for recorded sessions, then click **Next**.
7. Follow the prompts displayed to change any other configuration settings.

Removing an Audited Computer

If an audited computer has been removed from the installation, the audited computer will continue to be listed on the Audit Manager console as Disconnected. To remove the decommissioned audited computer, select Delete from its context menu.

Adding an Installation

Although a single installation is the most common deployment scenario, you can configure multiple installations. For example, you can use separate installations to provide concurrent production and test-bed deployments or to support multiple administrative domains within your organization.

To create a new installation:

1. Open Audit Manager.

2. Select the root node, right-click, then select **New Installation**.

3. Follow the prompts displayed.

   The steps are the same as the first installation. For more information, see Creating a new installation.

4. Choose the appropriate installation for each collector using the Collector Configuration wizard.

5. Choose the appropriate installation for each agent using the Agent Configuration wizard.

Delegating Administrative Tasks for a New Installation

The account you use to create a new installation is the default administrator and Master Auditor with full control over the entire installation and the ability to delegate administration tasks to other Active Directory users or groups. You can grant permission to perform administrative tasks to other users by opening the Properties for each component, then clicking the Security tab.

Opening an Installation in a New Console

If you create multiple installations at the same site, you can select the installation name, right-click, then select **New Window From Here** to keep consoles for different installations separate from each other. Creating a new window for each installation can help you avoid performing operations on one installation that you intended to perform on another.

Closing an Installation

The Audit Manager console allows you to manage multiple installations. To remove the current installation from the console, but not physically remove the database or the information published to Active Directory, you can select the installation name, right-click, then select **Close**.

Publishing Installation Information

DirectManage Audit publishes installation information to a service connection point (SCP) object in Active Directory so that audited computers and collectors can look up the information. If the published locations for multiple SCPs in the same installation are not the same, or if collectors cannot read from at least one of the published locations, the collectors are unable to determine which audit store is the best match for the sites and subnets, and so they do not attempt to connect to an audit store.

Permission to publish to Active Directory

Only administrators who have been delegated permission to modify various attributes of the installation can publish those attributes to Active Directory.

If you do not have Active Directory permission to modify the installation, the updates are kept in the audit management database, and a message is issued to notify you that the installation information could not be updated in Active Directory.

Synchronizing Installation Information

If you have an Active Directory account with permission to publish information about the installation, you can update the service connection point.

To publish the service connection point for an installation:

1. Open Audit Manager.
2. Select the installation name, right-click, then click **Properties**.
3. Click the **Publication** tab, then click **Synchronize** to publish the information.

   In a multi-forest or DMZ environment, this tab lists multiple Active Directory locations to which to publish.

4. Click **OK** to close the installation properties.

Removing or Deleting an Installation

Before you can remove or delete an installation, you must do the following:

- Run the setup program to remove all agents and collectors and collector service connection points (SCPs).
- Detach and remove all audit store databases.

- Open the Installation Properties and click the **Publications** tab to make sure only one installation service connection point (SCP) is listed.

  Note: {/b}To remove service connection points on other sites, contact an administrator with publication permission on those sites.

To remove or delete an installation, select the installation in the Audit Manager console, right-click, then select **Remove** to open the Remove installation dialog box.

- Click **Remove** to remove the installation but *not* delete the management database from the SQL Server instance.
- Click **Delete** to remove the installation and delete the management database from the installation of SQL Server.

  Note:All the publications published to Active Directory are removed when you remove or delete an installation.

Delinea software includes diagnostic tools and log files to help you trace the source of problems if they occur. Diagnostic reports and log files allow you to periodically check for issues and view information about operations on the computers you manage. The information is useful for troubleshooting and in resolving cases with the help of Delinea Support.

This chapter describes how to find log files, set the level of detail recorded in log files, and use diagnostic tools to retrieve information about the operation of the Agent and Server Suite components. This chapter also covers common questions to help you identify and correct problems on the computers you manage.

Solving Problems with Logging On

After you have installed the Agent for Windows and joined the computer to a domain, users cannot log on without a role assignment. The role, however, can be assigned to a local account or a domain account, or the role can be assigned the right to access a remote computer. Consequently, users might encounter problems logging on after the agent is deployed. For example, you might find that users can log on to the computer using a local account but cannot log on using their domain account or have trouble connecting to a remote server.

If users report problems logging on, there are some things you can try to troubleshoot the issue:

- Check the logon rights for the affected users.

  To do this, log on as an administrator and execute dzinfo *user-name* (where *user-name* is the name of the user experiencing problems logging on). You can also check user logon rights using the Authorization Center.

- Try to log on using a local user account or using a different domain account if you have more than one account available.

- Determine whether the computer you are using is connected or disconnected from the network. In rare cases, authorization information might not be available when a computer disconnected from the network.

- If users cannot log on to a remote computer, confirm that they have a role that has the remote logon system right and that the computer itself is configured to allow users to log on remotely. Open the Authorization Center to review the list of roles and their associated rights for any user.

- Check the computer's local security policy or applied group policies to verify whether the user is allowed to log on interactively or through a remote desktop connection. For example, most domain users are not allowed to log on locally on domain controllers.

  Depending on how your organization has configured native Windows security policies, users might need to be members of a specific Windows security group—such as Server Operators or Remote Desktop Users—to log on to specific computers locally or remotely even if they have been granted access rights using the Windows Login role or a custom role definition.

- Check to see whether the computer is in Rescue mode.

  In Rescue mode, access to a computer is granted only to users who have Rescue rights. For information about adding Rescue rights to a role, see System rights allow users to log on. In general, a computer enters Rescue mode because the Windows agent authorization service has stopped. Possible causes include the following:

  - The computer is not connected and the local authorization cache has not been initialized or is corrupt.
  - The local authorization cache cannot be updated because the file system is full.

    See Working with the authorization cache on managed computers for more information about the authorization cache and the conditions under which a computer is considered to be not connected.

Accessing Network Computers with Privileges

Depending on how you have defined the roles users are assigned, it is possible for users to see potentially misleading information in certain applications or be unable to perform the administrative tasks as they expect. For example, if users select a role with administrative privileges to access an application such as SQL Server Configuration Manager or Microsoft SQL Server Management Studio and connect to a remote SQL Server instances, it might appear as if they have permission to start and stop services or perform other tasks. However, if the role does not include network access rights for the remote SQL Server instance, users will not have the appropriate permission to perform those tasks.

You can check whether the selected role includes network access rights using the Authorization Center. If the role being used does not include network access rights, check whether the user has additional network roles available to use in conjunction with the local role. If the role being used includes network

access rights, you should check whether those rights are applicable on the network computer the user is attempting to manage. Users must be assigned to the role that has network access rights on the remote server.

Refreshing Cached Information on Managed Computers

Authorization information is cached on the local computer to improve performance and to allow the use of elevated privileges even if users are disconnected from the network. If you make changes to rights, role definitions, or role assignments, you can refresh the information stored in the cache on managed computers to ensure the agent has the most up-to-date information about current rights and roles. If users are experiencing authorization problems or issues with their access rights (for example, if the management console shows that a user has logon rights, but dzinfo or the authorization center does not show that the user has logon rights), you should try refreshing the cache to make sure any changes you have made take effect.

You can refresh the cache using agent configuration panel or the dzrefresh command line program in a Command Prompt window if you have the appropriate permissions.

Analyzing Information in Active Directory

One important way you can troubleshoot your environment is by running the Analyze command. The Analyze command enables you to selectively check the integrity of information stored in Active Directory. With the Analyze wizard, you can check for a variety of potential problems, such as empty zones, invalid role assignments, or orphaned role assignments.

> **Note**: When you run the Analyze command, only the zones that are open are checked.

To check for problems in the Active Directory forest:

1. Open Access Manager.

   If you are prompted to connect to a forest, specify the forest domain or domain controller to which you want to connect.

2. Select the root node, right-click, then click **Analyze**.

3. Select the types of checks you want to perform, then click **Next** to generate the report.

   You can select All to perform a complete check of the Active Directory forest. However, some of the analysis options are only applicable for Linux and UNIX computers or UNIX user and group profiles. For more information about any analysis option, see the Access Manager help or the *Administrator's Guide for Linux and UNIX*.

4. Review the result summary, then click **Finish**.

5. If the result summary indicates any issues, you can view the details by selecting **Analysis Results** in the console tree and viewing the information listed in the right pane.

6. Select individual warnings or errors, right-click, then select **Properties** for additional information.

Common Scenarios that Generate Errors and Warnings

For most organizations, it is appropriate to check the data integrity of the Active Directory forest on a regular basis. Although running the Analyze command frequently may not be necessary for small networks with few domain controllers, there are several common scenarios that you should consider to determine how often you should check the forest for potential problems.

The most likely reasons for data integrity issues stem from:

- Multiple administrators performing concurrent operations.
- Administrators using different domain controllers to perform a single operation.
- Replication delays that allow duplicate or conflicting information to be saved in Active Directory.
- Insufficient permissions that prevent an operation from being successfully completed.
- Network problems that prevent an operation from being successfully completed.
- Partial or incomplete upgrades that result in inconsistency of the information stored in Active Directory.
- Using scripts or ADSI Edit rather than the console to create, modify, or delete objects in Active Directory, which may lead to corrupted or invalid information.

Running Analyze periodically helps to ensure that the scenarios that can cause problems are reported in the Analysis Results, enabling you to take corrective action.

Responding to Errors and Warnings

Depending on the type of warning or error generated in the Analysis Results, you might be able to take corrective action or access additional information. For example, if a computer account lacks the necessary permission to update Active Directory with the agent version it has currently installed, the Analysis Result will enable you to update the computer's account permissions to allow changes to that attribute.

To review additional information or take corrective action, select the error or warning in the list of Analysis Results after running the Analyze wizard, right-click, then select Properties. For more information about responding to analysis results, see the Access Manager help or the *Administrator's Guide for Linux and UNIX*.

Running Diagnostics and Viewing Logs for the Agent

The Agent for Windows provides logging and diagnostic services. If you have administrative access on a local computer, you can generate diagnostic information about the operation of the Agent for Windows and view and save the current content of the log file from the agent configuration panel. For example, you can generate diagnostic information about user sessions, user roles, desktops, and elevated account access, as well as detailed information about auditing from the agent configuration panel.

There are three different types of diagnostics information available:

- **Audit & Monitoring Service** provides the diagnostic information related to the auditing and monitoring service.
- **Identity Platform** provides the diagnostic information related to Privileged Access Service, such as for MFA. This diagnostics tool runs the following tests:
  - **Agent Service Connectivity Check:** Checks to see if the agent is in service, and if the agent is running in a normal state. Also determines whether the agent is in a zone, or is configured to use zoneless mode.
  - **Connector Connectivity Check:** Determines whether all connectors in the network can be connected properly. whether the certificates (IWA and cloud) have been installed properly. Also determines whether the agent can be connected without a trusted certificate problem.
  - **Identity Platform Connectivity Check:** Determines whether a connection to the cloud tenant is functional. Checks for problems with DNS, the firewall, and proxy server settings.
  - **MFA Configuration Check:** Determines whether the local computer has been configured properly. If the computer is in a zone, the test also checks whether MFA complies with the configuration defined in the zone.
  - **MFA Role and Permission Check:** Verifies whether role permissions are set properly in the Privileged Access Service Admin Portal.
  - **Offline MFA Provisioning Check:** Determines if the computer has been configured with an offline MFA profile or not.
- **Privilege Elevation Service** provides the diagnostic information related to privilege management.

You can view these diagnostics tools either from the Windows system tray or from the agent configuration panel.

To view diagnostics from the Windows system tray:

1. Log on to a computer where the Agent for Windows is installed.
2. In the Windows system tray, right-click the Delinea icon and click **Troubleshooting**, then select the service for which you want to view diagnostic information (your options may vary depending on what services are enabled on the computer):
   - **Audit & Monitoring Service** opens a dialog box with a text-based summary of diagnostic auditing and monitoring information.
   - **Identity Platform** runs a series of connectivity tests and lists out the results of each test.
   - **Privilege Elevation Service** opens a dialog box with a text-based summary of diagnostic privilege elevation information.

To generate diagnostics or view the log file from the agent configuration panel:

1. Log on to a computer where the Agent for Windows is installed.
2. In the list of applications on the Windows Start menu, click **Agent Configuration** to open the agent configuration panel.
3. Select the service for which you want to view information:
   - **Audit & Monitoring Service** opens a dialog box with a text-based summary of diagnostic auditing and monitoring information.
   - **Identity Platform** runs a series of connectivity tests and lists out the results of each test.
   - **Privilege Elevation Service** opens a dialog box with a text-based summary of diagnostic privilege elevation information.
4. Click **Settings**.
5. Click the **Troubleshooting** tab.
6. Click **Diagnostics** to generate diagnostic information.
7. Select the Diagnostic Information displayed, right-click, then select **Copy** to copy and paste the output to a file for further analysis.
8. Click **View Log** to display the current log file for the local agent.
9. Click **Options** to see or change the location of the log file or the level of detail recorded in the log file.

Sample Diagnostic Report

For example, if you are viewing information about the privilege elevation service, the diagnostic report might be similar to this:

Product: Infrastructure Services (Name and Version information)
Computer: DC2008R2-LG

Done.

Enabling Detailed Logging for Audit and Monitoring Service Components

In addition to the log files for the Agent for Windows, there are log files for other audit and monitoring service components to record information about operations performed by those components on a local computer. If you have audit and monitoring service components installed, you can view the log files or change log file options for those components to assist Delinea Support when troubleshooting issues.

Enabling Detailed Logging for an Audited Computer

If you are troubleshooting an audit and monitoring service-related issue, you should enable detailed logging for the audit and monitoring service service on the computers being audited. For Windows computers, you can enable detailed logging using the agent configuration panel.

To enable detailed logging on an audited computer:

1. Log on to an audited computer.
2. In the list of applications on the Windows Start menu, click **Agent Configuration** to open the agent configuration panel.
3. Click **Audit & Monitoring Service**.
4. Click **Settings**.
5. Click the **Troubleshooting** tab.
6. Click **Options**, change the logging level to **Trace messages**, then click **OK**.
7. Note the log folder location or click **Browse** to specify a different location for the log file, then click **OK**.
8. Click **View Log** to view the current log file.

   From the log file window, you can also click **File > Save As** to save the log file.
9. Send an email to Delinea Support with the log file from the location specified in Step 7 as an attachment.
10. Click **Options**, change the logging level back to its default setting of **Informational messages**, then click **OK**.
11. Click **Close** to return to the agent configuration panel.

Enabling Detailed Logging for the Collector Service

If you are troubleshooting an audit and monitoring service-related issue, you should enable detailed logging for the collector service on the computers where the collector service runs.

To enable detailed logging on a collector:

1. In the list of applications on the Windows Start menu, click **Audit Collector Control Panel** to open the audit collector control panel.
2. Click the **Troubleshooting** tab.
3. Click **Options**, change the logging level to **Trace messages**, then click **Apply**.
4. Note the log folder location or click **Browse** to specify a different location for the log file, then click **OK**.
5. Click **View Log** to view the current log file.

   From the log file window, you can also click File > Save As to save the log file.
6. Send an email to Delinea Support with the log file from the location specified in Step 4 as an attachment.
7. Click **Options**, change the logging level back to its default setting of **Informational messages**, then click **OK**.
8. Click **Close** to return to the Collector Control Panel.

Enabling Detailed Logging for Audit and Monitoring Service Consoles

In most cases, troubleshooting audit and monitoring service-related issues requires information about the operation of the agent and the collector or database activity. However, in some cases, it might be necessary to capture detailed information about the operation of Audit Manager or Audit Analyzer.

To capture detailed information for Audit Manager or Audit Analyzer:

1. Log on to a computer where the Audit Manager or Audit Analyzer console is installed.
2. In the list of applications on the Windows Start menu, click **Agent Configuration** to open the agent configuration panel.
3. Click **Audit & Monitoring Service**.
4. Click **Settings**.
5. Click the **Troubleshooting** tab.
6. Click **Options**.
7. In the Log Settings tab, change the logging level to **Trace messages**, then click **OK**.
8. Note the log folder location or click **Browse** to specify a different location for the log file, then click **OK**.
9. Send an email to Delinea Support with the log file from the location specified in Step 8 as an attachment.
10. Click **Options**, change the logging level back to its default setting of **Warning messages**, then click **OK**.
11. Click **Close** to return to the agent configuration panel.

Enabling Audit and Monitoring Service Performance Counters for the Collector

If you have enabled audit and monitoring service and installed the collector service on a local Windows computer, you can add audit-specific performance counters to Performance Monitor to help you analyze and resolve audit-related issues. When you install the collector, the performance counters are added automatically. When you uninstall the collector, the counters are automatically removed from Performance Monitor.

For more information about troubleshooting in an audit installation, see the *Auditing Administrator's Guide*.

Tracking Database Activity

Database traces are used to help diagnose problems in the management database or audit store databases. For example, database traces can help to identify inconsistencies caused by hardware errors or network interruptions. After you enable database tracing, DirectManage Audit tracks all of the SQL statements and debug messages from the audit management database or audit store, and records the information in the database server.

> **Note**: Tracing database operations affects database performance. You should only activate a database trace if you require this information for troubleshooting. Before you start a database trace, try to reduce the load on the database instance as much as possible, then only perform the actions needed to reproduce the issue you are troubleshooting. Turn off database tracing as soon as you have logged the activity you need for the analysis of database operations. The trace for each database can take up to 800MB of server disk space. After you turn off database tracing, restart the SQL Server instance to reset the disk space.

Starting a Database Trace

You can start a database trace for a management database or an audit store database.

To start database tracing:

1. Open Audit Manager.
2. Select an installation name, right-click, then click **Properties**.
3. Click the **Database Trace** tab.

   This tab displays basic information about the management databases and audit store databases for the selected installation. In the Trace Status column, you can see whether tracing is enabled or disabled for each database.
4. Select a management or audit store database in the list, then click **Enable** to start tracing on the database selected.
5. Click **OK**, then perform the database actions for which you want to capture information.

Stopping the Database Trace

You should turn off database tracing immediately after you have logged the activity you need for the analysis of database operations.

To stop database tracing:

1. Open Audit Manager.
2. Select the installation name, right-click, then click **Properties**.
3. Click the **Database Trace** tab.

4. Select the management or audit store database that has tracing enabled, then click **Disable** to stop tracing on the database selected.
5. Click **Export** to save the database trace from the selected databases to a file with comma-separated values (.csv).
6. Follow the prompts displayed in the Export Database Trace wizard to save the information to a file.

Exporting the Database Trace for a Management Database

The Export Database Trace wizard prompts you for different information depending on whether the database trace is for a management database or an audit store database. For example, if you generate a database trace for a management database then click **Export**, the Export Database Trace wizard prompts you for user accounts.

To export the database trace:

1. Select a start date and time for the **From** filter and an end date and time for the **To** filter, then click **Next**.
2. Click **Add** to search for and select users, then click **Next**.

   By default, you can search for users in the entire directory, you can click **Object Types** or **Locations** to change the scope of the search scope, or click **Advanced** specify other criteria.
3. Accept the default folder location or click **Browse** to select a different location, then click **Next**.
4. Review your selections, then click **Next**.

   By default, the wizard save the file as *installation_name*.csv and opens the file location.
5. Click **Finish**, then click **OK** to close the installation properties.

Exporting the Database Trace for Audit Store Databases

When you select an audit store from the lower area of the **Database Trace** tab on the **Properties** page and click the lower **Export** button, the wizard opens with a date/time **Export Criteria** page. On the second page, the wizard asks you to pick the domain and computer.

To export the database trace:

1. Select a start date and time for the **From** filter and an end date and time for the **To** filter, then click **Next**.
2. Click **Add** to search for and select collectors, then click **Next**.

   By default, you can search for computers in the entire directory, you can click **Object Types** or **Locations** to change the scope of the search scope, or click **Advanced** specify other criteria.
3. Click **Add** to search for and select management database computers, then click **Next**.
4. Accept the default folder location or click **Browse** to select a different location, then click **Next**.
5. Review your selections, then click **Next**.

   By default, the wizard save the file as *audit_store_name*.csv and opens the file location.
6. Click **Finish**, then click **OK** to close the installation properties.

Delegating Database Trace Management

You can delegate the authority to manage database tracing by granting the Manage Database Trace permission to other users for a management database or an audit store database.

Controlling Audit Trail Events

By default, audit trail events are recorded when users log on, open applications, select roles that elevate their privileges, and perform other tasks. You can use domain group policies to control the global location of the audit trail events. For example, you might want to store audit trail events in the audit store database instead of the Windows event Application log if you want to make them available for querying and reports.

You can also override domain group policy and configure local or category-specific audit trail targets using a local administrative template or group policy.

To configure global or per-category audit trail targets using an ADM administrative template:

> **Note**: These settings override the settings defined in the **Set global audit trail targets** group policy.

1. Open the Group Policy Object Editor to display Local Computer Policy, and select **Computer Configuration > Administrative Templates**.
2. Right-click, select **Add/Remove Templates**, then click **Add**.
3. Navigate to the AuditManager folder, select auditrail.adm, click **OK**, then click **Close**.
4. Open the Classic Administrative Templates folder and select **AuditTrail**.
5. Specify global or separate targets for audit trail events:
   - Enable **Set global audit trail target settings** to configure a single location for audit trail events for Access Manager and the Agents.
   - If you want to have separate targets for audit trail events, you can enable the other audit trail group policies to override the global policy setting with a different target.
6. Specify the location for saving audit trail events, and then click **OK**:
   - 0 to disable audit trail events
   - 1 to store audit trail events in the audit store
   - 2 to send audit trail events to the Windows event Application log
   - 3 to send audit trail events to both the audit store and the Application log.

To configure per-category audit trail targets using a local group policy from an XML template:

> **Note**: These settings override the settings defined in the Set global audit trail targets group policy.

1. Ensure that the Audit Trail Settings were updated with the most recent XML template.
2. Open the Group Policy Object Editor to display **Local Computer Policy**, and select **Computer Configuration > Audit Trail Settings**.
3. In **Audit Trail Settings**, separate folders for each audit trail category contain **Send audit trail to Audit database** and **Send audit trail to log file** group policies. Enable these group policies in each category that you want to configure to use a specific audit trail target. The target that you specify for each category is used instead of the target specified in the **Set global audit trail targets** group policy.

Summary of Audit Trail Events

Different components log different audit trail events. For example, the auditing and authorization services on a managed Windows computer track successful logon attempts and the use of Window access rights. Access Manager audit trail events record changes to the configuration of zones, such as the delegation of administrative tasks, the assignment of roles, and changes to the user and group profiles in a zone. For your reference, the following sections summarize the audit trail events recorded by Agents on managed Windows computers.

Additional audit trail events for Access Manager, Audit Analyzer, Audit Manager, and UNIX commands can be recorded in the target you specify for the audit trail. The event message provides detailed information about the operation performed or unsuccessfully attempted, including in most cases the reason the operation was unsuccessfully.

For a complete list of audit trail event identifiers and their corresponding descriptions, see the AuditTrailEvent.xml file provided in the Documentation folder. This file is generated directly from the underlying source code and provides the most up-to-date information about the events on which you can query and report.

Offline MFA Profile Authentication

In some environments, using an offline MFA profile for multi-factor authentication is not compatible with FIPS mode. See the *Multi-factor Authentication Quick Start Guide* for details about this restriction.

Authentication Service Known Issues

When troubleshooting, be aware of the following issues and constraints:

- Import users and groups before importing the sudoers file (Ref: IN-90001).

  Sudoers Import creates user roles but not the users. It is recommended that you import users and groups prior to importing the sudoers file. Otherwise, no sysRights are created for the users.

- Pre-create computers before importing computer role from sudoers file (Ref: IN-90001).

  The computers contained in the sudoers file must either be joined to a zone or pre-created.

- Delegating zone administration permissions for SFU zones (Ref: IN-90001)

Delegate permissions to add, remove or modify users for SFU zone are not supported.

- Users with rights to import user and groups into a zone also gain rights to modify profiles (Ref: IN-90001)

  Any users who are given the right to "Import users and groups to zone" are automatically also given the right to "Modify user/group profiles".

- Using domain local groups to manage resources (Ref: IN-90001)

  Domain local groups can only be used to manage resources in the same domain as the group. So, for instance, a domain local group in domain A may be used to manage a computer in domain A but not one in domain B, despite a trust relationship between the two domains.

- Domain local groups from other domains shown in search dialog (Ref: IN-90001)

  When using the search dialog in the Access Manager to delegate zone control to a group, domain local groups from child domains will be shown incorrectly in the results and should be ignored. The search results when using the ADUC extension do not show these domain local groups.

- Analyze forest and SFU zones (Ref: IN-90001)

  The analyze forest feature in the Access Manager does not report empty zones or duplicated users or groups in a SFU zone.

- Working with users that have more than one UNIX mapping (Ref: IN-90001)

  Authentication Service supports Active Directory users that have more than one UNIX profile in a zone. However, if you are upgrading from DirectControl 4.x or earlier and have existing users with more than one UNIX mapping, you should use DirectControl 5.0.0 or later to remove all but one of the UNIX profiles for each of these Active Directory users and then re-add them.

  In addition, you should always use DirectControl console 5.0.0 or later when modifying these users.

- In the Profile tab of the Properties page of a computer joined to a hierarchical zone, you cannot move this computer to a classic zone. Nor can you move it to a zone in another domain. There are no such limitations with a computer joined to a classic zone. (Ref: IN-90001)

- Extra results when analyzing duplicate service principal names (Ref: IN-90001)

  When running the Analyze / Duplicate Service Principal Names report, kadmin/changepw is incorrectly returned as a duplicate. The SPN is actually found multiple times, but this is by Microsoft design as it is the default account for the Key Distribution Center service in all domains.

- Secondary groups not imported from XML files (Ref: IN-90009)

  Using the Import Wizard to import user information from XML files does not import secondary group membership.

This chapter provides a summary of the command line programs you can run on computers that have the Agent for Windows installed to perform troubleshooting and administrative operations.

Using CopyGroup and CopyGroupNested

The CopyGroup and CopyGroupNested commands help you provision users when there are trust relationships between domains. You can use them to mirror group membership and group hierarchy from a trusted domain and forest to a target domain and forest.

These utilities are located in the Zone Provisioning Agent's **Tools** folder.

To use these command line utilities, you must have an account that can log on to the trusted source domain and the target domain. The account should also have read permission on the source domain and permission to update the target domain.

For example, assume you have configured the AJAX domain to have a one-way trust with the DEVOPS domain and you have your Active Directory users and groups defined in the DEVOPS domain. If you want to allow the users and groups in the DEVOPS domain to log on to computers that are joined to the AJAX domain, you can log on to the AJAX domain controller with an account that has administrative privileges in both the AJAX and DEVOPS domains, then run the CopyGroup utility to mirror the group membership from a group in the DEVOPS source domain as zone users in the AJAX target domain.

For more information about the command line arguments and options for these utilities, see the usage message displayed for each utility.

Using dzinfo

The dzinfo command line program provides detailed information about the effective rights, role definitions, and role assignments for a specified user. The command output includes all of the same information that you can view using the Authorization Center as described in Using the Authorization Center directly on managed computers. However, using dzinfo as a command line utility allows you to view and capture all of the output from the command in a single window, which you can then save as a text file for troubleshooting and analysis or in reports.

The syntax for the dzinfo program is:

dzinfo [/v] [*user_name*] [/h]

The /v is an optional argument that enables you to view verbose output for the command. The *user_name* is an optional argument that enables you to view information for the specified user account. However, you must be logged on as a local administrator to specify the *user_name* argument. If you log on with an account that does not have local administrative privileges you cannot return authorization information for another user account.

If you run the dzinfo command without the *user_name* argument, the command returns authorization information for the currently logged-on user account.

The command returns detailed information about the rights, roles, and role assignments for the specified user (richl in the AJAX domain) similar to the following:

From the Access Manager

Effective roles for AJAX\richl:

Domain Admin/portland

Zone: CN=portland,CN=global,CN=Zones,OU=Acme,DC=ajax,DC=org

Status: Active

Windows Login/global

Zone: CN=global,CN=Zones,OU=Acme,DC=ajax,DC=org

Status: Active

None

Computer is joined to zone ajax.org/Acme/Zones/global/portland

Auditing for AJAX\richl:

Session ID 2:

Desktops:

Default: Not currently auditing.

Auditing is not available on this computer.

Using dzjoin

The dzjoin command line program enables you to automatically join users to the zone in which their roles and rights are assigned, or to join them to a specific zone by zone name, when they log on to their computer. The dzjoin command line program is particularly useful for organizations that use non-persistent virtual desktop infrastructures.

The syntax for the dzjoin command is:

dzjoin [/c <domain controller>] [/d] [/u <username>] [/f] [/h] [/r [y|n|yes|no]] {/z <zonename> | /s | /v]

Note: {/b}If the u option is specified but no password is found in the redirected input, you will be prompted for a password.

/c	Specify a domain controller to connect to.
/d	Retrieve zone data before restarting
/u	Specify the user name to join zone using custom credentials. The user name must be in the format: USER@DOMAIN or DOMAIN\USER. The credentials are for remote access only. For the password, you can specify by redirected input. Otherwise, this tool will prompt user for password.
/f	Suppress any warnings and/or questions.
/h	Displays the command help.
/r	Suppress the restart warning and specify to restart machine, if required, after joining zone. If no restart is required, this option is ignored. If no argument is provided, e.g. '/r', the default is to restart (example: '/r yes').
/z	Join a zone using the zone name. If the zone name is not unique, use the canonical name instead.
/s	Join to the zone where this computer is already pre-created in the zone or had previously been joined to the zone (but remotely left in a disconnected situation).
/v	Display the agent version.

Note: You can also use the PowerShell command Join-CdmZone to join a zone.

Using dzleave

To leave a zone, use the dzleave command. The syntax for the dzleave command is:

dzleave [/c <domain controller>] [/u <username>] [/a|/f] [/r [y|n|yes|no]] [/v] [/h]

/a	Remove the role assignment from the computer zone.

/c	Specify a domain controller to connect to.
/u	Specify the user name to leave zone using custom credentials. The user name must be in the format: USER@DOMAIN or DOMAIN\USER. The credentials are for remote access only. For the password, you can specify by redirected input. Otherwise, this tool will prompt user for password.
/f	Suppress any warning and/or question(s). In case the domain cannot be contacted, this tool will perform a local zone leave automatically.
/h	Displays the command help.
/r	Specify whether to restart machine, if required, after leaving zone without prompt. If no restart is needed, this option is ignored. If no argument is provided, example: '/r', the default is to restart ('/r yes').
/v	Show the agent version.

Note: You can also use the PowerShell command Exit-CdmZone to leave a zone.

Using dzdiag

The dzdiag command line program provides detailed diagnostic information for the local computer. The command output includes all of the same information that you can view by clicking Diagnostics on the Troubleshooting tab as described in Running diagnostics and viewing logs for the agent.

The syntax for the dzdiag command is:

dzdiag [/h] [/o]

The /h is an optional argument that displays the command help.

The /o is an optional argument that allows you to output just the offline MFA provisioning information. You can use this option to see if a user has configured an offline MFA profile or not and details about their offline MFA configuration.

You must be logged on as a local administrator to run the dzdiag command.

The command returns detailed information about desktop sessions similar to the following:

Product: Server Suite *version-number* (*build-number*)
Computer: SERVER01
Joined Domain: acme.local

Using dzrefresh

The dzrefresh command line program enables you to refresh the authorization cache from a Command Prompt window. Running the dzrefresh command provides the same functionality as clicking Refresh on the Troubleshooting tab in the local agent configuration panel as described in Performing cache operations.

The syntax for the dzrefresh command is:

dzrefresh

You must be logged on as a local administrator to run the dzrefresh command. The command output indicates whether the refresh of the authorization cache is successfully initiated.

Using dzflush

The dzflush command line program flushes the authorization cache and reloads all authorization information from Active Directory. Depending on the size of the authorization store, users might experience a temporary loss of the ability to use the rights granted to them while the authorization information is reloaded. To prevent any loss of access privileges, in most cases you should use the dzrefresh command instead of the dzflush command to ensure that the agent is using the latest authorization information. You should only use the dzflush command if Delinea Support recommends that you do so.

The syntax for the dzflush command is:

dzflush [/h] [/l]

/h	Show the command usage.
/l	Synchronize local Windows account information between Access Manager and the Windows systems where local account management is enabled. Note: Local account management is not supported on domain controllers.

You must be logged on as a local administrator to run the dzflush command. The command output indicates whether the authorization cache is successfully flushed.

Using dzdump

The dzdump command line program enables you to view and capture the current content of the authorization cache. You can use command line options to control the information contained in the output for the command.

The syntax for the dzdump command is:

dzdump [/d [*directory-path*]] [/w=*screen-width*] [/s] [/n] [/g] [/l] [/a]
[/r] [/i] [/t] [/z] [/u] [/h]

If you specify no command line arguments, the dzdump command returns complete inmemory information from the authorization agent (dzagent) cache. You can use the following command line arguments to refine the output for the command:

/d	Dump cache files from the default location or a specified location. You can use this option with a directory path to dump cache files from a specified location. For example, to dump cache files from the directory C:\AcmeAZstore:/d=C:\AcmeAZstore Note that you cannot use the /d option to dump cache files directly on a computer where the Agent for Windows is currently running. However, you create a copy of the cache, then dump the cache from the saved copy. For example, copy all files in the cache directory—the default location for cache directory is <!---

	TODO update path ---> c:\ProgramData\Centrify\DirectAuthorize\Cache—to a temporary directory. You can then dump the authorization cache by running dzdump and specifying the temporary location.
/w	Use the specified *screen-width* for word-wrapping the command output. If you don't specify this options, the default screen width is 80 characters. To disable word-wrapping of the command output, specify a *screen-width* of zero. For example: /w=0
/s	Display security identifier (SID) mappings
/n	Display name mappings
/g	Display assignee mappings
/l	Display assignments in the joined zone hierarchy
/a	Display assignments for security identifiers (SID)
/r	Display role definitions
/i	Display right definitions
/t	Display access token information
/z	Display zone hierarchy
/u	Display recent user logon activity
/h	Displays the command help

You can use any combination of display options to display only the information of interest. If you do not specify any display options, the dzdump command displays all of the information in the authorization cache.

You must be logged on as a local administrator to run the dzdump command. You should note that the command output from a dzdump command can contain sensitive information. You should only use the dzdump command if Delinea Support recommends that you do so.

Depending on the display options you specify, the command returns detailed information about the authorization cache.

Using runasrole

The runasrole command-line program enables you to run a specified Windows application using a specified access role. You can use command line options to control whether the role is used as a local role, a network role, or both, and whether to use the current environment or the environment variables associated with the "Run As" user account. The runasrole command line program is equivalent to selecting the Run with Privilege menu option when right-clicking an application shortcut or executable.

The syntax for the runasrole command is:

runasrole /role:*role*[*/zone*] [options] *application* [*argument*]

runasrole /localrole:*role*[*/zone*] [options] *application* [*argument*]

runasrole /networkrole:*role*[*/zone*] [options] *application* [*argument*]

You must specify the role to use in the *rolename*/*zonename* format. You must also specify an appropriate path to the *application* you want to access, including any required or optional arguments.

You can use the following command line arguments and options with the runasrole command:

/role	Use the role name you specify as both a local role and a network role. You can specify this option to run an application locally and access a remote server using the same role, if applicable. You should only use this option if the role you are assigned and want to use has both local and network access rights defined.
/localrole	Use the role name you specify as a local role.
/networkrole	Use the role name you specify as a network role.
/env	Use the current environment variables instead of the environment variables associated with the "Run As" user account.
/netdrives	Use mapped network drives when running an application with the selected role. By default, you cannot use mapped network drives that are associated with you logged-on user account when running applications using a role with elevated privileges. If you want to use a mapped network drive when accessing an application using a selected role, include the /netdrives option in the command line.
/removetimestamp	Remove the grace period on Windows authentication and MFA for the current user session.
/wait	Prevents the runasrole program from exiting immediately after opening the specified application. If you specify this option, the runasrole program starts the specified application and waits until the application session ends before exiting. When the application session ends, the runasrole program exits and returns the same result code as the application. If you specify this option and the application is a command line utility, the runasrole program redirects the application's input and output to the command line console. You should note that some applications use a Microsoft API that does not support redirection of standard input and output. For applications that don't support redirection, the /wait option has no effect and is ignored.
/h	Displays the command help.

Examples

To use the same role to open the Computer Management application locally and access a remote server in zone1, you might run a command similar to the following:

runasrole /role:role1/zone1 mmc.exe c:\windows\system64\compmgmt.msc

To use the role named SQLdba from the finance zone as a local role to open the Services application, you might run a command similar to the following:

runasrole /localrole:SQLdba/finance mmc.exe c:\windows\system64\services.msc

To use role1 from zone1 as a local role to open the Computer Management application and use network access rights from role2 in zone2, you might run a command similar to the following:

runasrole /localrole:role1/zone1 /networkrole:role2/zone2 mmc.exe compmgmt.msc

To open the Services application using the role named SQLdba from the finance zone and have the runasrole program remain open until you close the Services application, you might run a command similar to the following:

runasrole /wait /role:SQLdba/finance mmc.exe c:\windows\system64\services.msc

Running an application from a shortcut

In most cases, you can use the runasrole program to run specified Windows applications using the application shortcut. However, there are many different types of application shortcuts and the RunAsRole program does not support all of them. You can use the RunAsRole program to execute applications with the following recognized shortcut target extensions:

.bat

.cmd

.cpl

.exe

.msc

.msi

.msp

.ps1

.vbs

.wsf

How to determine whether RunAsRole supports an application shortcut

You can determine whether you can use the RunAsRole program to execute an application from the application shortcut by checking the file extension for the target application in the application's shortcut properties dialog box.

To check the file extension for a target application shortcut

1. Select an application shortcut.
2. Right-click the shortcut, then click **Properties** to display the file properties.
3. Click the Shortcut tab and check the target field.

   If the target file extension displayed is a supported file extension, you can use RunAsRole to execute the application from the application shortcut. You should note that a shortcut target field might include both the file name for the application executable and one or more arguments. As long as the application executable has a supported file extension, you can use RunAsRole to execute the application with the specified arguments from the shortcut. For example, if the shortcut target is C:\Windows\System64\control.exe printers, the application executable C:\Windows\System64\control.exe is a supported file extension with printers supplied as an argument. Therefore, you would be able use RunAsRole to run the application from its shortcut.

Using RunAsAlternate

The runasalternate command line program enables you to log in to an application using an alternate account.

For example, system administrators typically have several accounts, a user account for general log-ins and an administrative account to access specific systems and services.

The syntax for the runasalternate command is:

runasalternate [/account:accountname] application [argument] [/h]

You can use the following command line arguments to refine the output for the command:

application	Run an application using the alternate account set in Privileged Access Service.
argument	(optional) Specify an application argument
/account accountname	Specify the alternate account owned by this user for which the application is to be run. This can be useful in cases where a user has more than one alternate account.
/h	Display the command help

If you have only one alternate account defined, you don't need to specify the /account option.

For more information about alternate accounts, see Enabling users to run applications with alternate accounts.

The Agent for Windows can be installed on Windows computers that are configured to run the Server Core operating environment. Server Core is a Windows installation option that provides a low-maintenance server environment with limited functionality.

Most Agent operations are not affected by running on Server Core. However, there are specific features that are not available or not applicable because of the limitations of the Server Core environment itself. For example, the Run with Privilege menu option is not available on Server Core computers because Server Core does not support Windows Explorer and other graphical user interface applications. However, you can use the runasrole command line utility to run specific applications using a specified role.

Similarly, no Delinea notification area applet or desktop rights are available on Server Core computers. However, you can access the Authorization Center, agent configuration panel, and agent command-line utilities from the Server Core command prompt.

The following list summarizes the Agent for Windows features that are not supported on Server Core computers:

- You cannot create, select, or switch desktops or use any desktop-related features because the Windows desktop is not available on Server Core.
- You cannot select Run with Privilege as a right-click menu option for applications because Windows Explorer is not available on Server Core.
- You cannot open the Authorization Center or access the Delinea notification area applet because the Windows desktop and Windows Explorer are not available on Server Core.
- You cannot open applications such as the agent configuration panel from Start menu shortcuts because the Windows desktop and Windows Explorer are not available on Server Core.

You should note that only the Agent for Windows is supported for the Server Core environment. A small number of other Server Suite components for Windows support a command line interface, but are not configured to support a Server Core environment.

Server Core Supported PLatforms

Delinea supports the following versions of the Server Core environments:

- Windows Server 2008 R2 Server Core
- Windows Server 2012 Server Core
- Windows Server 2012 Minimal Server Interface
- Windows Server 2012 R2 Server Core
- Windows Server 2012 R2 Minimal Server Interface

You should note that Server Core is not supported on Windows Server 2008 because Windows Server 2008 Server Core does not support any version of the .NET Framework. The Agent for Windows requires the .NET Framework. For more information about the supported libraries and .NET functionality on Server Core, see the reference material available on the Microsoft Developer Network website for the operating system you have deployed.

For general information about Server Core on Windows Server 2008 R2, see: https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2008-R2-and-2008/cc753802(v=ws.10)

For general information about Server Core on Windows Server 2012 R2, see: https://docs.microsoft.com/en-us/previous-versions/windows/it-pro/windows-server-2012-R2-and-2012/hh831786(v=ws.11)

Installing the Agent on a Computer Running Server Core

You cannot use the autorun.exe or the setup.exe program to install components on a computer that is configured to run as a Server Core environment. Instead, you must install from Microsoft Installer (.msi) files using the msiexec command-line program.

To install the Agent for Windows on Server Core:

1. Use the Deployment Image Servicing and Management (DISM) or another command-line tool to enable the .NET Framework.

   For example, if you are using Windows Server 2012 or later and the .NET Framework is located on the installation media in the D:\sources\sxs folder, use the following command:

   DISM /Online /Enable-Feature /FeatureName:NetFx3 /All /LimitAccess /Source:D:\sources\sxs

   To install .NET Framework on Windows Server 2008 R2, run the following commands to enable the required features:

   Dism /Online /Enable-Feature /FeatureName:NetFx2-ServerCore-WOW64

Dism /Online /Enable-Feature /FeatureName:NetFx3-ServerCore-WOW64

Dism /Online /Enable-Feature /FeatureName:NetFx2-ServerCore

Dism /Online /Enable-Feature /FeatureName:NetFx3-ServerCore

2. Copy the Agent for Windows files to the Server Core computer.

   For example:

   copy D:\Common\Centrify* C:\Agent

   copy D:\Agent* C:\Agent

3. Install the Common Component service using the .msi file.

   For example, to install the Common Component on a computer with 64-bit architecture, you might use the following command:

   msiexec /i "Common Component64.msi" /qn

4. Install the Agent for Windows using the .msi file.

   Run the following command:

   msiexec /i "Agent for Windows64.msi" /qn

5. Restart the computer with the appropriate shutdown options to complete the installation and start agent services.

   For example, you might run the following command:

   shutdown /r

   Note that restarting the computer is not required if you install only auditing features.

Opening Consoles on Server Core Computers

Because the primary interface for the Server Core environment is a command prompt with only limited support for graphical user interface features, you must use the command line to open the consoles that enable you to join or leave a zone, view your rights and roles, and configure agent settings.

Joining a Zone

One of the first tasks after installing the Agent for Windows is to join a zone. You can do by launching the agent configuration panel from the command prompt.

To open the agent configuration panel to join a zone:

1. Navigate to the Agent for Windows installation directory.
2. By default, the agent files are installed in the C:\Program Files\Centrify\Agent for Windows directory. <!---TODO update path --->
3. Run Centrify.DirectAuthorize.Agent.Config.exe. <!---TODO update filename--->
4. Click **Change**.
5. Click **Browse**.
6. Type all or part of the zone name, click Find Now, then select the zone to join and click **OK**.
7. Click **Close** to exit the agent configuration panel.

If you later need to change the zone, run diagnostics, refresh the authorization cache, or view or modify log settings, you can run <!---TODO update filename---> Centrify.DirectAuthorize.Agent.Config.exe to perform those tasks.

Viewing Authorization Details

By default, identity management, privilege management, and audit and monitoring service features are enabled after you install and configure the Agent for Windows. To see details about your rights, role definitions, role assignments, and auditing status, you can launch the Authorization Center from the command prompt.

To open the Authorization Center on a computer with the Server Core operating system:

1. Navigate to the Agent for Windows installation directory.

   By default, the agent files are installed in C:\Program Files\Centrify\Agent for Windows directory. <!---TODO update path--->

2. Run Centrify.DirectAuthorize.Auth.Center.exe. <!---TODO update filename--->

Configuring Auditing Options

By default, identity management, privilege management, and audit and monitoring service features are enabled when you install the Agent for Windows. To configure audit and monitoring service options and specify the audit installation for the agent, you can launch the agent configuration panel from the command prompt.

To open the agent configuration panel to configure auditing features:

1. Navigate to the Agent installation directory.

   By default, the agent files are installed in the <!---TODO update path---> C:\Program Files\Centrify\Audit\Agent directory.

2. Run agent.configure.exe.
3. Click **Configure**.
4. Select a color quality, then click **Next**.

   Because the Server Core operating system uses very few graphical elements, in most cases you should accept the default setting of Low for the color quality. This setting minimizes the storage requirements for auditing if you have enabled video capture auditing.

5. Accept the default offline data location and maximum size or type a different location, then click **Next**.

   You can also drag the slider to change the maximum percentage of the drive the offline data can consume. In most cases, however, you should leave the default setting unchanged.

6. Select the audit installation, then click **Next**.
7. Review your configuration settings, then click **Next**.
8. Click **Finish** to close the configuration wizard.
9. Click **Close** to exit the agent configuration panel.

Running Command Line Programs

The Agent for Windows includes several command line programs for performing administrative tasks. The following command line programs are supported on Server Core computers:

- dzinfo
- dzjoin
- dzdiag
- dzrefresh
- dzflush
- dzdump
- runasrole

For more information about the command line options or output for these commands, see Using Windows command line programs or run the command with the /help option.

Unsupported Windows Server 2012 Features

Windows Server 2012 includes support for claims, compound authentication, and Kerberos armoring. The core Agent for Windows does not provide support for these advanced authentication features. To take full advantage of these advanced authentication services, however, requires you to make the following changes to your environment:

- Deploy Dynamic Access Control.

- Upgrade all of your domain controllers and application servers to Windows Server 2012 or later.
- Upgrade all of your workstations to Windows 8 or later.
- Raise the domain functional level to Windows Server 2012.

If you have a mixed environment that includes Windows 7 and Windows 8 or later workstations and Windows Server 2008 or Windows Server 2008 R2 domain controllers, you can configure the administrative template for claims, compound authentication, and Kerberos armoring to use the Not supported option (default).

To use the Supported configuration option, you must deploy Dynamic Access Control, configure Windows 8 and later client-side support for claims, compound authentication and Kerberos armoring, and ensure you have domain controllers running Windows Server 2012 to handle the authentication requests for those computers. You should not install the Agent for Windows on any computers configured to support claims, compound authentication and Kerberos armoring to prevent authentication failures.

In addition, Server Suite does not provide any specific support for authenticating access to Server Message Block 3.0 (SMB3.0) file shares that are supported in Windows Server 2012. The SMB protocol operates as an application layer for providing shared access to computers, printers, and other devices. This protocol has been extended to provide shared access to virtual machines and SQL user databases.

This *Quick Start Guide* provides a brief summary of the steps for installing and getting started with Server Suite software. For more information about any step, see the appropriate sections in the Unexpected Link Text or Unexpected Link Text.

1. Run the setup program for Authentication & Privilege components on a Windows administrator's workstation.

   The setup program simply copies the necessary files to the local Windows computer, so there are no special permissions required to run the setup program other than permission to install files. Follow the prompts displayed to select which components to install.

2. Open Access Manager to start the Setup Wizard and create an organizational structure and the containers for Licenses and Zones.

   In the Setup Wizard, you can accept the default organizational structure or create a custom organizational unit for Server Suite objects, add license keys, and configure a few basic permissions and setup options.

3. In Access Manager, create a new zone with the default options. For example, create a new zone named **Demo**.

4. In Access Manager, add Active Directory users to the new zone.

   - Select the new **Demo** zone.
   - Right-click, select **Add User** to Select User Type, then select Active Directory users to search for and select existing Active Directory users.
   - Select **Define user UNIX profile** and deselect assign roles.
   - Accept the defaults for all fields.

5. Create a child zone.

   - Select the **Demo** zone.
   - Right-click, then select **Create Child Zone**.
   - Type a name for the zone, for example, **Child1** and an optional description, then click **Next** and **Finish** to create the new child zone.

6. Assign a role for the users you added to the Demo zone.

   User profiles are inherited by child zones, so the users you added to the Demo zone automatically have a profile in Child1. To log on to a computer, users must have a profile and a role assignment. You can assign the default *UNIX Login* role to enable users to log on.

   - Expand **Child Zones**, **Child1**, and **Authorization**.
   - Select **Role Assignments**, right-click, then click **Assign Role**.
   - Select the **UNIX Login** role from the results and click **OK**.
   - Click **Add AD Account**.
   - Search for and select one of the Active Directory users you added to the Demo zone, then click **OK**.

7. On the Linux or UNIX computer, log on as root. if you are installing on a computer running Linux or UNIX.

8. Run the install.sh command.

   ```
   ./install.sh
   ```

   The installation script checks whether the computer meets all system requirements, such as a supported operating system, available disk space, DNS and network connectivity, and your Active Directory configuration.

   If the computer meets all requirements, you can choose to install all Server Suite, or a customized set of services. You can also choose whether to automatically join the domain and restart the local computer to complete the installation. After you make your selections, the script installs a platform-specific Server Suite Agent and any other packages.

   Alternatively, you can install using a native package manager or another software distribution utility. The command line syntax and the agent package name will depend on the operating system on which you are installing.

   To manually join the domain after installation, use the adjoin command. In either case, you must specify the zone to join. For example, if you created the Child1 zone, you might run a command similar to this:

   ```
   adjoin myDomain -z Child1
   ```

   In Step 4, you created a profile for an Active Directory user in the Demo zone. In Step 6, you assigned the user the UNIX Login role. You can now verify authentication by logging off as root and logging on to the computer you just joined to the Active Directory domain with the Active Directory user

account and password you assigned the UNIX Login role.

That's it!

From here, if you want to explore further, you can:

- Create and assign additional roles to users
- Create new child zones
- Import existing UNIX users and groups
- Override user attributes in child zones
- Set group policies for UNIX computers and users
- Run reports
- Import and manage NIS maps in Active Directory

For more information about any topic, see the Server Suite documentation set.

This guide is intended for UNIX or Windows administrators who intend to configure multi-factor authentication for computers managed by Server Suite.

Configuration information for Delinea customers who are not using Server Suite to manage their environment, but want to configure multi-factor authentication to log in Windows computers, should go to Downloading the Server Suite Agent for Windows.

There are two separate scenarios for which you might want to require multi-factor authentication:

- **Login** access to Server Suite-managed computers.
- As part of a **re-authentication** process so that users who are attempting to use Application, Network, and Desktop rights on Windows machines, or command rights with elevated privileges or in a restricted shell on UNIX machines, must provide a password and another form of authentication before they can execute the selected command.

With these two scenarios in mind, you can configure multi-factor authentication based on user roles or computer roles, for specific applications, or for individual commands. You can also skip multi-factor authentication for applications that do not support it or for other reasons on a case-by-case basis by enabling and applying group policy or by setting configuration parameters.

You can configure multi-factor authentication for users logging on to Server Suite-managed computers to improve the security of physical or virtual data centers. You can do this by assigning the predefined require MFA for login role to users who are required to provide more than one form of authentication. Alternatively, for UNIX and Linux roles, you can also create custom role definitions with the **Require multi-factor authentication for login** system right selected. Because the Windows Login role can be assigned to local accounts, there is no system right for multi-factor authentication, therefore you must assign users the require MFA for login role.

Roles and role assignments are important when configuring multi-factor authentication for login access to Server Suite-managed computers in hierarchical zones.

Before configuring multi-factor authentication, you should be aware that multi-factor authentication for Server Suite-managed computers relies on the infrastructure provided by the Delinea Platform.

Note: For Linux and UNIX computers, logging on requires a PAM application such as login, ssh, or a desktop manager. Most programs that enable users to log in support multi-factor authentication. However, some desktop manager programs that run on older operating systems might not support multi-factor authentication.

Multi-Factor Authentication and Smart Card PIN Login

A smart card user logging in by way of a Personal Identification Number (PIN) will not authenticated by multi-factor authentication. (Ref: CS-38641)

If you have installed Server Suite, you can require multi-factor authentication when users perform operations with an elevated access right, in addition to requiring multi-factor authentication when users log in. For Linux and UNIX computers, for example, you can also create command rights that require multi-factor authentication when executing commands using elevated privileges (dzdo) or in restricted shell (dzsh) environments. For Windows computers, you can create desktop, application, and network access rights that require two-step authentication to use the elevated privileges associated with the desktop, application, or network access.

Before configuring multi-factor authentication for any type of access right, you need to perform some preliminary steps to prepare your environment.

Because multi-factor authentication for Server Suite-managed computers relies on the infrastructure provided by the Delinea Platform, there are steps that require access to a Delinea Platform instance and the administrative portal. As a preview, here are the steps involved in preparing the identity platform to support multi-factor authentication for Server Suite-managed computers:

- Register for the **Delinea Platform**.
- Install and configure at least one Cloud Connector for communication with the platform. Your machine account must have login access to the connector machine.
- Verify the users who are required to provide more than one form of authentication have valid **Active Directory accounts** that are active in the platform.
- Add or select the **authentication profiles** that specify the types of authentication challenges to support.
- Create a role with the appropriate **computer members and administrative rights** for multi-factor authentication.
- Verify the **server authentication instance URL** you want to use if you have access to more than one authentication instance.

After you have completed the preliminary steps, you can assign users the predefined require MFA for login role or, for users of UNIX and Linux machines, a custom role with the **Require multi-factor authentication for login** system right to require two-step authentication when logging on. These preliminary steps are also required if you want to create command rights that require two-step authentication when executing commands using elevated privileges (dzdo) or in restricted shell (dzsh) environments on UNIX and Linux machines, or when creating roles with elevated Windows rights.

Multi-factor authentication for Server Suite-managed computers relies on the infrastructure provided by Privileged Access Service and authentication and privilege elevation. Privileged Access Service enables you to securely manage users, roles, policies, devices, and applications in the identity platform. You can also define the types of authentication challenges you support and where the multi-factor authentication rules apply.

Sign Up and Activate Your Account

To get started, you should register for an account in Privileged Access Service if you are not already a subscriber. You can request a free trial or subscribe to Privileged Access Service through the Delinea website.

If you don't already have a subscription, you can start by requesting access to Privileged Access Service by visiting the Delinea website.

After you register for a Delinea account with a valid email address, you will receive an "Activate Your Delinea Account" email followed by a "Your Delinea Account Is Ready Next Steps" email with your account details. Your account details include the user name and temporary password for an administrative account that is a member of the predefined System Administrator role and a unique customer identifier. For example, your email message might have account details similar to the following:

	https://abcd1234.my.centrify.net/manage
Your User Name:	admin_maya.garcia@acme.net
Your Temporary Password:	1234abcepassword (You'll be asked to change this when you log in)
Customer ID:	ABCD1234

Use your account details to log in and set a new password for your administrative account.

Start or Skip the Wizard

After you log in successfully, you will see a Welcome to Privileged Access Service message with the option to start or skip the quick start wizard.

If you click **Start the Wizard**, you are prompted to manage mobile devices, add web applications, add mobile applications, add users, and invite users. You can click Next to skip any or all steps. None of the steps in the wizard are required to set up multi-factor authentication.

If you are only interested in preparing for multi-factor authentication, you can select the **Don't show this to me again** option, then click **Skip**. If you click Skip now, you can run the wizard at any time after configuring multi-factor authentication by clicking **Start Wizard** on the Getting Started dashboard.

If you have not completed these preliminary steps, stop here and verify that you have received the "Your Delinea Account Is Ready - Next Steps" email and that you can log in to the Privileged Access Service platform with the account information in the email.

Plan Multi-Factor Authentication for Server Suite-Managed Computers

Privileged Access Service is most often used to store information about people and devices, to identify different classes of users and devices, and to define the policies that specify what different classes of users and devices can do. To support multi-factor authentication, however, you must also add Delinea-managed computers to the access service.

Any computer that will require multi-factor authentication must also be added as a member of an identity platform-based role. This step is similar to adding computers to a zone. For multi-factor authentication, an identity platform-based role has computers as members and is managed through Privileged Access Service. It is separate from the role definitions and role assignments you manage using Access Manager or other Server Suite components.

The connector is a multipurpose service that enables secure communication between your internal network and Privileged Access Service. Multi-factor authentication requires at least one connector to be installed on your network inside of the firewall. The connector provides the link between your internal Active Directory forest and the Privileged Access Service platform.

You can install more than one connector for your organization to support fail-over and load balancing. You might also want to install more than one connector if you are using multiple instances of Privileged Access Service or have access to more than one customer-specific Identity platform instance URLs. In most cases, you should install at least two connectors in a production environment.

Note: Make sure that the account you're logged into on the computer has the appropriate permissions to install the Cloud Connector.

For details about installing and configuring the connector, please see the following topics in the Privileged Access Service help:

- Installing a connector
- Configuring a connector
- Installing a connector
- Configuring a connector

Establishing a Connector Identity for Multi-Factor Authentication

In order to enable multi-factor authentication for Delinea-managed UNIX and Linux machines, the connector must validate the machine credentials using the Integrated Windows Authentication (IWA) service. To use the IWA service, your connectors must be configured to use an HTTPS-enabled port.

To configure connectors to use an HTTPS-enabled port, you must either download a host certificate issued by Delinea, or upload a host certificate issued by a Certificate Authority (CA) already trusted by your environment.

To configure Windows computers for multi-factor authentication, you must establish an initial trust relationship between the Windows machine and the Cloud Connector. Since the connector accesses the IWA service through a secure HTTPS channel, you must validate the correct certificate during installation when enabling multi-factor authentication for login.

If you are operating in an evaluation environment, and cannot easily set up the required certificate trust relationship, you have the option to skip this step during installation and trust your own connector without enrolling in the IWA service. In this case, the computer is connected directly to the Delinea Platform, and multi-factor authentication can be enabled. Note, however, that this should only be done in an evaluation environment, as it has serious security implications in a live production environment.

If you have chosen not to establish the trust relationship, but wish to do so in the future, you can either leave and then rejoin a zone if you are joined to one, or you can disable and then re-enable multi-factor authentication for login to launch the configuration wizard.

To configure a connector to use a Delinea-issued root certificate

1. In the Admin Portal, click **Settings > Network**.
2. Select the connector you want to configure, and choose **Modify** from the **Actions** menu.
3. In **IWA Service**, click **Download your IWA root CA Certificate** to retrieve the public certificate for the tenant-specific CA certificate issued by Delinea.
4. Click **Download** to download the host certificate issued by Delinea for your connector.

You can export the IwaTrustedRoot.cer trusted root CA certificate issued by Delinea and manually install it on a local computer, or use group policy to distribute the certificate file as a trusted root certificate to multiple computers

Note: Express users cannot use group policies to distribute certificates in bulk to UNIX and Linux computers. To distribute the certificates, you must download and install the certificate in the appropriate directory on each computer.

To Import the Certificate Manually to a Local Windows Computer

1. Right click on the certificate you downloaded in To configure a connector to use a Delinea-issued root certificate.
2. Select **Install Certificate** to start the Certificate Import Wizard.
3. Select **Local Machine** and click **Next**.
4. Select **Place all certificates in the following store** and click **Browse**.

5. Select **Trusted Root Certification Authorities** and click **OK**.
6. Click **Next** and then **Finish** to complete the Wizard.

   A Windows Security Warning may be displayed. Click Yes to finish installing the certificate.

To Export the Certificate for Bulk Group Policy Distribution

1. Select the trusted root certificate you downloaded, right-click, then click **Open**.
2. Click the **Details** tab and click **Copy to file** to start the Certificate Export Wizard, then click **Next**.
3. Select **DER encoded binary X.509 (.CER)** as the file format, then click **Next**.
4. Click **Browse** to select a location on the local server, type a file name and click **Save**, then click **Next**.
5. Click **Finish**.

To Distribute the Certificate using Group Policy

1. Open Group Policy Management to select the group policy object that defines the IP Security policies, then click **Edit**.
2. Click **Computer Configuration > Policies > Windows Settings > Security Settings > Public Key Policies > Trusted Root Certification Authorities**.
3. Select **Trusted Root Certification Authorities,** right click, and select **Import** to open the Certificate Import Wizard.
4. Click **Next** on the **Welcome** screen.
5. Browse to find the root certificate you downloaded, then click to accept the default values on each screen.
6. **Click Finish** to complete the wizard.

   The root certificate is now in the Active Directory Trusted Root Certification Authorities container. Group policy publishes all certificates in this container to computers joined to the domain. You can also run the gpupdate command from a command prompt to push the certificates to the computers in the domain.

Using a certificate not issued by Delinea with the Cloud Connector

If you want to use a certificate issued by a CA that is trusted by your organization, you must upload the certificate from the Cloud Connector Configuration program. Doing this ensures that the computer credentials can be validated for secure communication between the connector and the authentication server. The issuer of the certificate must also be trusted by resources running agents.

To use an externally issued certificate for a Cloud Connector

1. In the Admin Portal, click **Settings > Network > Centrify Connectors**.
2. Select the connector you want to configure, and choose **Modify** from the Actions menu.
3. Click **IWA Service**.
4. Click **Upload** and navigate to the location of the certificate trusted by your organization.

   Note: You may get the following error while enrolling a Windows agent/machine into the cloud-based CIS with debugging enabled:

```
An error occurred while sending the request. ---\> System.Net.WebException:
The underlying connection was closed: Could not establish trust relationship for
the SSL/TLS secure channel. ---\> System.Security.Authentication.AuthenticationException:
The remote certificate is invalid according to the validation procedure.
```

If so, check your local machine trusted root CA. The server may not have the corresponding DigiCert Global Root CA installed. If so, export the local certificate. Then import the certificate to the server. After that, you should be able to enroll the server.

Verify Open Ports

Multi-factor authentication requires the following ports to be open for inbound communication and domain traffic:

- Port 8080 for HTTP API proxy
- Port 8443 for secure HTTP (HTTPS) connections

Installing the connector automatically sets Windows firewall rules to open these ports. However, if you are using a third-party firewall instead of the default Windows firewall, you should manually modify the port rules to allow the Server Suite Agent for Windows to communicate with the Cloud Connector. Both ports are required because integrated Windows authentication over HTTPS uses port 8443 to enable the connector to receive inbound connections from the agents.

After you have installed and configured at least one connector, you can use either the Admin Portal or your default browser to log in to the Delinea Platform.

To log in and verify settings

1. Open a browser and log in to your customer-specific identity platform instance URL.
2. Type the user name from your account details and the password you set when you activated the service.

   If you see the Welcome message, select the "Don't show this to me again" option, then click **Close**.

   By default, the Getting Started dashboard is displayed in the Admin Portal. The Getting Started dashboard has links to topics that explain important tasks—such as creating roles and adding users—for the Delinea Platform. You will perform similar steps to prepare for multi-factor authentication. However, you can skip those steps for now. For multi-factor authentication, you should first verify some settings on your connector and, if necessary, prepare a new Active Directory group for the computers where you plan to use multi-factor authentication.
3. Click **Settings > Network > Centrify Connectors**.
4. Select the connector and then select **Modify** from the Actions menu to display the connector Configuration.
5. Verify the following options are selected under IWA Service:
   - Enable Web Server

     This option is required to enable integrated Windows authentication for agents and multi-factor authentication.
6. Click **Save**.

After verifying connector settings, you can use Active Directory Users and Computers or other tools to prepare an Active Directory group for the computers where you plan to require multi-factor authentication. Although you can use any existing Active Directory group for this purpose, the steps in this guide assume you will use a new group specifically for multi-factor authentication.

Multi-factor authentication requires computers to be members of an **identity platform role** assigned a specific **administrative right** in the Delinea Platform. You can add individual computers independently without using an Active Directory group. However, using an Active Directory group is the recommended approach and facilitates the deployment of computer roles that link user role assignments to computer groups.

To Add an Active Directory Group for Multi-Factor Authentication

1. Open Active Directory Users and Computers.
2. Select a location, right-click, then select **New** > **Group**.

   For example, if you are using the default deployment structure, you might expand the Centrify organization unit and select Computers, then right-click to create a new group in that organizational unit.
3. Type a group name, select the group scope, and verify the group type, then click **OK**.

   For example, type MFA-Group, select Global for the group scope, and verify the group type is Security, then click **OK**.

Offline MFA mode is not triggered during logon to the computer once the agent has successfully connected to the cloud. Logon will fail if the cloud fails to authenticate the user, the user is not allowed to perform the MFA logon, or if the user is not assigned to any profile in the portal.

To add a user or group to a role in the Admin Portal

1. Create a new role or double-click an existing role that is policy-specified.
2. Click **Members** › **Add**.
3. Enter a search string to locate the Active Directory groups or users you are using that require multi-factor.
4. Select the group or user and then click **Add**.
5. Click **Save**.

After you have prepared an Active Directory group for the computers where you plan to require multi-factor authentication, you can use the Admin Portal to prepare a role for those computers.

To prepare a role in the Admin Portal:

1. In the Admin Portal, click **Core Services**, then click **Roles**.
2. Click **Add Role**.
3. Type a role name and, optionally, a role description.

   For example, type MFA-LinuxComputers as the role name and Role for multi-factor authentication of Linux Computers as the role description, then click **Save**.
4. After naming the role, click **Members**, then click **Add**.
5. Type a search string to locate the Active Directory group you are using for computers that require multi-factor authentication.

   For example, if you created a group called Audited Servers in Preparing a group for Delinea-managed computers, you might type “aud” as the search string to locate that group. Alternatively, you can search for and add individual computers to the role if you are not using an Active Directory group. Adding individual computers to the role, however, is not a scalable approach for most organizations.

   This step creates the link between the Delinea-managed computers and the identity service. There is no change to how you manage the computers you add to the identity service. This link is required to allow Privileged Access Service to provide authentication profiles to managed computers.
6. Select the group, then click **Add**.
7. Click **Administrative Rights**, then click **Add**.
8. Select the **Computer Login and Privilege Elevation** administrative right, then click **Add**.

   This administrative right is only applicable for the computers that are members of the identity platform role. The right does not apply to users and is ignored for any users added as members of the role. In general, you should not add users to any role that is intended for multi-factor authentication on Delinea-managed computers.
9. Click **Save**.

With Server Suite, you can require multi-factor authentication for two distinct situations:

- As part of the **login** process so that users who are attempting to log in to Delinea-managed computers must provide multiple forms of authentication before they are granted access.
- As part of a **re-authentication** process so that users who are attempting to use Application, Network, and Desktop rights on Windows machines, or command rights with elevated privileges or in a restricted shell on UNIX machines, must provide a password and another form of authentication before they can execute the selected command.

To configure the types of authentication challenges allowed in each situation, you can prepare one or more **authentication profiles** in the Admin Portal. If you have already configured authentication profiles for other purposes, you can reuse those profiles for multi-factor authentication or add new profiles specifically for the computers you manage using Server Suite. You can prepare one profile to use for both login access and for the use elevated privileges or you can prepare separate profiles for each situation.

Create an Authentication Profile

The first step in preparing authentication profiles is to create the profile.

To create an authentication profile:

1. Open a browser and log on to Privileged Access Service using your customer-specific URL.
2. Navigate to **Settings** › **Authentication**.

   Three default authentication profiles are available out-of-the-box:

   - **Default New Device Login Profile**: Uses Password for the first challenge and Mobile Authenticator, Text message (SMS) confirmation code, Email confirmation code, or OATH OTP Client for the second challenge with a 12 hours pass-through duration.
   - **Default Other Login Profile**: Uses Password for the first challenge and no secondary challenge with a 12 hours pass-through duration.
   - **Default Password Reset Profile**: Gives the option for users to use Mobile Authenticator, Text message (SMS) confirmation code, Email confirmation code, or OATH OTP Client for the first challenge with a 12 hours pass-through duration.

3. Select an existing Authentication Profile or click **Add Profile**.

   The fields needed to **add new profile**.

   1. Type the authentication profile name.
   2. Select the types of authentication to present for the first challenge.

      Note: The second authentication is not needed. Challenge two is a third mechanism.

   3. Click **OK**.

The pass-through option does not apply to Windows, Linux, or UNIX MFA logins unless you specify otherwise in the policy settings.

Select the authentication mechanism(s) you require and want to make available to users. Some authentication mechanisms require additional configurations before users can authenticate using those mechanisms. See Authentication mechanisms for information about each authentication mechanism.

For example, you can require that the first challenge be the user's account password. Then for the second challenge, users can choose between an email confirmation code, security question, or text message confirmation code.

If you have multiple challenges, Privileged Access Service waits until users enter all challenges before giving the authentication response (pass or fail). For example, if users enter the wrong password for the first challenge, we will not send the authentication failure message until after users respond to the second challenge.

If users fail their first challenge and the second challenge is SMS, email, or phone call, the default configuration is that Privileged Access Service will not send the SMS/email or trigger the phone call. Contact support to change this configuration.

Assign Login Authentication Profiles

The next step is to assign login authentication profiles to policies. In this task, you set up a policy so that if specified conditions are met, the affected users proceed according to a specified authentication profile. If those conditions aren't met, you can specify a default authentication profile or block access entirely.

For example, you could set a policy that says that during work hours of Monday to Friday, 8:00 am to 5:00pm, users log in using an authentication profile that requires a password and a security question. For users logging in outside of those days or times, users will have to login with a password, security question, and an email confirmation code.

As a reminder, you use **authentication profiles** to define the necessary authentication methods to use. You define **authentication rules** to specify where to enforce those authentication profiles inside of a policy set.

To assign a login authentication profile to a policy set:

1. In the Admin Portal, go to **Access** > **Policies** and either click **Add Policy Set** to create a new policy or click an existing policy to edit.
2. Create or edit the policy set and assign it to the desired users or resources.

   For details, see "Creating policy sets and policy assignments" in the Privileged Access Service help.
3. In the Policy Settings area, navigate to Authentication > Centrify Server Suite Agents > and click one of the following settings:

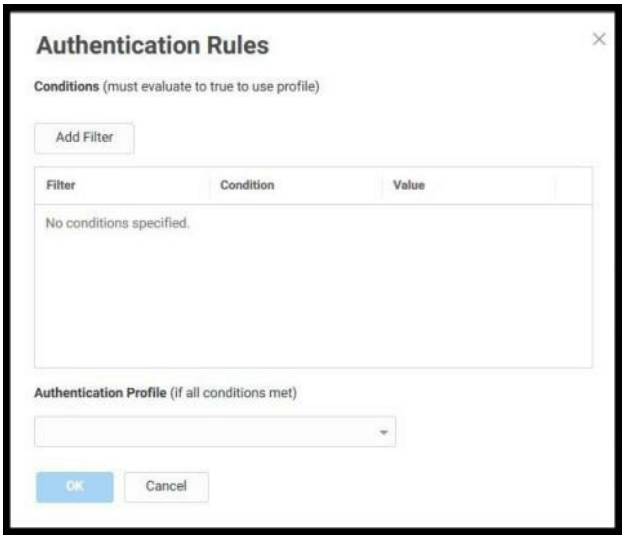
Linux, UNIX and Windows Servers	For Linux and UNIX Servers or Workstations where the Server Suite Agent for *NIX is installed and enabled. For Windows Servers where the Server Suite Agent for Windows is installed and enabled
Windows Workstations	For Delinea-managed workstations where the Server Suite Agent for Windows is installed and enabled. The operating system variant determines if it's a workstation.
Privilege Elevation	For systems where either the Server Suite Agent for *NIX or Serer Suite Agent for Windows is installed and enabled.

Note: For any of the above policy settings, the role assignment associated with this policy must include computer objects or groups in Active Directory and also the "Computer Login and Privilege Elevation" administrative rights.

1. Select **Yes** in the **Enable authentication policy controls** drop-down.

   The Authentication Rules section displays. You use this section to define which authentication profiles apply under which conditions.
2. (Optional) If you want to specify conditions for which different authentication rules apply, click **Add Rule**. Otherwise, proceed to step

   The Authentication Rules window displays.



3. Click **Add Filter**, and then click the same drop-down to spicy which kind of condition.

   For example, you can create a rule that requires a specific authentication method when users access Privileged Access Service from an IP address that is outside of your corporate IP range. Supported filters are:

IP Address	The authentication factor applies as follows: For Privileged Access Service on-premise, the authentication factor is the connector's IP address when you log in. When using HTTP proxy, the authentication factor is the HTTP Proxy server's IP address when you log in. For Privileged Access Service, the authentication factor is the tenant connectors' public IP address when you log in. When using HTTP proxy, the authentication factor is the HTTP proxy server's public IP address when you log in. This option requires that you have configured the IP address range under **Settings** > **Network** > **Corporate IP Range**. **Note**: For Windows machines that can access the Internet, the authentication factor is the machine's IP address when you log in.
Identity Cookie	The authentication factor is the cookie that is embedded in the current browser by the directory service after the user has successfully logged in.
Day of Week	The authentication factor is the specific days of the week (Sunday through Saturday) when the user logs in.
Date	The authentication factor is a date before or after which the user logs in that triggers the specified authentication requirement.
Date Range	The authentication factor is a specific date range.
Time Range	The authentication factor is a specific time range in hours and minutes.
Risk Level	Risk Level: The authentication factor is the risk level of the user logging on to Admin Portal. For example, a user attempting to log in to Privileged Access Service from an unfamiliar location can be prompted to enter a password and text message (SMS) confirmation code because the external firewall condition correlates with a medium risk level. This Risk Level filter, requires additional licenses. If you do not see this filter, contact Delinea support. The supported risk level are: Non Detected — No abnormal activities are detected. Low — Some aspects of the requested identity activity are abnormal. Remediation action or simple warning notification can be raised depending on the policy setup. Medium — Many aspects of the requested identity activity are abnormal. Remediation action or simple warning notification can be raised depending on the policy setup. High — Strong indicators that the requested identity activity is anomaly and the user's identity has been compromised. Immediate remediation action, such as MFA, should be enforced. Unknown — Not enough user behavior activities (frequency of system use by the user and length of time user has been in the system) have been collected.
	For the Day/Date/Time related conditions, you can choose between the user's local time and Universal Time Coordinated (UTC) time.

4. Click the **Add** button associated with the filter and condition.
5. Select the authentication profile you want applied if all filters/conditions are met in the **Authentication Profile** drop-down.

   The authentication profile defines which authentication methods to use. If you have not created the necessary authentication profile, select the **Add New Profile** option in the list (it's at the bottom of the list).
6. Click **OK** to close the Authentication Rules dialog box.
7. If desired, continue adding authentication rules. You can drag the rules to change the order of priority. The highest priority rule is at the top of the list.
8. Select a default profile to be applied if a user does not match any of the configured conditions in the **Default Profile (used if no conditions matched)** drop-down.

   Note: If you have no authentication rules configured and you select **Not Allowed** in the **Default Profile** dropdown, users will not be able to log in to the service.
9. If this policy setting is for Linux, UNIX, and Windows Servers, you have the option to configure how the pass-through duration applies. The pass-through duration is how long before the user needs to re-authenticate, and you define the pass-through duration in the authentication profile (for example, the default is 30 minutes). Select one of the following options:

- **Never (default):** Always prompt for MFA and ignore the pass-through setting.
- **If Same Source and Target**: Apply the pass-through duration if the user is logging in from the same system and where they're logging in to is the same system as compared to the initial login.
- **If Same Source**: Apply the pass-through duration if the user is logging in from the same system as compared to the initial login.
- **If Same Target**: Apply the pass-through duration if the user is logging in to is the same system as compared to the initial login.

10. If desired, you can add multiple policy settings to the same policy set.
11. Click **Save**.

Assigning Privilege Elevation (Re-authentication) Profile

Finally, you must assign privilege elevation profiles.

1. For Elevated Privileges Profile, click **Privilege Elevation Policies > Privilege Elevation**, select **Yes** for Enable authentication policy controls, and **Add Rule > Add Filter,** click **Authentication Profiles** and display the list of existing profiles and select a profile to use or click **Add New Profile**.

   You can use the same profile for server access, and to re-authenticate for roles and rights that require multi-factor authentication. However, if you want to specify different authentication challenges from which a user can select when executing UNIX commands or accessing Windows applications, select **Add New Profile**.

   As with the Login Authentication Profile, you can select multiple types of authentication to present for the first and second challenges. However, only the authentication challenges that are applicable for a user can be presented when the user attempts to access privileged Windows rights or execute UNIX commands with elevated privileges (dzdo) or in a restricted shell (dzsh).

2. Click **Save**.

You can prepare for multi-factor authentication before or after installing Server Suite components. The steps in this section summarize what to do to finish configuring multi-factor authentication for login access and executing commands for computers in hierarchical zones. You can use Access Manager, adedit, or Access Module for PowerShell scripts to complete most of the next steps.

For more information about performing these tasks, see the following documentation:

- Planning and Deployment Guide
- Administrator's Guide for Linux and UNIX
- Administrator's Guide for Windows

For example, see the *Administrator's Guide for Linux and UNIX* for more detailed information about how to create zones, configure role definitions, and add command rights for Linux and UNIX computers.

To Configure Multi-Factor Authentication

1. Install Access Manager and other components.
2. Create at least one hierarchical zone.
3. Verify the Identity platform instance URL for the zone by displaying the zone properties, then clicking the Platform tab.

   If necessary, you can click Browse to select a different Identity platform instance if you have access to more than one customer-specific Identity platform instance URL.
4. Assign the predefined require MFA for login role definition to the Active Directory users who have access to computers where you want to require multi-factor authentication and who are already assigned the UNIX Login or Windows Login role.

   Alternatively, you can create one or more custom UNIX or Linux role definitions that include the **Require multi-factor authentication** system right. Note that you can also use the Access Module for PowerShell to set the system right described in this step.
5. Define the rights you would like to add to the role and select the **Require multi-factor authentication** reauthentication option on the Attributes tab.

   After you create rights that require multi-factor authentication, add the rights to the appropriate role definitions and assign the roles to the appropriate Active Directory users.

   Note that you can also use the Access Module for PowerShell to require multi-factor authentication for command execution.
6. Refresh the agent.

   For a UNIX computer requiring multi-factor authentication, run `adflush -f` or restart the agent to test multi-factor authentication for login access and command execution.

   For a Windows computer requiring multi-factor authentication, run `dzrefresh` from a command prompt. Depending on your permission settings, you may need to open the command prompt using "Run as administrator."

   Note: When you initially update or install the Server Suite Agent for Windows and configure multi-factor authentication for login, there may be a slight delay while the cache refreshes. During this short period, users who are required to use multi-factor authentication to log in may only be asked for their Active Directory credentials. When they logout from their machine, the cache will have refreshed, and they will then be required to use multi-factor authentication in future login attempts.

After you have completed the basic steps to enable multi-factor authentication, you might want to customize the configuration to suit your environment or to address specific scenarios. For example, you might want to enable group policies or set configuration parameters if you want to modify the default multi-factor authentication operations.

For more information on setting group policies for multi-factor authentication, please see the *Group Policy Guide*. For information on setting configuration parameters, see the *Configuration and Tuning Reference Guide*.

The next sections discuss the most common customization scenarios.

Add Rescue Rights

You should have at least one role with the "rescue" system right for the UNIX and Linux computers in hierarchical zones where you are requiring multi-factor authentication. This system right enables selected users to log in in cases where multi-factor authentication cannot be completed. For example, if a UNIX computer where multi-factor authentication is required is disconnected from the network and cannot access the Delinea Platform, only users with the "rescue" right will be able to log in until the connection to the identity platform is restored.

Configuring Secure Shell (ssh) for Multi-Factor Authentication

If you are planning to require multi-factor authentication for secure shell (ssh) sessions and you want to use a native secure shell package, you should review the settings in the secure shell configuration file (sshd_config) to be sure that the ChallengeResponseAuthentication option is set to yes.

You can edit the file manually or enable the "Allow challenge-response authentication" group policy to automatically configure this setting. You can find this group policy in the Group Policy Management Editor under Computer Configuration > Policies > Centrify Settings > SSH Settings. For more information about adding, enabling, and applying Centrify group policies and the other group policies you can use for secure shell sessions, see the *Group Policy Guide*.

Enforcing Multi-Factor Authentication for Single Sign-on Login Access

If you use the Delinea OpenSSH package, you can require multi-factor authentication for secure shell connections even for single sign-on access to remote computers. In this scenario, users must respond to the authentication challenges to open the secure shell connection then be silently authenticated to additional services and computers. Note that this scenario is only supported if you are using the Delinea version of the OpenSSH package and not supported for native secure shell packages. To enable multi-factor authentication for single sign-on using secure shell sessions, you must enable and apply the Enable SSO MFA group policy. You can find this group policy in the Group Policy Management Editor under Computer Configuration > Policies > Centrify Settings > SSH Settings. For more information about adding, enabling, and applying Centrify group policies and the other group policies you can use for secure shell sessions, see the *Group Policy Guide*.

If you are not enabling and applying group policies for Delinea-managed computers, you can manually enforce multi-factor authentication for single sign-on by setting the secure shell configuration parameter SSOMFA to yes in the /etc/centrifydc/sshd/sshd_config file.

If you enable the group policy or set the parameter and auditing is set to required, users who access a Delinea-managed computer using ssh or PuTTY are prompted to respond to the multi-factor authentication challenges before starting the shell session. Securing the shell session with multi-factor authentication prevents unauthorized users from using the secure shell session to connect to remote services and computers.

Require Multi-Factor Authentication for PAM Applications

If you select the "Multi-factor authentication required" system right in a role definition, the PAM applications you add to the role will require users to provide a secondary form of authentication to log in successfully. You define the forms of authentication available and presented to the user in the **authentication profile** you have configured in the Privileged Access Service using the administrative portal.

Note that some applications do not support multi-factor authentication and users might be denied access to applications that they would otherwise be able to use. For example, if a specific version of an application that you want to use only supports a single layer of authentication—such as a password challenge—users would be prevented from logging on and using the service even if they are assigned to a role with the predefined login-all PAM application right.

If you want to grant access to applications that only support one layer of authentication in roles where you are generally using the "Multi-factor authentication required" system right, you must add those applications to the list of applications for which you want to skip multi-factor authentication. You can update the list of applications for which to skip multi-factor authentication by enabling and modifying the "Specify programs for which multi-factor authentication is ignored" group policy or setting the pam.mfa.program.ignore configuration parameter in the centrifydc.conf file.

Before assigning roles with multi-factor authentication required to users, you should test access to all of the applications you expect users to access to verify

they won't be unexpectedly denied access simply because multi-factor authentication isn't supported. Because the applications that don't support multi-factor authentication will depend on the platforms and the versions of the applications you plan to support, testing in your own environment is the only way to determine which applications to add to the pam.mfa.program.ignore configuration parameter.

The most common applications that are known to only support a single password challenge and response for authentication are ignored for multi-factor authentication by default. For example, some versions of vsftpd, java, and httpd do not support multi-factor authentication and are ignored by default.

Additionally, while some platforms support multi-factor authentication for all PAM applications, they may not allow you to require multi-factor authentication for GUI log in. For example, for users running AIX, Solaris, and HP-UX, multi-factor authentication for GUI login is not supported.

Configure Multi-Factor Authentication in Legacy Zones

If you want to configure multi-factor authentication for UNIX and Linux computers in classic zones or in Auto Zone, you must follow different steps than in hierarchical zones. For multi-factor authentication on computers in the "legacy" types of zones, you must either enable and apply group policies or set configuration parameters.

You can find these group policies in the Group Policy Management Editor under Computer Configuration › Policies › Centrify Settings › DirectControl Settings › MFA Settings. For more information about adding, enabling, and applying Delinea group policies, see the *Group Policy Guide*. For more information about setting configuration parameters, see the *Configuration and Tuning Reference Guide*.

The following sections describe multi-factor authentication configuration options for Server Suite-managed Windows computers. In addition to these options, you can use group policies to customize basic operations for connecting to the Delinea Platform and multi-factor authentication on Windows computers. For more information on these group policies, please see the *Group Policy Guide*.

You can find the group policies for multi-factor authentication and the grace period on Windows computers in the Group Policy Management Editor under **Computer Configuration > Centrify Settings > Windows Settings > MFA Settings**.

To set the grace period, use the following group policies:

- Configure multi-factor authentication lock screen grace period. This group policy enables the grace period for lock screen.
- Configure multi-factor authentication user privilege elevation grace period
  This group policy allows the administrator to set the grace period for privilege elevation for users.

Reset Password

Password reset is a very popular self-service capability for Identity and Access Management solutions: It reduces calls to the help-desk and enables users to become productive quickly. The system allows the user to make a limited number of reset password requests within a specified period.

Note: This feature does not enable the user to unlock their account.

To reset your password (user instructions):

1. On the login screen, click the **Forgot Password** link.

   A prompt appears asking the user name. (If the user already entered their username using the login screen, it appears in this user name field.)

2. Complete the MFA challenges, which are based on the password reset profile.

3. A new prompt asks you to enter a new password and confirm it.

   After resetting the password, you can log in using the normal login screen.

Disable Self-Service Password Reset

Configuring this policy setting allows the administrator to force disable the password reset.

You can use this group policy to allow the administrator to force disabling of the password reset feature. There are two settings for this group policy:

- Enabled: If this policy is set to **Enabled**, the self-service password reset feature on the machine is disabled, including the cloud-enabled self-service password reset.

- If this policy is set to **Disabled** or **Not Configured**, the self-service password reset feature on the machine follows the cloud policy setting (cloud policy settings can be found at: **Policy Settings** › **User Security Policies** › **Self Service** › **Password Reset**). The cloud policy settings are accessed through the Admin Portal.

  Note: The Admin Portal is available after you log in to a Delinea Platform instance.

Configure Offline Multi-factor Authentication and Rescue Users

When a Windows computer that is running a Server Suite Agent is not configured to use multi-factor authentication, you can use a local account to rescue that system when it cannot connect to the Delinea Platform.

Local users do not require MFA challenge. For non-safe mode in Windows Operating System:

- With **Privilege Elevation Service** (zone mode) a local user can log in without MFA whenever they cannot connect to the Centrify Platform. The exception is that the local user does not assign roles for either "Window login permit" or "rescue user."
- Without the **Privilege Elevation Service** (zoneless mode) a local user is allowed to log in without MFA.

For safe mode in Windows Operating System, a local user can only log in as a rescue user. To set a rescue user for zone mode, go through the Access Manager to assign roles. To set a rescue user for zoneless mode, go through Group Policies to configure.

If a computer that is joined to a zone starts in Safe Mode, only users who are assigned a Login role with the system rescue right selected will be able to access the machine. These users will not be required to use multi-factor authentication.

Users who are required to use multi-factor authentication to log in to their Windows workstations can set up an offline MFA profile to use as a second form of authentication in the event that their machine cannot connect to the Delinea Platform. These users will see a system notification urging them to set up this passcode each time they log in to their machine until they configure it.

Users set up their offline MFA profile in following way:

To set up an offline MFA profile:

1. Right click the Delinea notification icon in the system notification area, and select **Setup Offline MFA Profile**.
2. Click **Next** to begin the Offline Authentication Wizard.
3. Select one of the following methods to create a authenticator account profile on your mobile device:
    - **Scan barcode**

      If you select this option, a QR code is displayed for you to scan using your mobile authenticator application. You can use either the Delinea application or a third-party authenticator application.
    - **Manual entry**

      If you select this option, you must manually enter the displayed account profile information into your authenticator application.
    - **Program YubiKey**

      If you select this option, you can use a YubiKey as the second form of authentication. You'll then need to select which slot on the YubiKey to use, and whether or not to use Yubikey's touch-to-sign feature.
4. Enter the passcode that is generated after you have created your authenticator profile. Click **Next**.
5. Click **Finish** to exit the Wizard.

After a user has set up their offline MFA profile, they will be prompted to enter the mobile passcode generated by their authentication application or YubiKey as the second form of authentication when they attempt to log in to their machine if it cannot connect to the Delinea Platform instance.

Note: If you have already set up your offline MFA profile and want to reconfigure (override) it, you will be prompted for multi-factor authentication. That profile is set in the MFA Login Policy.

Require Multi-Factor Authentication using Computer Roles

Computer roles can enable you to group and provide access to computers through role assignments. One strategy you might find useful is to use computer roles to control where multi-factor authentication should apply. For example, you might have several computers with highly sensitive material where you want to ensure all user access will require multi-factor authentication. To accomplish this goal, you can configure a computer role, then add and remove computers with sensitive information to control whether multi-factor authentication is required.

To require multi-factor authentication based on a computer role

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that will contain the new computer role.
3. Expand Authorization to select Computer Roles, right-click, then click **Create Computer Role**.
4. Type the role name and, optionally, a role description, then select **<Create group>** for the Computer group to create a new Active Directory group for computers.

   For example, to create a new Active Directory security group for the computers with sensitive information, click **Browse** to select the Active Directory location for the new group. If you are using the default deployment structure, you would browse to a location similar to acme.sales.org/ACME/Computer Roles then type a group name such as mfa_required_consols, select a scope, and click **OK**.
5. Click **OK** to save the new computer role.

6. Add the computers that require multi-factor authentication for access to the mfa_required_consoles Active Directory security group.

   As you add computers to the Active Directory security group, the computers are listed as Members of the computer role.

7. Expand the computer role you created in Step 4, select Role Assignments, right-click, then select **Assign Role**.

   For example, if you created a new computer role with the role name CR_MFA_required, expand that computer role name to select Role Assignments, right-click, then select **Assign Role**.

8. Select the predefined require MFA for login role definition, then click **OK**.

9. Select **All Active Directory accounts**, then click **OK**.

Using Multi-Factor Authentication when there are Selective Cross-Forest Trusts

If you have domains in different forests that have a two-way selective trust relationship, any computer or user accounts that are used to log on to the remote forest must be granted the "Allowed to authenticate" right on the domain controllers in both forests to get role information.

In addition to granting the "Allowed to authenticate" right to users and to computers with the Server Suite Agent for Windows installed, the right must also be granted to computers that host your Cloud Connectors. <

After you grant these computers and users the "Allowed to authenticate" right for the domains in both forests, users that are assigned a role with a multi-factor authentication right for login and privilege elevation will be able to authenticate using any of the authentication mechanisms that you have assigned to them.

If a connector is not allowed to authenticate on the remote domain controller, some multi-factor authentication mechanisms may fail to authenticate users.

Configuring MFA with RADIUS for Privilege Elevation Service for Windows Checklist

This document provides a configuration checklist for 3rd party multi-factor authentication providers such as Duo, Okta, SecurID (or any other vendor that provides a RADIUS service) to provide identity validation with the Privilege Elevation Service in the Microsoft Windows platform.

If you have an identity service provider (such as Duo, Okta, SecureID, and so forth) that you use for MFA logins, you can integrate authentication and privilege elevation with your identity provider and the RADIUS protocol to require MFA for privilege elevation tasks, such as Run with Privilege and New Desktop.

Make sure that you work with your RADIUS expert along with your network and directory services lead administrators during the design and configuration tasks.

The checklist below includes links to documented procedures.

Note: If you use Privileged Access Service, although you can enable MFA with RADIUS, the recommended practice is that you use the native integration.

	RADIUS requirements	
1	Gather the following settings for your RADIUS service: IP address or fully qualified domain name Port Timeout settings Pre-shared secret	
2	Verify that you can generate a RADIUS one-time password successfully.	
	Verify that identity	

3	authentication is working correctly with your RADIUS system.	
4	Have access to someone who is knowledgeable about your RADIUS system and can answer questions or help troubleshoot issues, if needed.	
	Windows and Active Directory requirements for RADIUS configuration	
5	A Windows computer to use as a RADIUS client for initial testing, including: Client name Client IP address	
6	Make sure that client systems can reach the RADIUS server over the network (check your firewall settings). You may need help also from your network team if your RADIUS cluster has a load-balancer in the front end.	
7	You have administrative access to the designated Windows computer so that you can install software and do configurations.	
8	You have Active Directory account access so that you can modify group policies that apply to the target computer.	
9	You have access to the Group Policy Management Console.	
10	Your Active Directory expert must decide how the group policy layout and scope will be designed so that the group policies	

	are applied to the clients based on their RADIUS service availability.	
	Authentication and Privilege Elevation Services Requirements for RADIUS configuration	
11	Access Manager console is installed on the client computer.	For details, see "Run the setup program on a Windows computer" in the *Administrator's Guide for Windows*.
12	The Agent for Windows is installed on the client system, you've configured the system to work with Privilege Elevation Service, including joining the computer to a zone.	For details, see "Install agents for Windows" in the *Administrator's Guide for Windows*.
13	You have administrative access to Access Manager so that you can manage roles and rights.	
14	The group policy templates from release 19.6 or later are installed. For RADIUS configuration, you need at least the Centrify Windows settings group policies.	For details, see "Install group policy extensions separately from Access Manager" in the *Administrator's Guide for Windows*.
15	If you want to capture the RADIUS events in your SIEM system, make sure the Audit trail is configured to go to the local log file.	In GPME, go to computer Configuration > Policies > Centrify Audit Trail Settings > Centrify Global Settings > Send audit trail to log file (this is not configured by default). For details, see "Send audit trail to log file" in the *Group Policy Guide*. For details, see "Send audit trail to log file" in the *Group Policy Guide*.
16	You have a role and user to test with. Make sure the role has rights for privilege elevation, such as New Desktop rights or Run as Role.	Make sure that you can elevate privileges successfully for that user and role before you try to configure RADIUS authentication.
	Configure a system to use RADIUS for privilege elevation (using group policies)	
		Configure the following group policies: Windows > MFA Settings > Specify the authentication source for privilege

17	Enable and configure the RADIUS group policies.	elevation : set this policy to RADIUS Authentication. Windows > MFA Settings > Remote Authentication Dial-In User Service (RADIUS) Settings > Enable Remote Authentication Dial-In User Service (RADIUS): enable this policy. Specify the RADIUS connection timeout: Configure to match your RADIUS timeout setting. Specify the RADIUS server IP address: enter your RADIUS IP address. Specify the RADIUS server port number: enter your RADIUS port number (the default is 1812). For details, see "Remote Authentication Dial-In User Service (RADIUS) Service Settings" in the *Group Policy Guide*. For details, see "Remote Authentication Dial-In User Service (RADIUS) Service Settings" in the *Group Policy Guide*. After you update the policies, do a group policy update on the Windows client computer.
18	Configure the role to require re-authentication using multi-factor authentication.	For example: Right-click your test role and choose Properties. The Role Properties dialog box opens. Click the Run As tab. Select Re-authenticate current user and then select Require multi-factor authentication. Click OK to apply the changes.
19	Run dzflush to make sure that the agent has the changes from Access Manager.	For details, see "Using dzflush" in the *Administrator's Guide for Windows*.
20	Set the RADIUS shared secret.	The RADIUS secret is unique to each system and will match the secret that the RADIUS server has. You can set the pre-shared secret by either of the following methods on the client computer: Run the Set-CdmRadiusSecret cmdlet to set the RADIUS shared client secret. For details, see the DirectAuthorize PowerShell cmdlet help. Use the Agent Configuration settings dialog box to configure the RADIUS server, including the pre-shared secret. For details, see "Configuring agent settings for the Identity Services Platform" in the *Administrator's Guide for Windows*.
	TEST AND VERIFY	
21	Verify that a user can elevate privileges by entering the RADIUS one-time password.	For example, if your role has New Desktop rights: Right-click the System Tray and select New Desktop. In the dialog box that appears, select your test role and click OK. If the RADIUS authentication has been configured successfully, you are prompted to enter a password for RADIUS authentication. Enter the password and click Next to continue. You can also view the audit trails for the successful authentication in the system's event log.
22	Verify that a user cannot elevate privileges after entering an incorrect RADIUS one-time password.	

Because multi-factor authentication for Delinea-managed computers relies on the infrastructure of the Privileged Access Service, troubleshooting the configuration of your environment and potential connectivity issues can be challenging. To help you test and verify the proper configuration of an integrated environment, Delinea provides several diagnostic tools.

The following Delinea diagnostic tools are available on Windows computers:

- **Diagnostics Tool.** The diagnostics tool is available through the Agent Configuration service, and is described in Viewing Windows diagnostics.
- **Privilege Elevation Service Diagnostic Information panel** (formerly the DirectAuthorize Agent Control Panel) The information panel is available from the Agent Configuration service, and is described in the *Administrator's Guide for Windows*.
- **The dzdiag command.** The command is available from the Windows command prompt, and is described in the *Administrator's Guide for Windows*.

The following diagnostic tool is available on UNIX and Linux computers:

- **The adcdiag program.** The program is available from the UNIX or Linux command line, and is described in Viewing UNIX and Linux diagnostics.

Viewing Windows Diagnostics

The Server Suite Agent for Windows provides logging and diagnostic services. If you have administrative access on a local computer, you can generate diagnostic information about the operation of the agent for Windows and view and save the current content of the log file from the agent configuration panel. For example, you can generate diagnostic information about user sessions, user roles, desktops, and elevated account access, as well as detailed information about auditing from the agent configuration panel.

There are three different types of diagnostics information available:

- **Centrify Audit & Monitoring Service** provides the diagnostic information related to the auditing and monitoring service.
- **Centrify Identity Platform** provides the diagnostic information related to Privileged Access Service, such as for MFA. This diagnostics tool runs the following tests:
  - **Agent Service Connectivity Check:** Checks to see if the agent is in service, and if the agent is running in a normal state. Also determines whether the agent is in a zone, or is configured to use zoneless mode.
  - **Centrify Connector Connectivity Check:** Determines whether all connectors in the network can be connected properly.
  - **Centrify Identity Platform Certificate Validation Check:** Checks whether the certificates (IWA and cloud) have been installed properly. Also determines whether the agent can be connected without a trusted certificate problem.
  - **Centrify Identity Platform Connectivity Check:** Determines whether a connection to the cloud tenant is functional. Checks for problems with DNS, the firewall, and proxy server settings.
  - **MFA Configuration Check:** Determines whether the local computer has been configured properly. If the computer is in a zone, the test also checks whether MFA complies with the configuration defined in the zone.
  - **MFA Role and Permission Check:** Verifies whether role permissions are set properly in the Privileged Access Service Admin Portal.
  - **Offline MFA Provisioning Check:** Determines if the computer has been configured with an offline MFA profile or not.
- **Centrify Privilege Elevation Service** provides the diagnostic information related to privilege management.

You can view these diagnostics tools either from the Windows system tray or from the agent configuration panel.

For more details, see the Administrator's Guide for Windows.

To view diagnostics from the Windows system tray:

1. Log on to a computer where the Agent for Windows is installed.
2. In the Windows system tray, right-click the Centrify icon and click **Troubleshooting**, then select the service for which you want to view diagnostic information (your options may vary depending on what services are enabled on the computer):
   - **Centrify Audit & Monitoring Service** opens a dialog box with a text-based summary of diagnostic auditing and monitoring information.
   - **Centrify Identity Platform** runs a series of connectivity tests and lists out the results of each test.
   - **Centrify Privilege Elevation Service** opens a dialog box with a text-based summary of diagnostic privilege elevation information.

To generate diagnostics or view the log file from the agent configuration panel:

1. Log on to a computer where the Agent for Windows is installed.
2. In the list of applications on the Windows Start menu, click **Agent Configuration** to open the agent configuration panel.
3. Select the service for which you want to view information:
   - **Centrify Audit & Monitoring Service** opens a dialog box with a text-based summary of diagnostic auditing and monitoring information.

- **Centrify Identity Platform** runs a series of connectivity tests and lists out the results of each test.
- **Centrify Privilege Elevation Service** opens a dialog box with a text-based summary of diagnostic privilege elevation information.

4. Click **Settings**.
5. Click the **Troubleshooting** tab.
6. Click **Diagnostics** to generate diagnostic information.
7. Select the Diagnostic Information displayed, right-click, then select **Copy** to copy and paste the output to a file for further analysis.
8. Click **View Log** to display the current log file for the local agent.
9. Click **Options** to see or change the location of the log file or the level of detail recorded in the log file.

The adcdiag program performs a set of tests to check for access to a Delinea server authentication instance, the availability of one or more connectors, whether the computer is joined to an Active Directory domain, and whether the connector you are attempting to use is configured to use integrated Windows authentication.

To perform the set of tests to verify a UNIX or Linux computer can be configured to use multi-factor authentication, run the following command:

/usr/share/centrifydc/bin/adcdiag

By default, the command displays the test results in standard output (stdout) and generates a diagnostic report in the /var/centrify/tmp directory with a dated time stamp similar to the following:

adcdiagCheckingReport_20160307_151128.log

If any of the tests returned errors or warnings, you can check the diagnostic report for additional information, including suggestions for resolving any issues found. For details about the command-line options available for the adcdiag command, see the man page for the command.

Depending on how your Windows environment is set up, you may have to specify a trusted host certificate in order to enable multi-factor authentication. If you do not do this, you will see an error message during installation and configuration.

In a production environment, it is strongly recommended that you specify an existing trusted host certificate from a known third-party certificate authority, such as GoDaddy or Verisign. Using a self-signed certificate in a production environment can leave your environment vulnerable to security breaches.

For details about importing a trusted host certificate, see To import the certificate manually to a local Windows computer.

Privileged Access Service cannot manage the password for a user if multi-factor authentication is required for the user to log in. You can still add a multi-factor authentication-required user account to a PAS resource – with “Manage this password” unchecked - to log in from PAS. However, you may see the status as “Failed” due to system delay. If the operation is successful, then no status will be shown for this user.

If you have installed the agent and enabled the privilege elevation service and users can't log in for some reason, try to log in to the agent system in either Windows Safe mode or rescue mode.

We also recommend that you assign some users to the "Rescue - always permit login" role; that way, they can still log in even if the agent providing MFA isn't working for some reason. For details, see Configuring offline multi-factor authentication and rescue users.

Typically, a Unix/Linux system running the Server Suite Agent for *NIX is located on a private network. By default, the agent uses the Cloud Connector as a HTTP proxy server for connecting to the Cloud Connector to, for example, perform multi-factor authentication.

However, you may prefer to reconfigure the agent to use a different proxy server. The following sections explain how to do that.

Requirements

The configuration described in these sections require the following conditions:

- The HTTP proxy server is used only for communication between the agent and the Delinea Platform. It does not provide proxy services for another purpose.
- All of the Agents must use the same proxy server.
- You have installed DirectControl on the system.

Also note the following points:

- All of the agents use a single proxy server configuration (multiple configurations not supported)
- The machine password keytab must contain at least two versions of the key.
- This proxy server configuration supports all zone types.
- The information in the following sections does not apply to Mac OS X.

Configure the Agent to Use a Custom HTTP Server

To configure the Agent to use a custom HTTP server, use the following command syntax to set the custom HTTP proxy server:

adwebproxyconf --set,-S [--username,-u <username>]
[--password, -p <password>] [--machine,-m]
[--server,-s <servername:portI>*]*
[--authreq,-r <truelfalseI>] [--authtype, -t <type>],
'--version,-v','--help,-h' and '--verbose,-V'

For example, enter the following command (replacing the angle brackets and placeholders with actual values):

adwebproxyconf --set --username <username>
--password <password> --server <servername:port>
--authreq <true> --authtype <type>

Change the value of adclient.cloud.direct.connection to false.

Verify that the new configuration works. Enter:

adwebproxyconf --test --cip <cip url>
--server <servername:port>

For more information, see Command Reference.

HTTP Proxy Credential Local Storage

This section describes how the HTTP proxy credentials are stored locally on the Unix/Linux system that's running the agent.

The HTTP proxy credentials are be stored only in the local kset file: /var/centrifydc/httpproxy.cred

This httpproxy.cred file is only readable and write-able by root.

For security, remove httpproxy.cred. from the system when you remove the system from the domain.

For security, the proxy user's password is encrypted before being stored in httpproxy.cred.

Password Encryption

The proxy user's password is encrypted using the system's principal key, which is normally stored in /etc/krb5.keytab.

It should use the latest key to do encrypt the password. By default, it uses AES256-CTS-HMAC-SHA1-96 encryption.

If the key for a particular encryption type is not available, the Agent uses the next preferred and available encryption type that has a key in the system's keytab file.

When the system password changes, the agent uses it to re-encrypts the proxy server password. The system keytab file keeps the two latest versions of key.

If the Agent on the Unix/Linux system has FIPS Mode enabled, only a FIPS-compliant encryption type is allowed to encrypt the proxy credential password.

If a password is encrypted with non-FIPS-compliant encryption type, even if the machine keytab contains a valid key, the agent will not be able to decrypt it. If that happens, set the proxy password again so that it is encrypted using a FIPS-compliant encryption type.

Encrypted Password Storage

The encrypted password and relevant information is represented in ASN.1 as shown below and is encoded using ASN.1 Basic Encoding Rule (BER) as defined in Section 5.1 of the RFC 4511 LDAP Protocol (https://www.ietf.org/rfc/rfc4511.txt):

```
username STRING,
kvno UInt32,
etype Int32,
cipher OCTET_STRING
}
Int32 ::= INTEGER (-2147483648..2147483647) -- signed values re-presentable in 32 bits
UInt32 ::= INTEGER (0..4294967295) -- unsigned 32 bit values
```

Where:

- username: The proxy user's name.
- kvno: The version number of the key under which the data is encrypted
- etype: The encryption type used to encrypt the cipher. The encryption type number MUST be a type that is supported by the Kerberos protocol.
- cipher: The encrypted password

Local Machine Account Support

In some cases, the current system account's Kerberos credentials should be configured, the username be S-1-5-18, and the cipher part must contain an octet string with 0 length.

Command Reference

adwebproxyconf

The adwebproxyconf command configures the HTTP proxy server settings and credentials on the local system. Typical use cases are:

- Set up the HTTP proxy credential to be used by agent.
- Delete the HTTP proxy credentials.
- Get information about the HTTP proxy credentials.
- Test the proxy connection using the configured credentials
- Test the proxy connection using the supplied credentials

Requirements

- Only root can run this command.
- To run, the system must have joined a zone.

Synopsis

```
adwebproxyconf --set,-S [--username,-u \<username\>]
 [--password, -p \<password\>] [--machine,-m]
 [--server,-s \<servername:port\|""\>]
 [--authreq,-r \<true\|false\|""\>]
 [--authtype,-t \<basic\|digest\|ntlm\|negotiate\|anyauth\|""\>],
 '--version,-v','--help,-h' and '--verbose,-V'
 adwebproxyconf --delete,-D
 adwebproxyconf --list,-L
```

adwebproxyconf --test,-T \<--cip,-c \<cip url\> \>
[--server, -s \<servername:port\>]
[--username,-u \<username\>]
[--password, -p \<password\>] [--machine,-m]

Command Options

--set,-S

Set the HTTP proxy server and credentials for the local system. After using adwebproxyconf -S, use adreload to force the agent process (adclient) to reload its configuration files.

the configuration properties in the /etc/

centrifydc.conf file and in other files in the /etc/

centrifydc directory.

--delete,-D

Delete the HTTP proxy credentials from the local computer and reset the HTTP Proxy configurations in centrifydc.conf:

- HTTP Proxy Server
- HTTP Proxy authentication type
- HTTP Proxy authentication required

--list,-L

List the HTTP proxy username and server from the configuration on the local system.

--test,-T

Test the HTTP proxy credential using configured or supplied settings.

--username,-u ‹username›

Proxy username. If a username is not supplied but --password is supplied, the username defaults to Administrator'

--password, -p ‹password›

Proxy user's password, if not provided, will be prompted

--machine,-m

Use local machine account for proxy authentication, and SPNEGO authentication is used.

This option cannot be used with -u, -p, or -t.

--authreq,-r ‹truelfalsel""›

Specify if HTTP Proxy authentication is required in centrifydc.conf, Optional.

Can use individually or with other options.

--authtype,-t ‹basicldigestlntlmlnegotiatelanyauthl""›

Specify if HTTP Proxy authentication authentication type in centrifydc.conf. Optional.

Please refer to above section for valid values.

Can use individually or with other options.

--server, -s ‹servername:portl""›

Specify HTTP Proxy Server to use to update to centrifydc.conf. Optional.

Empty string unsets the value in centrifydc.conf.

Can use individually or with other options.

--version,-v

Specify the version.

--help,-h

Get command line help.

--verbose,-V

Get additional details while the settings are being applied.

--cip,-c <cip url>

Specify the URL of the identity platform.

Must be specified.

--server, -s <servername:port>

Specify HTTP Proxy Server to test.

If not specified, get it from centrifydc.conf

--username,-u <username>

Proxy username.

If not specified, get it from proxy cred file.

--password,-p <password>

Proxy user's password.

If username is specified, but password is not, prompt for it.

If both username and password are not specified, get it from proxy cred file.

--machine,-m

Use local machine account for proxy authentication, and SPNEGO auth type is used.

This option cannot be used with -u, -p, or -t.

This test option always use the proxy credential to check the connection to CIP thru the specified HTTP Proxy server.

You can also use the adcdiag command to check HTTP proxy server settings.

If you have an identity service provider (such as Duo, Okta, SecureID, and so forth) that you use for MFA logins and you've integrated that with Server Suite and you have a RADIUS server for MFA with your identity provider and also a RADIUS server integrated with Server Suite, you can set up silent authentication so that your users don't have to enter their passwords or security question answers twice.

You can configure the credential provider to silently send the user's password as the first response to the authentication workflow. This feature prevents prompting the user for password multiple times when a 3rd party radius is being used as the authentication mechanism.

You can deploy these registry settings as group policies.

To control this new feature we have 3 new registry settings:

- **SilentAuthPromptDetectionRegex** (string)

  This is a regular expression that we match against an authentication prompt that RADIUS sends us. If there is a match, we'll try to automatically respond. For example, if the RADIUS prompt is "Enter your password" we can set this regular expression to

  .*password.*

- **SilentAuthPromptResponseType** (uint):

  This setting controls the kind of response we provide.

  0 - (default) No auto-response: The service prompts the user for the password even if there's a regular expression match.

  1 - Silent auto-response: The service responds with the same password that the user just entered as a Windows login credential.

  2 - Fixed response: Instead of responding automatically with the password, we respond automatically with a fixed response (a static string, for example "This is an automatic response"). Use the **SilentAuthPromptFixedResponse** to store the fixed response text.

- **SilentAuthPromptFixedResponse** (string):

  The fixed response if the **SilentAuthPromptResponseType** is configured as 2. Use this setting to store the fixed response, such as "This is an automatic response."

When you create these registry entries, put them in HKEY_LOCAL_MACHINE\SOFTWARE\Centrify\DirectAuthorize\Agent.

If you are an administrator of Server Suite-managed UNIX or Linux computers, you can use this guide to help you set up a Certificate Authority with the Microsoft Windows certificate auto-enrollment feature to automatically manage certificates for UNIX and Linux computers in your domain. While there are many ways to deploy certificates, this guide describes how to use Active Directory server roles and Windows Group Policy to set up automatic enrollment.

This area includes the following topics:

The Server Suite Agent uses the Microsoft Windows public key infrastructure (PKI) to obtain the certificates used by your Server Suite-managed UNIX or Linux computers that are joined to a domain. By joining to the domain, these computers become eligible for auto-enrollment.

The most basic configuration of the Windows PKI environment utilizes a Windows server as the Certificate Authority (CA) that issues and manages security credentials and public keys through the exchange of encrypted digital certificates. The Server Suite Agent then uses the Microsoft Windows certificate auto-enrollment feature of the Certificate Authority to make certificates available to UNIX computers.

This section describes how to set up a basic environment that has a single, enterprise root Certificate Authority (CA). In this scenario, the Certificate Authority is a Microsoft Enterprise Certificate Server that issues all certificates. In a production environment, you may have more complex requirements that include multiple CAs configured for a domain. However, setting up this sample environment should give you enough information to extend your PKI configuration to a more complex environment.

The Server Suite Agent requires a Microsoft Windows Server to be configured as the Certification Authority (CA) for the Active Directory forest. Additionally, auto-enrollment is not supported for certificates issued by other public or private Certificate Authority services or organizations.

The first step in configuring the environment is to identify a computer to be the Certificate Authority server for the Active Directory forest. This computer must be connected to a network with a server that has Windows Server 2008 (or later) Domain Name Service installed, and it must be joined to the Active Directory domain. In most cases, the computer designated to be the CA should not be a domain controller in a live production environment. To configure the computer as a Certificate Authority, you must install Microsoft Internet Information Services (IIS) and Certificate Services.

Microsoft Internet Information Services (IIS) are required to handle Certificate Revocation List (CRL) requests made by the authentication service and to provide the virtual directories required to issue and manage certificates.

Certificate Services are required to enable the computer to act as a Certificate Authority (CA) and issue certificates to other computers that join the domain. The Application server role, which installs IIS, and the Certificate Services server role must be on the same computer. Therefore it is recommended that you install IIS at the same time you install Certificate Services.

What's Required to Install Certificate Services

Before installing Certificate Services, check that you have the following:

- Account credentials for an account that is an Enterprise Administrator and a Domain Administrator of the forest root domain of the Active Directory forest.
- A computer with Windows Server 2008 Enterprise Edition or later. Previous versions of Windows Server do not support auto-enrollment within the certificate templates. In addition, the computer must be running Enterprise Edition because Standard Edition does not support the V2 or V3 certificate templates that are required for auto-enrollment.
- Active Directory services must be installed on the Certificate Services server. If you install the Certificate Services server role on a domain controller, no further action is required. When you promote a computer to be a domain controller, the Active Directory services are installed automatically.

  Note: This guide details how to configure auto-enrollment on a computer running Windows Server 2012 R2. For information on configuring auto-enrollment for computers running other versions of Windows Server, please visit the Microsoft website.

Adding the Required Server Roles to Make the Computer a Certificate Authority

After you have verified that you have an appropriate account and computer configuration, you can use Server Manager to add the appropriate server roles.

To install IIS and Certificate Services on a Windows Server

1. Open the Server Manager Dashboard and click **Add Roles and Features**.

   Click **Next**.

2. For Installation Type, select **Role-based or feature-based installation**, then click **Next**.

3. Ensure that **Select a server from the server pool** is selected and highlight the server on which you would like to install roles and features. Click **Next**.

4. Select **Active Directory Certificate Services**, then click **Add Required Features** in the pop-up window.

   Click **Next**.

5. Click **Next** to accept the default selections for Select Features.

6. Click **Next** on the notification that you will be unable to change the domain settings after installing Certificate Services.

7. Select **Certification Authority** and click **Next**.

8. Click **Install**.

After Windows restarts, you will see a new Role in Server Manager called AD CS. In the following procedure, you will configure this role to allow your server to act as a Certification Authority.

Configuring the Certificate Authority

1. Click the notification icon in the Server Manager command bar to open the **Add Roles and Features Wizard**.
2. Click the link, **Configure Active Directory Certificate Services on the destination server**.
3. In the AD CS configuration screen, verify that you are logged on as an administrator and click **Next**.
4. Select **Certification Authority** and click **Next**.
5. Select **Enterprise CA** and click **Next**.

   Note: You must be a member of both the Enterprise Admins group and the Domain Admins group to configure an Enterprise Certificate Authority.
6. Select **Root CA** and click **Next**.
7. Select **Create a new private key** and click **Next**.
8. Accept the defaults for the cryptographic provider, key length, and hash algorithm. Click **Next**.
9. Enter a name for the Certificate Authority or accept the defaults, and click **Next.**.

   Note: After the Certificate Authority is configured, you will not be able to change the name.
10. Specify the validity period of the certificate, click **Next**.
11. Accept the default location for the certificate database and click **Next**.
12. Review your CA configuration and click **Configure**.
13. Click **Close** when the confirmation message appears, and restart the server to retrieve a certificate from the CA.

You can use the certificate snap-in to make a copy of a certificate to use on another computer, or to create a backup copy.

In order to establish a chain of trust for your PKI environment, you identify the copy of the CA you just created as a trust anchor.

To establish the CA as a trust anchor, add the root certificate for the CA to the **Trusted Root Certification Authorities** container in the group policy object that defines the IP Security policies.

To Add a Trusted Root Certificate to the Group Policy Object

1. Open the Certificates (MMC) snap-in.

   If the Certificates snap-in is not available, you can run MMC and click **File > Add/Remove Snap-in** to add it.

2. Select Computer account, and click **Next**.
3. Select Local computer, then click **Next**.
4. Click **Certificates > Trusted Root Certification Authorities > Certificates**.
5. Select the root certificate generated by the CA you created in the previous procedure, then double-click it to see its Properties page.
6. Click the **Details** tab; then click **Copy to file** to start the Certificate Export Wizard. In the wizard, make the following selections:
   - **File format**: *DER encoded binary X.509 (.CER)*
   - **File Name**: Anywhere on the local server
   - **Include all certificates in the certification path**: *No*
7. Open the Group Policy Object Editor and select the group policy object that defines the IP Security policies.

   Click **Computer Configuration > Policies > Windows Settings > Security Settings > Public Key Policies > Trusted Root Certification Authorities**.

8. Select **Trusted Root Certification Authorities**, right click, and select **Import** to open the Certificate Import Wizard.
9. Click **Next** on the **Welcome** screen.
10. Browse to find the root certificate you copied in Step 6, then click to accept the default values on each screen.
11. Click **Finish** to complete the wizard.

The root certificate is now in the Active Directory Trusted Root Certification Authorities container. Certificates in this container are downloaded to any computer that joins the domain to establish trust for the root CA.

The Server Suite Agent uses the Microsoft Windows certificate auto-enrollment feature to make certificates available to UNIX computers. If auto-enrollment is enabled, when a UNIX computer joins a domain, the Server Suite Agent requests certificates from the CA based on particular templates, and installs them on the joined computer.

To enable auto-enrollment, you must do the following:

- Enable auto-enrollment for the group policy.
- Create a certificate template with auto-enrollment enabled.

Enabling Auto-Enrollment for the Group Policy

To enable auto-enrollment for the group policy:

1. Open the Group Policy Management Editor and select the group policy object that defines IPsec policies.

   Click **Computer Configuration > Policies > Windows Settings > Security Settings > Public Key Policies > Certificate Services Client - Auto Enrollment**.

2. Double-click **Certificate Services Client - Auto-Enrollment**, select Enabled, and check the following boxes:

   - **Renew expired certificate, update pending certificates, and remove revoked certificates**
   - **Update certificates that use certificate templates**

3. Click **OK** to save the auto-enrollment settings.

Creating a Certificate Template

To configure a template with auto-enrollment:

1. Open the MMC Certificate Template snap-in.

   Another way to open the Certificate Template console is to open the Certification Authority console, right-click **Certificate Templates**, and select Manage.

2. Select a template, then right-click and select **Duplicate Template** to create a new template that you can modify.

   For example, select the Workstation Authentication template.

3. On the Properties page for the new template, do the following:

   1. Select the **General** tab and enter a name for the template.
   2. Select the **Security** tab and select **Domain Computers**. Then select **Read** and **Autoenroll** permissions.
   3. Select the **Subject Name** tab. For **Subject name format**, select **Fully distinguished name**.
   4. Select the **Extensions** tab. Then select **Application Policies**.
   5. Click **Edit**. **Client Authentication** should already be shown.
   6. Click **Add**, then scroll and select **Server Authentication**.
   7. Click **OK**.

4. Click **OK** to save the new template.

You can now assign the newly created template to the Certificate Authority. Whenever a computer joins the domain, the CA issues a certificate based on the template, and the Server Suite Agent downloads the certificate to the computer.

To assign the template to a CA:

1. Open the Certification Authority console.
2. Click **Certification Authority** › *CA_name* › **Certificate Templates**, where *CA_name* is the container for the CA you set up earlier in Preparing a computer to be a Certificate Authority (CA).
3. Right-click and select **New** › **Certificate Template to Issue**. Select the template you just created and click **OK**.

The root CA is now set up to issue certificates based on the template you created.

Delinea

Generating a certificate revocation list (CRL) is the method a Certificate Authority (CA) uses to maintain the validity of the certificates that it issues. A CRL contains a list of certificates (or more specifically, a list of serial numbers for certificates) that have been revoked or are no longer valid, and therefore should not be relied upon. The agent retrieves CRLs from CAs after specific events (such as joining a domain) and at specific intervals to determine which certificates, if any, have been revoked, and thus whether to request new certificates.

> **Note**: The current version of the Server Suite Agent only supports complete certificate lists, not delta CRLs, which only describe the updates since the complete list was published.

Generating a Certificate Revocation List (CRL)

A CRL is generated by a CA and contains a list of certificates to revoke from the list of certificates that the CA has issued.

Typically, a CA automatically generates a CRL at a specified interval, anywhere from two hours to one year, at which point the new CRL with the list of revoked certificates is available for clients to request.

The CRL itself contains the interval period, which allows clients, such as Server Suite Authentication Service, to determine when to request a new CRL. See Retrieving a certificate revocation list and verifying certificates for information about retrieving CRLs.

In addition to automatic generation of a CRL, an administrator can use specific Active Directory utilities that allow them to manually revoke certificates and publish a CRL on the CA. In this case, the CRL-publishing interval is reset so the next automatic publishing operation will occur in the appropriate amount of time.

Retrieving a Certificate Revocation List and Verifying Certificates

At specific times (when the UNIX system joins a domain, the administrator issues the adgpupdate command, or the group policy refresh interval occurs), the Server Suite Agent performs certain tasks, including determining whether to retrieve a CRL (Certificate Revocation List). Specifically, the agent does the following:

- Identifies the CA that issued certificates for the system.
- Looks at the refresh interval in the current CRL to determine whether to retrieve a new CRL.
- If the interval has expired, retrieves a new CRL by using the IIS Web Server for the CA.
- Verifies the currently issued certificates against the CRL and requests new certificates for certificates that have been revoked.

  > **Note**: When you manually revoke a certificate, it is possible that the certificate will appear as valid even after running the adgpupdate command to trigger an IPsec update. When you revoke a certificate, the Server Suite Agent first looks at the current CRL to determine the validity of the certificates that have been issued. In this case, the newly revoked certificate still appears as valid. Immediately afterwards, because of the IPsec update, the agent requests a new CRL. The new CRL shows that the certificate in question is invalid, but the agent will not look at the new CRL until the next scheduled update, or until you run the adgpupdate command again. Therefore, to be certain to have current information, if you manually revoke certificates, you can issue the adgpupdate command twice in sequence.

Delinea

Reports and Events

- Reporting Admin Guide
- Audit Events Admin Guide

This guide is for individuals who need to extract audit event information from UNIX and Linux syslogs and Windows application event logs. Additionally, this information is available in the Audit Analyzer. Audit events are organized into categories in the Audit Analyzer and these categories are identified in this document.

Depending on your environment and role as an administrator or auditor, you may want to read portions of this guide selectively. This guide provides the following information:

- Overview of Centrify Server Suite Audit Events provides an overview of how to read audit events.
- Centrify Server Suite Audit Events identifies the different audit event categories. Each audit event includes a sample log with an explanation of how to read the log as well as a list of the available audit events.

Overview of Delinea Server Suite Audit Events

To familiarize yourself with the elements of audit event logs, read the explanations of Windows and UNIX/Linux audit events, and then review how to read Server Suite audit event data.

- Windows and UNIX/Linux Audit Events
- How to Read Audit Event Data
- Configuring the Audit Event Log Location
- Which Events Only in Centrify Audit & Monitoring Service

Windows and UNIX/Linux Audit Events

Review the following examples to understand the Windows and UNIX/Linux audit event logs, and then review how to read audit event data to understand the similarities and differences.

Windows Audit Event Log Line Example

The following is an example of a Centrify audit event recorded in the Windows application event log. Standard Windows audit event fields (in black) contain information about the Centrify event. Centrify augments these standard fields with additional data (in red) to help you to track logon and privilege activity data.

```

	sshRights	shell
	command	(none)

How to Read Audit Event Data

The following information can help you understand how to read Centrify audit events.

Event ID/CentrifyEventID

Every Windows and UNIX/Linux audit event includes two numeric IDs that describe the event. The Event ID in the header fields identifies the unique ID of the event within a particular event category, whereas the CentrifyEventID in the common fields identifies the unique ID among all Centrify audit event types.

Windows Example

	Product Version	1.0	
	Event ID	3	
	Event Name	Remote login success	5
Centrify audit event common fields	user	administrator@member.acme.vms	
	userSid	S-1-5-21-3789923312-3040275127-1160560412-500	
	DAInst	AuditingInstallation	
	DASessID	c72252aa-e616-44ff-a5f6-d3f53f09bb67	
	sessionId	6	
	Centrify EventID	6003	

UNIX/Linux Example

	Product	Centrify Suite
	Category	Centrify sshd
	Product Version	1.0
	Event ID	100
	Event Name	SSHD granted
	Severity	5
Centrify audit event common fields	user	dwirth(type:ad,dwirth@acme.vms)
	pid	7456
	utc	1459784055479
	Centrify EventID	27100
	DAInst	AuditingInstallation

	DASessID	
c72252aa-e616-44ff-a5f6-d3f53f09bb67		
	status	GRANTED
	service	ssh-connection

Severity

Severity is defined by an integer from 0 - 10, with 10 being the most important level. Centrify events are typically a Severity 5.

Spacing

A field name is one word (no spaces) in the audit event file. When the file is processed into a readable format, spaces are added to field names. For example, if you need to search for Management Database Property, you should search on the following term: managementdatabaseproperty.

Case-Insensitive Field Names

Use case-insensitive field names in all search filters.

Configuring the Audit Event Log Location

You can configure audit event logs to go to DirectAudit or your system's default logging system (Windows event log or UNIX syslog). You configure the log location either manually for each computer or by way of group policy.

You can also configure a global audit event logging behavior or specify different settings for different feature areas.

Configuring the Audit Event Logging Location by Group Policy

Audit trail group policies are located in category-specific subfolders (such as **Audit Analyzer Settings**, **Audit Manager Settings**, and so on.

Additionally, a **Centrify Global Settings** subfolder contains group policies that you can set at a global level.

Any category-specific audit trail targets that you set (for example, **Audit Manager Settings** › **Send audit trail to log file**) override global audit trail targets (for example, **Centrify Global Settings** › **Send audit trail to log file**). Each subfolder in **Centrify Audit Trail Settings** contains the same set of group policies.

> **Note**: To send audit trail events to both the database and the local logging facility, enable both of these group policies.

Send Audit Trail to Audit Database

Enable this group policy to specify that audit events for this component **Audit Analyzer**, **Audit Manager**, and so on are sent to the active audit store database.

See the **Explain** tab in the group policy for details about which parameter each group policy sets in the agent configuration file.

Send Audit Trail to Log File

Enable this group policy to specify that audit events for this component such as **Audit Analyzer**, **Audit Manager**, and so on are sent to the local logging facility (syslog on UNIX systems, Windows event log on Windows systems).

See the **Explain** tab in the group policy for details about which parameter each group policy sets in the agent configuration file.

Set Global Audit Trail Targets

Specify the target for audit trail information.

If you set this group policy to **Not configured** or **Disabled**, the destination of audit trail information depends on which version of DirectAudit is installed. If DirectAudit 3.2 or later is installed, audit trail information is sent to the local logging facility and DirectAudit. If a DirectAudit version earlier than 3.2 is installed, audit trail information is only sent to the local logging facility.

If you set this group policy to **Enabled**, you can specify the target for audit trail information. Possible settings are:

- 0 (Audit information is not sent.)
- 1 (Audit information is sent to Centrify Audit & Monitoring Service. This capability is supported by DirectAudit version 3.2 and later.)
- 2 (Audit information is sent to the local logging facility, either syslog on UNIX systems or Windows event log on Windows systems.)
- 3 (Audit information is sent to both DirectAudit and the local logging facility.)

This group policy modifies the audittrail.targets setting in the agent configuration file.

Which Events are Only in Centrify Audit & Monitoring Service

Audit events may come from Centrify Authentication Service, Centrify Privilege Elevation Service, or Centrify Audit & Monitoring Service. If you are using only authentication and privilege elevation, the following events will not be available to you as they are from audit and monitoring service:

- All the audit events from the following categories:
  - Audit Analyzer
  - Audit Manager
  - Command
  - Centrify Audit & Monitoring Service - Windows
  - Centrify Audit & Monitoring Service System Management
  - Centrify Audit & Monitoring Service UNIX Agent
  - Centrify Audit & Monitoring Service advanced monitoring
- The following audit events from the category Centrify Commands
  - Auditing enabled (Centrify Event Id 18000)
  - Auditing not enabled (Centrify Event Id 18001)
  - Auditing disabled (Centrify Event Id 18100)
  - Auditing not disabled (Centrify Event Id 18101)

Server Suite Audit Events

This section includes the following topics:

Audit Analyzer

The Audit Analyzer console is a graphical user interface that administrators can use to query and review captured user sessions. The Audit Analyzer is available with the Centrify Audit & Monitoring Service. The Audit Analyzer events focus on session modification.

Audit Analyzer Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 3001. This log sample documents a session being deleted. The change was made by user=administrator@acme.vms on April 20, 2016 at 05:51:01.

Audit Manager

Audit Manager is a Microsoft management console (MMC) that you can use to configure and manage the deployment of audit components, such as audit stores and audit store databases, audit roles, collectors, and agents. Audit Manager is available with Server Suite. Audit events generated by Audit Manager primarily involve the installation and configuration of auditing components such as management databases, audit stores, and audit store databases, and changes to audit role and user permissions.

Centrify Commands (UNIX Commands)

Audit events in the Centrify Commands category are focused on capturing command line activity. Audit events are recorded when users or administrators run command line programs to enable or disable auditing, join or leave a domain, query Active Directory for user or group information, change their password configuration settings or license mode, or perform other operations.

Centrify Command Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 18000. This log sample documents auditing being enabled. The change was made by user=root on April 5 at 11:37:28.

```

Centrify Configuration

Centrify hierarchical zones are used to enable information about non-Windows computers, user profiles, access rights, and roles to be stored in Active Directory. Hierarchical zones can be used to segregate and perform privilege management on both UNIX/Linux and Windows systems. These configuration audit events focus on zones, computers, groups, users, rights, and roles.

Centrify Configuration Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 36101. This log sample documents a user giving zone administrative tasks to another user. The change was made by user=dwirth@acme.vms on April 19, 2016 at 03:01:04.

Centrify sshd

Centrify sshd is Centrify's enhanced version of OpenSSH. This software program uses the secure shell protocol to connect to a remote computer. Centrify sshd audit events identify DZ SSH rights and SSHD activities.

Centrify sshd Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 27000. This log sample documents the rights granted to the DZ SSH shell client. The change was made by user=dwirth(type:ad,dwirth@acme.vms) on April 4 at 01:04:15.

```

Command (Audited and Successfully Executed Commands)

Command audit events are recorded when Centrify UNIX command-line programs are used on Centrify-managed computers. Centrify UNIX command audit events focus on the execution success or failure of the audited command.

Command Audit Event Log Sample

```

Centrify Audit & Monitoring Service Advanced Monitoring

If you have enabled Centrify Audit & Monitoring Service for advanced monitoring, you can generate data for three additional auditing reports, as follows:

- Monitored execution report: This report shows the monitored commands being executed on the audited machines—including information on commands that are run individually or as part of scripts.
- Detailed execution report: This report shows all of the commands being executed on the audited machines—including commands that are run as part of scripts or other commands.
- File monitor report: This report shows the sensitive files being modified by users on the audited machines.

Advanced Monitoring Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 57300. This log sample documents a session where a user attempted to modify a monitored file. The change was made by root@al_rhel6_2.altest.acme.com on November 2, 2016 at 06:09:01.

Centrify Audit & Monitoring Service System Management

The auditing module's detailed, real-time auditing of privileged user sessions on Windows, UNIX, and Linux systems provides a full accounting of user activity and system access. Centrify Audit & Monitoring Service System Management is available with Centrify Audit & Monitoring Service. The audit and monitoring service audit events focus on collector service, collector settings, and agent settings.

Centrify Audit & Monitoring Service System Management audit event log sample

The following is a sample of an audit event log for Centrify Audit Event ID 42251. This log sample documents the successful start of the collector service on computer 'MEMBER'. The change was made by user=system@nt authority on April 05, 2016 at 14:59:56.

Centrify Privilege Elevation Service – Windows

Centrify Privilege Elevation Service for Windows provides role-based access control for Windows desktops and applications, and to remote Windows servers. Centrify Privilege Elevation Service for Windows audit events focus on successful and failed local console and remote log in attempts, administrative activity using desktop or application privileges, network access to remote servers, changes to the zone information for Windows computers and changes to role information for Windows users.

Centrify Privilege Elevation Service Windows Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 6029. This log sample documents a user with local and network role privileges launching a .msc file.

Centrify Authentication Service UNIX Agent

The Centrify Authentication Service UNIX Agent audit events are focused on the success or failure of starting and stopping the Centrify Agent: **adclient**.

Centrify Authentication Service UNIX Agent Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 17000. This log sample documents the successful start of the Centrify Agent: adclient. The change was made by user=root on April 05 at 06:46:43.

dzdo

For Linux and UNIX computers, Server Suite includes authorization services that enable users to run with elevated privileges using the dzdo command line program. The dzdo program is similar to sudo except that, instead of using a sudoers configuration file, the program uses the role-based access rights for zones stored in Active Directory.

dzdo Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 30004. This log sample documents that the dzdo service has been granted authorization.The change was made by user=dwirth(type:ad,dwirth@acme.vms) on April 7 at 01:20:12.

30101	dzdo command execution ends added in release 18.11	

dzinfo

The dzinfo command displays rights, roles, and role assignments events. The dzinfo audit events focus on the success and failure of the dzinfo command.

dzinfo Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 42001. This log sample documents that a user failed run dzinfo to view another user's settings; only the user=root can view other user's settings. The change was made by user=eugene.user(type:ad,eugene.user@CENTSPLUNK.COM) on April 28 at 10:35:47.

License Management

Auditing licenses are issued for each computer that will be connected to an auditing collector, and are managed by the Centrify Licensing Service. You can use the Licensing Service control panel as described in the *License Management Administrator's Guide* to add and remove licenses, monitor license usage, and configure license usage notification.

License Management Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 20101. This log sample documents a user being denied an adjoin command execution due to missing license information. The change was made by user=root on October 27 at 17:24:25.

Kerberos

Audit events in the Kerberos category are focused on the success or failure of kerberos credential access. Audit events are recorded when programs access the KCM (Kerberos Cache Manager) credential cache.

Local Account Management

Centrify administrators use the Local Account Management feature to create, manage, lock, and delete local UNIX and Linux user and group accounts. The Local Account Management audit events focus on local users, groups, and accounts.

Local Account Management Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 51300. This log sample documents the removal of a local user from a local password file. The change was made by user=root on November 25 at 16:51:20.

Local Account Management Audit Events

Event Source Category: Local Account Management

51100	Adding enabled local user to local passwd file	enabledUser: enabled local user
51200	Adding disabled local user to local passwd file	disabledUser: disabled local user
51300	Removing local user from local passwd file	removedUser: removed local user
51400	Local user is marked as disabled	localUser: local user
51500	Local user is marked as enabled	localUser: local user
51101	Local passwd file update failed	reason: error message
51600	Invoking notification cli succeeded	parameters: parameters
51601	Invoking notification cli failed	reason: error message
52000	Adding enabled local group to local group file	enabledGroup: enabled local group
52100	Removing local group from local group file	removedGroup: removed local group
52001	Local group file update failed	reason: error message
53000	Managing local accounts succeeded	parameters: parameters
53001	Managing local accounts failed	parameters: parameters reason: error message
53100	Added enabled local user added in Release 2020	localuser: user name
53101	Added disabled local user added in Release 2020	localuser: user name
53102	Failed to add local user added in Release 2020	localuser: user name reason: error message
53103	Removed local user added in Release 2020	localuser: user name
53104	Failed to remove local user added in Release 2020	localuser: name reason: error message

53105	Enabled local user added in Release 2020	localuser: user name
53106	Failed to enable local user added in Release 2020	localuser: user name reason: error message
53107	Disabled local user added in Release 2020	localuser: user name
53108	Failed to disable local user added in Release 2020	localuser: user name reason: error message
53109	Modified local user added in Release 2020	localuser: user name
53110	Failed to modify local user added in Release 2020	localuser: user name reason: error message
53111	Added local group added in Release 2020	localgroup: group name
53112	Failed to add local group added in Release 2020	localgroup: group name reason: error message
53113	Removed local group added in Release 2020	localgroup: group name
53114	Failed to remove local group added in Release 2020	localgroup: group name reason: error message
53115	Modified local group added in Release 2020	localgroup: group name
53116	Failed to modify local group added in Release 2020	localgroup: group name reason: error message
53117	Managed local users and groups added in Release 2020	
53118	Failed to manage local users and groups added in Release 2020	reason: Reason for failure
53119	Invoked notification command added in Release 2020	command: notification command
53120	Failed to invoke notification command added in Release 2020	reason: Reason for failure

Multi-Factor Authentication

Multi-factor authentication (MFA) strengthens security by requiring users to provide more than one form of identification to authenticate their identity when they attempt to access servers or applications. Multi-factor authentication challenges might require users to type a password, respond to an email message or phone call, enter a passcode, or answer a security question. Audit events in the MFA category focus on the success and failure of MFA challenges.

Multi-Factor Authentication Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 54100. This log sample documents the success of an MFA challenge. The change was made by user=laniu1(type:ad,laniu1@SINGLE01.CDC) on April 20 at 14:51:18.

54211	MFA challenge failed added in release 19.6	

PAM

A pluggable authentication module (PAM) is a mechanism to integrate multiple low-level authentication schemes into a high-level application programming interface (API). The PAM audit events include authorization, credentials, account management, password changes, open session, and multi-factor authentication.

PAM Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 24100. This log sample documents PAM authentication being granted. The change was made by user=dwirth(type:ad,dwirth@acme.vms) on April 4 at 21:04:14.

```

Delinea

Trusted Path

The trusted path configuration parameter (audittrail.Centrify_Suite.Trusted_Path.machinecred.skipda) specifies whether trusted path audit trail events are sent to the audit installation database in situations where the user is using a computer credential. The audit events identify a granted and denied Trusted Path.

Trusted Path Audit Event Log Sample

The following is a sample of an audit event log for Centrify Audit Event ID 23700. This log sample documents a Trusted Path being granted. The change was made by user=newcentos$@acme.vms on April 04 at 21:02:09.

```
Apr 4 21:02:09 newcentos adclient[1395]: INFO AUDIT
_TRAILICentrify SuitelTrusted Pathl1.0l2700lTrusted path
grantedl5luser=newcentos$@acme.vms pid=1395

Trusted Path Audit Events

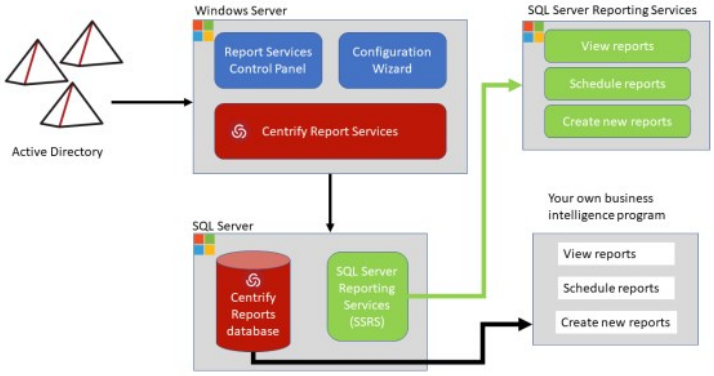
23700	Trusted path granted	server: server
23701	Trusted path denied	server: server reason: error message

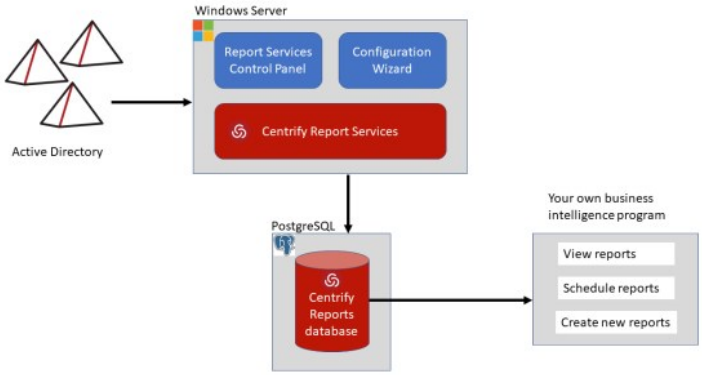
Report services provides reports on your Active Directory environment and the data is stored in a database that's optimized for reporting. You can synchronize your Active Directory information to your reporting database, and then allow your users access to the reporting data.

You can choose to use SQL Server or PostgreSQL for your report database. If you use PostgreSQL, you must provide your own report software to create and view reports.

If you're using SQL Server, the following diagram illustrates the main report services architecture components:



If you're using PostgreSQL, the following diagram illustrates the main report services architecture components:



Report services takes data from Active Directory at a particular point in time. The data collected at that point is sometimes referred to as a *snapshot*. The Active Directory data synchronization service puts the Active Directory data into tables in the reporting database, and then runs some algorithms on those tables. Some data is pulled over directly from Active Directory as it is, and some data is calculated.

For example, the effective role assignment for each computer and user is calculated rather than stored. Delinea does store the effective role assignment information at the levels of role, computer, and zone. This information is then stored in the database views, and those database views provide the information that you see in the reports.

The reporting service populates *database views* based on the data in those tables, and those views are what are used to populate reports.

Database views provide an easier and more secure way to share the reporting data without having to expose the database tables directly. Each view is essentially a database query. Some columns refer to columns in other views, and these relationships are noted.

Each default report is based on one or more of those database views, and you can build custom reports based on the information stored in one or more of those views.

For SQL Server databases, Delinea report services uses Microsoft SQL Server Reporting Services as the reporting engine for deploying and customizing

reports. You can use any reporting service to generate reports by connecting to the reporting database.

Reporting Data Based on Domains or Zones

Here are some key points to be aware of if you're thinking of using report data based on zones:

- For zone-based reporting, each synchronization includes all Active Directory data from the specified zones. In comparison, for domain-based reporting, synchronizations after the first one include just the changes to Active Directory data.
- For zone-based reporting, the service account needs just read permission to Active Directory. In comparison, for domain-based reporting, the service account needs permission to replicate directory changes.
- For zone-based reporting, report services does not synchronize license information nor auto-zone computer information.
- For zone-based reporting, you can include zones from other trusted forests. For domain-based reporting, you can add trusted forest domains.

gMSA Accounts

Report services treats gMSA accounts (group Managed Service Accounts) as Active Directory users.

Information not included in the reporting database

There are few limitations on the kinds of data that can be stored in the reporting database. The following is not included:

- NIS maps
- UNIX import information

Report Services and Report Center

Report services provides more reports and features than the previous Report Center in Server Suite. Report Center has been deprecated and removed.

Report Services Tools Overview

Here's an overview of the tools specific to Delinea report services. You'll use some to all of these tools, depending on whether you're completing your initial installation or changing some configuration settings later on.

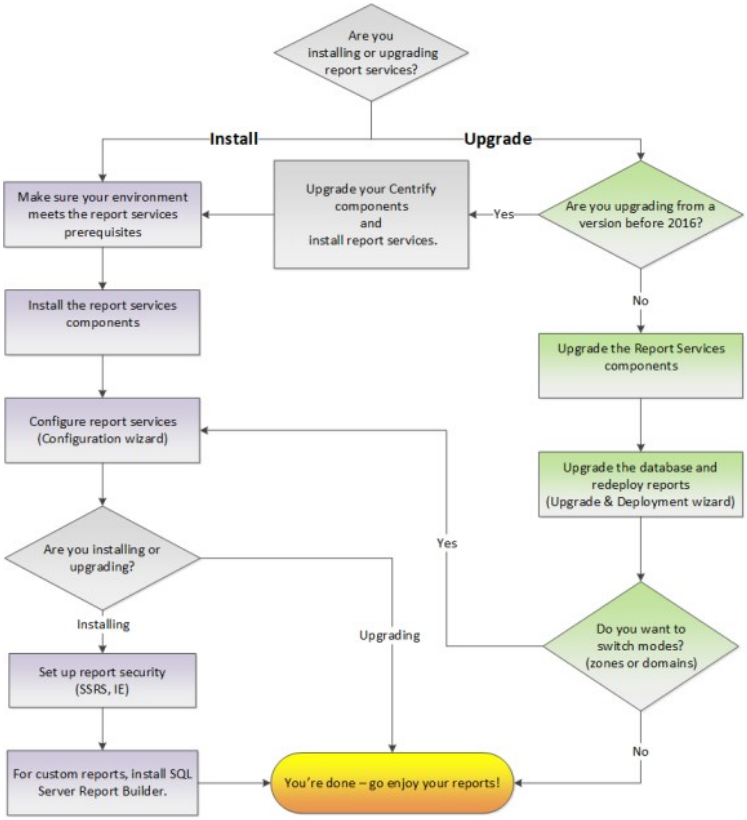
Report Services shortcut	Use this shortcut to open Delinea report services in Internet Explorer.
Configuration wizard	Use the configuration wizard to do the initial setup of your database and reports. Re-run the configuration wizard only if you need to change some report services configuration settings or change whether you gather report data from Active Directory based on zones or domains. For instructions, see Configuring Report Services and Deploying Your Reports .
Upgrade & Deployment wizard	Use the Upgrade & Deployment wizard to upgrade your report database and deploy updated reports. For instructions, see Upgrading your report services.
Report Services Control Panel	Use the control panel to view the synchronization status of domains or zones, refresh report data, configure the synchronization schedule, add or remove domains or zones, change the user account that runs the report service, and view error logs. For more details, see Administering Delinea Report Services with the Report Control Panel.
Server Suite installer	Use the installer to either install or upgrade the report services and other Server Suite components. For instructions, see Installing Delinea Report Rervices .

Overview of How to Set Up Reporting

If you're installing an evaluation version of Delinea report services, you can take a few shortcuts, such as using virtual machines. This section includes

recommendations for both evaluation and production deployments.

The diagram below outlines the overall process for installation or upgrade.



Evaluation Deployment Overview

For evaluation purposes, you can just install the SQL Server Express version that's packaged with the Server Suite software.

How to set up an evaluation version of Delinea report services:

1. Prepare your environment:
    - Users and groups with required permissions
        1. service account - the user account that runs the reporting service (in the background)
        2. installer/administrator - the user account that installs and configures the Delinea reporting service.
        3. Report administrator - user(s) who can run reports, edit reports, build new reports
        4. Report reader - user(s) who can view reports but not edit them nor create new ones.
    - An existing database instance, if you're planning to use an existing instance.
    - The correct operating system that supports what you need. For evaluation purposes only, you can install all the software on one computer. Be sure to check that your operating system is supported for Delinea software, SQL Server, and Microsoft SQL Server Reporting Services (SSRS).
    - You've configured Internet Explorer to allow access to the reporting web site. For details, see Adding Your Report Services Web Site to your Internet Explorer Trusted Sites.
2. Run the Delinea installer. Install the report services on ONE computer in your domain.
    - Do not install Delinea report services on a domain controller.
    - If you're upgrading from a prior version of Server Suite or Server Suite, the Access Manager reports are still there and they are installed anywhere you install Access Manager. In contrast, the new reporting service installs into one place in your forest. Plus, the database is optimized for reporting and retrieval.
3. Do the reporting configurations:
    - Run the Report Services Configuration wizard to configure the reporting service as needed, including starting the service.
    - Set up the report security for report administrators by assigning users and groups to SSRS roles. By default, all authenticated users have access to view reports.

    - Configure Internet Explorer.
4. View and share the reports.
5. For custom report building, make sure that you've installed Report Builder for your version of SQL Server, if you don't have it installed already. You may need to download this separately.

Production Deployment Overview

For production deployments:

- Delinea recommends that you use a production-capable version of SQL Server and not SQL Server Express.

  SQL Server Express has a limit of 10Gb of data, does not provide the ability to schedule tasks

- Delinea recommends that you do not use virtual machines.
- Use at least 4 GB memory and 2 cores. leave enough memory for the operating system and allocate the rest to SQL server. For more details, see Memory Requirements.
- Delinea recommends that you use a new database instance; do not use an existing instance of SQL server. The reason for this is because uninstalling SSRS leaves some files behind and can cause problems with re-installation, if you're reusing the database instance. For more information, see Impact of Using a New or Existing SQL Server instance.
- If you're using a PostgreSQL database, Delinea recommends using a new PostgreSQL installation.
- Do not install Delinea report services on a domain controller.

How to Set up a Production Version of Delinea Report Services

1. Prepare your environment:
    - Users and groups with required permissions. For details, see Before Installing - Prerequisites.
        1. service account - the user account that runs the reporting service (in the background)
        2. installer/administrator - the user account that installs and configures the Delinea reporting service.
        3. Report administrator - user(s) who can run reports, edit reports, build new reports
        4. Report reader - user(s) who can view reports but not edit them nor create new ones.
    - The correct operating system that supports what you need. The operating system needs to be supported for Delinea software, SQL Server, and SQL Server Reporting Services (SSRS).

      Don't install SSRS on the domain controller.

      IMPORTANT: Use an existing database instance with a real version of SQL Server, not the Express version. Express isn't designed to handle the performance needs of a production environment.
2. Run the Server Suite installer. Install the report services in ONE place in your forest.
    - If you're upgrading from a prior version of Server Suite, the Access Manager reports are still there and they are installed anywhere you install Access Manager. In contrast, the new reporting service installs into one place in your forest. Plus, the database is optimized for reporting and retrieval.
3. Do the reporting configurations:
    - Configure the reporting service as needed, including starting the service.
    - Set up the report security: assign users and groups to SSRS roles and configure Internet Explorer.
4. View and share the reports.
5. For custom report building, make sure that you've installed Report Builder for your version of SQL Server, if you don't have it installed already. You may need to download this separately.

Upgrade Overview

How to upgrade Delinea Report Services:

1. If you're upgrading from a version of Server Suite before version 2016, you need to install the report services components after you upgrade the other components.

   For details, see Upgrading from a Prior Version.

2. Run the installer program to upgrade your report services components.

   For details, see Upgrading from a Prior Version and the *Upgrade and Compatibility Guide*.

3. Upgrade the report database and, if you're ready to do so, redeploy your reports.

   For details, see Upgrading your Report Services Database.

4. (Optional) If you want to switch from domain-based reporting to zone-based reporting, or the other way around, run the Configuration wizard to switch modes.

   This step is optional and you can do switch modes at any time, not just during upgrade.

   For details, see Configuring Report Services and Deploying Your Reports.

Using this Guide

The guide provides the following information:

- What Report Services Provides provides an overview of the report services features and tools, including deployment overviews for production and evaluation deployments.
- Installing and Configuring Delinea Report Services provides detailed instructions for installing, upgrading, and configuring report services.
- Viewing Default Reports covers how to open a report, and provides some basic information on each of the default reports.
- Building Custom Reports provides some information about how to build your own, custom reports.
- Views to Use in Custom Reports lists the database views that you can use to populate your custom reports.
- Configuring Report Services for Large Active Directory Environments provides helpful information unique to large deployments.
- Troubleshooting Reports provides some helpful tips with common installation or configuration issues.
- Synchronized Active Directory attributes for Reports lists the object attributes that report services synchronizes from Active Directory.

Installing and Configuring Report Services

This section includes the following topics:

- Before Installing - Prerequisites
- Installing Delinea Report Services
- Configuring Report Services and Deploying Your Reports
- Doing a Silent Install and Configuration
- Upgrading from a Prior Version
- Administering Delinea Report Services with the Report Control Panel
- Configuring SQL Server Reporting Services (SSRS)
- Re-deploying SQL Server Reports To SSRS

  Note: If you are deploying into a large Active Directory environment, be sure to also read Memory Recommendations and Requirements for large Active Directory environments.

Before Install: Prerequisites

Note: For the full set of platform requirements, please visit this web page in the Delinea Technical Support area:

https://www.centrify.com/support/whats-new/infrastructure-services/

Supported Versions of SQL Server and SSRS

To use Delinea report services, you need to use a SQL Server that is one of the following versions:

- SQL Server 2008 R2
- SQL Server 2012
- SQL Server 2012 R2
- SQL Server 2014
- SQL Server 2016

For Microsoft SSRS, use the version that correlates with your SQL Server version. For example, if you're using SQL Server 2012 R2, then use Microsoft SSRS version 2012 R2.

Note: If you choose to use a version of SQL Server that requires .NET version 3.5 SP1, be sure to install .NET before configuring report services.

Note: If you run Report Services with Microsoft SQL Server 2012 Service Pack 2 and Visual Studio 2010 on the same system, please update Visual Studio 2010 to Service Pack 1. (Ref: CS-38553a)

Supported Versions of PostgreSQL

Delinea Report Services works with PostgreSQL databases that are version 11 or later.

Supported Browser Versions

Use the web browser versions that Microsoft supports for use with SQL Server Reporting Services, as mentioned in this page:

https://msdn.microsoft.com/en-us/library/ms156511.aspx

For Internet Explorer, the version of SQL Server and SQL Server Reporting Services (SSRS) that you use also determines which version of Internet Explorer is compatible with your deployment. Please consult the Delinea Knowledge Base article KB-6671 for details about which version of Internet Explorer you should use.

Required User Permissions for Report Services

Before you install Delinea report services, be sure you have the appropriate software and user accounts, which includes the following:

- Users with required permissions. Before installation, you must have users to run the Delinea installer.
- Report service account
- SQL Server service account (this is needed if you're installing using an existing instance)
- User accounts that can run the Report Configuration Wizard and the Reporting Control Panel. There are a few user accounts that you need to set up for use with Delinea report services. Here is a summary of the user accounts that you need to create and the permissions you need to explicitly grant.

Report Services Account Permissions

	For domain-based reporting: Replicating directory changes

report service account to run the Reporting Service	at the domain level (ADUC) and replicate directory changes in ADSI For zone-based reporting: Read permission	Log on as a service		
SQL Server service account to run SQL Server	n/a	Log on as a service		member of the securityadmin role
PostgreSQL service account				the account must have permission to connect to PostgreSQL and create a database
report admin to run the Report Configuration wizard or the Upgrade & Deployment wizard and deploy reports to an existing SQL Server instance	needs to be a member of the domain	n/a	Folder Settings > Content Manager role	member of the securityadmin role (At the very least, the user needs permission to connect to SQL Server and create a database.)
report admin to modify the Reports Control Panel	Read permission to the domain root object of the selected domain. Read permission to all computer objects in the selected domain.	n/a		
Report viewer to view reports from SSRS/Internet Explorer			Site settings > System user role Folder settings > browser (assign SSRS roles to Active Directory group or users)	
Report writer read, write, edit access for reports, in addition to the permissions needed to view reports			Site settings > System user role Folder settings > Content Manager role (assign SSRS roles to Active Directory group or users)	

> **Note**: Delinea Report Services requires administrator permission to install and upgrade. That also means that only an administrator can uninstall and repair Delinea Report Services. (Ref: CS-40808a)

Grant the Report Service Account Permissions

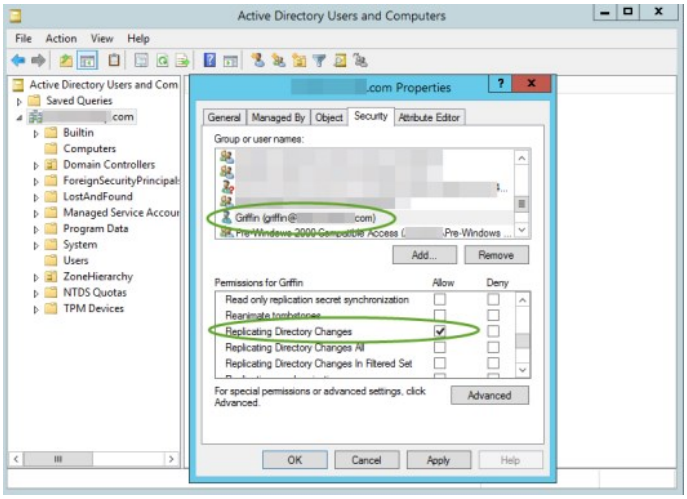
For your convenience, below are reminders for how to grant the two sets of required permissions for the report service account.

Grant the Permission to Replicate Directory Changes in ADUC

To grant the permission to replicate directory changes at the domain level (read only):

1. Open Active Directory Users and Computers.
2. From the View menu, select **Advanced Features**.

3. Right-click the domain object and select **Properties**.
4. Click the **Security** tab.
5. Select the desired user account (add the account if it's not listed there already).
6. In the Permissions area, next to **Replicating Directory Changes**, click **Allow**.



7. Click OK to save your changes.

   For more information about setting this permission, see https://support.microsoft.com/en-us/kb/303972.

Grant the Permission To Replicate Directory Changes In ADSI

In addition to granting the replicate directory changes permission in Active Directory Users and Computers (ADUC), you also need to grant the same permission in the ADSI Edit (Active Directory Services Interfaces Editor) console.

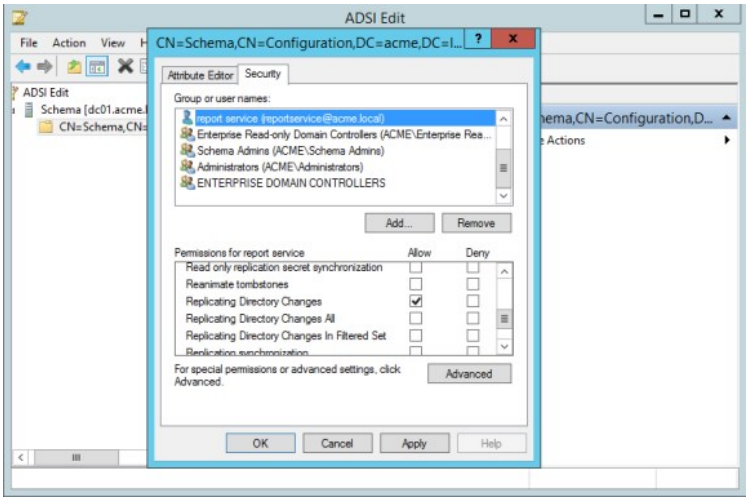
To grant the permission to replicate directory changes in ADSI (read only):

1. Open the ADSI Edit console.
2. From the Action menu, select **Connect to**.

   The Connection Settings dialog box opens.
3. For the Connection Point, go to the "Select a well known Naming Context" drop-down menu and select **Schema**.
4. Click **OK** to close the dialog box.

   The schema for the current domain displays in the ADSI Edit console.
5. Expand the schema listing so that you can see the first node of the schema, and right-click that node and select **Properties**.

   The Attribute Editor dialog box opens.
6. Click the **Security** tab.
7. Select the desired user account (add the account if it's not listed there already).
8. In the Permissions area, next to **Replicating Directory Changes**, click **Allow**.



9. Click OK to save your changes.

Grant the Permission to Log on as a Service

To grant the log on as a service permission:

1. In the Group Policy Management Editor, apply the following policy to your desired user or group of users:

   Local Computer Policy > Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment > Log on as a Service.

For more details about granting the log on as a service policy, see https://technet.microsoft.com/en-us/library/dn221981(v=ws.11).aspx.

SQL Server permissions that are set by the Configuration Wizard

Here are the SQL server permissions that report services grants to each user type, for your information. The Report Services Configuration wizard sets these permissions automatically.

Sql Server Permissions Set by the Report Services Configuration Wizard (table)

report services account to run the SQL Server Reporting Service	Snapshot Service (predefined role)
SQL Server service account to run SQL Server	If you deploy to an existing SQL Server instance, the configuration wizard makes no changes to the SQL Server service account. If you deploy to a new SQL Server instance: --If the operating system is Windows 2008 and you're using a SQL Server version later than 2012, virtual accounts are used for various SQL Server components, as follows: SQL Server engine: NT SERVICE\MSSQL$<InstanceName> SQL Server Agent: NT SERVICE\SQLAgent$<InstanceName> Full text search: NT SERVICE\MSSQLFDLauncher$<InstanceName> SSRS: NT SERVICE\ReportServer$<InstanceName> --Otherwise, the SQL Server service accounts are configured as follows: SQL Server engine: NT Authority\Network Service SQL Server Agent: NT Authority\Network Service Full text search: NT Authority\Local Service SSRS: NT Authority\Local Service
report admin to run the Report	

Configuration Wizard and deploy reports to an existing SQL Server instance	Connect SQL (cannot be revoked after setup) Create Database, Create any database, or Alter any database member of securityadmin role, or Alter any login permission
report admin to modify the Reports Control Panel	SnapshotAdmin (predefined role)
Report viewer to view reports from SSRS/Internet Explorer	Login permission SnapshotViewer (predefined role)
Report writer read, write, edit access for reports, in addition to the permissions needed to view reports	Login permission SnapshotViewer (predefined role)

> **Note**: Microsoft SQL Server Reporting System (SSRS) affords only role-based security in their reports. Be sure to grant appropriate access to reports. For example, if a user has access to only some data in the specified domain but all reports, they will be able to view all reports on all data from Active Directory.

PostgreSQL Permissions that are Set by the Configuration Wizard

When you create the PostgreSQL database with the Configuration wizard, the wizard grants the administrator user one permission for Create Database.

Memory Requirements

Be sure that your computers running the following components meet or exceed the RAM requirements listed below.

Domain Controller Memory Requirements

The minimum amount of RAM that you should have available for your domain controller is the sum of the following:

- Active Directory database size (for example, C:\Windows\NTDS\)
- Total SYSVOL size (for example, C:\Windows\SYSVOL)
- Recommended amount of RAM for your operating system
- Vendor recommended amount of RAM for your various background software agents, such as anti-virus, monitoring, backup, and so forth.
- Additional RAM to accommodate growth over the lifetime of the server.

For more information, see Microsoft recommendations here: http://social.technet.microsoft.com/wiki/contents/articles/14355.capacity-planning-for-active-directory-domain-services.aspx.

Windows Memory Requirements

Here are the minimum and recommended memory requirements for report services and the report database:

- Delinea report services: minimum 2 GB RAM, recommended 4 GB or above

- SQL Server report database: minimum 4 GB RAM, recommended 32 GB or above
- PostgreSQL report database: minimum 4 GB RAM, recommended 32 GB or above

SQL Server Recovery Model Requirement

In order for report services to function efficiently, it's recommended that you configure your SQL Server database to use the Simple recovery model. The recovery model configuration determines how SQL Server logs transactions, whether a database backs up the transaction log, and what kinds of restore options are available.

For more information about recovery models, please visit https://msdn.microsoft.com/en-us/library/ms189275.aspx.

To configure the SQL Server database recovery model:

1. In SQL Server Management Studio, navigate to the database that you use for report services.
2. Right-click the database and select **Properties**.
3. In the Select a Page area, click **Options**.
4. For the Recovery Model option, select **Simple**.
5. Click **OK** to save the changes.

Impact of Using a New or Existing SQL Server Instance

When you set up your installation of Delinea report services, you have the option of either using an existing SQL Server instance or installing a new instance. Delinea recommends that you use a new SQL Server instance, if possible.

If you choose to install a new instance from the Delinea Management Services installer program, the program installs an instance of SQL Server Express 2008 R2 with Advanced Services.

If you have an existing installation of SQL Server, you can create a new instance there first on your own, using your own installation media. When you install or configure Delinea report services, you then configure report services to use your existing instance that you created. That way your SQL Server instances use the same edition and version.

Tip: {/b}Please see the information at the following link for details about installing multiple versions and instances of SQL Server:

https://msdn.microsoft.com/en-us/library/ms143694(v=sql.130).aspx

Here are some issues to be aware of if you're going to use a *new* SQL Server instance:

- With a new SQL Server instance, you can avoid any potential problematic issues with SSRS, particularly if you need to reinstall SSRS.
- SSRS won't slow down the regular database operations on other instances.
- To prevent the SQL Server instance from consuming too much memory, it's recommended to use the max server memory to control each SQL Server instance's memory usage. The total allowance is not more than the total physical memory on the machine. If user is not running all of the instances, none of the running instances will be able to utilize the remaining free memory.

Here are some issues to be aware of if you're going to use an *existing* SQL Server instance:

- There can be issues with SSRS and existing instances. If you have to uninstall and reinstall SSRS, it leaves files behind with the existing instance.
- Using an existing SQL server instance can use all the free memory with a larger limit of the max server memory setting.

If you choose to deploy report services using an existing instance of SQL Server, your database administrator may need to know what changes that report services needs to make to the database. (KB-8042)

The only modification that report services makes to an existing database instance is to add two Windows integrated logins, as follows:

<The specified service account>	SnapshotService
[NT Authority\Authenticated Users]	SnapshotViewer

> **Note**: If these logins already exist, report services does not re-create them.

Deploy in Multi-Forest Environments

If you're deploying report services across multiple forests, there are a few tips to be aware of.

- It is best to install report services once in a forest, and then monitor domains or zones in other trusted forests.
- If you use domain-based mode, you need to install report services once in the domain. Make sure that any users who run report services and the service account have access to the domains for which you want to run reports.

  > **Note**: If you need to grant access to a user account across a forest with a one-way selective trust, you enable selective authentication for that user.

Enable Selective Authentication Across a Forest with a One-Way Selective Trust

The instructions below are provided as a courtesy; for more information on selective authentication, see the following article:

https://technet.microsoft.com/en-us/library/cc794747(v=ws.10).aspx

How to enable selective authentication for a user across an Active Directory forest that has a one-way selective trust:

1. Open **Active Directory Domains and Trusts.**
2. In the console tree, right-click the domain node for the forest root domain, and then click **Properties**.
3. On the **Trusts** tab, under either **Domains trusted by this domain** (outgoing trusts) or **Domains that trust this domain** (incoming trusts), click the forest trust that you want to administer, and then click **Properties**.
4. On the **Authentication** tab, click **Selective authentication**, and then click **OK**.
5. Open **Active Directory Users and Computers**.
6. Navigate to the Domain Controller the Report Services will use, right-click the computer object, and then click **Properties**.
7. On the Security tab add the desired user and grant Allow for the **Allowed to authenticate** permission.

See also the Delinea knowledge base article KB-8071.

Virtual Machines and Report Services

For production deployments, it is recommended to avoid using virtual machines for use with report services. (KB-7038)

In general, report services works well in virtual machines, including the case of installing SQL Server in a virtual machine.

However, in a large enterprise environment (such as where more than 100,000 users are enabled for authentication service), the SQL queries used for generating reports may have significant CPU, memory and I/O requirements. In these situations, Delinea recommends the use of physical machines for SQL Server to allow for better tuning of SQL Server without impacting other systems.

Alternatively, you can install SQL Server in a virtual machine. In such cases, Delinea recommends that you follow the guidelines provided by the virtualization vendors:

https://www.vmware.com/files/pdf/solutions/SQL_Server_on_VMware-Best_Practices_Guide.pdf

http://download.microsoft.com/download/6/1/d/61dde9b6-ab46-48ca-8380-d7714c9cb1ab/best_practices_for_virtualizing_and_managing_sql_server_2012.pdf

Installing Report Services

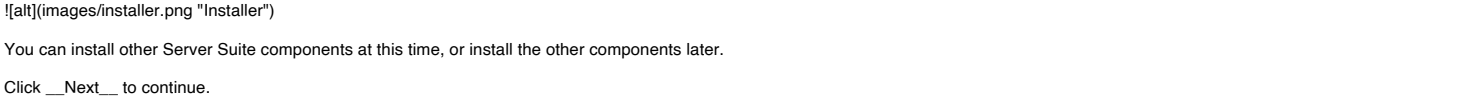
You use the same installer to install report services that you use to install other Server Suite components.

To install Delinea Report services:

1. Run the Delinea Management Services installer program that's appropriate for your Windows system (64-bit only).
2. In the Getting Started screen, click **Access**.
3. In the Welcome screen, click **Next** to continue.
4. Review the license agreement, and click the option that indicates that you agree to the terms.

   Click **Next** to continue.
5. In the User Registration screen, enter your name and company name.

   Click **Next** to continue.
6. Select the **Centrify Report Services** item.



7. In the Choose Destination Folder screen, specify the folder you want to install the software.

   If you're also installing Access Manager, you can select the options to automatically install desktop shortcuts.

   Click **Next** to continue.

   In the Confirm Installation Settings screen, review the list of components that will be installed. If the list is correct, click **Next** to continue.

   The program installs the files.
8. In the completion screen, select **Configure Report Services** and click **Finish**. Proceed to the next section, Configuring report services and deploying your reports .
9. If you don't want to configure report services right now, deselect the **Configure Report Services** option and click **Finish**. You can run the configuration wizard later, if desired.

Configuring Report Services and Deploying Your Reports

You use the configuration wizard to both set up a new report services deployment or reconfigure an existing one.

If you want to just redeploy your reports, see Re-deploying SQL Server reports to SSRS.

Configuring a SQL Server Report Services Deployment

Follow these instructions if you're creating a new report services deployment using SQL Server or reconfiguring an existing SQL Server report services deployment.

To configure report services with a SQL Server database:

1. If you need to start the Delinea Report Services configuration wizard, go to the **Start** menu > **All Programs** > **Centrify Server Suite 2021.1** > **Report Services**, and choose **Configuration Wizard.**

   If you're continuing from the Delinea Management Services installer, the installer started the configuration wizard for you.

2. On the Welcome screen, click **Next** to continue.
3. If you have already set up report services, the Reconfiguring Report Services screen displays. Select **Reconfigure** and click **Next** to continue.
4. On the Database Type screen, select **SQL Server** and click **Next** to continue.
5. Configure the SQL Server database connection:
   1. Specify the SQL Server instance name.

      Either specify a new SQL Server instance name, or select an existing SQL Server instance name. (The default instance name is CENTRIFYSUITE.)

      The SQL Server instance name must be 16 characters or less, the name cannot begin with an underscore (_) or dollar sign ($), and the instance name cannot contain any of the following special characters: a blank space, backslash (\), comma (,), colon (:), semi-colon (;), single quotation mark ('), ampersand (&), hyphen (-), number sign (#), or at sign (@).

      If you select an existing SQL Server instance, be aware that the SQL Server browser service must be running if SQL Server is a named instance or using dynamic ports. If for some reason the SQL Server service can't be started, you need to provide the SQL Server instance name and port number in order to connect to the database successfully. For additional details, see https://technet.microsoft.com/en-us/library/ms181087(v=sql.105).aspx.

      Delinea recommends that you use a new SQL Server instance, if possible. For more information, see Impact of using a new or existing SQL Server instance.

   2. The default database name is *Report*. You can change this, if desired.

      The SQL Server database name must be 16 characters or less, the name cannot contain any of the following special characters: backslash (\), forward slash (/), colon (:), asterisk (*), question mark (?), double quotes ("), less-than sign (<), greater-than sign (>), pipe (|), comma (,) or single quotation mark (').

   3. Click **Next** to continue.
   4. If you selected to install a new SQL Server instance, click **Browse** to navigate to and specify the location of the SQL server installation executable (*.exe file).

      The installer program installs SQL Server 2008 R2 Express with Advanced Services.

      You can download the SQL Server Express with Advanced Services package directly from Delinea, for your convenience. Or, download the package from Microsoft.

      Please ensure to download the file name SQLEXPRADV_x64_ENU.exe (1,008.6 MB in size) as this is the one containing the 64-bit edition of SQL 2008 R2 with the necessary additional components to support Delinea Reporting Services.

   5. Click **Next** to continue.
6. Deploy the reports:

1. In the SQL Server Reporting Services screen, specify whether to deploy the Server Suite reports (or not).

   If you plan to use a reporting solution other than Microsoft SQL Server Reporting Services, do not deploy the reports.

   
   This screen also lists the URLs for the Reporting Web Service and Report Manager. You'll use these URLs later to access to the reports.

   If you're using a production server of SQL Server and SSRS, you can configure them to use HTTPS. For details, see Microsoft SQL Server and SSRS documentation, such as https://msdn.microsoft.com/en-us/library/ms345223.aspx.

   The configuration wizard populates the report URLs automatically. If you had specified to use an existing SQL Server instance, the configuration wizard retrieves the existing web service URL and report manager URL for your SQL Server instance.

   For an existing SQL Server instance, you can open the Microsoft Reporting Services Configuration Manager to view the Web Service and Report Manager URLs.

2. Click **Next** to continue.

7. Choose domain or zone reporting:

   Specify whether you want to choose data for reporting based on domains or zones. The default is domain-based reporting.

   Click **Next** to continue. If you selected domain-based reporting, proceed to the next step. For zone-based reporting, go to Step 8.

8. If you selected domain-based reporting:

   1. In the Monitored Domain(s) screen, you can review and edit the list of domains that will be included for reporting. Add or remove domains as desired.

      For each domain, the configuration wizard lists the domain name and the domain controller name.

   2. Click **Next** to continue.

9. If you selected zone-based reporting and you use hierarchical zones:

   1. If you want data from all zones, select **Monitor all hierarchical zones from forest(s)**. You can add or edit forests by clicking **Edit** and then adding or removing forests.
   2. Or, if you want to report data from specific zones, select **Monitor only specific hierarchical zones**.
   3. Click **Edit**.

      The Specify Forest for zone selection dialog box opens.

   4. Enter the forest name where the desired zones are and click **OK**.

      The Edit Monitored Hierarchical Zones dialog box opens.

   5. Enter the hierarchical zones by name, or expand the list of zones to locate the desired zones manually.
   6. If desired, specify to select the parent or child zones automatically.
   7. Select the zone by putting a checkmark in the box next to the zone name.

8. When you're done specifying which hierarchical zones to monitor, click **OK** to close the dialog box and return to the Configuration wizard.

   Each zone that you've selected is listed in the Hierarchical Zones screen.

9. Click **Next** to continue.

10. If you selected zone-based reporting and you use classic zones:

    1. If you want data from all zones, select **Monitor all classic zones from forest(s)**. You can add or edit forests by clicking **Edit** and then adding or removing forests.
    2. Or, if you want to report data from specific zones, select **Monitor only specific classic zones**.
    3. Click **Edit**.

       The Specify Forest for zone selection dialog box opens.

    4. Enter the forest name where the desired zones are and click **OK**.

       The Edit Monitored Classic Zones dialog box opens.

    5. Select the classic zones to include in your reports. Select the zone by putting a checkmark in the box next to the zone name.

       You can filter the list of zones by entering a portion of the name and clicking **Filter**.

    6. When you're done specifying which classic zones to monitor, click **OK** to close the dialog box and return to the wizard. Click **Next** to continue.

11. For zone-based reporting, you can also specify which domain controller(s) that the report service connects to.

    If you don't specify which domain controller(s) to use, report services will use the default domain controller.

    1. Click **Add**.

       The Add Domain Controller dialog box opens.

    2. Enter the domain name and then select the domain controller from the list.
    3. Click **OK** to return to the Configuration wizard.

       The domain controllers that you selected are listed in the wizard screen.

    4. Click **Next** to continue.

12. In the Synchronization schedule screen, specify how often you want the reporting service to pull data from Active Directory.

    You can specify that the service synchronizes weekly, daily, every certain number of days, or every certain number of hours. The limit is 32,767 days or weeks.

    Click **Next** to continue.

13. Configure the user account that runs the service:

    1. In the Report Services options screen, specify the user account that will be used to run the service that synchronizes data from Active Directory and the reporting database.

       You can select a network service account, a managed service account, or another user account in Active Directory.

       You must specify a user account that has the required permissions. The configuration wizard verifies that the user has the correct level of access.

    2. Click **Next** to continue.
    3. The configuration wizard verifies that the specified user account has the required permission. An error displays if the permissions are inadequate.
    4. If the permission verification is successful, click **Close** to close the Verify permission window.

14. Review and complete the installation:

1. In the Summary screen, review the installation details. If the installation settings are correct, click **Next** to continue.

   If you're installing a new database, it may take a few minutes.

2. (Optional) In the completion screen, if the installation is successful, you can select the option to synchronize Active Directory data with the report database immediately. Depending on the Active Directory configuration and domain size, this operation can take awhile to complete.

   Or, alternatively, you can run the synchronization at a more convenient time, using the Report Services Control Panel.

3. Click **Finish** to close the configuration wizard.

   If the configuration was not successful, the configuration wizard provides some notes as to why the configuration failed. The notes may or may not include knowledge base articles that are available at the Delinea Technical Support web site.

Configuring a PostgreSQL Report Services Deployment

Follow these instructions if you're creating a new report services deployment using PostgreSQL or reconfiguring an existing PostgreSQL report services deployment.

To configure report services with a PostgreSQL database:

1. If you need to start the Delinea Report Services configuration wizard, go to the **Start** menu > **All Programs** > **Centrify Server Suite 2021.1** > **Report Services**, and choose **Configuration Wizard.**

   If you're continuing from the Delinea Management Services installer, the installer started the configuration wizard for you.

2. On the Welcome screen, click **Next** to continue.

3. If you have already set up report services, the Reconfiguring Report Services screen displays. Select **Reconfigure** and click **Next** to continue.

4. On the Database Type screen, select **PostgreSQL** and click **Next** to continue.

5. On the PostgreSQL screen, specify to create a new PostgreSQL installation or use an existing one.

   Because PostgreSQL doesn't have instances the way other databases do, Delinea recommends that you use an existing PostgreSQL database, if you already have one set up.

   For existing PostgreSQL installations, go to Step 8. Otherwise, for new installations, continue to Step 6.

6. To install a new PostgreSQL server, specify the PostgreSQL installer file location. You must specify a PostgreSQL installer version 11 or later. You can find the installer file in Common\PostgreSQL.

   Click **Next** to continue.

7. Specify the location of the PostgreSQL ODBC driver installer file. Delinea includes this file with the report services installer in Common\PostgreSQL.

   If you already have the official PostgreSQL ODBC drivers installed, this screen doesn't display.

   Click **Next** to continue.

8. Specify the PostgreSQL database settings:

   - **ODBC Driver**: For the PostgreSQL version that comes with report services, keep the default setting of PostgreSQL Unicode. This field can't be changed for new installations.
   - **Server**: If you're using an existing PostgreSQL server, enter the server name. For example, localhost or servername.acme.com.
   - **Port**: If you don't enter a port number, report services uses the default port 5432.
   - **Database**: This is the database name. The name can be up to 63 characters long, and the name cannot begin with an underscore (_) or dollar sign ($), and the instance name cannot contain any of the following special characters: a blank space, backslash (\), comma (,), colon (:), semi-colon (;), single quotation mark ('), ampersand (&), hyphen (-), number sign (#), or at sign (@).
   - **Database User**: This is your PostgreSQL administrator user. If you're using an existing PostgreSQL installation, the user must have the Create Database permission.

- **Password**: This is the password for your PostgreSQL administrator user. If you're using an existing PostgreSQL installation, this is the password for the user with the Create Database permission.
- **Confirm Password:** If you're creating a new installation, enter your password again to ensure the password is correct.
- **Additional Parameters**: Enter as needed. If you need to enter multiple characters, separate them with a colon (:).

  Note: The Configuration wizard verifies these settings after you've continued through all the configuration screens. Also, if you haven't installed the PostgreSQL ODBC driver, the Configuration wizard cannot verify these database settings.

9. If you selected domain-based reporting:
   1. In the Monitored Domain(s) screen, you can review and edit the list of domains that will be included for reporting. Add or remove domains as desired.

      For each domain, the configuration wizard lists the domain name and the domain controller name.
   2. Click **Next** to continue.
10. If you selected zone-based reporting and you use hierarchical zones:
    1. If you want data from all zones, select **Monitor all hierarchical zones from forest(s)**. You can add or edit forests by clicking **Edit** and then adding or removing forests.
    2. Or, if you want to report data from specific zones, select **Monitor only specific hierarchical zones**.
    3. Click **Edit**.

       The Specify Forest for zone selection dialog box opens.
    4. Enter the forest name where the desired zones are and click **OK**.

       The Edit Monitored Hierarchical Zones dialog box opens.
    5. Enter the hierarchical zones by name, or expand the list of zones to locate the desired zones manually.
    6. If desired, specify to select the parent or child zones automatically.
    7. Select the zone by putting a checkmark in the box next to the zone name.
    8. When you're done specifying which hierarchical zones to monitor, click **OK** to close the dialog box and return to the Configuration wizard.

       Each zone that you've selected is listed in the Hierarchical Zones screen.
    9. Click **Next** to continue.
11. If you selected zone-based reporting and you use classic zones:
    1. If you want data from all zones, select **Monitor all classic zones from forest(s)**. You can add or edit forests by clicking **Edit** and then adding or removing forests.
    2. Or, if you want to report data from specific zones, select **Monitor only specific classic zones**.
    3. Click **Edit**.

       The Specify Forest for zone selection dialog box opens.
    4. Enter the forest name where the desired zones are and click **OK**.

       The Edit Monitored Classic Zones dialog box opens.
    5. Select the classic zones to include in your reports. Select the zone by putting a checkmark in the box next to the zone name.

       You can filter the list of zones by entering a portion of the name and clicking **Filter**.
    6. When you're done specifying which classic zones to monitor, click **OK** to close the dialog box and return to the wizard. Click **Next** to continue.

12. For zone-based reporting, you can also specify which domain controller(s) that the report service connects to.

    If you don't specify which domain controller(s) to use, report services will use the default domain controller.

    1. Click **Add**.

       The Add Domain Controller dialog box opens.

    2. Enter the domain name and then select the domain controller from the list.
    3. Click **OK** to return to the Configuration wizard.

       The domain controllers that you selected are listed in the wizard screen.

    4. Click **Next** to continue.

13. In the Synchronization schedule screen, specify how often you want the reporting service to pull data from Active Directory.

    You can specify that the service synchronizes weekly, daily, every certain number of days, or every certain number of hours. The limit is 32,767 days or weeks.

    Click **Next** to continue.

14. Configure the user account that runs the service:

    1. In the Report Services options screen, specify the user account that will be used to run the service that synchronizes data from Active Directory and the reporting database.

       You can select a network service account, a managed service account, or another user account in Active Directory.

       You must specify a user account that has the required permissions. The configuration wizard verifies that the user has the correct level of access.

    2. Click **Next** to continue.
    3. The configuration wizard verifies that the specified user account has the required permission. An error displays if the permissions are inadequate.
    4. If the permission verification is successful, click **Close** to close the Verify permission window.

15. Review and complete the installation:

    1. In the Summary screen, review the installation details. If the installation settings are correct, click **Next** to continue.

       If you're installing a new database, it may take a few minutes.

    2. (Optional) In the completion screen, if the installation is successful, you can select the option to synchronize Active Directory data with the report database immediately. Depending on the Active Directory configuration and domain size, this operation can take awhile to complete.

       Or, alternatively, you can run the synchronization at a more convenient time, using the Report Services Control Panel.

    3. Click **Finish** to close the configuration wizard.

       If the configuration was not successful, the configuration wizard provides some notes as to why the configuration failed. The notes may or may not include knowledge base articles that are available at the Delinea Technical Support web site.

       Note: Delinea Report Services does not include a reporting solution for use with PostgreSQL.

Changing the Monitoring Mode for an Existing Report Services Deployment

You can easily switch from gathering report data based on domains or zones.

To change the monitoring mode for an existing report services deployment:

1. If you need to start the Delinea Report Services configuration wizard, go to the **Start** menu > **All Programs** > **Centrify Server Suite2021.1** > **Report Services**, and choose **Configuration Wizard.**

   If you're continuing from the Delinea Management Services installer, the installer started the configuration wizard for you.

2. On the Welcome screen, click **Next** to continue.
3. On the Reconfiguring Report Services screen, select **Switch the monitor mode** if you want to change whether report services uses domains or zones to synchronize Active Directory data. Click **Next** to continue.
4. On the Switch Monitor Mode screen, review the current and new mode settings. Click **Next** to continue.
    - To switch to domain-based reporting, go to Step 5.
    - To switch to zone-based reporting for hierarchical zones, go to Step 6.
    - To switch to zone-based reporting for classic zones, go to Step 7.
5. If you selected domain-based reporting:
    1. In the Monitored Domain(s) screen, you can review and edit the list of domains that will be included for reporting. Add or remove domains as desired.

        For each domain, the configuration wizard lists the domain name and the domain controller name.
    2. Click **Next** to continue.
6. If you selected zone-based reporting and you use hierarchical zones:
    1. If you want data from all zones, select **Monitor all hierarchical zones from forest(s)**. You can add or edit forests by clicking **Edit** and then adding or removing forests.
    2. Or, if you want to report data from specific zones, select **Monitor only specific hierarchical zones**.
    3. Click **Edit**.

        The Specify Forest for zone selection dialog box opens.
    4. Enter the forest name where the desired zones are and click **OK**.

        The Edit Monitored Hierarchical Zones dialog box opens.
    5. Enter the hierarchical zones by name, or expand the list of zones to locate the desired zones manually.
    6. If desired, specify to select the parent or child zones automatically.
    7. Select the zone by putting a checkmark in the box next to the zone name.
    8. When you're done specifying which hierarchical zones to monitor, click **OK** to close the dialog box and return to the Configuration wizard.

        Each zone that you've selected is listed in the Hierarchical Zones screen.
    9. Click **Next** to continue.
7. If you selected zone-based reporting and you use classic zones:
    1. If you want data from all zones, select **Monitor all classic zones from forest(s)**. You can add or edit forests by clicking **Edit** and then adding or removing forests.
    2. Or, if you want to report data from specific zones, select **Monitor only specific classic zones**.
    3. Click **Edit**.

        The Specify Forest for zone selection dialog box opens.
    4. Enter the forest name where the desired zones are and click **OK**.

        The Edit Monitored Classic Zones dialog box opens.
    5. Select the classic zones to include in your reports. Select the zone by putting a checkmark in the box next to the zone name.

        You can filter the list of zones by entering a portion of the name and clicking **Filter**.

6. When you're done specifying which classic zones to monitor, click **OK** to close the dialog box and return to the wizard. Click **Next** to continue.

8. For zone-based reporting, you can also specify which domain controller(s) that the report service connects to.

   If you don't specify which domain controller(s) to use, report services will use the default domain controller.

   1. Click **Add**.

      The Add Domain Controller dialog box opens.

   2. Enter the domain name and then select the domain controller from the list.

   3. Click **OK** to return to the Configuration wizard.

      The domain controllers that you selected are listed in the wizard screen.

   4. Click **Next** to continue.

9. Configure the user account that runs the service:

   1. In the Report Services options screen, specify the user account that will be used to run the service that synchronizes data from Active Directory and the reporting database.

      You can select a network service account, a managed service account, or another user account in Active Directory.

      You must specify a user account that has the required permissions. The configuration wizard verifies that the user has the correct level of access.

   2. Click **Next** to continue.

   3. The configuration wizard verifies that the specified user account has the required permission. An error displays if the permissions are inadequate.

   4. If the permission verification is successful, click **Close** to close the Verify permission window.

10. Review and complete the installation:

    1. In the Summary screen, review the installation details. If the installation settings are correct, click **Next** to continue.

       If you're installing a new database, it may take a few minutes.

    2. (Optional) In the completion screen, if the installation is successful, you can select the option to synchronize Active Directory data with the report database immediately. Depending on the Active Directory configuration and domain size, this operation can take awhile to complete.

       Or, alternatively, you can run the synchronization at a more convenient time, using the Report Services Control Panel.

    3. Click **Finish** to close the configuration wizard.

       If the configuration was not successful, the configuration wizard provides some notes as to why the configuration failed. The notes may or may not include knowledge base articles that are available at the Delinea Technical Support web site.

Doing a Silent Install and Configuration

You can do what's called a silent install and configuration of Report Services, where you don't have to interact with a user interface and you plug in some configuration values ahead of time.

Doing a Silent Install of Report Services

Follow this procedure if you're installing Report Services components newly or upgrading to the latest version.

To silently install Report Services

1. Open a command window and run it as administrator.
2. Navigate to the Report Services folder in the installer package:

   Centrify-Server-Suite-**version**-mgmt-win64\DirectManage\Report Services

   where **version** refers to the Server Suite release version.
3. Run the following command to install the Report Services files:

   Centrify_RptServices-**version**-win64.msi /quiet

   where **version** refers to component version.

   The program installs the Report Services files into the default installation folder. You'll know that the install worked if you see newer files in that folder.

   You're now ready to configure Report Services. For new installations, see the next procedure. For upgrades, see Upgrading the reporting database silently.

Configuring a New Report Services Deployment Silently

There are a few main factors that drive which parameters to use in configuring Report Services silently (automatically without interaction):

- Are you creating a new database instance or publishing to an existing instance?
- Are you using PostreSQL or Microsoft SQL Server?
- Are you using Report Services in zone mode or domain mode?

When doing a silent configuration of report services, you create a file named config.json with the configuration parameters that you need for your deployment. For a list of the available parameters, see Report Services silent configuration parameters

Before you run the configuration program, be sure that you have the parameters set in the configuration file (config.json) and that you have the following ready to enter at the command line:

- ServiceAccount and ServiceAccountPassword
- PgSQLUser and PgSQLUserPassword (if using PostgreSQL)

The installer also supplies some sample configuration files (in the Report Services installation folder) that you can use as a guideline, depending on your deployment:

Microsoft SQL Server	config_sql_server_domain_mode_sample.json	config_sql_server_zone_mode_sample.json
PostgreSQL	config_postgresql_domain_mode_sample.json	config_postgresql_zone_mode_sample.json

To silently configure Report Services

1. Prepare the configuration file according to the settings you need.
2. Open a command line window as an administrator and run the report services configuration command according to the following usage:

```
Centrify.Report.Configuration.CLI.exe --ConfigFile "C:\\config.json" --ServiceAccount "Local System" --ServiceAccountPassword --PgSQLUser --PgSQLUserPassword
```

--ConfigFile	The configuration json file, including the path. You can name this file as desired, as long as it's a .json file.
--IsGroupManagedServiceAccount	Use this option to specify that the service account is a group managed service account (gmsa).
--ServiceAccount	The service account to use to configure report services.
--ServiceAccountPassword	The service account password. If you're using a built-in account such as "Local System", you don't have to specify the password.
--PgSQLUser	If you use PostrgreSQL as your database, specify the PostreSQL user name
--PgSQLUserPassword	The PostgreSQL password

The command does the configuration. If there is an issue or error, the command displays a message in red text. When the configuration succeeds, there's a message in green text indicating that the configuration is done.

Report Services Silent Configuration Parameters

Use the following parameters in the Report Services configuration file (config.json). You don't need to use all of them; it depends on which kind of database you use and whether you're configuring Report Services in domain mode or zone mode. These parameters match what you would enter in the installer interface.

The installer also supplies some sample configuration files (in the Report Services installation folder) that you can use as a guideline, depending on your deployment:

Microsoft SQL Server	config_sql_server_domain_mode_sample.json	config_sql_server_zone_mode_sample.json
PostgreSQL	config_postgresql_domain_mode_sample.json	config_postgresql_zone_mode_sample.json

AdditionalParam	string	(PostgreSQL only) Use this parameter if you have any additional PostgreSQL parameters that you need to specify.	
DBInstallerPath	string	If you're creating a new database instance, this parameter specifies the location of the database installer file.	"DBInstallerPath": "D:\\Common\\SQLEXPR\\SQLEXPRADV_x64_ENU.exe"
DBInstallationPath	string	If you're creating a new database instance, this parameter specifies where to install the new database instance. For directories or path separators, use \\ instead of \.	"DBInstallationPath": "C:\\Program Files\\Microsoft SQL Server\\130"
DBName	string	If you're creating a new database instance, the name of the new database.	"DBName": "Report"
DomainControllers	dictionary	(Zone mode only) -- key = domain, value = domain controller	{"test.com": "dc.test.com"}
		(Domain mode only) Use this parameter to specify	

DomainMode		domain mode. Inside of this parameter you specify the domains to synchronize to the reporting database.	"DomainMode": { "MonitoredDomains": { "test.com": "dc.test.com", "us.test.com": "dc.us.test.com" } }
ForestsForClassicZones	list of string values	(Zone mode only) The forest that contains the classic zones	
ForestsForHierarchicalZones	list of string values	(Zone mode only) The forest that contains the hierarchical zones	["companyA.com", "companyB.com"]
InstanceName	string	(SQL Server only) If you're creating a new database instance, the name of the new database instance. For directories or path separators, use \\ instead of \.	"InstanceName": "REPORTS"
IsDeployReport	true or false	(SQL Server only) Specifies whether or not to deploy reports.	"IsDeployReport": true
LogLevel	string	Specifies the amount of detail that the installer includes in the log file. The format of the parameter is as follows: Log level (Off|Critical|Error|Warning|Information|Verbose|Trace)	"LogLevel": "verbose"
MonitoredClassicZones (list)	list of string values	(Zone mode only) If you use classic zones, use this parameter to specify the list of zones to synchronize with report services.	["test.com/Program Data/Zones/ZoneC", "test.com/Program Data/Zones/ZoneD"]
MonitoredHierarchicalZones	list of string values	(Zone mode only) The list and location of hierarchical zones	["test.com/Program Data/Zones/hZoneA", "test.com/Program Data/Zones/hZoneB"]
NewDB	true or false	Specifies whether to create a new database instance or not	"NewDB": true
OdbcName	string	(PostgreSQL only) The name of the ODBC driver to use to connect with the PostgreSQL database.	"OdbcName": "PostgreSQL Unicode"
OdbcInstaller	string	(PostgreSQL only) The path and filename of the PostgreSQL installer file.	
Port	integer	(PostgreSQL only) The port for the PostgeSQL database. If you don't specify this parameter, the default port of 5432 is used.	"Port": "5432"
ReportManagerUrl	string	(SQL Server only) Specifies the report manager URL. You use this URL to edit, publish, and administer reports.	"ReportManagerUrl": "http://MYCOMPUTER/Reports_REPORTS"
ReportWebServiceUrl	string	(SQL Server only) Specifies the web service URL for deploying reports. You use the web service URL to read reports.	"ReportWebServiceUrl": "http://MYCOMPUTER/ReportServer_REPORTS"
		You use this parameter in conjunction with the ScheduleRule setting. With this parameter, you specify the number of hours, days, or weeks to configure how often the report synchronization will	"ScheduleRule": "interval", "ScheduleFrequency": 2, The

ScheduleFrequency	integer	happen. For example, if you set ScheduleRule to weekly and you specify ScheduleFrequency to 1, the synchronization will happen every week. If you change the ScheduleFrequency to 3, the synchronization will happen every 3 weeks.	above example specifies that the report synchronization will happen every 2 hours.
ScheduleRule	string	You use this parameter in conjunction with the ScheduleFrequency setting. With this parameter, you specify what sets of time to count when scheduling the frequency of report services synchronization. The options that you can specify are "daily", "interval", or "weekly". Interval specifies an hourly interval.	"ScheduleRule": "weekly", "ScheduleFrequency": 2, The above example specifies that the report synchronization will happen every 2 weeks.
ScheduleStartTime (string)	string	Specifies the time of day to start the report services synchronization, in the 24 hour format of hh:mm:ss.	"ScheduleStartTime": "14:00:00",
ScheduleWeekDays (list)	list of string values	Specifies on which days of the week the report services synchronization will happen. You can specify "all" for a daily synchronization or "none" to just do it manually as needed. Otherwise, you can specify one or more of the following for days of the week: "mon", "tue", "wed", "thu", "fri", "sat", "sun"	"ScheduleWeekDays": ["mon", "wed", "fri"]
Server	string	(PostgreSQL only) The name of the PostgreSQL server.	"Server":"localhost"
SqlCmdTimeout	int	SqlCommand timeout (second)	"SqlCmdTimeout": 3300
ZoneMode		(Zone mode only) Use this parameter to specify zone mode. Inside of this parameter you specify the MonitoredClassicZones and the MonitoredHierarchicalZones parameters and their respective settings.	ZoneMode": { "MonitoredClassicZones": [], "MonitoredHierarchicalZones": ["test.com/Program Data/Zones/hZoneA"], "ForestsForClassicZones": ["test.com"], "ForestsForHierarchicalZones": [], "DomainControllers": { "test.com": "dc.test.com", "us.test.com": "dc.us.test.com" } }

Upgrading from a Prior Version

You can install or upgrade the report services components using the Delinea Management Services installer and then use either the Report Services Configuration wizard or the Database Upgrade and Deployment wizard to get your database and reports set up. This table highlights which tools you can use, depending on whether you have a previous version of report services installed or not.

No	Install the report services components	Run the Configuration wizard to configure report services and deploy reports. For details, see Configuring Report Services and Deploying your Reports
Yes	Upgrade your report services components.	Run the Database Upgrade and Deployment wizard to upgrade your report database and deploy reports. For details, see Upgrading your report services database.

If you're upgrading from a version of Server Suite prior to 2016 or you don't currently have report services installed, you'll need to specifically indicate during the installation when you want to install the report services components - they aren't installed by default during an upgrade.

> **Note**: The Access Manager reports are still available, wherever you've installed Access Manager. Report services are in addition to the standard Access Manager reports.

Upgrading Your Report Services Database

If you're upgrading from a previous release of report services, you need to make sure that your report database is up to date. You'll also need to deploy your reports again so that they are based on the updated database.

The following SQL Server permissions are required in order to upgrade the report database with the Upgrade and Deployment wizard:

- Execute stored procedure permission on report database
- Create schema permission on report database
- Create table permission on report database
- Create view permission on report database
- Create stored procedure permission on report database
- Create type permission on report database
- Alter any schema permission on report database
- Insert, Delete, Update, Select and Execute permissions on the schema "Dbo", "RawData", "ReportData", "ReportView" and "ConfigData" on report database

In order to deploy reports, you must have the Microsoft SQL Server Reporting Services role of Content Manager. For details for how to grant SSRS roles, see Granting access in SSRS to reports.

To upgrade your report database:

1. From the Start menu, locate and run the **Delinea Report Services Upgrade and Deployment wizard**.
2. In the initial screen, click **Next** to continue.
3. The wizard upgrades the database automatically.

   The database upgrade changes are saved to the database after you exit the wizard later.
4. If you have deployed reports before, configure where to back up the existing reports and where the new reports will be deployed.

   If you haven't deployed reports before, you're prompted to specify where to deploy reports.

   If desired, you can select the option to not backup nor deploy reports.

   Click **Next** to continue.
5. In the Summary screen, review the settings and if they're correct, click **Next** to continue.

The wizard upgrades your report database.

6. In the completion screen, click **Finish** to exit the wizard.

   (If the upgrade failed for any reason, the Summary screen displays some details about why the upgrade failed.)

   Your report database is updated and your reports are deployed, if you specified the option to do so.

   Note: After upgrade, you should perform a full synchronization before an incremental update is allowed. (Ref: CS-40029a)

Upgrading from Versions Before 2016

As of Server Suite 2016 the report services feature provides reports. If you're upgrading from a version prior to release 2016 and you're accustomed to the Access Manager reports, this section covers the differences between the reports.

If you want to know which Delinea report services reports correspond to the Access Manager reports, below is a list. The reports are listed according to the Access Manager report so that you can easily determine which new report you want to use instead.

Classic Zone Access Manager Reports

These Classic Zone reports correspond to the report services reports as follows:

Classic Zone - Authorization Report for Computers	Lists each computer in the zone and indicates which users are allowed to access each computer.	Authorization Report
Classic Zone - Authorization Report for Users	Lists each user account in the zone and indicates which computers each user can access.	
Classic Zone - User Privileged Command Rights Grouped by Zone	Lists the privileged commands that each user has permission to run and the scope to which the user's rights apply.	Classic Zone - User Privileged Command Rights Report
Classic Zone - User Role Assignments Grouped by Zone	Lists the role assignments for each user in each zone.	Classic Zone - User Role Assignment Report
Classic Zone - Users Report	Lists information from the UNIX profile for each user in each classic zone.	
Classic Zone - Zone Role Privileges	Lists the roles that are defined for each classic zone and the rights granted by each of these roles.	Zone Role Privileges Report

Hierarchical Zone Access Manager Reports

These Hierarchical Zone reports correspond to the report services reports as follows:

Hierarchical Zone - Computer Effective Audit Level	Lists the audit level in effect for computers in each zone.	Hierarchical Zone - Effective Audit Level
Hierarchical Zone - Computer Effective Rights	Lists the privileges granted on each computer.	Hierarchical Zone - Effective Rights Report
Hierarchical Zone - UNIX User Effective Rights	Lists the effective rights for each UNIX user on each computer. The report shows the name of the right, it's type, and where it is defined.	
Hierarchical Zone - Windows User	Lists the effective rights for each Windows user on each computer. The report	

Effective Rights	shows the name of the right, it's type, and where it is defined.	
Hierarchical Zone - Computer Effective Roles	Lists the roles assigned on each computer.	Hierarchical Zone - Effective Role Report
Hierarchical Zone - Computer Role Assignments	Lists the computer roles that are defined for each zone. The report includes the users and groups and their associated roles.	Hierarchical Zone - Computer Role Assignments Report
Hierarchical Zone - Computer Role Membership	Lists the computer roles that are defined for each computer and the zone to which they belong.	Hierarchical Zone - Computer role Membership Report
Hierarchical Zone - Computer Role Membership Grouped by Zone	Lists the computer roles that are defined for each computer grouped by the zone to which they belong.	

All Zone Access Manager Reports

These reports correspond to report services reports as follows:

Computer Summary Report	Lists computer account information for each computer in each zone.	Computers Summary Report
Computers Report	Lists computer account information for each computer in each zone.	
Groups Report	Lists group information for each group in each zone.	Groups Report
Stale Computers Report	Lists the stale computers.	Stale Computers Report
User Accounts Report	Lists account details for the users that have UNIX profiles in each zone. The report includes the Active Directory display name, the Active Directory login name, the Active Directory domain for the account, and details about the account status, such as whether the account is configured to expire, locked out, or disabled and the date and time of the account's last login.	User Accounts Report
Zones Report	Lists the zone properties for each zone. The report includes the zone name, list of available shells, the default shell, the default home directory path, the default primary group, the next available UID, reserved UIDs, the next available GID, and reserved GIDs.	Zones Report

Reports that are New to Access Manager Report Users

In addition to converting the content of the Access Manager reports into the report services reports, there are also the following new reports:

- Hierarchical Zone - Computer Role Effective Assignments Report (one for UNIX, one for Windows)
- Hierarchical Zone - Zone Effective Assignments Report (one for UNIX, one for Windows)
- Attestation reports for SOX and PCI compliance

Upgrading the Reporting Database Silently

If desired, you can upgrade your report services database without any user interaction, after you install the latest version of the Report Services components. You supply any of the parameters in the table below when you run the command line program. These parameters match the settings in the Upgrade and Deployment wizard.

ReDeployReport	switch	Specifies whether or not to redeploy reports after you upgrade the database. If you include this parameter, the service will redeploy reports. If you don't include this parameter, the service doesn't redeploy reports.	--ReDeployReport
ReportBackupFolder	string	Specifies the path and folder location to backup existing reports before upgrading. This option only applies if you specify ReDeployReport to yes. If you don't specify a value for this property, the service uses the default value of "Backup reports".	
WebServiceURL	string	Specifies the web service URL for deploying reports. You use the web service URL to read reports. If you don't specify this value, the service uses the current setting.	"ReportWebServiceUrl": "http://server1/ReportServer_REPORTS"
ReportManagerURL	string	Specifies the report manager URL. You use this URL to edit, publish, and administer reports. If you don't specify this value, the service uses the current setting.	"ReportManagerUrl": "http://server1/Reports_REPORTS"

To silently upgrade Report Services:

1. Install the latest version of the Report Services components. For details, see Silently installing Report Services.
2. At the command line (be sure to run as administrator), run the following command with the desired upgrade parameters, as listed in the table above. None of the parameters are mandatory.

   ```
   Centrify.Report.Upgrade.Cli.exe --ReDeployReport --ReportBackupFolder "previous-reports"
   ```

The upgrade program lists out each upgrade task that it performs as it progresses. When the program finishes, there's a message that says the upgrade is finished.

Administering Report Services with the Report Control Panel

You can use the Delinea Report Services Control Panel for the following tasks:

General Tab

- View the status of data synchronization from Active Directory to the report database
- View the domains or zones that are included for reporting
- Start, stop, or restart the reporting service.

Monitored Zones Tab

> **Note**: This tab appears only if you've configured reporting based on specific zones instead of domains.

- Edit the Hierarchical or Classic zones that you want to include in your reports. You can add or remove zones, as desired, and you can select zones from other trusted forests.

Settings Tab

- Configure when the reporting service synchronizes data from Active Directory to the reporting database
- Change the user account that runs the reporting service.
- Add, edit, or remove domain controllers (in zone-based monitor mode) or domains (in domain-based monitor mode).
- If you're using a PostgreSQL database, you can test the connection to the database.

Troubleshooting Tab

- View the log files and set the level of detail that are collected in the log files.
- Export diagnostics data for use by Delinea Technical Support (if technical support requests that you do so).
- Rebuild or refresh the reports data
- Validate that the reporting service has the correct permissions to read data from the monitored domains and replicate the data.

Configuring SQL Server Reporting Services (SSRS)

This section includes the following topics:

- Adding your report services web site to your Internet Explorer trusted sites
- Granting access in SSRS to reports
- Providing reports to your users or auditors
- Sharing reports by email or file sharing with report subscriptions

Adding Your Report Services Web Site to Your Internet Explorer Trusted Sites

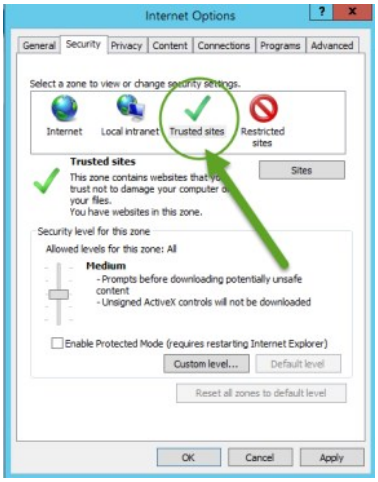
Chrome, Firefox, and Safari are NOT supported for SSRS. This is a Microsoft limitation.

In order to view the reports in Internet Explorer, you also have to add the report server as a trusted site. (If you're running an evaluation version, you can also choose to disable the Internet Enhanced Security configuration, but it's not recommended to do so.)

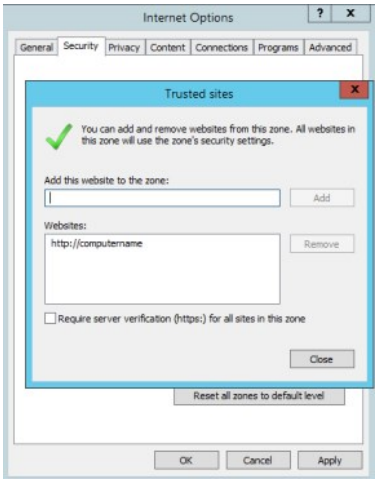
Please consult Microsoft documentation for the most current instructions for Internet Explorer configuration. However, for your convenience, here's a quick reminder of how to add a trusted site.

To configure Internet Explorer to trust the report services deployment site in the local intranet zone:

1. In Internet Explorer, go to **Tools** > **Internet Options**.
2. Click **Security**.
3. In the Zones area, click **Trusted Sites**.



4. Click **Sites**.
5. In the Trusted Sites dialog box, enter the web site address for your report services deployment, and click **Add**.



For example, enter a URL that looks something like this: http://computername/reportinstancename.

6. Click **Close**, and then click **OK** to save the changes.

Granting Access in SSRS to Reports

Before you provide reports to your users, you need to give them the appropriate access within the Microsoft SQL Server Reporting Services application. You use the SSRS role-based security to assign Active Directory users and groups to SSRS roles for both the site and folders.

Anyone reading reports will also need to configure their Internet Explorer installation, as mentioned in Adding your report services web site to your Internet Explorer trusted sites.

Please consult Microsoft documentation for the most current instructions for security configuration and granting access in SSRS. For example, some information can be found at this link:

https://docs.microsoft.com/en-us/sql/reporting-services/report-server/configure-a-native-mode-report-server-for-local-administration-ssrs?view=sql-server-2016

However, for your convenience, a couple procedures are below.

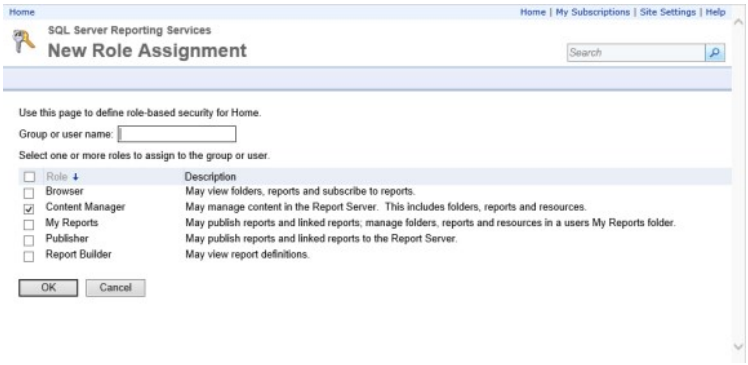
To grant report **administrator** access in SSRS (SQL Server Reporting Services):

1. Run Internet Explorer as Administrator.
2. In Internet Explorer, go to your Report Manager URL.

   You can open the Microsoft Reporting Services Configuration Manager to view the Report Manager URL.

   Internet Explorer opens SQL Server Reporting Servies to your Report Manager URL.
3. Click **Site Settings**, and create a new role assignment so that you can assign the desired Active Directory group to the "System Administrator" role in SSRS.

   To create a new role assignment, click **Security**, then **New Role Assignment**.
4. Enter the group or user name (in the domain\username formet), select **System Administrator**, and click **OK**.
5. Click **Home**, and then click **Folder settings**. From there, create a new role assignment so that you can grant access to the "Content Manager" role.



6. To grant access so that the user can **edit or build** reports, you can give them additional permissions in SSRS, such as the Report Builder permission to the Home folder.

To grant report **read** access in SSRS (an overview):

1. In SSRS, go to Site Settings, and create a new role assignment so that you can assign the desired Active Directory group to the "System user" role in SSRS.

   By default, all authenticated users are assigned to the System User role.

2. In SSRS, go to the Home folder, and then click Folder settings. From there, create a new role assignment so that you can grant access to at least the "Browser" role.

3. To grant access so that the user can **edit or build** reports, you can give them additional permissions in SSRS, such as the Report Builder permission to the Home folder.

Providing Reports to Your Users or Auditors

After you've made sure that your users have the appropriate read access to reports within SSRS, you provide the report URL to your users and instruct them to access that URL within your domain and using the Internet Explorer browser. They may also need to add the report URLs to their trusted domains list; for details, see Adding your report services web site to your Internet Explorer trusted sites.

Sharing Reports by Email or File Sharing with Report Subscriptions

You can also create report subscriptions so that you can easily share reports by way of email or a file share. These are features of Microsoft SSRS, and the Microsoft documentation has the latest information.

In order to share reports by email, you first need to configure your report server for email delivery. For details, see https://msdn.microsoft.com/en-us/library/ms345234(v=sql.110).aspx.

For details for how to share reports by email or file sharing, see https://msdn.microsoft.com/en-us/library/ms189680(v=sql.110).aspx.

Re-Deploying the SQL Server Reports to SSRS

You can re-deploy your reports without needing to go through the entire Delinea Report Services configuration wizard. You can only re-deploy reports if you use SQL Server for your report database.

To configure Delinea report services using the configuration wizard:

1. If you need to start the Delinea Report Services configuration wizard, go to the **Start** menu › **All Programs** › **Centrify Server Suite 2021.1** › **Report Services**, and choose **Configuration Wizard.**

   If you're continuing from the Delinea Management Services installer, the installer started the configuration wizard for you.

2. On the Welcome screen, click **Next** to continue.

3. On the Reconfiguring Report Services screen, select **Deploy reports only** and click **Next** to continue.

4. Deploy the reports:

   1. In the SQL Server Reporting Services screen, specify whether to deploy the Server Suite reports (or not).

      If you plan to use a reporting solution other than Microsoft SQL Server Reporting Services, do not deploy the reports.

      
      This screen also lists the URLs for the Reporting Web Service and Report Manager. You'll use these URLs later to access to the reports.

      If you're using a production server of SQL Server and SSRS, you can configure them to use HTTPS. For details, see Microsoft SQL Server and SSRS documentation, such as https://msdn.microsoft.com/en-us/library/ms345223.aspx.

      The configuration wizard populates the report URLs automatically. If you had specified to use an existing SQL Server instance, the configuration wizard retrieves the existing web service URL and report manager URL for your SQL Server instance.

      For an existing SQL Server instance, you can open the Microsoft Reporting Services Configuration Manager to view the Web Service and Report Manager URLs.

   2. Click **Next** to continue.

      Review and complete the installation:

   3. In the Summary screen, review the installation details. If the installation settings are correct, click **Next** to continue.

      If you're installing a new database, it may take a few minutes.

   4. (Optional) In the completion screen, if the installation is successful, you can select the option to synchronize Active Directory data with the report database immediately. Depending on the Active Directory configuration and domain size, this operation can take awhile to complete.

      Or, alternatively, you can run the synchronization at a more convenient time, using the Report Services Control Panel.

   5. Click **Finish** to close the configuration wizard.

      If the configuration was not successful, the configuration wizard provides some notes as to why the configuration failed. The notes may or may not include knowledge base articles that are available at the Delinea Technical Support web site.

Viewing Default Reports

This section covers how to open a report, and provides some basic information on each of the default reports.

Opening a Report

You open a report by going to the report folder URL in Internet Explorer. Click a report to open it.

In general, you and your users access the reports from a URL. The URL has a format like this:

"http://hostname/Reports_reportDBname"

Filtering Report Data by Zone

When you view a report, you can filter the report data by zone. In the zone drop-down filter, report services lists each zone by its full zone hierarchy, so that you can choose based on parent or child zones. For example, if you have a child zone named California as part of a parent zone West which is part of the parent zone United States, the zone appears in the list as "United States/West/California.

Zones are listed in the zone drop-down filter in alphabetical order, and the first zone in the list is the default zone. When you first open a report, report services initially generates the report data based on the default zone.

Default Access Manager Reports

Report Services Reports: Not Specific to Classic or Hierarchical Zones

Authorization report	This report lists each computer or user account, and which users are allowed to access each computer.	Access Level Computer domain Computer Name User domain User name User Type Zone Zone domain
Computers Summary report	Lists computer account information for each computer in each zone.	Computer domain Computer name Platform Zone Zone domain Zone type
Delegation report	Lists which users, groups, computers, group managed service accounts (gMSA), managed service accounts (MSA), and which well-known SIDs have which delegation tasks.	Delegation Task Target Target Domain Target Name Trustee Trustee Domain Trustee Type Zone
Effective delegation report	Lists which Active Directory users, Active Directory groups, group managed service accounts (gMSA), and managed service accounts (MSA) have which delegation tasks.	Active Directory User Domain Active Directory User Name Delegation Task Target Target Domain Target Name Zone
Groups report	Lists group information for each group in each zone, including the Active Directory group name, the UNIX group name, the UNIX group identifier (GID), and whether the group is an orphan. If the group is for local users, the local group status indicates whether the group is enabled or disabled for local access.	Active Directory Group name Active Directory Group domain Group Type Is Orphan Local Group Status UNIX Group Name Zone Zone Domain Zone Type
Stale Computers report	Lists the stale computers. Stale computers are those where the password hasn't changed for 90 or more days.	Computer Domain Computer Name Zone Zone domain
User Accounts Report	Lists account details for Active Directory users who are related to each zone. The report includes the Active Directory display name, the Active Directory login name, the Active Directory domain for the account, and details about the account status, such as whether the account is configured to expire, locked out, or disabled and the date and time of the account's last login.	Active Directory user name Domain Enabled

Users Report	Lists user information for each user in each zone. If the user is a local user, the local user status indicates whether the user is enabled or disabled for local access.	Active Directory user Active Directory user domain UNIX name Enabled Is Orphan Local User Status User Type Zone Zone domain Zone type
Zone Role Privileges Report	Lists the roles that are defined for each hierarchical zone and the rights granted by each of these roles.	Right name Right type Role name Zone Zone domain Zone type
Zones Report	Lists the administrative tasks and properties for each zone and the users or groups have been delegated to perform each task. This report indicates which users or groups have permission to perform specific tasks, such as add groups, join computers to a zone, or change zone properties.	Zone Zone domain

Delinea Report Services Reports: Classic Zone Reports

Classic Zone - User Privileged Command Rights Report	Lists the privileged commands that each user has permission to run and the scope to which the user's rights apply.	Classic zone Privileged command name User name Zone domain
Classic Zone - User Role Assignment Report	Lists information from the UNIX profile for each user in each classic zone. Lists the role assignments for each user in each zone. The report includes the domain name, user profile name, the list of roles the user is assigned to in each zone, and the scope to which the user's role assignment applies.	Classic zone Role User domain User name Zone domain

Delinea Report Services Reports: Hierarchical Zone Reports

Hierarchical zone - Computer Role Assignments Report	Lists the computer roles that are defined for each zone. The report includes the users and groups and their associated roles.	Role name Computer Role name Zone Zone domain
Hierarchical zone - Computer Role Effective Assignments Report	Lists the roles assigned on each computer. There are separate reports for UNIX and Windows computers.	Computer role Right Right type Role User Domain User Name Zone Zone Domain
Hierarchical Zone - Computer Role Membership Report	Lists the computer roles that are defined for each computer and the zone to which they belong.	Computer Domain Computer Name Computer Role in Zone Computer Role Name Join To Zone Domain
Hierarchical Zone - Effective Audit Level Report	Lists the audit level in effect for computers in each zone.	computer domain computer name User domain user name zone zone domain
Hierarchical Zone - Effective Rights Report	Lists the privileges granted on each computer and the effective rights for each Windows and UNIX user on each computer.	computer domain computer name Right Right type Role User domain user name zone zone domain

Hierarchical Zone - Effective Role Report	Lists the role assignment on each computer in the zone.	computer domain computer name Role User domain user name zone zone domain
Hierarchical Zone - Users Report	Lists the users and the computers to which they have access in the zone. If the user is a local user, the local user status indicates whether the user is enabled or disabled for local access.	Active Directory user Active Directory user domain Computer Computer domain Is orphan Is secondary Local User Status UNIX name User type Zone Zone domain
Hierarchical Zone - Zone Effective Assignments Report	Lists the roles that are defined for each hierarchical zone and the rights granted by each of these roles, including where each right is defined. There are separate reports for UNIX and Windows users.	Right Right type Role User domain user name zone zone domain

Default SOX Attestation Reports

To help your department comply with Sarbanes-Oxley audit requirements, Delinea provides some default SOX reports. These reports show you who has access to computers, what roles and rights users have, and similar data that's needed to show SOX compliance.

SOX reports provide the following kinds of information:

- **Computers**: Who has access to these computers, what are the roles, rights, and groups that they belong to
- **Groups**: Which users are in which groups, what are the roles, rights, and what computers can these users access
- **Users**: What their role assignments are, what rights the users have, which groups they belong to, and which computers they have access to
- **Roles**: Which computers the rules have access to, what rights are assigned to the group, and which groups are assigned to which roles

You can find the SOX reports in SSRS by going to the Centrify Report Services > Attestation > SOX reports folder.

> **Note**: In larger environments, you can save processing time when running an attestation report (PCI or SOX report) by choosing to exclude the chart from the report. When you open the report, select **True** for the **Exclude chart for faster report generation** option.

For a description of how report services calculates the data for the charts in the SOX reports, see How objects are counted for the PCI and SOX report charts.

Here is a list of the SOX reports, along with a brief description and how you can filter the results.

SOX - Login Report - By Computer	For each computer, this report displays the users who can log in. For each user who can log in, the report shows the role, assignment location, and assignee.	Computer Computer group Computer role Zone Zone Domain Zone Type
SOX - Login Report - By Group	For each Active Directory group, this report lists the computers and role assignment information.	Active Directory group Zone Zone Domain Zone Type
SOX - Login Report - By Role	For each role, this report lists the computers assigned to that role.	Role Zone Zone Domain Zone Type
SOX - Login Report - By User	For each user, this report lists the computers that the user can access as well as the role assignment information.	User Zone Zone Domain Zone Type
SOX - Login Summary Report	This report provides a summary of who can log in to which computer.	Computer Computer group Computer role Local User Status User User group User type Zone domain Zone type Zone
SOX - Rights Report - By Computer	For each computer, this report lists the users who have which login and other privileges and what the role assignments are.	Computer Computer Group Computer role Right type Zone Zone Domain Zone Type

SOX - Rights Report - By Group	For each Active Directory group, this report lists the computers have which login and other privileges and what the role assignments are.	Active Directory group Right type Zone Zone Domain Zone Type
SOX - Rights Report - By Role	For each role, this report lists the computer and rights available on that computer.	Role Zone Zone Domain Zone Type
SOX - Rights Report - By User	For each user, this report lists the Active Directory group, computers, and role assignment.	Right type User Zone Zone Domain Zone Type
SOX - Rights Summary Report	This report provides a summary of which rights are granted to which users on which computers.	Computer Computer group Computer role Local User Status Right type User group User User type Zone Zone Domain Zone type

Note: When you view the collection of reports in Internet Explorer, you may also see some sub-reports listed. These are not actual reports but views that support the actual reports; due to a limitation with Microsoft SSRS, these sub-reports may display even though they're not meant to be used. Please do not click any reports that have names that begin with SubReport.

Note: In these reports, Computer Role and Computer Group filters return records assigned to those roles or groups but not where the role assignment is defined. For example, if you filter records for Zone1_CompRoleA, the report lists all computers that are in the computer role named Zone1_CompRoleA.

Note: The charts in the PCI & SOX reports do not consider role assignments that are granted to "All Active Directory Users," and the reports only consider role assignments that are granted to specific users and groups when counting computer access and privileges. On the other hand, the detailed report shows all the login and privilege information from all role assignments (including those that are granted to "All Active Directory Users").

Default PCI Attestation Reports

To help your department comply with PCI audit requirements, Delinea provides some default PCI attestation reports. These reports show you who has access to computers, what roles and rights users have, and similar data that's needed to show PCI compliance.

PCI reports provide the following kinds of information:

- Computers: Which users have access to these computers, what are their roles and rights
- Groups: Which users are in which groups, what are their roles and rights, and which computers do they have access to
- Users: What role is the user assigned to, what rights does the user have, and which computers does the user have access to
- Roles: What computers do these roles have access to and what rights do they have

You can find the PCI reports in SSRS by going to the Centrify Report Services > Attestation > PCI reports folder.

Note: In larger environments, you can save processing time when running an attestation report (PCI or SOX report) by choosing to exclude the chart from the report. When you open the report, select **True** for the **Exclude chart for faster report generation** option.

For a description of how report services calculates the data for the charts in the PCI reports, see How objects are counted for the PCI and SOX report charts.

Here is a list of the PCI reports, along with a brief description and how you can filter the results.

PCI - Login Report - By Computer	For each computer, this report displays the users who can log in. For each user who can log in, the report shows the role, assignment location, and assignee.	Computer Computer group Computer role Zone Zone Domain Zone Type
PCI - Login Report - By Group	For each Active Directory group, this report lists the computers and role assignment information.	Active Directory group Zone Zone Domain Zone Type

PCI - Login Report - By Role	For each role, this report lists the computers assigned to that role.	Role Zone Zone Domain Zone Type
PCI - Login Report - By User	For each user, this report lists the computers that the user can access as well as the role assignment information.	User Zone Zone Domain Zone Type
PCI - Login Summary Report	This report provides a summary of who can log in to which computer.	Computer Computer group Computer role Local User Status User User group User type Zone domain Zone type Zone
PCI- Rights Report - By Computer	For each computer, this report lists the users who have which login and other privileges and what the role assignments are.	Computer Computer Group Computer role Right type Zone Zone Domain Zone Type
PCI- Rights Report - By Group	For each Active Directory group, this report lists the computers have which login and other privileges and what the role assignments are.	Active Directory group Right type Zone Zone Domain Zone Type
PCI- Rights Report - By Role	For each role, this report lists the computer and rights available on that computer.	Role Zone Zone Domain Zone Type
PCI- Rights Report - By User	For each user, this report lists the Active Directory group, computers, and role assignment.	Right type User Zone Zone Domain Zone Type
PCI - Rights Summary Report	This report provides a summary of which rights are granted to which users on which computers.	Computer Computer group Computer role Local User Status Right type User group User User type Zone Zone Domain Zone type

Note: When you view the collection of reports in Internet Explorer, you may also see some sub-reports listed. These are not actual reports but views that support the actual reports; due to a limitation with Microsoft SSRS, these sub-reports may display even though they're not meant to be used. Please do not click any reports that have names that begin with SubReport.

Note: In these reports, Computer Role and Computer Group filters return records assigned to those roles or groups but not where the role assignment is defined. For example, if you filter records for Zone1_CompRoleA, the report lists all computers that are in the computer role named Zone1_CompRoleA.

Note: The charts in the PCI & SOX reports do not consider role assignments that are granted to "All Active Directory Users," and the reports only consider role assignments that are granted to specific users and groups when counting computer access and privileges. On the other hand, the detailed report shows all the login and privilege information from all role assignments (including those that are granted to "All Active Directory Users").

How Objects are Counted for the PCI and SOX Report Charts

This section describes how objects are counted for the charts that you see in the PCI & SOX reports.

Login Report Charts

In login reports, we count how many computers each user can log in to, how many users can log in to each computer, and how many roles are granted with login rights.

In hierarchical zones, a role is considered to be granted with a login right if one or more of the following rights are granted to the role:

- Console login is allowed
- Remote login is allowed
- Password login and non-password login are allowed
- Non password login is allowed

In classic zones, a role is considered to be granted with a login right if at least one PAM right is granted to the role.

In the graphs that report the number of users who can log in to a computer, or the number of computers that a user is logged in to; the graphs only consider effective users. An effective user is one who has a complete user profile in a classic zone. In hierarchical zones, an effective user must also have been granted the login right through any role that is assigned to users/groups. Note that a "login right" obtained from a role that is assigned to "All AD users" is not considered in the graphs.

A local user is counted as an effective user in hierarchical zones if the user is granted the "User is visible" right from any effective role assignment.

Login Report – By Computer charts

Computers with Most Access chart

This chart ranks the computers by the number of effective users and shows the top 10 computers.

User Roles Count for Computers with Most Access chart

This chart ranks the computers by the number of roles that assign login rights to users or groups on the computer.

Users with Most Access chart

This chart ranks the users by the number of computers that each one can log in to, and shows the top 10 users.

Login Report – By Group charts

Roles with Most Access chart (by Group)

This chart ranks all the roles that are assigned to any group by the number of computers that the role grants login access to (regardless of how many groups are assigned to each role), and shows the top 10 roles.

Groups with Most Members chart

This chart shows the top 10 groups that have most members, including those from nested groups.

Login Report – By Role charts

Roles with Most Access chart (by Role)

This chart ranks all the roles that are assigned by the number of computers that the role grants login access to, and shows the top 10 roles.

Roles with Most Users chart

This chart ranks the number of users for which each role is effective (regardless of the role assignment scope), and shows the top 10 roles.

Roles with Most Rights chart

This chart ranks the assigned roles (regardless of the role assignment scope) with login rights by the number of granted privilege access rights.

Login Report – By User charts

Users with Most Access On Computers chart

This chart ranks the users by the number of computers that each one can log into, and shows the top 10 users.

Login Roles Count for Users with Most Access On Computers chart

This chart ranks the users by the number of effective roles that grant login access to any computer, and shows the top 10 users.

Login Summary Report charts

Computers With Most Access chart

This chart ranks the computers by the number of effective users and shows the top 10 computers. Both Active Directory and local effective users are considered.

Users With Most Access chart

This chart ranks all effective users by the number of computers that each user can log into, and shows the top 10 users.

Rights Report Charts

In each rights report, the privileged access right enables the user to create additional working environments or to run specified applications with different privileges. The following five privileged access rights are included in rights reports.

- Network Access right
- Desktop right
- Application right
- Commands
- Use restricted environment

Each privileged access right is counted in the reports only when the role with one of these rights is assigned to users and/or groups. However, the privileged right granted using 'All AD user' is not counted.

Rights Report – By Computer Charts

Computers with Most Privileged Access chart

This chart ranks the computer by the number of distinct privileged access rights that are effective on each computer, and shows the top 10 computers. A privileged access right is counted as one regardless of the number of users or roles that is granted or assigned the right in the computer.

Computer Roles with Most Privileged Access Chart

This chart ranks all the computer roles by the number of distinct privileged access rights assigned to each computer role, and shows the top 10 computer roles.

Privileged Access with Most Computers Chart

This chart ranks all privileged access rights by the number of computers that each right is effective on, and shows the top 10 rights.

Rights Report – By Group Charts

Groups with Most Privileged Access Chart

This chart ranks the group by the number of distinct privilege access rights granted to each group, and shows the top 10 groups. The privilege access rights are evaluated based on all roles that are assigned to groups, regardless of the scope of the assignments.

Rights Report – By Role Charts

Computer Roles with Most Privileged Access Chart

This chart ranks all the computer roles by the number of distinct privileged access rights assigned to each computer role, and shows the top 10 computer roles.

User Roles with Most Privileged Access Chart

This chart ranks the assigned roles (regardless of the role assignment scope) with login rights by the number of granted privileged access rights.

Rights Report – By User Charts

Users with Most Privileged Access Chart

This chart ranks all users by the number of distinct privileged access rights granted (regardless of the number of computers) and shows the top 10 users.

Computer Role Count for Users with Most Privileged Access Chart

This chart ranks all users by the number of distinct privilege access rights granted. For the top 10 users, it shows the number of computer roles where the user is assigned to any role in that computer role.

Rights Summary Report Charts

Computers with Most Privileged Access Chart

This chart ranks the computer by the number of distinct privileged access rights that are effective on each computer, and shows the top 10 computers. A privileged access right is counted as one regardless of the number of users or roles that is granted or assigned the right in the computer.

Users with Most Privileged Access Chart

This chart ranks all effective users by the number of distinct privileged access rights granted (regardless of the number of computers) and shows the top 10 users.

Most Dominant Privileges on Computers chart

This chart ranks all privileged access rights by the number of computers that each right is effective on and shows the top 10 rights. The number of users where the right is effective in each computer is not considered in the ranking.

Building Custom Reports

You can build your own reports with data from the Delinea report services database by using your own reporting tool or Microsoft SQL Server Reporting Services.

Requirements and Recommendations

In order to build your own reports or customize existing reports, you also need to have the SSRS Report Builder installed where you have SSRS installed.

Known Limitations and Recommendations

- Use the same domain where Microsoft SSRS is installed. If you try to use SSRS in a domain that is different from the domain where SSRS is installed, you may have some difficulty accessing reports. For example, if your computer runs in the acme.com domain and you have SSRS installed in a test domain of wiley.coyote.com, you may run into issues accessing the reports.
- If you're accessing SSRS from a different domain, make sure that you enter your credentials and save them.
- When you log in to SSRS, make sure that the user you're logging in as has at least the system user role, and at least read access to the folder (according to the folder settings in SSRS).

An Overview of Report Building Tasks

Microsoft documentation contains specific instructions for how to create custom reports using SSRS Report Builder. Included here is the overall process; please consult Microsoft SSRS Report Builder documentation for details.

For example, here's a link to Microsoft information on using SQL Server Reporting Services 2012: https://technet.microsoft.com/en-us/library/hh338693.aspx.

An overview of how to build custom reports using SSRS and Delinea report services data:

1. Open Internet Explorer to the deployed reports URL.
    - Make sure that you have the correct access permissions in SSRS for building reports. For details, see Granting Access in SSRS to Reports.
    - It's recommended that you log in to the deployed reports URL as a user with Report Building permissions, but not database administrator permissions. If you log in as a user with access to all tables in the reporting database, you may see tables that you cannot use in custom reports. Delinea exposes the views for you to use in your custom reports.
2. Open Microsoft SQL Server Report Builder, and create the dataset that connects you to the reporting data source.

    (The dataset is the set of data retrieved from the database, and the data source is the connection information for the database.)
3. Create a new report that's based on the data set that you just created.
4. Design a query using the provided views.
5. Run the report to make sure that you get data in the report.
6. Edit the report as desired.
7. Save the report.

    Microsoft SSRS saves the report as a .RDL file.
8. Publish the report by publishing the RDL file.

Migrating Custom Reports from SQL Server Express

If you create custom reports using the included version of SQL Server 2008 R2 Express edition, you can migrate those custom reports over to a production SQL Server. You'll need to download each custom report and then re-upload them into the production system.

To download your custom reports from SQL Server Express:

1. Create a temporary folder on your local computer.

    You'll use this folder to store your downloaded custom reports temporarily.

2. Open Delinea Report Services in Internet Explorer.
3. Navigate to the Custom Reports folder.
4. Select a report and select **Download** from the report's action menu.
5. Save the downloaded report in the temporary folder that you already created.

   Repeat this process for each report.
6. Close Internet Explorer.

To upload your custom reports to your production instance of SQL Server:

1. Run the Delinea Report Services Configuration wizard.
2. In the configuration wizard, choose the production SQL Server instance where you want to deploy the reports, then close the wizard.
3. Open Delinea Report Services in Internet Explorer.
4. Navigate to the Custom Reports folder.
5. For each report:
    1. Click **Upload File** and select the custom report that you downloaded from your other instance.
    2. After the report is uploaded, select the report and click **Manage**.
    3. Click the **Data Sources** tab.
    4. Select **A shared data source** and click **Browse**.
    5. In the folder listing, expand the **Centrify Report Services** folder.
    6. Select **ReportDataSource** and click **OK**.
    7. In the Data Sources page, click **Apply**.

You can now open the custom report successfully using data in your production SQL Server instance.

Views to Use in Custom Reports

Database views provide an easier and more secure way to share the reporting data without having to expose the database tables directly. Each view is essentially a database query. Some columns refer to columns in other views, and these relationships are noted.

Understanding the Differences Between Views

There are many views that are very similar to each other but provide different levels of details related to role assignments and so forth. This section briefly covers the differences between views so that you can decide which view to use, based on your needs.

When choosing which view to use, keep in mind that a view that provides less detail results in a faster query response time.

A list of who can log in to which computers	EffectiveAuthorizedUsers_Computer (Including computers in classic and hierarchical zones) EffectiveAuthorizedUsers_Computer_Classic (Only computers in classic zones) EffectiveAuthorizedUsers_Computer_Hierarchical (Only computers in hierarchical zones
A list of who can log in to which computer and what privileges are granted to these users	EffectiveLoginUserPrivileges_Computer EffectiveAuthorizedUserPrivileges_Computer (Same as EffectiveLoginUserPrivileges_Computer, just to consist the naming as the other views)
A list of Active Directory users' effective role assignments	EffectiveRoleAssignment (Both hierarchical & classic zones) EffectiveRoleAssignment_Classic (Classic zones only) EffectiveRoleAssignment_Hierarchical (Hierarchical zones only)
A list of the Active Directory users' effective privileges at the computer level (The Active Directory users list in the view may not have the access right to the computer)	EffectiveRolePrivileges_Computer
A list of the Active Directory users' effective system rights at the computer level (The Active Directory users list in the view might not have the access right to the computer)	EffectiveSysRights
A list of the authorized users' privileges The list indicates if a role or right supports its accessibility to the computer	EffectiveUserPrivileges_Computer
A list of the Active Directory users' privileges at the computer role level	EffectiveUserPrivileges_ComputerRole_Unix (Assuming all computers managed by the Computer Role are UNIX) EffectiveUserPrivileges_ComputerRole_ Windows (Assuming all computers managed by the Computer Role are Windows)
A list of the Active Directory users' privileges at the Zone level	EffectiveUserPrivileges_Zone_Unix (Assuming all computers managed by the Zone are UNIX) EffectiveUserPrivileges_Zone_Windows (Assuming all computers managed by the Zone are UNIX)
Local users	EffectiveAuthorizedLocalUsers_Computer (A local users' version to the EffectiveAuthorizedUsers_Computer) EffectiveAuthorizedLocalUserPrivileges_Computer (A Local users' version to the EffectiveLoginUserPrivileges_Computer) EffectiveLocalUsersRoleAssignment (A Local users' version to the EffectiveRoleAssignment)

ADComputers View

The ADComputers view lists all Active Directory computers for each monitored domain.

ADComputer_-Account-Enabled	1 – Active Directory computer's account is enabled, 0 – account is disabled

ADComputer_AccountEnabled_Desc	The display value for ADComputer_Role (Yes/No)	
ADComputer_-Canonical-Name	Active Directory computer's canonical name	
ADComputer_CnName	The Active Directory computer's common name.	
ADComputer_-Description	The description to the Active Directory computer	
ADComputer_-Dns-Host-Name	Active Directory computer's dnsHostName	
ADComputer_DomainId	The identification number of the computer's domain.	Domains.Id
ADComputer_Domain-Name	The name of the domain that the Active Directory computer belongs to.	
ADComputer_-GUID	The object GUID of the Active Directory computer	
ADComputer_Location	The Active Directory computer's location.	
ADComputer_ManagerGUID	The hosting Active Directory computer's GUID for the user or group.	
ADComputer_ManagerObjectName	The Active Directory computer's manager object name.	
ADComputer_ManagerType	The type of computer manager. 1=user, 2=group.	
ADComputer_ManagerType_Desc	The description of the Active Directory manager type.	
ADComputer_ObjectName	The object name of the computer, in the format of <computer CN>.<computer domain>.	
ADComputer_-OS	Active Directory computer's operating system	
ADComputer_-Os-Version	Active Directory computer's operating system version	
ADComputer_OU	The OU of the Active Directory computer. It will be null if the computer is not under an OU	
ADComputer_PwdLastChangedTime	The last changed time for Active Directory computer's password (UTC time). This is an approximation only.	
ADComputer_Role	Whether the computer is running as a domain controller or not 1 - workstation role, 2 - domain controller role	
ADComputer_Role_Desc	The display value for ADComputer_Role (Workstation/Domain Controller)	
ADComputer_-Sam-Account-Name	Active Directory computer's samAccountName	
ADComputer_-Time-Created	The creation time of the Active Directory computer (UTC time)	
ADComputer_TrustedDelegate	Allows services to act on behalf of another user.	

Adcomputers Columns Used in Other Views

ADComputer_-GUID	ADGroupComputerMembers.ADComputer_GUID ComputerRoleMembership.ADComputer_GUID ZoneComputers.ZoneComputer_ADComputerId

ADComputers_Stale View

The ADComputers_Stale view lists all stale Active Directory computers for each domain. Computers are considered as stale if the passwords for them haven't changed for 90 or more days.

ADComputer_AccountEnabled	1 – Active Directory computer's account is enabled, 0 – account is disabled	
ADComputer_AccountEnabled_Desc	The display value for ADComputer_Role (Yes/No)	
ADComputer_-Canonical-Name	Active Directory computer's canonical name	
ADComputer_CnName	The Active Directory computer's common name.	
ADComputer_-Description	The description about the Active Directory computer	
ADComputer_DnsHostName	Active Directory computer's dnsHostName	
ADComputer_DomainId	The ID of the computer's domain	Domains.Id
ADComputer_DomainName	The name of the domain which the Active Directory computer belongs to	
ADComputer_GUID	The object GUID of the Active Directory computer	
ADComputer_ObjectName	The object name of the computer, in the format of <computer CN>.<computer domain>.	
ADComputer_OS	Operating system of Active Directory computer	
ADComputer_OsVersion	The operating system version number of the Active Directory computer.	
ADComputer_OU	The OU of the Active Directory computer. It will be null if the computer is not under an OU	
ADComputer_PwdLastChangedTime	The last changed time for Active Directory computer's password (UTC time). This is an approximation only.	
ADComputer_-Role	Whether the computer is running as a domain controller or not 1 - workstation role, 2 - domain controller role	
ADComputer_Role_Desc	The display value for ADComputer_Role (Workstation/Domain Controller)	
ADComputer_SamAccountName	Active Directory computer's samAccountName	
ADComputer_-Time-Created	The creation time of the Active Directory computer (UTC time)	

ADGroupComputerMembers View

The ADGroupComputerMembers lists all computers that are members for each Active Directory group. Nested members are included.

ADComputer_CanonicalName	The canonical name of the Active Directory computer	
ADComputer_CnName	The Active Directory computer's common name.	
ADComputer_DnsHostName	The DNS host name of the Active Directory computer	

ADComputer_GUID	The GUID of the Active Directory computer	ADComputers.ADComputer_GUID
ADComputer_ObjectName	The object name of the computer, in the format of <computer CN>.<computer domain>.	
ADComputer_Os	The operating system name of the Active Directory computer	
ADComputer_OsVersion	The OS version of the Active Directory computer	
ADComputer_SamAccountName	The samAccountName of the Active Directory computer	
ADGroup_CanonicalName	The canonical name of the Active Directory group	
ADGroup_GUID	The GUID of the Active Directory group	ADGroups.GUID
ADGroup_Name	The name of the Active Directory group	
ADGroup_ObjectName	The display name for the Active Directory group, formatted as <group samAccountName>@<domain name>.	

ADGroups View

The ADGroups view lists all Active Directory groups for each domain.

ADGroup_ManagerGUID	The hosting Active Directory computer's GUID for the user or group.	
ADGroup_ManagerObjectName	The object name for the user or group who manages this group.	
ADGroup_ManagerType	The type of object that is the manager for this group. 1=user, 2=group.	
ADGroup_ManagerType_Desc	The description of the Active Directory manager type.	
CanonicalName	Active Directory group's canonical name	
Description	Active Directory group's description	
DomainId	The identification for the domain which the Active Directory group belongs to	Domains.Id
Email	Active Directory group's email	
GroupName	Active Directory group's name	
GUID	The object GUID of the Active Directory group.	
IsBuiltIn	1 – is built in group, 0 – is not built in group	
NTLogonName	The NT logon name (samAccountName) of the Active Directory group	
ObjectName	The display name for the Active Directory group, formatted as <group samAccountName>@<domain name>.	
OU	The OU of the Active Directory group. It is null if the group is not under an OU	

TimeCreated	The creation time of the Active Directory group (UTC time)	
Type	The scope of the Active Directory group 1 - domain local, 2 - global, 3 - universal	

ADGroups columns used in other views

ADGroups.GUID	ADGroupComputerMembers.ADGroup_GUID ADGroupUserMembers.ADGroup_GUID EffectiveZoneGroups.ZoneGroup_ADGroup_GUID ZoneGroups.ZoneGroup_ADGroup_GUID EffectiveUserPrivileges_Computer.Trustee_Id EffectiveUserPrivileges_ComputerRole.Trustee_Id EffectiveUserPrivileges_Zone.Trustee_Id

ADGroupSubGroups View

Lists the Active Directory group and the nested groups, including children groups and grand-children groups.

ParentGroup_CanonicalName	The canonical name of the parent group	
ParentGroup_DomainId	The domainID of the parent group	Domains.Id
ParentGroup_DomainName	The domain name of the parent group	
ParentGroup_GroupType	The group type of the parent group 1-Domain local, 2-Global, 3-Universal	
ParentGroup_GroupTypeDesc	The display value for ParentGroup_GroupType (Domain local/Global/Universal)	
ParentGroup_NTLogonName	The NTLogonName of the parent group	
ParentGroup_ObjectName	The object name of the parent group. The general display value for the AD group in precanned report. Format: < AD group samAccountName > @ < domain Name >	
ParentGroup_ParentGroupGUID	The object GUID of the parent group	ADGroups.GUID
ParentGroup_ParentGroupName	The name of the parent group	
SubGroup_CanonicalName	The canonical name of the sub group	
SubGroup_DomainId	The domainIDof the sub group	Domains.Id
SubGroup_DomainName	The domain name of the sub group	
SubGroup_EffectiveSubGroupGUID	The object GUID of the sub group	ADGroups.GUID
SubGroup_GroupName	The group name of the sub group	
SubGroup_GroupType	The group type of the sub group 1-Domain local, 2-Global, 3-Universal	
SubGroup_GroupTypeDesc	The display value for SubGroup_GroupType (Domain local/Global/Universal)	
SubGroup_NTLogonName	The NTLogon name of the sub group Note: There is also a column with a similar name, SubGroup_NTLogoName, that will be deprecated in a future release.	

SubGroup_ObjectName	The object name of the sub group. The general display value for the AD group in precanned report. Format: <AD group samAccountName>@<domain Name>	

ADGroupUserMembers View

The ADGroupUserMembers view lists all user members for each Active Directory group. Nested members are included.

ADGroup_CanonicalName	The canonical name of the Active Directory group	
ADGroup_GUID	The GUID of the Active Directory group	ADGroups.GUID
ADGroup_Name	The name of the Active Directory group	
ADGroup_ObjectName	The display name for the Active Directory group, formatted as <group samAccountName>@<domain name>.	
ADUser_GUID	The GUID of the Active Directory user	ADUsers.ADUser_GUID
ADUser_Name	The name of the Active Directory user	
ADUser_ObjectName	The object name for the Active Directory user.	
ADUser_SamAccountName	The samAccountName of the Active Directory user	
ADUser_UPN	The upn name of the Active Directory user	

ADUsers View

The ADUsers view lists all Active Directory users for each monitored domain.

ADUser_AccountExpiryDate	The expiration date for the Active Directory user account.	
ADUser_AccountLockedUntil	The date and time until which time that the user's account is locked.	
ADUser_AccountLockedUntil_Desc	The description text string for the ADUser_AccountLockedUntil field.	
ADUser_CannotBeDelegated	Cannot be delegated.	
ADUser_CanonicalName	The canonical name of the Active Directory user	
ADUser_City	The city of the Active Directory user	
ADUser_Company	The company of the Active Directory user	
ADUser_Country	The country of the Active Directory user	
ADUser_CreationTime	The creation time of the Active Directory user	
ADUser_Department	The department of the Active Directory user	
ADUser_Description	The description of the Active Directory user	

ADUser_DialInCallbackNumber	The dialin callback number of the Active Directory user	
ADUser_DialInCallbackOptions	The dialin callback options of the Active Directory user	
ADUser_DialInCallerId	The dialin callerIDof the Active Directory user	
ADUser_DialInStaticIp	The dialin static IP address of the Active Directory user	
ADUser_DialInStaticRoutes	The dialin static routes of the Active Directory user	
ADUser_DisplayName	The display name of the Active Directory user	
ADUser_DomainId	TheIDof the Domain	Domains.Id
ADUser_DomainName	The name of the Domain	
ADUser_Email	The email of the Active Directory user	
ADUser_Enabled	If the Active Directory user account is enabled 1 – Enabled, 0 - Disabled	
ADUser_Enabled_Desc	The description string for the aduser_enabled (Yes / No)	
ADUser_FaxNumbers	The fax numbers of the Active Directory user	
ADUser_FirstName	The first name of the Active Directory user	
ADUser_GUID	The GUID of the Active Directory user	
ADUser_HomePhoneNumbers	The home phone numbers of the Active Directory user	
ADUser_Initials	The initials of the Active Directory user	
ADUser_IpPhoneNumbers	The ip phone numbers of the Active Directory user	
ADUser_IsNeverExpire	Specifies if the user account is set to never expire.	
ADUser_IsNeverExpire_Desc	The description text string for the ADUser_IsNeverExpire column.	
ADUser_JobTitle	The job title of the Active Directory user	
ADUser_LastLogonTime	The last logon time of the Active Directory user	
ADUser_LastName	The last name of the Active Directory user	
ADUser_LogonScriptPath	The logon script path of the Active Directory user	
ADUser_ManagerGUID	The hosting Active Directory user's GUID of the user or group	
ADUser_ManagerObjectName	The Active Directory user's manager object name	
ADUser_ManagerType	The Active Directory user's manager type 1 - User, 2-Group	
ADUser_ManagerType_Desc	The Active Directory user's manager type description (User/Group)	
ADUser_MobilePhoneNumbers	The mobile phone numbers of the Active Directory user	

ADUser_Name	The name of the Active Directory user	
ADUser_ObjectName	The display name for the Active Directory user, formatted as <user samAccountName>@<domain name>.	
ADUser_Office	The office of the Active Directory user	
ADUser_PagerPhoneNumbers	The pager phone numbers of the Active Directory user	
ADUSer_PasswordNeverExpire	Password set to never expire.	
ADUser_PhoneNumbers	The phone numbers of the Active Directory user	
ADUser_PoBox	The post office box address of the Active Directory user.	
ADUser_PostalCode	The postal code (zip code) of the Active Directory user.	
ADUser_PreauthenticationNotRequired	Pre-authentication not required.	
ADUser_PrimaryGroupId	The primary group ID of the Active Directory group.	
ADUser_ProfileHomeFolder	The profile home folder of the Active Directory user	
ADUser_ProfilePath	The profile path of the Active Directory user	
ADUser_PwdLastSetTime	The password last set time of the Active Directory user. This is an approximation only.	
ADUser_PwdStoreUsingReversibleEncryption	Password stored using reversible encryption.	
ADUser_RemoteAccessPermissions	The remote access permissions of the Active Directory user	
ADUser_SamAccountName	The samAccountName of the Active Directory user	
ADUser_SmartCardNeededForLogon	Smart card needed for login.	
ADUser_State	The state of the Active Directory user	
ADUSer_Street	The Active Directory user's street address.	
ADUser_TrustedForDelegation	Trusted for delegation.	
ADUser_Upn	The upn name of the Active Directory user	
ADUser_UseDesEncryption	Uses DES Encryption.	
ADUser_WebPages	The web pages of the Active Directory user	

ADUser Columns Used in Other Views

ADUsers.ADUser_GUID	ADGroupUserMembers.ADUser_GUID EffectiveUserPrivileges_Computer.ADUser_GUID EffectiveUserPrivileges_ComputerRole.ADUser_GUID EffectiveUserPrivileges_Zone.ADUser_GUID EffectiveZoneUsers.ZoneUser_ADUserGUID ZoneUsers.ZoneUser_ADUserGUID EffectiveUserPrivileges_Computer.Trustee_Id EffectiveUserPrivileges_ComputerRole.Trustee_Id EffectiveUserPrivileges_Zone.Trustee_Id

ApplicationRight View

The ApplicationRight view lists the detailed attributes for each application right.

Right_Description	The description of the application right	
Right_FullName	The full name of the right <right name>/<zone name>	
Right_GUID	The GUID of the Right	Rights.Right_GUID
Right_Name	The name of the application right	
Right_Priority	The priority of the application right	
Right_RequireAuthentication	If this right requires authentication 1 – Yes, 0 – No	
Right_RequireAuthentication_Desc	If this right requires authentication (Yes/No)	
Right_RunasUser	Run as the specified AD user	
Right_ZoneId	The Id of the Zone that the Right belongs to	Zones.Zone_Id
Right_ZoneName	The name of the Zone that the Right belongs to	

AutoZoneComputers View

The AutoZoneComputers view lists the computers that are joined to the AutoZone.

ZoneComputer_ADComputerCnName	AD computer's cn name	
ZoneComputer_ADComputerId	The GUID of the AD computer	ADComputers_ADComputer_GUID
ZoneComputer_ADComputerName	AD computer's name	
ZoneComputer_ADComputerObjectName	Format: <AD computer CN>.<AD computer domain> Mainly used by precanned-report	
ZoneComputer_AgentVersion	The agent version of the Auto Zone Computer	
ZoneComputer_ComputerType	The IDof the computer type of the Auto Zone Computer. This value is always 2	
ZoneComputer_ComputerType_Desc	The computer type of the Auto Zone Computer. This value is always 'Unix'	
ZoneComputer_Id	The ID of the Auto Zone Computer	
ZoneComputer_IsOrphan	To identifier if this is an orphan Auto Zone Computer 1 – Yes, 0 – No	
ZoneComputer_IsOrphan_Desc	(Yes/No)	

ZoneComputer_Name	The name of the Auto Zone Computer	
ZoneComputer_ZoneId	The ID of the zone. Always be -1	
ZoneComputer_ZoneName	The name of the zone. The value is always 'Auto Zone'	

CommandRight View

This view lists the detailed attributes for each command right.

Right_AddVar	Comma separated list of environment variable name-value pairs to add	
Right_AllowNested	Nested command execution is allowed or not 1 – Yes, 0 – No	
Right_AllowNested_Desc	The description to the Right_AllowNested (Yes/No)	
Right_Authentication	Type of authentication required to run the command	
Right_DeleteVar	Comma separated list of environment variables to delete in addition to the default set	
Right_Description	The description of the command right	
Right_DzdoRunAsGroup	Comma separated list of groups allowed to run this command using dzdo	
Right_DzdoRunAsUser	Comma separated list of users, uids, groups or gids allowed to run this command using dzdo	
Right_DzshRunas	The user this command will run as under dzsh	
Right_FullName	The full name of the command rights. Format <command right name>/<zone name>	
Right_GUID	The GUID of the command right	Rights.Right_GUID
Right_KeepVar	Comma separated list of environment variables to keep in addition to the default set	
Right_MatchPath	The match path of the command right	
Right_Name	The name of the command right	
Right_Pattern	The pattern of the command right	
Right_PatternType	The type of the command right pattern 0 – Global, 1 – Regular expression	
Right_PatternType_Desc	The description of the type of the command right pattern (Global / Regular expression)	
Right_PreserveGroup	Preserve group membership or not	
Right_Priority	The priority of the command right	
Right_UMask	The umask value used to define who can execute the command	
Right_ZoneId	The ID of the zone that the command right is defined	Zones.Zone_Id
Right_ZoneName	The name of the zone that the command right is defined	

ComputerRoleCustomAttribute View

This view lists the computer role custom attributes.

RoleAssignment_GUID	The computer role's object GUID.	ComputerRoles.ComputerRole_GUID
CustomAttribute_Name	The custom attribute's name.	
CustomAttribute_Value	The custom attribute's value.	

ComputerRoleEffectiveMembers View

This view lists the effective members of a computer role.

ComputerRole_GUID	The GUID of the Computer Role	
ComputerRole_ZoneId	The zone ID where the Computer Role is defined	Zones.Zone_Id
ComputerRole_ComputerRoleName	The name of the Computer Role	
ADComputer_GUID	The object GUID of the Active Directory computer	ADComputes.ADComputer_GUID
ADComputer_DomainId	The ID of the computer's domain	Domains.Id
ADComputer_ObjectName	Format: <AD computer CN>.<AD computer domain> This field is mainly used by the default reports.	
ADComputer_CnName	The Active Directory computer's cnName	
ADComputer_DnsHostName	The DNS host name of the Active Directory computer	
ZoneComputer_Id	The ID of the computer	
ZoneComputer_ZoneId	The ID of the zone that the computer is managed by	Zones.Zone_Id
ZoneComputer_Name	The name of the computer	
ZoneComputer_AgentVersion	The agent version of the computer	
ZoneComputer_Platform	The platform of the computer 1 – Windows, 2 – UNIX	
ZoneComputer_Platform_Desc	The description string of the ZoneComputer_Platform (Windows/UNIX)	
ZoneComputer_IsOrphan	If the computer is orphan 1 – Yes, 0 – No	
ZoneComputer_JoinDate	The date when the computer joined zone (UTC time)	

ComputerRoleMembership View

The ComputerRoleMembership view lists all computer members for each Computer Role. The view includes computers that have been added into the zone.

ADComputer_CnName	The Active Directory computer's common name.	
ADComputer_DnsHostName	The dns host name of the Active Directory Computer	
ADComputer_DomainId	The domain ID of the Active Directory computer	Domains.Id
ADComputer_GUID	The GUID of the Active Directory computer	ADComputes.ADComputer_GUID
ADComputer_ObjectName	The object name of the computer, in the format of <computer CN>.<computer domain>.	
ComputerRole_ComputerRoleName	The name of the Computer Role	
ComputerRole_GUID	The object GUID of the computer role	
ComputerRole_ZoneId	The ID of the zone where this computer role is defined	Zones.Zone_Id
ZoneComputer_AgentVersion	The agent version of the computer	
ZoneComputer_Id	The ID of the computer	
ZoneComputer_IsOrphan	If the computer is orphaned 1 – Yes, 0 – No	
ZoneComputer_JoinDate	The date when the computer joined zone (UTC time)	
ZoneComputer_Name	The name of the computer	
ZoneComputer_Platform	The computer platform 1 – Windows, 2 – Unix	
ZoneComputer_PlatformDesc	The display value of ZoneComputer_Platform (Windows/Unix)	
ZoneComputer_ZoneId	The ID of the zone where the computer is joined to	Zones.Zone_Id

ComputerRoles View

This view lists the computer role information.

ComputerRole_Description	The description of the Computr Role	
ComputerRole_GroupGUID	The GUID of the AD group which the Computer Role monitoring	ADGroups.GUID
ComputerRole_GroupName	The name of the AD group which the Computer Role monitoring	
ComputerRole_GUID	The GUID of the Computer Role	
ComputerRole_Name	The name of the Computer Role	
ComputerRole_ZoneId	The ID of the zone where the Computer Role is defined	Zones.Zone_Id
ComputerRole_ZoneName	The name of the zone where the Computer Role is defined	

DelegationTasks View

This view lists which user, group, computer, or well-known SID have which delegation tasks.

Target	The target in which the Server Suite task is delegated	
Target_DomainId	The domain ID of the target	Domains.Id
Target_GUID	The GUID of the target	
Zone_Id	The zone ID	Zones.Zone_Id
Scope	The scope in which the Server Suite task is delegated	
Scope_Id	The scope ID: 1 - Zone; 2 - UNIX Computer; 3 - WINDOWS Computer; 4 - Computer Role	
Trustee_Name	The trustee name	
Trustee_Type	The trustee type is one of the following: 1 - User; 2 - UNIX computer; 3 - Windows computer; 4 - computer role.	
Trustee_Type_Desc	The description of the trustee type	
Trustee_DomainId	The domain ID of the trustee	Domains.Id
Task_Id	Task Id	DelegationTaskType.Task_Id
Task_Name	Task name	

DelegationTaskType View

This view lists the Server Suite delegation tasks.

Task_Name	Task name	
Task_Id	Task Id	

Domains View

The Domains view lists all monitored domains.

Dc	The domain controller for the monitored domain
DomainName	The name of the monitored domain
Id	The ID of the monitored domain

Domains Columns Used in Other Views

Domains.Id	ADComputers.ADComputer_DomainID ADComputers_Stale.ADComputer_DomainId ADGroups.DomainId ADUsers.ADUser_DomainID ComputerRoleMembership.ADComputer_DomainId RoleAssignments_ComputerRole.RoleAssignment_ZoneDomainId UserAccounts.ADUser_DomainId ZoneRolePrivileges.ZoneRolePrivileges_RightZoneDomainId Zones.Zone_DomainID Zones_Classic.Zone_DomainID Zones_Hierarchical.Zone_DomainID

EffectiveAuthorizedUserPrivilegesSummary View

This view lists effective privileges rights granted to Active Directory users for both hierarchical and classic zones.

ADUser_GUID	The object GUID of the Active Directory user that the user profile refers to.	ADUsers.ADUser_GUID
ZoneComputer_ID	The object GUID ID of the computer profile	ZoneComputers. ZoneComputer_Id
Right_GUID	The GUID of the right	Rights.Right_GUID

EffectiveAuthorizedUserPrivilegesSummary__Hierarchical View

This view lists effective privileges rights granted to Active Directory users for just hierarchical zones.

ADUser_GUID	The object GUID of the Active Directory user that the user profile refers to.	ADUsers.ADUser_GUID
ZoneComputer_ID	The object GUID ID of the computer profile	ZoneComputers. ZoneComputer_Id
Right_GUID	The GUID of the right	Rights.Right_GUID

EffectiveAuthorizedUserPrivilegesSummary_Classic View

This view lists effective privileges rights granted to Active Directory users for just classic zones.

ADUser_GUID	The object GUID of the Active Directory user that the user profile refers to.	ADUsers.ADUser_GUID
ZoneComputer_ID	The object GUID ID of the computer profile	ZoneComputers. ZoneComputer_Id
Right_GUID	The GUID of the right	Rights.Right_GUID

EffectiveAuthorizedLocalUserPrivileges_Computer View

This view lists the authorized local user's effective rights and privileges for each computer.

ADComputer_CanonicalName	The canonical name of the Active Directory computer	
ADComputer_CnName	The cn name of the Active Directory computer	
ADComputer_DnsHostName	The dns host name of the Active Directory computer	
ADComputer_ObjectName	The object name of the Active Directory computer	

Assigned_Location	The display value of the source assignment location	
Assigned_LocationType	The source assignment location	
Assigned_LocationType_Desc	The type of the source assignment location 1 – Zone 2 – Computer 3 – Computer Role	
EffectiveZone_Id	The auto generated ID of the Zone	Zones.Zone_Id
EffectiveZone_Name	The name of the Zone	
LocalUser_Name	The name of the local user	
LocalUser_ProfileState	The profile state of the local user 1 =Enabled, 2 = Disabled, 3 = Removed from /etc/passwd	
LocalUser_ProfileState_Desc	The display value for LocalUser _ProfileState (Enabled/Disabled/Removed from /etc/passwd)	
Right_FullName	The full name of the right. Format in <Right name> / <Right's zone name>	
Right_Grants_Logon	If this right could support a user to logon to a system 1 – Yes, 0 – No	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	The ID of the right platform	
Right_Platform_Desc	The display value of the right platform	
Right_Type	The type ID of the right	RightType.RightTypeId
Right_Type_Desc	The type description of the right	
Role_FullName	The full name of the role. Format in <Role name> / <Role's zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
Trustee_Name	The trustee name of the role assignment	
Trustee_Type	The trustee type ID of the role assignment	TrusteeTypes.TrusteeType_Id
Trustee_Type_Desc	The type description of the trustee	
ZoneComputer_Id	The object GUID ID of the computer profile	ZoneComputers. ZoneComputer_Id

EffectiveAuthorizedLocalUsers_Computer View

This view lists the effective, authorized local users for each computer.

LocalUser_Name	The name of the local user	ZoneLocalUsers.ZoneLocalUser_Name
ZoneComputer_Id	The ID of the zone computer	ZoneComputers.ZoneComputer_Id
LocalUserProfileState	The state of the local user profile, indicated by a number: Enabled Disabled Removed from /etc/passwd	
LocalUser_ProfileState_Desc	The text description of LocalUserProfileState	

EffectiveAuthorizedUserPrivileges_Computer View

This view lists the users who are authorized to log in and the computers that they can log in to. This EffectiveAuthorizedUserPrivileges_Computer view is the same as EffectiveLoginUserPrivilege_Computer View .

EffectiveAuthorizedUsers_Computer View

This view lists the users who can log in and the computers that they can log in to.

ADUser_GUID	The object GUID of the Active Directory user that the user profile refers to.	ADUsers.ADUser_GUID
ZoneComputer_Id	The computer profile's object GUID.	ZoneComputer.ZoneComputer_ID

EffectiveAuthorizedUsers_Computer_Classic View

This view lists the users who can log in and the classic zone computers that they can log in to.

ADUser_GUID	The object GUID of the Active Directory user that the user profile refers to.	ADUsers.ADUser_GUID
ZoneComputer_Id	The computer profile's object GUID.	ZoneComputer.ZoneComputer_ID

EffectiveAuthorizedUsers_Computer_Hierarchical View

This view lists the users who can log in the hierarchical zone computers that they can log in to.

ADUser_GUID	The object GUID of the Active Directory user that the user profile refers to.	ADUsers.ADUser_GUID
ZoneComputer_Id	The computer profile's object GUID.	ZoneComputer.ZoneComputer_ID

EffectiveAuthorizedZoneLocalUsers View

This view lists the effective user profiles for local users who can log in and the computers that they can log in to.

EffectiveZone_Id	The auto generated ID of the Zone	Zones.Zone_Id
EffectiveZone_Name	The name of the Zone	

EffectiveZone_DomainId	The domain ID of the Zone	
ZoneLocalUser_Id	The auto generated ID of the local user profile	ZoneLocalUsers. ZoneLocalUser_Id
ZoneLocalUser_Name	The name of the local user profile	
ZoneLocalUser_HomeDirectory	The home directory of the local user profile	
ZoneLocalUser_PrimaryGroupId	The primary group ID of the local user profile	
ZoneLocalUser_PrimaryGroupName	The primary group name of the local user profile	
ZoneLocalUser_Shell	The shell of the local user profile	
ZoneLocalUser_Uid	The UID of the local user profile	
ZoneLocalUser_GECOS	The GECOS of the local user profile	
ZoneLocalUser_ProfileState	The profile state of the local user profile 1 means Enabled, 2 means Disabled, 3 means Removed from /etc/passwd	
ZoneLocalUser_ProfileState_Desc	The display value for ZoneLocalUser_ProfileState (Enabled/Disabled/Removed from /etc/passwd)	
ZoneLocalUser_AssignmentLocation_Type	The type code of the location where the zoned local user is assigned	
ZoneLocalUser_AssignmentLocation_Type_Desc	The display text of the type of the location where the zoned local user is assigned	
ZoneLocalUser_AssignmentLocation_GUID	The GUID of the location object where the zoned local user is assigned	
ZoneLocalUser_AssignmentLocation_Name	The name of the location object where the zoned local user is assigned	
ZoneComputer_Id	The object GUID of the computer profile	ZoneComputers. ZoneComputer_Id
ADComputer_ObjectName	The object name of the ad computer	
ADComputer_DnsHostName	The DNS host name of the ad computer	
ADComputer_CnName	The CN name of the ad computer	
ADComputer_Os	The operating system of the Active Directory computer	
ADComputer_DomainId	The domain ID of the Active Directory computer	

EffectiveAuthorizedZoneUsers View

This view lists the authorized Active Directory user's effective user profiles for each computer.

EffectiveZone_Id	The auto-generated ID of the Zone	Zones.Zone_Id

EffectiveZone_Name	The name of the Zone	
EffectiveZone_DomainId	The domain ID of the Zone	
ZoneUser_Id	The auto generated ID of the user profile	ZoneUsers. ZoneUser_Id
ZoneUser_Name	The name of the user profile	
ZoneUser_HomeDirectory	The home directory of the user profile	
ZoneUser_PrimaryGroupId	The primary group ID of the user profile	
ZoneUser_PrimaryGroupName	The primary group name of the user profile	
ZoneUser_Shell	The shell of the user profile	
ZoneUser_Uid	The UID of the user profile	
ZoneUser_GECOS	The GECOS of the user profile	
ZoneUser_IsSecondaryProfile	Whether the user profile is a secondary profile or not: 1 – Yes 0 – No	
ZoneUser_IsSecondaryProfile_Desc	The display value for ZoneUser_IsSecondaryProfile (Yes/No)	
ZoneUser_AssignmentLocation_Type	The type code of the location where the zoned user is assigned	
ZoneUser_AssignmentLocation_Type_Desc	The display text of the type of the location where the zoned user is assigned	
ZoneUser_AssignmentLocation_GUID	The GUID of the location object where the zoned user is assigned	
ZoneUser_AssignmentLocation_Name	The name of the location object where the zoned user is assigned	
ADUser_DomainId	The domain ID of the Active Directory user	
ADUser_GUID	The GUID of the ad user	
ADUser_ObjectName	The object name of the Active Directory user	
ZoneComputer_Id	The object GUID ID of the computer profile	ZoneComputers. ZoneComputer_Id
ADComputer_ObjectName	The object name of the Active Directory computer	
ADComputer_DnsHostName	The DNS host name of the Active Directory computer	
ADComputer_CnName	The CN name of the Active Directory computer	
ADComputer_Os	The operating system of the Active Directory computer	
ADComputer_DomainId	The domain ID of the Active Directory computer	

EffectiveDelegationTasks View

This view lists which Active Directory user has which delegation tasks.

Target	The target in which the Server Suite task is delegated	
Target_DomainId	The domain ID of the target	Domains.Id
Target_GUID	The GUID of the target	
Zone_Id	The zone ID	Zones.Zone_Id
Scope	The scope in which the Server Suite task is delegated	
Scope_Id	The scope ID: 1 - Zone; 2 - UNIX Computer; 3 - WINDOWS Computer; 4 - Computer Role	
Trustee_Name	The trustee name	
Trustee_GUID	The GUID of trustee	
Trustee_DomainId	The domain ID of the trustee	Domains.Id
Task_Id	Task Id	DelegationTaskType.Task_Id
Task_Name	Task name	

EffectiveGroupPrivileges_Computer View

This view lists the consolidated role assignments, logon privileges, system rights privileges for each group and computer. This view only lists the role assignments that are assigned to Active Directory groups, and lists the trustee Active Directory groups and nested groups.

ADComputer_CanonicalName	The canonical name of the Active Directory Computer in where the privileges effective	
ADComputer_CnName	The CN name of the Active Directory Computer in where the privileges effective	
ADComputer_DnsHostName	The DNS host name of the Active Directory Computer in where the privileges effective	
ADComputer_ObjectName	The object name of the Active Directory Computer in where the privileges effective	
ADGroup_CanonicalName	The canonical name of the effective assigned Active Directory group	
ADGroup_GUID	The GUID of the effective assigned Active Directory group	ADGroups.GUID
ADGroup_Name	The name of the effective assigned Active Directory group	
ADGroup_ObjectName	The object name of the effective assigned Active Directory group. The format is ‹samAccountName›@‹domain name›	
ADGroup_SamAccountName	The samAccountName of the effective assigned Active Directory group	
Assigned_Location	The name of the assignment location	
Assigned_LocationType	The type of the assignment location 1 – Zone, 2 – Computer, 3 – Computer Role	

Assigned_LocationTypeDesc	The description fo the type of the assignment location (Zone, Computer, Computer Role)	
Computer_Platform	The platform ID of the Active Directory Computer in where the privileges effective 1 – Windows, 2 – UNIX	
Computer_Platform_Desc	The platform description name of the Active Directory Computer in where the privileges effective (Windows/UNIX)	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	
Right_FullName	The full name of the right	
Right_Grants_Logon	If this right could support a user to logon to a system 1 – Yes, 0 – No	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	The platform ID of the right 0 – Windows, 1 – UNIX, 2 – Windows/UNIX	
Right_Platform_Desc	The platform description of the right (Windows, UNIX, Windows/UNIX)	
Right_Type	The type ID of the right	RightType.RightTypeId
Right_Type_Desc	The type description of the right	
Role_FullName	The full name of the role <role name>/<zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
Trustee_Id	The GUID of the Trustee	ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type ID of the trustee type	TrusteeTypes.TrusteeType_Id
Trustee_Type_Desc	The type description of the trustee type	
ZoneComputer_Id	The ID of the Zone Computer in where the privileges effective	ZoneComputer.ZoneComputer_Id

EffectiveLocalUserPrivilegesSummary View

This view lists effective privileges rights granted to local UNIX users for both hierarchical and classic zones.

LocalUser_Name	The name of the local user	ZoneLocalUsers.ZoneLocalUser_Name

LocalUser_ProfileState	The state of the local user profile, indicated by number: Enabled Disabled Removed from /etc/passwd	
LocalUser_ProfileState_Desc	The text description of LocalUser_ProfileState.	
ZoneComputer_Id	The object GUID ID of the computer profile	ZoneComputers. ZoneComputer_Id
Right_GUID	The GUID of the right	Rights.Right_GUID

EffectiveLocalUsersRoleAssignment View

This view lists the effective role assignments for local users for each computer.

Assigned_Location	The name of the assigned location	
Assigned_LocationTypeDesc	The assigned location: zone, computer, or computer role	
LocalUser_Name	The name of the local user	ZoneLocalUsers.ZoneLocalUser_Name
LocalUser_ProfileState	The state of the local user profile, indicated by number: Enabled Disabled Removed from /etc/passwd	
LocalUser_ProfileState_Desc	The text description of LocalUser_ProfileState.	
Role_GUID	The GUID for the role.	Roles.Role_Id
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Name	The trustee name	
Trustee_Type	The type of trustee, indicated by number: Active Directory user Active Directory group Local UNIX user Local UNIX group Local Windows user Local Windows group All Active Directory users All local UNIX users All local Windows users local UNIX UID	
Trustee_Type_Desc	The text description of the Trustee_Type	
ZoneComputer_Id	The ID of the zone computer.	ZoneComputers.ZoneComputer_Id

EffectiveLoginUserPrivilege_Computer View

This view lists the users who can log in and the computers that they can log in to. .

ADComputer_CanonicalName	The canonical name of the AD Computer in where the privileges effective	

ADComputer_CnName	The Cn name of the AD Computer in where the privileges effective	
ADComputer_DnsHostName	The dns host name of the AD Computer in where the privileges effective	
ADComputer_ObjectName	The object name of the AD Computer in where the privileges effective	
ADUser_CanonicalName	The canonical name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_FullName	The full name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_GUID	The GUID of the assigned Active Directory user. It will be null when trustee type = 7	ADUsers.ADUser_GUID
ADUser_Name	The name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_ObjectName	The display name for the Active Directory user, formatted as ‹user samAccountName›@‹domain name›.	
ADUser_SamAccountName	The samAccount name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_Upn	The upn name of the assigned Active Directory user. It will be null when trustee type = 7	
Assigned_Location	The name of the assignment location	
Assigned_LocationType	The type of the assignment location 1 – Zone, 2 – Computer, 3 – Computer Role	
Assigned_LocationTypeDesc	The description fo the type of the assignment location (Zone, Computer, Computer Role)	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	
Right_FullName	The full name of the right	
Right_Grants_Logon	If this right could support a user to logon to a system 1 – Yes, 0 – No	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	The platform ID of the right 0 – Windows, 1 – UNIX, 2 – Windows/UNIX	
Right_Platform_Desc	The platform description of the right (Windows, UNIX, Windows/UNIX)	

Right_Type	The type ID of the right	RightType.RightTypeId
Right_Type_Desc	The type description of the right	
Role_FullName	The full name of the role <role name>/<zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
Trustee_ID	The ID of the Trustee	Trustee_Type = 1: ADUsers.ADUser_GUID Trustee_Type = 2: ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type ID of the trustee type	TrusteeTypes.TrusteeType_Id
Trustee_Type_Desc	The type description of the trustee type	
ZoneComputer_Id	The ID of the Zone Computer in where the privileges effective	ZoneComputer.ZoneComputer_Id

EffectiveRoleAssignment View

This view lists all effective role assignments for each user and for each computer.

ADUser_GUID	The object GUID of the AD user which the user profile referring to.	ADUsers.ADUser_GUID
Assigned_Location	The source assignment location	
Assigned_LocationType	The type of the source assignment location 1 – Zone 2 – Computer 3 – Computer Role	
Assigned_LocationType_Desc	The display value of the source assignment location	
Role_GUID	The object GUID ID of the role	Roles.Role_Id
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Id	The trustee ID of the role assignment	
Trustee_Name	The trustee name of the role assignment	
Trustee_Type	The trustee type ID of the role assignment	TrusteeTypes.TrusteType_Id
Trustee_Type_Desc	The type description of the trustee	
ZoneComputer_Id	The object GUID ID of the computer profile	ZoneComputer.ZoneComputer_Id

EffectiveRoleAssignment_Classic View

This view lists all effective role assignments in classic zones for each user and for each computer.

ADUser_GUID	The object GUID of the AD user which the user profile referring to.	ADUsers.ADUser_GUID
Assigned_Location	The source assignment location	
Assigned_LocationType	The type of the source assignment location 1 – Zone 2 – Computer 3 – Computer Role	
Assigned_LocationType_Desc	The display value of the source assignment location	
Role_GUID	The object GUID ID of the role	Roles.Role_Id
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Id	The trustee ID of the role assignment	
Trustee_Name	The trustee name of the role assignment	
Trustee_Type	The trustee type ID of the role assignment	TrusteeTypes.TrusteType_Id
Trustee_Type_Desc	The type description of the trustee	
ZoneComputer_Id	The object GUID ID of the computer profile	ZoneComputer.ZoneComputer_Id

EffectiveRoleAssignment_Hierarchical View

This view lists all effective role assignments in hierarchical zones for each user and for each computer.

ADUser_GUID	The object GUID of the AD user which the user profile referring to.	ADUsers.ADUser_GUID
Assigned_Location	The source assignment location	
Assigned_LocationType	The type of the source assignment location 1 – Zone 2 – Computer 3 – Computer Role	
Assigned_LocationType_Desc	The display value of the source assignment location	
Role_GUID	The object GUID ID of the role	Roles.Role_Id
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	

RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Id	The trustee ID of the role assignment	
Trustee_Name	The trustee name of the role assignment	
Trustee_Type	The trustee type ID of the role assignment	TrusteeTypes.TrusteType_Id
Trustee_Type_Desc	The type description of the trustee	
ZoneComputer_Id	The object GUID ID of the computer profile	ZoneComputer.ZoneComputer_Id

EffectiveRolePrivileges_Computer View

This view lists the consolidated role assignments, logon privileges, system rights privileges for each computer. This view does not expand the trustee to individual Active Directory users.

ADComputer_CanonicalName	The canonical name of the AD Computer in where the privileges effective	
ADComputer_CnName	The Cn name of the AD Computer in where the privileges effective	
ADComputer_DnsHostName	The dns host name of the AD Computer in where the privileges effective	
ADComputer_ObjectName	The object name of the AD Computer in where the privileges effective	
Assigned_Location	The name of the assignment location	
Assigned_LocationType	The type of the assignment location 1 – Zone, 2 – Computer, 3 – Computer Role	
Assigned_LocationTypeDesc	The description fo the type of the assignment location (Zone, Computer, Computer Role)	
Computer_Platform	The platform ID of the AD Computer in where the privileges effective 1 – Windows, 2 – UNIX	
Computer_Platform_Desc	The platform description name of the AD Computer in where the privileges effective (Windows/UNIX)	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	
Right_Description	The description of the right.	
Right_FullName	The full name of the right	
Right_Grants_Logon	If this right could support a user to logon to a system 1 – Yes, 0 – No	

Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	The platform ID of the right 0 – Windows, 1 – UNIX, 2 – Windows/UNIX	
Right_Platform_Desc	The platform description of the right (Windows, UNIX, Windows/UNIX)	
Right_Type	The type ID of the right	RightType.RightTypeId
Right_Type_Desc	The type description of the right	
Role_FullName	The full name of the role <role name>/<zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
Trustee_GUID	The GUID of the Trustee	Trustee_Type = 1: ADUsers.ADUser_GUID Trustee_Type = 2: ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type ID of the trustee type	TrusteeTypes.TrusteeType_Id
Trustee_Type_Desc	The type description of the trustee type	
ZoneComputer_Id	The ID of the Zone Computer in where the privileges effective	ZoneComputer.ZoneComputer_Id

EffectiveSysRights View

This view lists the effective system rights in hierarchical zones for each user and for each computer.

ADUser_GUID	The object GUID of the AD user which the user profile referring to.	ADUsers.ADUser_GUID
ZoneComputer_Id	The object GUID ID of the computer profile	ZoneComputer.ZoneComputer_Id
-Audit-Level	The role's audit level (It will be null for classic zone's role) 0 – audit not required, 1 – audit if possible, 2 – audit required	
AuditLevel_Desc	The display value of Role_AuditLevel (It will be null for classic zone's role) (Audit not Required/Audit if Possible/Audit required)	
Always-Permit-Logon	(It will be null for classic zone's role) 1 – always permit, 0 – not always permit	
AlwaysPermitLogon_Desc	The display value of -Always-Permit-Logon (It will be null for classic zone's role) (Always permit/Not always permit)	
AllowPasswordLogon	Allow Password Logon 0 – No, 1 – Yes, Null – N/A	

AllowPasswordLogon_Desc	The display value of AllowPasswordLogon (No, Yes, N/A)	
AllowPsRemoteAccess	Allow PowerShell remote access 0 - No, 1- Yes, Null - N/A	
AllowPsRemoteAccess_Desc	The display value of AllowPsRemoteAccess (No, Yes, N/A)	
AllowNonPasswordLogon	Allow Non Password Logon 0 – No, 1 – Yes, Null – N/A	
AllowNonPasswordLogon_Desc	The display value of AllowNonPasswordLogon (No, Yes, N/A)	
AllowConsoleLogon	Allow Console Logon 0 – No, 1 – Yes, Null – N/A	
AllowConsoleLogon_Desc	The display value of AllowConsoleLogon (No, Yes, N/A)	
AllowRemoteLogon	Allow Remote Logon 0 – No, 1 – Yes, Null – N/A	
AllowRemoteLogon_Desc	The display value of AllowRemoteLogon (No, Yes, N/A)	
HasVisibleRight	Has Visible Right 0 – No, 1 – Yes, Null – N/A	
HasVisibleRight_Desc	The display value of HasVisibleRight (No, Yes, N/A)	
IgnoreDisabled	If this user has 'ignore disabled' right on this computer 0 – No, 1 – Yes, Null – N/A	
IgnoreDisabled_Desc	The display value of IgnoreDisabled (No, Yes, N/A)	

EffectiveUserPrivileges_Computer View

The EffectiveUserPrivileges_Computer view lists consolidated role assignments, logon privileges, and system rights' privileges for each user and computer.

ADComputer_CanonicalName	The canonical name of the computer	
ADComputer_CnName	The Active Directory computer's common name.	
ADComputer_DnsHostName	The DNS host name of the computer	
ADComputer_ObjectName	The object name of the computer, in the format of <computer CN>.<computer domain>.	
ADUser_CanonicalName	The canonical name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_FullName	The full name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_GUID	The GUID of the assigned Active Directory user. It will be null when trustee type = 7	ADUsers.ADUser_GUID
ADUser_Name	The name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_ObjectName	The display name for the Active Directory user, formatted as <user samAccountName>@<domain name>.	

ADUser_SamAccountName	The samAccount name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_Upn	The upn name of the assigned Active Directory user. It will be null when trustee type = 7	
Assigned_Location	The name of the source assignment location. It might be the zone name, computer dns host name or Computer Role name, depends on the location type	
Assigned_LocationType	The type of the source assignment location 1 – Zone 2 – Computer 3 – Computer Role	
Assigned_LocationTypeDesc	The display value of the source assignment location Zone Computer Computer Role	
Effective_AllowConsoleLogon	If this user has 'console logon' right on this computer 0 – No, 1 – Yes, Null – N/A	
Effective_AllowLogon	If this user can logon this computer	
Effective_AllowNonPasswordLogon	If this user has 'non password logon' right on this computer 0 – No, 1 – Yes, Null – N/A	
Effective_AllowNonRestrictedShell	If this user has 'non restricted Shell' right on this computer 0 – No, 1 – Yes, Null – N/A	
Effective_AllowPasswordLogon	If this user has 'password logon' right on this computer 0 – No, 1 – Yes, Null – N/A	
Effective_AllowPsRemoteAccess	If this user has the 'PowerShell Remote Access' right on this computer 0 - No; 1 - Yes; Null - N/A	
Effective_AllowRemoteLogon	If this user has 'remote logon' right on this computer 0 – No, 1 – Yes, Null – N/A	
Effective_AuditLevel	The human readable text of the effective audit level for this user on this computer 0 – Audit not required, 1 –Audit if possible, 2 – Audit required	
Effective_CloudAuthorizationRequired	If this user has 'Cloud authorization required' right on this computer 0 – No, 1 – Yes, Null – N/A	
Effective_HasRescueRight	If this role grants 'rescue' right to this user on this computer 0 – No, 1 – Yes	
Effective_HasVisibleRight	Specifies if the user is visible on this computer	
Effective_IgnoreDisabled	If this user has 'ignore disabled' right on this computer 0 – No, 1 – Yes, Null – N/A	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id Zones_Hierarchical.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	

Grants_AuditLevel	If this role grants the effective Audit level 0 – Audit not required, 1 – Audit if possible, 2 – Audit required Given the Effective AuditLevel is 0 If this roles's AuditLevel equals to the Effective Audit Level, then this column is 1 – Yes, Otherwise, 0 -- No	
Grants_CloudAuthorizationRequired	If this role grants 'Cloud authorization required' right to this user on this computer 0 – No, 1 – Yes, Null – N/A	
Grants_ConsoleLogon	If this role grants 'console logon' right to this user on this computer 0 – No, 1 – Yes, Null – N/A	
Grants_HasVisibleRight	Specifies if the role grants the visible right to this user on this computer.	
Grants_IgnoreDisabled	If this role grants 'ignore disabled' right to this user on this computer 0 – No, 1 – Yes, Null – N/A	
Grants_Logon	If this role grants logon	
Grants_NonPasswordLogon	If this role grants 'non password logon' right to this user on this computer 0 – No, 1 – Yes, Null – N/A	
Grants_NonRestrictedShell	If this role grants 'non restricted Shell' right to this user on this computer 0 – No, 1 – Yes, Null – N/A	
Grants_PasswordLogon	If this role grants 'password logon' right to this user on this computer 0 – No, 1 – Yes, Null – N/A	
Grants_PsRemoteAcccess	If this role grants the 'PowerShell Remote Access' right to this user on this computer 0 - No; 1 - Yes; Null - N/A	
Grants_RemoteLogon	If this role grants 'remote logon' right to this user on this computer 0 – No, 1 – Yes, Null – N/A	
Grants_RescueRight	If this user has 'rescue' right on this computer 0 – No, 1 – Yes	
Right_FullName	The full name of the right. Format in <Right name> / <Right's zone name>	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	Whether the right applies to windows, unix or both.	
Right_Platform_Desc	The display value of the right platform	
Right_Type	The ID of the right type	RightType.RightTypeId
Right_Type_Desc	The display value of the right type (see RightTypes view)	
Role_FullName	The full name of the role. Format in <Role name> / <Role's zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	

RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
Trustee_Id	The GUID of the trustee	Trustee_Type = 1: ADUsers.ADUser_GUID Trustee_Type = 2: ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type of the trustee 1 – Active Directory users 2 – Active Directory groups 7 – All Active Directory users	
Trustee_Type_Desc	The display value of the trustee Active Directory users Active Directory groups All Active Directory users	
ZoneComputer_Id	The zone computer ID	ZoneComputer.ZoneComputer_Id

EffectiveUserPrivileges_ComputerRole_UNIX View

The EffectiveUserPrivileges_ComputerRole_UNIX view lists effective computer role level role assignments for each user. This view assumes that all computers within the computer role are UNIX computers. The assigned Active Directory users must have at least one completed profile in the zone where the computer role is defined. Assignee "All Active Directory users" will be expanded to Active Directory users.

ADUser_CanonicalName	The canonical name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_FullName	The full name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_GUID	The GUID of the assigned Active Directory user. It will be null when trustee type = 7	ADUsers.ADUser_GUID
ADUser_Name	The name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_ObjectName	The general display value for the Active Directory use in the default report. The format is <Active Directory samAccountName>@<domain name>.	
ADUser_SamAccountName	The samAccount name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_Upn	The upn name of the assigned Active Directory user. It will be null when trustee type = 7	
Assigned_Location	The name of the source assignment location. For this view, it will be always the Computer Role name	
Assigned_LocationType	The type of the source assignment location 3 – Computer Role	
Assigned_LocationTypeDesc	The display value of the source assignment location Computer Role	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id Zones_Hierarchical.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	

Right_FullName	The full name of the right. Format in <Right name> / <Right's zone name>	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	The ID of the right platform	
Right_Platform_Desc	The display value of the right platform	
Right_Type	The ID of the right type	RightType.RightTypeId
Right_Type_Desc	Whether this right is for Unix, Windows or both	
Role_FullName	The full name of the role. Format in <Role name> / <Role's zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Id	The GUID of the trustee	If Trustee_Type = 1: ADUsers.ADUser_GUID If Trustee_Type = 2: ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type of the trustee 1 – Active Directory users 2 – Active Directory groups 7 – All Active Directory users	TrusteeTypes.TrusteeType_Id
Trustee_Type_Desc	The display value of the trustee Active Directory users Active Directory groups All Active Directory users	

Note: Assigned_LocationType and Assigned_LocationTypeDesc might be removed in subsequent release.

EffectiveUserPrivileges_ComputerRole_Windows View

The EffectiveUserPrivileges_ComputerRole_Windows view lists effective computer role level role assignments for each user. This view assumes that all computers within the computer role are Windows computers. Assignee "All Active Directory users" are NOT expanded to Active Directory users.

ADUser_CanonicalName	The canonical name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_FullName	The full name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_GUID	The GUID of the assigned Active Directory user. It will be null when trustee type = 7	ADUsers.ADUser_GUID

ADUser_Name	The name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_ObjectName	The general display value for the Active Directory use in the default report. The format is <Active Directory samAccountName>@<domain name>.	
ADUser_SamAccountName	The samAccount name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_Upn	The upn name of the assigned Active Directory user. It will be null when trustee type = 7	
Assigned_Location	The name of the source assignment location. For this view, it will be always the Computer Role name	
Assigned_LocationType	The type of the source assignment location 3 – Computer Role	
Assigned_LocationTypeDesc	The display value of the source assignment location Computer Role	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id Zones_Hierarchical.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	
Right_FullName	The full name of the right. Format in <Right name> / <Right's zone name>	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	The ID of the right platform	
Right_Platform_Desc	The display value of the right platform	
Right_Type	The ID of the right type	RightType.RightTypeId
Right_Type_Desc	Whether this right is for Unix, Windows or both	
Role_FullName	The full name of the role. Format in <Role name> / <Role's zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Id	The GUID of the trustee	If Trustee_Type = 1: ADUsers.ADUser_GUID If Trustee_Type = 2: ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type of the trustee 1 – Active Directory users 2 – Active Directory groups 7 – All Active Directory users	TrusteeTypes.TrusteeType_Id

Trustee_Type_Desc	The display value of the trustee Active Directory users Active Directory groups All Active Directory users	

EffectiveUserPrivileges_Zone_UNIX View

The EffectiveUserPrivileges_Zone view lists effective zone level role assignments for each user. This view assumes that all computers in the zone are UNIX computers. The assigned Active Directory users must have at least one completed profile in the zone. Assignee "All Active Directory users" is expanded to Active Directory users.

ADUser_CanonicalName	The canonical name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_FullName	The full name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_GUID	The GUID of the assigned Active Directory user. It will be null when trustee type = 7	ADUsers.ADUser_GUID
ADUser_Name	The name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_ObjectName	The display value for the Active Directory in the default report. The format is <Active Directory samAccountName>@<domain name>.	
ADUser_SamAccountName	The samAccount name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_Upn	The upn name of the assigned Active Directory user. It will be null when trustee type = 7	
Assigned_Location	The name of the the source assignment location. For this view, it will be always the same as the EffectiveZone_Name	
Assigned_LocationType	The type of the source assignment location 1 – Zone	
Assigned_LocationTypeDesc	The display value of the source assignment location Zone	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	
Right_FullName	The full name of the right. Format in <Right name> / <Right's zone name>	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	Whether this right is for Unix, Windows or both	
Right_Platform_Desc	The display value of the right platform	
Right_Type	The ID of the right type	RightType.RightTypeId

Right_Type_Desc	The display value of the right type	
Role_FullName	The full name of the role. Format in <Role name> / <Role's zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Id	The GUID of the trustee	if Trustee_Type = 1: ADUsers.ADUser_GUID If Trustee_Type = 2: ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type of the trustee 1 – Active Directory users 2 – Active Directory groups 7 – All Active Directory users	TrusteeTypes.TrusteeType_Id
Trustee_Type_Desc	The display value of the trustee: Active Directory users Active Directory groups All Active Directory users	

Note: Assigned_LocationType and Assigned_LocationTypeDesc may be removed in a subsequent release.

EffectiveUserPrivileges_Zone_Windows View

This view lists the effective role assignments for each user, assuming that all computers within the zone are Windows computers. Assignee "All Active Directory users" is NOT expanded to Active Directory users.

ADUser_CanonicalName	The canonical name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_FullName	The full name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_GUID	The GUID of the assigned Active Directory user. It will be null when the trustee type = 7	ADUsers.ADUser_GUID
ADUser_Name	The name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_ObjectName	The display value for the Active Directory in the default report. The format is <Active Directory samAccountName>@<domain name>.	
ADUser_SamAccountName	The samAccount name of the assigned Active Directory user. It will be null when trustee type = 7	
ADUser_Upn	The UPN name of the assigned Active Directory user. It will be null when trustee type = 7	

Assigned_Location	The name of the the source assignment location. For this view, it will be always the same as the EffectiveZone_Name	
Assigned_LocationType	The type of the source assignment location 1 – Zone	
Assigned_LocationTypeDesc	The display value of the source assignment location Zone	
EffectiveZone_Id	The ID of the effective zone for the privilege assignment	Zones.Zone_Id
EffectiveZone_Name	The name of the effective zone for the privilege assignment	
Right_FullName	The full name of the right. Format in <Right name> / <Right's zone name>	
Right_GUID	The GUID of the right	Rights.Right_GUID
Right_Name	The name of the right	
Right_Platform	Whether this right is for Unix, Windows or both	
Right_Platform_Desc	The display value of the right platform	
Right_Type	The ID of the right type	RightType.RightTypeId
Right_Type_Desc	The display value of the right type	
Role_FullName	The full name of the role. Format in <Role name> / <Role's zone name>	
Role_GUID	The GUID of the role	Roles.Role_Id
Role_Name	The name of the role	
RoleAssignment_GUID	The object GUID of the role assignment	RoleAssignments.RoleAssignment_GUID
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Trustee_Id	The GUID of the trustee	if Trustee_Type = 1: ADUsers.ADUser_GUID If Trustee_Type = 2: ADGroups.ADGroup_GUID
Trustee_Name	The name of the trustee	
Trustee_Type	The type of the trustee 1 – Active Directory users 2 – Active Directory groups 7 – All Active Directory users	TrusteeTypes.TrusteeType_Id
Trustee_Type_Desc	The display value of the trustee: Active Directory users Active Directory groups All Active Directory users	

EffectiveZoneGroups View

The EffectiveZoneGroups view lists effective group profiles for each computer and zone.

ZoneGroup_ADGroupGUID	The object GUID of the Active Directory group which the group profile referring to.	ADGroups.GUID
ZoneGroup_AssignmentLocation_GUID	The object GUID of the assignment location	
ZoneGroup_AssignmentLocation_Name	The name of the assignment location	
ZoneGroup_AssignmentLocation_Type	The type code of the assignment location type 1 – Zone, 2 – Computer	
ZoneGroup_AssignmentLocation_TypeDesc	(zone/Computer)	
ZoneGroup_Gid	The GID of the group profile	
ZoneGroup_Id	The auto generated ID of the group profile	ZoneGroups.ZoneGroup_Id
ZoneGroup_Name	The UNIX name of the group	
ZoneGroup_ZoneComputerId	The ID of the computer where the group profile is effective	ZoneComputers.ZoneComputer_Id
ZoneGroup_ZoneId	The ID of the zone where the group profile is defined	Zones.Zone_Id

EffectiveZoneLocalGroupMembers View

This view lists the effective local group members for each computer and zone.

ZoneLocalGroup_ZoneId	The ID of the zone where the local group profile under	Zones.Zone_Id
ZoneLocalGroup_ZoneComputerId	The ID of the computer profile where the local group profile effective in	ZoneComputers.ZoneComputer_Id
ZoneLocalGroup_Name	The UNIX name of the local group	
ZoneLocalGroup_MemberName	The name of the local group's member	
ZoneLocalGroup_AssignmentLocation_Type	The type code of the assignment location type 1 – Zone, 2 – Computer	
ZoneLocalGroup_AssignmentLocation_TypeDesc	(zone/Computer)	
ZoneLocalGroup_AssignmentLocation_GUID	The object GUID of the assignment location	
ZoneLocalGroup_AssignmentLocation_Name	The name of the assignment location	

EffectiveZoneLocalGroups View

This view lists the effective local group profiles for each computer and zone.

ZoneLocalGroup_Id	The auto generated ID of the local group profile	ZoneLocalGroups.ZoneLocalGroup_Id
ZoneLocalGroup_ZoneId	The ID of the zone where the local group profile under	Zones.Zone_Id

ZoneLocalGroup_ZoneComputerId	The ID of the computer profile where the local group profile effective in	ZoneComputers.ZoneComputer_Id
ZoneLocalGroup_Name	The UNIX name of the group	
ZoneLocalGroup_Gid	The GID of the local group profile	
ZoneLocalGroup_ProfileState	The profile state of the local group profile 1 = Enabled, 3 = Removed from /etc/group	
ZoneLocalGroup_ProfileState_Desc	The display value for ZoneLocalGroup_ProfileState (Enabled/Removed from /etc/group)	
ZoneLocalGroup_IsCompleteProfile	To indicate if this profile was a complete profile 1 – Yes, 0 - No	
ZoneLocalGroup_IsCompleteProfile_Desc	The description to the ZoneLocalGroup_IsCompleteProfile (Yes/No)	
ZoneLocalGroup_AssignmentLocation_Type	The type code of the assignment location type 1 – Zone, 2 – Computer	
ZoneLocalGroup_AssignmentLocation_TypeDesc	(zone/Computer)	
ZoneLocalGroup_AssignmentLocation_GUID	The object GUID of the assignment location	
ZoneLocalGroup_AssignmentLocation_Name	The name of the assignment location	

EffectiveZoneLocalUsers View

This view lists the effective local user profiles for each computer and zone.

ZoneLocalUser_Id	The auto generated ID of the local user profile	ZoneLocalUsers.ZoneLocalUser_Id
ZoneLocalUser_ZoneId	The ID of the zone where the local user profile under	Zones.Zone_Id
ZoneLocalUser_ComputerProfileId	The name of the zone where the local user profile under	ZoneComputers.ZoneComputer_Id
ZoneLocalUser_HomeDirectory	The local user profile's home directory	
ZoneLocalUser_Name	The local user profile's unix name	
ZoneLocalUser_PrimaryGroupId	The local user profile's primary group id	
ZoneLocalUser_PrimaryGroupName	The local user profile's primary group name	
ZoneLocalUser_GECOS	The local user profile's GECOS	
ZoneLocalUser_Shell	The local user profile's shell	
ZoneLocalUser_Uid	The local user profile's UID	
ZoneLocalUser_ProfileState	The profile state of the local user 1= Enabled, 2 = Disabled, 3 = Removed from /etc/passwd	

ZoneLocalUser_ProfileState_Desc	The display value for ZoneLocalUser_ProfileState (Enabled/Disabled/Removed from /etc/passwd)	
ZoneLocalUser_IsCompleteProfile	To indicate if this profile was a complete profile 1 – Yes, 0 - No	
ZoneLocalUser_IsCompleteProfile_Desc	The description to the ZoneLocalUser_ IsCompleteProfile (Yes/No)	
ZoneLocalUser_AssignmentLocation_Type	The type code of the location where the zoned user is assigned	
ZoneLocalUser_AssignmentLocation_TypeDesc	The display text of the type of the location where the zoned local user is assigned	
ZoneLocalUser_AssignmentLocation_GUID	The GUID of the location object where the zoned local user is assigned	
ZoneLocalUser_AssignmentLocation_Name	The name of the location object where the zoned local user is assigned	

EffectiveZoneLocalWinGroupMembers View

This view lists the effective local Windows group members for each computer and zone.

ZoneLocalGroup_ZoneId	The ID for the zone that contains the local Windows group profile	Zones.Zone_Id
ZoneLocalGroup_ZoneComputerId	The ID of the computer profile where the local Windows group profile is effective	ZoneComputers.ZoneComputer_Id
ZoneLocalGroup_Name	The name of the local Windows group	
ZoneLocalGroup_MemberName	The name of the local Windows group's member	
ZoneLocalGroup_AssignmentLocation_Type	The type code of the assignment location type 1 – Zone, 2 – Computer	
ZoneLocalGroup_AssignmentLocation_TypeDesc	The display value for ZoneLocalGroup_AssignmentLocation_Type (zone/Computer)	
ZoneLocalGroup_AssignmentLocation_GUID	The object GUID of the assignment location	
ZoneLocalGroup_AssignmentLocation_Name	The name of the assignment location	

EffectiveZoneLocalWinGroups Views

This view lists the effective local Windows group profiles for each computer and zone.

ZoneLocalGroup_Id	The auto-generated ID of the local Windows group profile	ZoneLocalGroups.ZoneLocalGroup_Id
ZoneLocalGroup_ZoneId	The ID of the zone that contains the local Windows group profile	Zones.Zone_Id

ZoneLocalGroup_ZoneComputerId	The ID of the computer profile where the local Windows group profile is effective	ZoneComputers.ZoneComputer_Id
ZoneLocalGroup_Name	The name of the local Windows group	
ZoneLocalGroup_Description	The description of the local Windows group	
ZoneLocalGroup_ProfileState	The profile state of the local Windows group profile 1 = Enabled, 3 = Removed	
ZoneLocalGroup_ProfileState_Desc	The display value for ZoneLocalGroup_ProfileState (Enabled/Removed)	
ZoneLocalGroup_AssignmentLocation_Type	The type code of the assignment location type 1 – Zone, 2 – Computer	
ZoneLocalGroup_AssignmentLocation_TypeDesc	The display value for ZoneLocalGroup_AssignmentLocation_Type(zone/Computer)	
ZoneLocalGroup_AssignmentLocation_GUID	The object GUID of the assignment location	
ZoneLocalGroup_AssignmentLocation_Name	The name of the assignment location	

EffectiveZoneLocalWinUsers View

This view lists the effective local Windows user profiles for each computer and zone.

ZoneLocalUser_Id	The auto-generated ID of the local windows user profile	ZoneLocalUsers.ZoneLocalGroup_Id
ZoneLocalUser_ZoneId	The ID of the zone that contains the local Windows user profile	Zones.Zone_Id
ZoneLocalUser_ComputerProfileId	The ID of the computer profile where the local Windows user profile is effective	ZoneComputers.ZoneComputer_Id
ZoneLocalUser_Name	The name of the local Windows user	
ZoneLocalUser_FullName	The full name of the local Windows user	
ZoneLocalUser_PasswordOption	The password option of the local Windows user	
ZoneLocalUser_Description	The description of the local Windows user	
ZoneLocalUser_ProfileState	The profile state of the local Windows user profile 1 = Enabled, 2 = Disabled, 3 = Removed	
ZoneLocalUser_ProfileState_Desc	The display value for ZoneLocalUser_ProfileState (Enabled/Disabled/Removed)	
ZoneLocalUser_AssignmentLocation_Type	The type code of the assignment location type 1 – Zone, 2 – Computer	
ZoneLocalUser_AssignmentLocation_TypeDesc	The display value for ZoneLocalUser_AssignmentLocation_Type (zone/Computer)	

ZoneLocalUser_AssignmentLocation_GUID	The object GUID of the assignment location	
ZoneLocalUser_AssignmentLocation_Name	The name of the assignment location	

EffectiveZoneUsers View

The EffectiveZoneUsers view lists effective user profiles for each computer and zone,

ZoneUser_ADUserGUID	The object GUID of the Active Directory user which the user profile referring to.	ADUsers.ADUser_GUID
ZoneUser_AssignmentLocation_GUID	The GUID of the location object where the zoned user is assigned	
ZoneUser_AssignmentLocation_Name	The name of the location object where the zoned user is assigned	
ZoneUser_AssignmentLocation_Type	The type code of the location where the zoned user is assigned	
ZoneUser_AssignmentLocation_TypeDesc	The display text of the type of the location where the zoned user is assigned	
ZoneUser_ComputerProfileId	The name of the zone computer where the user profile is effective	ZoneComputers.ZoneComputer_Id
ZoneUser_GECOS	The user profile's GECOS	
ZoneUser_HomeDirectory	The user profile's home directory	
ZoneUser_Id	The auto generated ID of the user profile	ZoneUsers.ZoneUser_Id
ZoneUser_IsCompleteProfile	To indicate if this profile was a complete profile 1 – Yes, 0 - No	
ZoneUser_IsCompleteProfile_Desc	The description string for ZoneUser_ IsCompleteProfile (Yes/No)	
ZoneUser_IsEnabled	To indicate if this profile was enabled. Only available to classic zone's profile. For hierarchical zone profile, it will always be null 1 – Yes, 0 - No	
ZoneUser_IsEnabled_Desc	The description string for ZoneUser_ IsEnabled (Yes/No)	
ZoneUser_IsOrphan	1 – It is an orphan user profile. 0 – It is not an orphan profile 1 – Yes, 0 - No	
ZoneUser_IsOrphan_Desc	The description to the ZoneUser_ IsOrphan (Yes/No)	
ZoneUser_IsSecondaryProfile	To indicate if this profile was a secondary profile 1 – Yes, 0 - No	
ZoneUser_IsSecondaryProfile_Desc	The description string for ZoneUser_IsSecondaryProfile (Yes/No)	
ZoneUser_Name	The user profile's unix name	
ZoneUser_PrimaryGroupId	The user profile's primary group id	
ZoneUser_PrimaryGroupName	The user profile's primary group name	
ZoneUser_Shell	The user profile's shell	

ZoneUser_Uid	The user profile's uid	
ZoneUser_ZoneId	The ID of the zone where the user profile under	Zones.Zone_Id

Rights View

The Rights view lists all rights and system rights defined for each zone.

Grants_Logon	Specifies whether the right allows a user to log on to a computer.	
Right_-Description	The description of the right	
Right_-Full-Name	The full name of the right. The format of the full name is: Right_-Name/Right_ZoneName	
Right_-GUID	The object GUID of the right	
Right_-Type	The ID of the right type 1 – Network Access right 2 – Desktop right 3 – Application right 4 – PAM Access right 5 – SSH right 6 – Command right 7 – Restricted Environment 101 – Allow password logon 102 – Allow non password logon 103 – Ignore disabled 104 – Allow non restricted shell 105 – Allow console logon 106 – Allow remote logon 107 – Always permit logon 108 – Audit level – Not required 109 – Audit level – If possible 110 – Audit level – Required 111 – Cloud Authorization Required	RightType.RightTypeId
Right_Type_Desc	The display value of the right type: Network Access right Desktop right Application right PAM Access right SSH right Command right Restricted Environment Allow password logon Allow non password logon Ignore disabled Allow non restricted shell Allow console logon Allow remote logon Always permit logon Audit level – Not required Audit level – If possible Audit level – Required Cloud Authorization Required	
Right_ZoneId	The zone ID of the right. It will be null for system rights	Zones.Zone_Id
Right_-ZoneName	The zone name of the right. It will be null for system rights	

Rights columns used in other views

Rights.Right_GUID	EffectiveUserPrivileges_Computer.Right_GUID EffectiveUserPrivileges_ComputerRole.Right_GUID EffectiveUserPrivileges_Zone.Right_GUID

RightType View

The RightType view provides the type of rights that are defined in the zone and what operating system platform the type applies to.

Grants_Logon	Specifies if the right can support a user to log on to a system. 0 – No 1 – Yes
RightPlatformId	The platform ID of the right type 0 – Unix 1 – Windows 2 – Unix/Windows
RightTypeDesc	The display value of the right type
RightTypeId	The ID of the right type

RightType columns used in other views

RightType.RightTypeId	EffectiveUserPrivileges_Computer.Right_Type EffectiveUserPrivileges_ComputerRole.Right_Type EffectiveUserPrivileges_Zone.Right_Type Rights.Right_Type ZoneRolePrivileges.ZoneRolePrivileges_RightType

RoleAssignmentCustomAttribute View

This view lists the role assignment's custom attributes.

Role_Id	The role's object GUID.	Roles.Role_Id
CustomAttribute_Name	The custom attribute's name.	
CustomAttribute_Value	The custom attribute's value.	

RoleAssignments View

This view lists the role assignments, based on zones, computer roles, or computers.

RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_GUID	The object GUID of the role assignment	
RoleAssignment_StartTime	The start date and time for the role assignment.	
RoleAssignment_ZoneId	The ID of the zone where the role assignment belongs to	Zones.Zone_Id
RoleAssignment_ZoneName	The name of the zone where the role assignment belongs to	
RoleAssignment_ZoneDomainId	The ID of the domain where the role assignment belongs to	Domains.Id
Assigned_Location	The name of the location where the role assignment is created	
Assigned_LocationType	The type of the location where the role assignment was created 1 - Zone , 2 - Computer, 3 - Computer Role	
Assigned_LocationType_Desc	The type description of the location where the role assignment was created 1 - Zone , 2 - Computer, 3 - Computer Role	
RoleAssignment_TrusteeName	The name of the trustee	
RoleAssignment_TrusteeType	The type of the trustee 1 - AD user 2 - AD group 3 - Local UNIX user 4 - Local UNIX group 5 - Local Windows user 6 - Local Windows group 7 - All AD users 8 - All UNIX user 9 - All Windows users	
RoleAssignment_TrusteeType_Desc	The type description of the trustee	
RoleAssignment_RoleGUID	The object GUID of the assigned role	Roles.Role_Id

RoleAssignment_RoleName	The name of the assigned role	
RoleAssignment_RoleFullName	The full name of the assigned role	
RoleAssignment_Description	The description of the role assignment	

RoleAssignments_Computer View

This view lists the role assignments defined for computers.

RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_GUID	The object GUID of the role assignment	
RoleAssignment_ZoneComputerId	The ID of the zone computer where the role assignment is defined	ZoneComputers.ZoneComputer_Id
RoleAssignment_ADComputer_ObjectName	The name of the zone computer where the role assignment is defined	
RoleAssignment_ADComputer_CnName	The Active Directory computer's CN name of the zone computer where the role assignment is defined	
RoleAssignment_ADComputer_CanonicalName	The Active Directory computer's canonical name of the zone computer where the role assignment is defined	
RoleAssignment_ADComputer_DnsHostName	The Active Directory computer's Dns host name name of the zone computer where the role assignment is defined	
RoleAssignment_StartTime	The start date and time for the role assignment.	
Computer_Platform	The platform of the zone computer where the role assignment is defined 1 - Windows 2 - UNIX	.
Computer_Platform_Desc	The platform description of the zone computer where the role assignment is defined 1 - Windows 2 - UNIX	
RoleAssignment_ZoneId	The ID of the zone where the role assignment belongs	Zones.Zone_Id
RoleAssignment_ZoneName	The name of the zone where the role assignment belongs	
RoleAssignment_ZoneDomainId	The ID of the domain where the role assignment belongs	Domains.Id
RoleAssignment_TrusteeName	The name of the trustee	
RoleAssignment_TrusteeType	The type of the trustee 1 - AD user 2 - AD group 3 - Local UNIX user 4 - Local UNIX group 5 - Local Windows user 6 - Local Windows group 7 - All AD users 8 - All UNIX user 9 - All Windows users	
RoleAssignment_TrusteeType_Desc	The type description of the trustee .	
RoleAssignment_RoleGUID	The object GUID of the assigned role	Roles.Role_Id
RoleAssignment_RoleName	The name of the assigned role	

RoleAssignment_RoleFullName	The full name of the assigned role	
RoleAssignment_Description	The role assignment description	

RoleAssignments_ComputerRole View

The RoleAssignments_Computer Role view lists the role assignments for each computer role.

RoleAssignment_ComputerRoleDescription	The description of the Compute Role	
RoleAssignment_ComputerRoleGUID	The GUID of the Computer Role	
RoleAssignment_ComputerRoleName	The name of the Computer Role	
RoleAssignment_Description	The description of the role assignment	
RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_GUID	The object GUID of the role assignment	
RoleAssignment_RoleFullName	The effective end time of the role assignment	
RoleAssignment_RoleGUID	The GUID of the assigned role	Roles.Role_Id
RoleAssignment_RoleName	The object GUID of the role that is being assigned	
RoleAssignment_StartTime	The start date and time for the role assignment.	
RoleAssignment_TrusteeName	The trustee name of the role assignment	
RoleAssignment_TrusteeType	The trustee type code of the role assignment 1 – Active Directory user 2 – Active Directory group 3 – Local UNIX user 4 – Local UNIX group 5 – Local Windows user 6 – Local Windows group 7 – All Active Directory users 8 – All UNIX user 9 – All Windows users	
RoleAssignment_TrusteeType_Desc	The display value of the trustee type: Active Directory user Active Directory group Local UNIX user Local UNIX group Local Windows user Local Windows group All Active Directory users All UNIX user All Windows users	
RoleAssignment_ZoneDomainId	The zone's domain ID of the role assignment	Domains.Id
RoleAssignment_ZoneId	The zone ID of the role assignment	Zones.Zone_Id

RoleAssignments_Zone View

This view lists the role assignments defined in zones.

RoleAssignment_EndTime	The end date and time for the role assignment.	
RoleAssignment_GUID	The object GUID of the role assignment	

RoleAssignment_StartTime	The start date and time for the role assignment.	
RoleAssignment_ZoneId	The ID of the zone where the role assignment belongs	Zones.Zone_Id
RoleAssignment_ZoneName	The name of the zone where the role assignment belongs	
RoleAssignment_ZoneDomainId	The id of the domain where the role assignment belongs	Domains.Id
RoleAssignment_TrusteeName	The name of the trustee	
RoleAssignment_TrusteeType	The type of the trustee 1 - AD user 2 - AD group 3 - Local UNIX user 4 - Local UNIX group 5 - Local Windows user 6 - Local Windows group 7 - All AD users 8 - All UNIX user 9 - All Windows users	
RoleAssignment_TrusteeType_Desc	The type description of the trustee	
RoleAssignment_RoleGUID	The object GUID of the assigned role	Roles.Role_Id
RoleAssignment_RoleName	The name of the assigned role	
RoleAssignment_RoleFullName	The full name of the assigned role	
RoleAssignment_Description	The description of the role assignment	

RoleCustomAttribute View

This view lists the computer role's custom attributes.

RoleAssignment_GUID	The role assignment's object GUID.	RoleAssignments.RoleAssignment_GUID
CustomAttribute_Name	The custom attribute's name.	
CustomAttribute_Value	The custom attribute's value.	

RoleRights View

This view lists the rights for each role.

Role_GUID	The object GUID ID of the role	Roles.Role_Id
Role_-Name	The name of the role	
Role_-Full-Name	The full name of the role. The format of the full name is: <Role_Name>/<Role_ZoneName>	
Right_GUID	The object GUID of the right	Rights.Right_Id
Right_-Name	The zone name of the right. It will be null for system rights.	
Right_-Full-Name	The full name of the right. The format of the full name is: Right_-Name/Right_ZoneName	
Right_ZoneId	The zone ID of the right. This column is null for system rights.	Zones.Zone_Id

Right_-Type	The ID of the right type 1 – Network Access right 2 – Desktop right 3 – Application right 4 – PAM Access right 5 – SSH right 6 – Command right 7 – Restricted Environment 101 – Allow password logon 102 – Allow non password logon 103 – Ignore disabled 104 – Allow non restricted shell 105 – Allow console logon 106 – Allow remote logon 107 – Always permit logon 108 – Audit level – Not required 109 – Audit level – If possible 110 – Audit level – Required 111 – Cloud Authorization Required	RightType.RightTypeId
Right_Type_Desc	The display value of the right type: Network Access right Desktop right Application right PAM Access right SSH right Command right Restricted Environment Allow password logon Allow non password logon Ignore disabled Allow non restricted shell Allow console logon Allow remote logon Always permit logon Audit level – Not required Audit level – If possible Audit level – Required Cloud Authorization Required	
Right_-Description	The description of the right	
Right_Platform	The platform ID of the right 0 – Windows, 1 – UNIX, 2 – Windows/UNIX	
Right_Platform_Desc	The platform description of the right (Windows, UNIX, Windows/UNIX)	
Right_Grants_Logon	If this right could support a user to logon to a system 1 – Yes, 0 – No	

Roles View

The Roles view lists all roles for each zone. This view is a combined view of the Roles_Classic and Roles_Hierarchical views.

Role_-Always-Permit-Logon	(It will be null for classic zone's role) 1 – always permit, 0 – not always permit	
Role_AlwaysPermitLogon_Desc	The display value of _-Always-Permit-Logon (It will be null for classic zone's role) (Always permit/Not always permit)	
Role_-Audit-Level	The role's audit level (It will be null for classic zone's role) 0 – audit not required, 1 – audit if possible, 2 – audit required	
Role_AuditLevel_Desc	The display value of Role_AuditLevel (It will be null for classic zone's role) (Audit not Required/Audit if Possible/Audit required)	
Role_-Description	The description of the role	
Role_-Full-Name	The full name of the role. The format of the full name is: <Role_Name>/<Role_ZoneName>	
Role_-Id	The object GUID of the role	
Role_-Name	The name of the role	
Role_-Zone-Id	The ID of the zone where the role is defined	Zones.Zone_Id
Role_ZoneName	The name of the zone where the role is defined	

Roles Columns Used In Other Views

Roles.Right_GUID	ZoneRolePrivileges.ZoneRolePrivileges_RightGUID

Roles.Role_Id	EffectiveUserPrivileges_Computer.Role_GUID EffectiveUserPrivileges_ComputerRole.Role_GUID EffectiveUserPrivileges_Zone.Role_GUID RoleAssignments_ComputerRole.RoleAssignment_RoleGUID ZoneRolePrivileges.ZoneRolePrivileges_RoleGUID

Roles_Classic View

The Roles_Classic view lists all roles for each classic zone.

Role_-Always-Permit-Logon	(It will be null for classic zone's role) It is NULL in this view as Audit Level is not applicable in classic zone	
Role_AlwaysPermitLogon_Desc	The display value of Role_-Always-Permit-Logon (It will be null for classic zone's role) It is NULL in this view as Audit Level is not applicable in classic zone	
Role_-Audit-Level	The role's audit level (It will be null for classic zone's role) It is NULL in this view as Audit Level is not applicable in classic zone	
Role_AuditLevel_Desc	The display value of Role_AuditLevel (It will be null for classic zone's role) It is NULL in this view as Audit Level is not applicable in classic zone	
Role_-Description	The description of the role	
Role_-Full-Name	The full name of the role. The format of the full name is: <Role_Name>/<Role_ZoneName>	
Role_-Id	The object GUID of the role	
Role_-Name	The name of the role	
Role_-Zone-Id	The ID of the zone where the role is defined	Zones.Zone_Id
Role_ZoneName	The name of the zone where the role is defined	

Roles_Hierarchical View

The Roles_Hierarchical view lists all roles for each hierarchical zone.

Role_-Always-Permit-Logon	1 – always permit, 0 – not always permit	
Role_AlwaysPermitLogon_Desc	The display value of Role_-Always-Permit-Logon (Always permit/Not always permit)	
Role_-Audit-Level	The role's audit level 0 – audit not required, 1 – audit if possible, 2 – audit required	
Role_AuditLevel_Desc	The display value of Role_AuditLevel (Audit not Required/Audit if Possible/Audit required)	
Role_-Description	The description of the role	
Role_-Full-Name	The full name of the role. The format of the full name is: <Role_Name>/<Role_ZoneName>	
Role_-ID	The object ID of the role	
Role_-Name	The name of the role	

Role_-Zone-Id	The ID of the zone where the role is defined	Zones.Zone_Id
Role_ZoneName	The name of the zone where the role is defined	

TrusteeTypes View

This view lists the role assignment trustee types.

TrusteeType_Id	The type ID of the trustee	
TrusteeType_Desc	The type description of the trustee	

Zone_Classic View

The Zones_Classic view lists all Classic zones.

Zone_AvailableShells	Zone's Available shells	
Zone_CanonicalName	The canonical name of the Zone	
Zone_DefaultGroup	Zone's default group	
Zone_DefaultHomeDirectory	Zone's default home directory	
Zone_DefaultPrimaryGroupId	The default primary group	
Zone_DefaultPrimaryGroupName	The name of the default primary group	
Zone_DefaultShell	Zone's default shell	
Zone_DomainId	The name of the domain which the Active Directory user belongs to	Domains.Id
Zone_DomainName	The ID of the domain which the Active Directory user belongs to	
Zone_Id	The auto generated ID of the Zone	
Zone_IsHierarchical	If the zone was a Hierarchical zone or not 1 – Is Hierarchical Zone, 0 – Classic Zone	
Zone_IsHierarchical_Desc	The display value for Zone_IsHierarchical (Yes/No)	
Zone_IsSFU	If the zone was a SFU zone or not 1 – SFU Zone, 0 – Non SFU Zone	
Zone_IsSFU_Desc	(Yes/No)	
Zone_Name	The name of the Zone	
Zone_NextGID	Zone's next gid	
Zone_NextUID	Zone's next uid	
Zone_NISDomain	Zone's NIS domain	

Zone_ReservedGID	Zone's reserved gid	
Zone_ReservedUID	Zone's reserved uid	
Zone_SFUDomain	Zone's SFU domain	

Zone_Hierarchical View

The Zones_Hierarchical view lists all Hierarchical zones.

Zone_AvailableShells	Zone's Available shells	
Zone_CanonicalName	The canonical name of the Zone	
Zone_DefaultGroup	Zone's default group	
Zone_DefaultHomeDirectory	Zone's default home directory	
Zone_DefaultPrimaryGroupId	The default primary group	
Zone_DefaultPrimaryGroupName	The name of the default primary group	
Zone_DefaultShell	Zone's default shell	
Zone_DomainId	The name of the domain which the Active Directory user belongs to	Domains.Id
Zone_DomainName	The ID of the domain which the Active Directory user belongs to	
Zone_Id	The auto generated ID of the Zone	
Zone_IsHierarchical	If the zone was a Hierarchical zone or not 1 – Is Hierarchical Zone, 0 – Classic Zone	
Zone_IsHierarchical_Desc	The display value for Zone_IsHierarchical 1 – Yes, 0 - No	
Zone_IsSFU	If the zone was a SFU zone or not 1 – SFU Zone, 0 – Non SFU Zone	
Zone_IsSFU_Desc	1 – Yes, 0 - No	
Zone_Name	The name of the Zone	
Zone_NextGID	Zone's next gid	
Zone_NextUID	Zone's next uid	
Zone_NISDomain	Zone's NIS domain	
Zone_ReservedGID	Zone's reserved gid	
Zone_ReservedUID	Zone's reserved uid	
Zone_SFUDomain	Zone's SFU domain	
Zone_TrustedCloudInstanceUrl	Trusted cloud instance URL	

Zones_Hierarchical Columns Used in Other Views

Zones_Hierarchical.Zone_Id	EffectiveUserPrivileges_Computer.EffectiveZone_Id EffectiveUserPrivileges_Computer.ZoneUser_Id EffectiveUserPrivileges_ComputerRole.EffectiveZone_Id

ZoneComputers View

The ZoneComputers view lists computer profiles for each zone.

ZoneComputer_ADComputerCnName	The Active Directory computer's common name.	
ZoneComputer_ADComputerDnsHostName	The Active Directory computer's DNS hostname	
ZoneComputer_ADComputerDomainId	The domain ID of the Active Directory computer which is managed by the zone	
ZoneComputer_ADComputerId	The object GUID of the Active Directory computer which is managed by the zone	ADComputers.ADComputer_GUID
ZoneComputer_ADComputerName	The name of the Active Directory computer which is managed by the zone	
ZoneComputer_ADComputerObjectName	The object name of the computer, in the format of <computer CN>.<computer domain>.	
ZoneComputer_AgentVersion	The agent version of the managed computer	
ZoneComputer_ComputerType	The type of the managed computer 1 – Windows, 2 – Unix	
ZoneComputer_ComputerType_Desc	The display value of the ZoneComputer_ComputerType (Windows/Unix)	
ZoneComputer_Id	The object GUID of the computer profile	
ZoneComputer_IsHierarchical	1 – It is managed by a hierarchical zone, 0 – It is managed by a classic zone	
ZoneComputer_IsHierarchical_Desc	The display value of the ZoneComputer_IsHierarchical (Yes/No)	
ZoneComputer_IsOrphan	1 – It is an orphan profile, 0 – It is not an orphan profile	
ZoneComputer_IsOrphan_Desc	The display value of the ZoneComputer_IsOrphan (Yes/No)	
ZoneComputer_IsZoned	If the computer joined zone 1 – Joined zone, 0 – Only has machine overrides	
ZoneComputer_JoinDate	The date when the managed computer joined zone (UTC time)	

ZoneComputer_LicenseType	Specifies the type of computer license. 1 - Server, 2-Workstation, 3-UNIX, 4-Express	
ZoneComputer_LicenseType_Desc	The description of the license type.	
ZoneComputer_Name	The name of the managed computer	
ZoneComputer_PreferredSite	The preferred site of the computer.	
ZoneComputer_PreferredSubnetSite	The preferred subnet site of the computer.	
ZoneComputer_ZoneDomainId	The domain ID of the zone by which the computer is managed	
ZoneComputer_ZoneId	The ID of the zone by which the computer managed	Zones.Zone_Id
ZoneComputer_ZoneName	The name of the zone by which the computer managed	

ZoneComputer Columns Used in Other Views

ZoneComputer.ZoneComputer_Id	EffectiveUserPrivileges_Computer.ZoneComputer_Id EffectiveZoneGroups.ZoneGroup_ZoneComputerId EffectiveZoneUsers.ZoneUser_ComputerProfileId

ZoneGroups View

The ZoneGroups view lists group profiles for each zone.

ZoneGroup_-ADGroup-GUID	The object GUID of the Active Directory group which the group profile referring to.	ADGroups.GUID
ZoneGroup_ADGroupName	The name of the Active Directory group which the user profile referring to.	
ZoneGroup_-Gid	The group profile's gid	
ZoneGroup_-Id	The auto generated ID of the group profile	
ZoneGroup_IsOrphan	If the zone group referencing to a valid Active Directory group 1 – It is an orphan user profile. 0 – It is not an orphan profile	
ZoneGroup_IsOrphan_Desc	The display value for ZoneGroup_IsOrphan 1 – Yes, 0 – No	
ZoneGroup_-Name	The group profile's name	
ZoneGroup_-Zone-Id	The ID of the zone where the group profile is defined	Zones.Zone_Id
ZoneGroup_ZoneName	The name of the zone where the group profile is defined	

ZoneGroup Columns Used in Other Views

ZoneGroups.ZoneGroup_Id	EffectiveUserPrivileges_Computer.ZoneComputer_Id EffectiveZoneGroups.ZoneGroup_ZoneComputerId EffectiveZoneUsers.ZoneUser_ComputerProfileId	

ZoneHierarchy View

ParentZone_Id	The ID of the parent zone.	Zones.Zone_Id
ParentZone_Name	The name of the parent zone.	
ParentZone_DomainID	The domain ID of the parent zone.	Domains.Id
ChildZone_Id	The ID of the child zone.	Zones.Zone_Id
ChildZone_Name	The name of the child zone.	
ChildZone_DomainId	The domain ID of the child zone.	Domains.Id

ZoneLocalGroupMembers View

This view lists the local group members for each zone.

ZoneLocalGroup_-Id	The auto generated ID of the local group profile	
ZoneLocalGroup_-Zone-Id	The ID of the zone where the local group profile is	Zones.Zone_Id
ZoneLocalGroup_ZoneName	The name of the zone where the local group profile is	
ZoneLocalGroup_-Name	The local group profile's name	
ZoneLocalGroup_MemberName	The name of the local group's member	

ZoneLocalGroups View

This view lists the local group profiles for each zone.

ZoneLocalGroup_-Id	The auto generated ID of the local group profile	
ZoneLocalGroup_-Zone-Id	The ID of the zone where the local group profile is	Zones.Zone_Id
ZoneLocalGroup_ZoneName	The name of the zone where the local group profile is	
ZoneLocalGroup_-Gid	The local group profile's GID	
ZoneLocalGroup_-Name	The local group profile's name	
ZoneLocalGroup_ProfileState	The profile state of the local group profile 1 = Enabled, 3 = Removed from /etc/group	
ZoneLocalGroup_ProfileState_Desc	The display value for ZoneLocalGroup_ProfileState (Enabled/Removed from /etc/group)	

ZoneLocalUsers View

This view lists the local user profiles for each zone.

ZoneLocalUser_Id	The auto generated ID of the local user profile	
ZoneLocalUser_ZoneId	The ID of the zone where the local user profile is	Zones.Zone_Id
ZoneLocalUser_ZoneName	The name of the zone where the local user profile is	
ZoneLocalUser_Name	The local user profile's UNIX name	
ZoneLocalUser_HomeDirectory	The local user profile's home directory	
ZoneLocalUser_PrimaryGroupID	The local user profile's primary group ID	
ZoneLocalUser_PrimaryGroupName	The local user profile's primary group name	
ZoneLocalUser_IsHierarchical	If the zone user was defined in a hierarchical zone or not 1 – It is defined in a hierarchical zone. 0 – Is is defined in a classic zone	
ZoneLocalUser_IsHierarchical_Desc	The display value for ZoneLocalUser_IsHierarchical (Yes/No)	
ZoneLocalUser_Shell	The shell of the zone user	
ZoneLocalUser_GECOS	The GECOS of the zone user	
ZoneLocalUser_Uid	The zone user's uid	
ZoneLocalUser_ProfileFlag	The profile state of the local user 1 means Enabled, 2 means Disabled, 3 means Removed from /etc/passwd	
ZoneLocalUser_ProfileFlag_Desc	The display value for ZoneLocalUser_ProfileState (Enabled/Disabled/Removed from /etc/passwd)	

ZoneLocalWinGroupMembers View

This view lists the local Windows group members for each zone.

ZoneLocalGroup_Id	The auto-generated ID of the local Windows group profile	
ZoneLocalGroup_ZoneId	The ID of the zone that contains the local Windows group profile	Zones.Zone_Id
ZoneLocalGroup_ZoneName	The name of the zone that contains the local Windows group profile	
ZoneLocalGroup_Name	The local Windows group profile's name	
ZoneLocalGroup_MemberName	The name of the local Windows group's member	

ZoneLocalWinGroups View

This view lists the local Windows group profiles for each zone.

ZoneLocalGroup_Id	The auto-generated ID of the local Windows group profile	
ZoneLocalGroup_ZoneId	The ID of the zone that contains the local Windows group profile	Zones.Zone_Id
ZoneLocalGroup_ZoneName	The name of the zone that contains the local Windows group profile	
ZoneLocalGroup_Name	The local Windows group profile's name	
ZoneLocalGroup_ProfileState	The profile state of the local Windows group profile 1 = Enabled, 3 = Removed	
ZoneLocalGroup_ProfileState_Desc	The display value for ZoneLocalGroup_ ProfileState (Enabled/Removed)	

ZoneLocalWinUsers View

This view lists the local Windows user profiles for each zone.

ZoneLocalUser_Id	The auto generated ID of the local Windows user profile	
ZoneLocalUser_ZoneId	The ID of the zone where the local Windows user profile is	Zones.Zone_Id
ZoneLocalUser_ZoneName	The name of the zone where the local Windows user profile is	
ZoneLocalUser_Name	The local Windows user profile's name	
ZoneLocalUser_IsHierarchical	If the zone user was defined in a hierarchical zone or not 1 – It is defined in a hierarchical zone. 0 – It is defined in a classic zone	
ZoneLocalUser_IsHierarchical_Desc	The display value for ZoneLocalUser_IsHierarchical (Yes/No)	
ZoneLocalUser_FullName	The full name of the local Windows user	
ZoneLocalUser_Description	The description of the local Windows user	
ZoneLocalGroup_ProfileFlag	The profile state of the local Windows user profile 1 = Enabled, 2 = Disabled, 3 = Removed	
ZoneLocalGroup_ProfileFlag_Desc	The display value for ZoneLocalUser_ ProfileState (Enabled/Disabled/Removed)	

ZoneRolePrivileges View

The ZoneRolePrivileges view lists the roles that are defined for each zone and the rights that are granted by each of these roles.

ZoneRolePrivileges_RightFullName	The full name of the right	
ZoneRolePrivileges_RightGUID	The GUID of the right	Roles.Right_GUID
ZoneRolePrivileges_RightName	The name of the right	
ZoneRolePrivileges_RightPlatform	Whether the right is for Unix, Windows or both	

ZoneRolePrivileges_RightPlatform_Desc	The display value of the right platform	
ZoneRolePrivileges_RightType	The type ID of the right	RightType.RightTypeId
ZoneRolePrivileges_RightType_Desc	The display value of the right's type	
ZoneRolePrivileges_RightZoneDomainId	The domain ID of the zone of the right	Domains.Id
ZoneRolePrivileges_RightZoneId	The zone ID of the right	Zones.Zone_Id
ZoneRolePrivileges_RightZoneIsHierarchical	If the zone of the right is hierarchical 1 – Yes, 0 – No	
ZoneRolePrivileges_RightZoneIsHierarchical_Desc	The display value of the ZoneRolePrivileges_RightZoneIsHierarchical (Yes/No)	
ZoneRolePrivileges_RightZoneName	The zone name of the right	
ZoneRolePrivileges_RoleFullName	The full name of the role	
ZoneRolePrivileges_RoleGUID	The GUID of the role	Roles.Role_Id
ZoneRolePrivileges_RoleName	The name of the role	
ZoneRolePrivileges_RoleZoneDomainId	The domain ID of the zone of the domain	
ZoneRolePrivileges_RoleZoneId	The zone ID of the role	Zones.Zone_Id
ZoneRolePrivileges_RoleZoneIsHierarchical	If the zone of the role is hierarchical 1 – Yes, 0 – No	
ZoneRolePrivileges_RoleZoneIsHierarchical_Desc	The display value of the ZoneRolePrivileges_RoleZoneIsHierarchical (Yes/No)	
ZoneRolePrivileges_RoleZoneName	The zone name of the role	

Zones View

The Zones view lists all the zones in the domain. This view is a combination of both Zones_Classic and Zones_Hierarchical.

Zone_AvailableShells	Zone's Available shells	
Zone_CanonicalName	The canonical name of the Zone	
Zone_DefaultGIDType	The ID of the default GID type 1—Use the auto-incremented GID 2—Use the generated GID from the SID 3—Use the Apple GID scheme	
Zone_DefaultGIDType_Desc	The description of the default GID type (Use auto-incremented GID, Generated GID from SID, or Use Apple GID scheme)	
Zone_DefaultGroup	Zone's default group	
Zone_DefaultHomeDirectory	Zone's default home directory	
Zone_DefaultPrimaryGroupId	The default primary group	

Zone_DefaultPrimaryGroupName	The name of the default primary group	
Zone_DefaultShell	Zone's default shell	
Zone_DefaultUIDType	The ID of the default UID type (applies to hierarchical zones only) 1—Use auto-incremented UID 2—Generated UID from SID 3—Use Apple UID scheme	
Zone_DefaultUIDType_Desc	The description of the default type. For hierarchical zones, this is one of the following: Use auto-incremented UID, Generated UID from SID, or Use Apple UID scheme. For classic zones: Use auto-incremented UID.	
Zone_DefaultUserName	The description of the zone scheme ID, such as Standard, RFC 2307, or SFU.	
Zone_DomainId	The name of the domain which the Active Directory user belongs to	Domains.Id
Zone_DomainName	The ID of the domain which the Active Directory user belongs to	
Zone_Id	The auto generated ID of the Zone	
Zone_IsHierarchical	If the zone was a Hierarchical zone or not 1 – Is Hierarchical Zone, 0 – Classic Zone	
Zone_IsHierarchical_Desc	If the zone was a Hierarchical zone or not (Yes/No)	
Zone_IsSFU	If the zone was a SFU zone or not 1 – SFU Zone, 0 – Non SFU Zone	
Zone_IsSFU_Desc	If the zone was a SFU zone or not (Yes/No)	
Zone_Name	The name of the Zone	
Zone_NextGID	Zone's next gid	
Zone_NextUID	Zone's next uid	
Zone_NISDomain	Zone's NIS domain	
Zone_ReservedGID	Zone's reserved gid	
Zone_ReservedUID	Zone's reserved uid	
Zone_Schema	The ID of the zone scheme: 1—Standard 2—RFC 2307 3—SFU	
Zone_SFUDomain	Zone's SFU domain	
Zone_Type	The zone type (hierarchical or classic)	
Zone_TrustedCloudInstanceUrl	Trusted cloud instance URL	

Zone view columns used in other views

Roles_Classic.Role_ZoneId ComputerRoleMembership.ComputerRole_ZoneId ComputerRoleMembership.ZoneComputer_ZoneId EffectiveUserPrivileges_Computer.EffectiveZone_Id EffectiveUserPrivileges_ComputerRole.EffectiveZone_Id

ZoneUsers View

The ZoneUsers view lists the user profiles for each zones.

ZoneUser_ADUserGUID	The object GUID of the Active Directory user which the user profile referring to.	ADUsers.ADUser_GUID
ZoneUser_ADUserName	The name of the Active Directory user which the user profile referring to.	
ZoneUser_GECOS	The GECOS of the zone user	
ZoneUser_HomeDirectory	The user profile's home directory	
ZoneUser_Id	The auto generated ID of the user profile	
ZoneUser_IsHierarchical	If the zone user was defined in a hierarchical zone or not 1 – It is defined in a hierarchical zone. 0 – Is is defined in a classic zone	
ZoneUser_IsHierarchical_Desc	The display value for ZoneUser_IsHierarchical (Yes/No)	
ZoneUser_IsOrphan	If the zone user referencing to a valid Active Directory user 1 – It is an orphan user profile. 0 – It is not an orphan profile	
ZoneUser_IsOrphan_Desc	The display value for ZoneUser_IsOrphan (Yes/No)	
ZoneUser_IsSFU	If the zone user was defined in a SFU zone or not 1 – It is defined in a SFU zone. 0 – Is is not defined in a SFU zone	
ZoneUser_IsSFU_Desc	The display value for ZoneUser_IsSFU (Yes/No)	
ZoneUser_Name	The user profile's unix name	
ZoneUser_PrimaryGroupID	The user profile's primary group id	
ZoneUser_PrimaryGroupName	The user profile's primary group name	
ZoneUser_Shell	The shell of the zone user	
ZoneUser_Uid	The zone user's uid	
ZoneUser_UserEnabled	If the zone user is enabled (For classic zone user only, it will be null for Hierarchical zone user) 1 – enabled, 0 – disabled, NULL – not applicable	
ZoneUser_UserEnabled_Desc	(Yes/No)	
ZoneUser_ZoneId	The ID of the zone where the user profile under	Zones.Zone_Id
ZoneUser_ZoneName	The name of the zone where the user profile under

Configuring Report Services for Large Active Directory Environments

Configuration issues can significantly affect the performance of synchronizing Active Directory information and report queries and generation. This section describes additional considerations for deploying Delinea Report Services successfully in a large Active Directory environment.

Memory Recommendations and Requirements for Large Active Directory Environments

Domain Controller Memory

Symptoms

The domain controller runs slower or stops responding.

You can use the Performance monitor tool to evaluate if the system is operating within adequate capacity thresholds.

For details, see: http://social.technet.microsoft.com/wiki/contents/articles/14355.capacity-planning-for-active-directory-domain-services.aspx#Monitoring_For_Compliance_With_Capacity_Planning_Goals

Resolution

Ensure the system has a sufficient amount of RAM. The minimum amount of RAM should be the sum of:

- Active Directory database size (such as the size of the C:\Windows\NTDS\ folder)
- Total SYSVOL size (such as the size of the C:\Windows\SYSVOL folder)
- Operating system recommended amount of RAM
- Vendor recommendations for the agents (antivirus, monitoring, backup, and so on)
- Additional amount of RAM to accommodate growth over the lifetime of the server.

For details, see: http://social.technet.microsoft.com/wiki/contents/articles/14355.capacity-planning-for-active-directory-domain-services.aspx

Windows Memory Requirements

Here are the memory requirements for different versions of Windows:

Windows 2008, 2008 R2	512 MB minimum 2 GB or more is recommended
Windows 2012, 2012 R2	512 MB minimum
Windows 7, 8, 8.1, 10	2 GB minimum for 64-bit systems

References

http://windows.microsoft.com/en-us/windows7/products/system-requirements

http://windows.microsoft.com/en-US/windows-8/system-requirements

http://www.microsoft.com/en-us/windows/windows-10-specifications

https://technet.microsoft.com/en-us/windowsserver/bb414778.aspx

https://technet.microsoft.com/en-us/library/dn303418.aspx

Sql Server Memory

Symptoms

- Delinea Report Services fails to rebuild or refresh a snapshot because of insufficient system memory or an out of memory error.

- You cannot open reports in SSRS because of insufficient system memory or an out of memory error.

Resolution

Ensure that your SQL Server deployment has sufficient memory. Different versions of SQL Server have different memory requirements. For details, please see:

https://msdn.microsoft.com/en-us/library/ms143506.aspx

In addition to Microsoft's recommended memory requirement for SQL Server, an additional amount of memory is required for SQL Server in order to rebuild/refresh snapshot data and render the report successfully.

For more information, see Configuration Recommendations for Large Active Directory Environments.

Configuration Recommendations for Large Active Directory Environments

The major factor of evaluating the configuration requirements for SQL Server is the total number of effective users who can access the computers that are joined to zone in the Active Directory environment. You can estimate the total number of effective users by multiplying the number of computers joined to the zone by the average number of users who can access the computer.

Below lists the recommended configurations for SQL Server for some sample Active Directory environments.

Active Directory environment Sample #1:

Average number of users who can access the computer	500
Total number of effective users	500 * 1000= 500,000
90% of user profiles and role assignments are explicitly defined at the zone level	

Active Directory environment Sample #1 configuration recommendations :

SQL Server memory	8 GB
SQL Server disk space	30 GB

Active Directory environment Sample #2:

Average number of users who can access the computer	3,000
Total number of effective users	3,000 * 5,000 = 15,000,000
90% of user profiles and role assignments are explicitly defined at the zone level	

Active Directory environment Sample #2 configuration recommendations :

SQL Server memory	64 GB
SQL Server disk space	80 GB

Setting the Maximum Server Memory for SQL Server

To prevent Microsoft SQL Server from consuming too much memory, you can use the following formula to determine the recommended maximum server memory:

- Reserve 4GB from the first 16GB of RAM and then 1GB from each additional 8GB of RAM for the operating system and other applications.
- Configure the remaining memory as the maximum server memory allocated for the Microsoft SQL Server buffer pool.

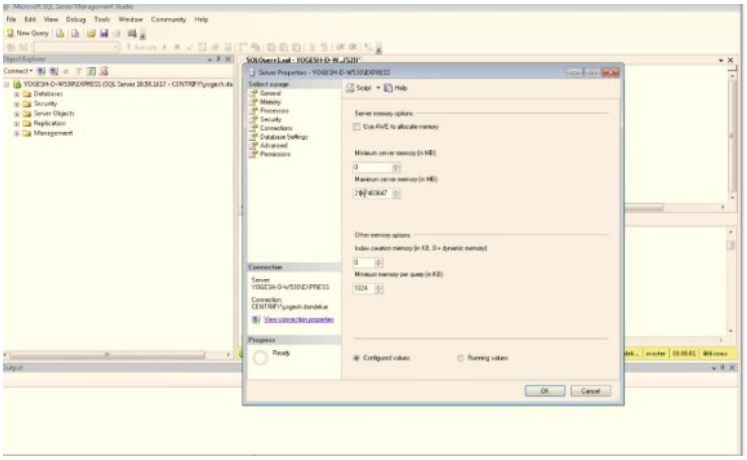
For example, if the computer hosting the Microsoft SQL Server instance has 32GB of total physical memory, you would reserve 4GB (from first 16 GB) + 1GB (from next 8 GB) + 1 GB (from next 8 GB) for the operating system, then set the Maximum server memory for Microsoft SQL Server to 26GB (32GB – 4GB – 1GB – 1GB = 26).

Reference:

https://msdn.microsoft.com/en-us/library/ms178067(v=sql.105).aspx

To set the maximum server memory for SQL Server:

1. Open the SQL Server Management Studio, enter the SQL Server properties:
2. Set the maximum server memory (in MB).



Using Report Filters to Limit the Output Data of a Report

Symptoms

In large Active Directory environments, the following reports can take too long to render because they generate a huge volume of output:

- Authorization Report
- Classic Zone – User Privileged Command Rights Report
- Classic Zone – User Role Assignment Report
- Hierarchical Zone - Computer Role Effective Assignments Report (UNIX)
- Hierarchical Zone - Computer Role Effective Assignments Report (Windows)
- Hierarchical Zone - Effective Audit Level Report
- Hierarchical Zone - Effective Rights Report
- Hierarchical Zone - Effective Role Report
- Hierarchical Zone - Users Report
- Hierarchical Zone - Zone Effective Assignments Report (UNIX)
- Hierarchical Zone - Zone Effective Assignments Report (Windows)
- All PCI reports
- All SOX reports

Resolution

You can use report filters to limit the report to only list data for specific zone types and zones in a specific domain. This can reduce the amount of data output from the report and the report will take less time to render.

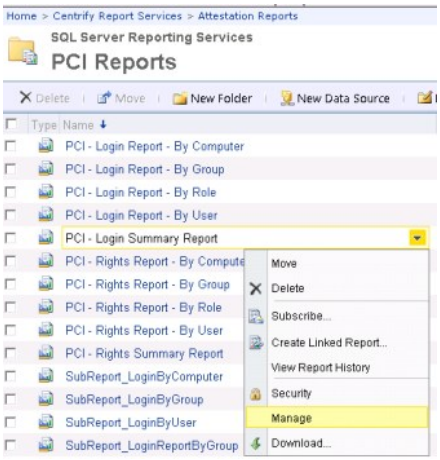
If you are opening the PCI and SOX reports, you can use the Zone Type filter to limit the reports to only list data for Classic zones or Hierarchical zones.

For all reports, you can use the Zone Domain filter to limit the reports to only list data for zones in a specific domain. By default, the Zone Domain filter of all the reports is set to the first zone domain.

By default, reports are set to run automatically when you open the report. If you prefer to set the reports to not run automatically upon opening, do the following. You must have manage report permission in order to configure the report.

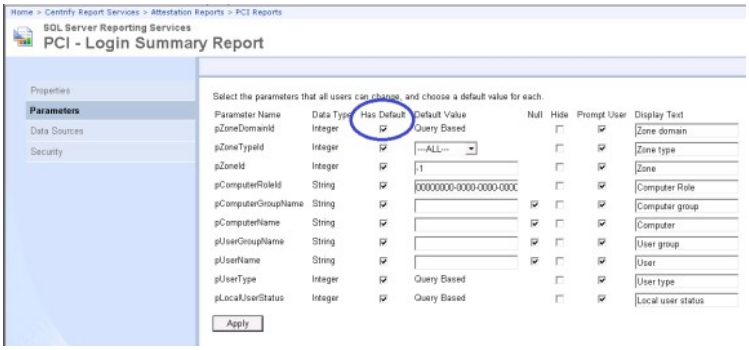
To configure a report to not run automatically when you open the report:

1. In the list of reports in the web browser, locate the desired report.
2. Move your mouse pointer over the report to open the report context menu.
3. From the context menu, select **Manage**.

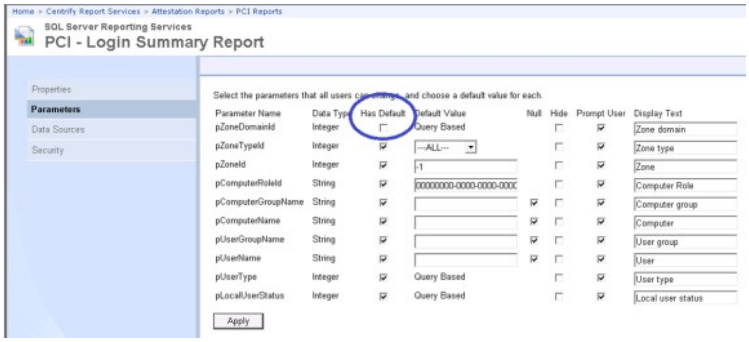


4. Select the **Parameters** page.

   Notice that 'Has Default' is selected for all parameters.

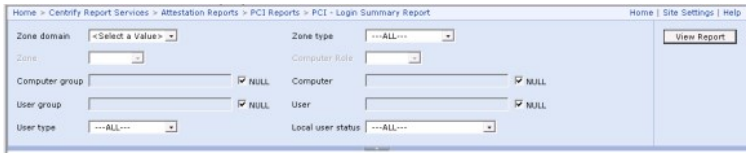


5. Deselect the 'Has Default' setting for any one parameter.
6. Click **Apply** to save the changes.



7. Open the report.

   The report does not run automatically. You can specify the filter values and click “View Report” button to run the report.



Increasing the Time-Out Value for Rebuild/Refresh Data Operations

Delinea Report Services invokes multiple database operations when it refreshes and rebuilds its cache of information stored in Active Directory. These database operations can be time-consuming in a large Active Directory environment. If any such database operation cannot be completed within a certain time period, the Delinea Report Services control panel will show that the Refresh/Rebuild process failed.

Symptom

When Delinea Report Services perform a snapshot rebuilding or refreshing and the amount of the monitored data is too large to be processed within the time-out period, this error will occur:

A database operation error occurred. Please contact your administrator to make sure the remote database is accessible and working properly. ---> System.Data.SqlClient.SqlException: Timeout expired. The timeout period elapsed prior to completion of the operation or the server is not responding.

Resolution

You can change the time-out value (3,600 seconds by default) for that time period by performing the following steps:

1. Open the registry editor and then locate the key 'SQLCmdTimeout' under HKLM\Software\Centrify\Report Services\Service. If you cannot find it under the path, create one with the same name and as 'DWORD' type.
2. Set to 'SQLCmdTimeout' to a large enough value (unit in second) so that the rebuild/refresh/computing can be finished within the time period.

   Note: Set the SQLCmdTimeout to 0 (ZERO) mean no time-out. Customer should contact Delinea Technical Support first before changing SQLCmdTimeout to 0.

Increasing the Time-Out Values for Microsoft SQL Server Reporting Services

Consider increasing the following SSRS configuration parameter values so that the large reports can be opened successfully.

Report Execution Time-out

A report execution time-out value is the maximum number of seconds that report processing can continue before it is stopped. This value is defined at the system level. You can vary this setting for individual reports.

Symptoms

For example, you can run a report that has underlying queries that cannot be completed within the time-out period. The following error will be shown on the Report Manager like this:

An error has occurred during report processing. (rsProcessingAborted)
Query execution failed for dataset 'DataSet1'. (rsErrorExecutingCommand)
A severe error occurred on the current command. The results, if any, should be discarded. Operation cancelled by user.

Resolution

Increase the Report execution time-out value. For details, see https://msdn.microsoft.com/en-us/library/ms155782.aspx.

HTTP Runtime Execution Timeout

Symptoms

You cannot open the report and you get the following error instead. This error generally occurs when the HTTP runtime execution timeout is too short.

The remote server returned an error: (500) Internal Server Error.

Resolution

1. Open the Report Server's Web.config file, which is usually in this location:

   <Drive>:\Program Files\Microsoft SQL Server\MSRS<version number>.<instance name>\Reporting Services\ReportServer

2. Locate the HttpRuntime parameter and alter the value. If it doesn't exist, you will have to create it within the section.

```
    <trace enabled="false" requestLimit="10" pageOutpu
    <sessionState mode="Off" />
    <httpHandlers>
      <add verb="*" path="Reserved.ReportServer" type=
      <add verb="*" path="Reserved.ReportViewerWebCont
Culture=neutral, PublicKeyToken=89845dcd8080cc91" />
      <add verb="GET,HEAD" path="ScriptResource.axd" t
PublicKeyToken=31bf3856ad364e35" validate="false" />
    </httpHandlers>
    <httpModules>
      <clear />
      <add name="OutputCache" type="System.Web.Caching
      <add name="WindowsAuthentication" type="System.W
      <add name="FormsAuthentication" type="System.Web
      <add name="PassportAuthentication" type="System.
      <add name="RoleManager" type="System.Web.Securit
      <add name="UrlAuthorization" type="System.Web.Se
      <add name="FileAuthorization" type="System.Web.S
      <add name="AnonymousIdentification" type="System
      <add name="Profile" type="System.Web.Profile.Pro
      <add name="ErrorHandlerModule" type="System.Web.
/>
    </httpModules>
    <globalization requestEncoding="utf-8" responseEnc
    <httpRuntime executionTimeout="9000" />
    <securityPolicy>
      <trustLevel name="RosettaSrv" policyFile="rssrvp
    </securityPolicy>
    <trust level="RosettaSrv" originUrl="" />
    <webServices>
      <soapExtensionTypes>
        <add type="Microsoft.ReportingServices.WebServ
```

   The default value is 9000, and the value is in the seconds. The maximum value is 922337203685.

3. Increase the executionTimeout value to allow the report to be rendered.

Increasing the ReceiveTimeOut Value for Internet Explorer

Symptoms

The following error is shown when you try to open a report:

An unknown error occurred while processing the request on the server. The status code returned from the server was: 12002

Resolution

> **Note**: The resolution for this symptom involves changing a registry setting. Before you change this registry setting, you should contact Delinea Technical Support first.

You can change the ReceiveTimeout setting for Internet Explorer using the following steps:

1. Start the Windows Registry Editor.
2. Locate the following subkey:

   HKEY_CURRENT_USER\SOFTWARE\Microsoft\Windows\CurrentVersion\Internet Settings
3. In this subkey, add a ReceiveTimeout DWORD entry that has a value of (<number of seconds>)*1000.

   For example, if you want the time-out duration to be 120 minutes, set the value of the ReceiveTimeout entry to 7200000 (<120*60>*1000).
4. Restart the computer.

Using a URL to Export Report Data to CSV

Symptoms

The underlying queries in some reports take a long time to execute and you may get the following errors when opening reports:

The remote server returned an error: (500) Internal Server Error.

Resolution

Besides using the report filters to make the report take less time to execute as described in earlier section, you can export the report to CSV by using a URL. In addition, you can skip exporting the chart data for the following reports:

- PCI – Login Summary Report
- PCI – Right Summary Report
- SOX – Login Summary Report
- SOX – Right Summary Report

To configure the report URL to export to CSV and skip the chart data in the exported file:

1. Compose the URL in the following format:

   http://\<hostname\>:\<port\>/ReportServer_\<instancename\>?\<report path\>&rs:Command=Render&rs:Format=CSV&pZoneDomainId=-1&SkipChartData=True

   For example:

   This is a URL to export the PCI – Login Summary report:

   http://win2012r2/ReportServer_CENTRIFYSUITE?%2fcentrify+Report+Services%2fAttestation+Reports%2fPCI+Reports%2fPCI+-+Login+Summary+Report&rs:Command=Render&rs:Format=CSV&SkipChartData=True&pZoneDomainId=-1

   This is a URL to export the PCI – Right Summary report:

   http://win2012r2/ReportServer_CENTRIFYSUITE?%2fcentrify+Report+Services%2fAttestation+Reports%2fPCI+Reports%2fPCI+-+Right+Summary+Report&rs:Command=Render&rs:Format=CSV&SkipChartData=True&pZoneDomainId=-1
2. Access the URL in Internet Explorer.
3. Save the exported CSV file.

https://msdn.microsoft.com/en-us//library/ms153586.aspx

https://msdn.microsoft.com/en-us/library/ms159261.aspx

Creating the Report Subscription for CSV Export

This section shows how to use the SQL Server Reporting Services (SSRS) subscription feature to export report data to CSV regularly.

Prerequisites

- Please check whether your SQL Server edition supports the reporting subscription feature.

https://msdn.microsoft.com/en-us/library/cc645993(v=sql.100).aspx

- SQL Server Agent is already installed and running.

Configuring The Report Data Source For Subscriptions

To configure a report subscription in SSRS for CSV export and skip the chart data in the export:

1. Open Delinea Report Services.
2. Click **ReportDataSource** to open the report data source properties page.
3. Configure the report data source to store connection credentials in the report server:
    1. For the connection method, select **Credentials stored securely in the report server**.
    2. Enter the login user name and password.
    3. Select **Use as Windows credentials when connecting to the data source**.
    4. The following screenshot is an example of the connection settings configuration:

4. Secure access to the reports and the report data by adding or editing role assignments for the report folder.
    1. Open the Security page for the report folder 'Access Manager Reports' and 'Attestation Reports'.
        1. Here you can view, add, edit, or delete role assignments for the report folder.
        2. The data source uses stored credentials, which means that users who are able to view the reports would be able to read the report data. To avoid this potential risk, you can define role-based security for reports in the Security page, as shown below.

    2. Delete the default role assignment that assigns the Browser role to NT AUTHORITY\Authenticated Users to remove report read access to all authenticated users.
    3. In the report folder's Security page, click New Role Assignment.
    4. Enter the users or groups who can access the reports.

5. Select one or more roles to assign to the specified user(s).

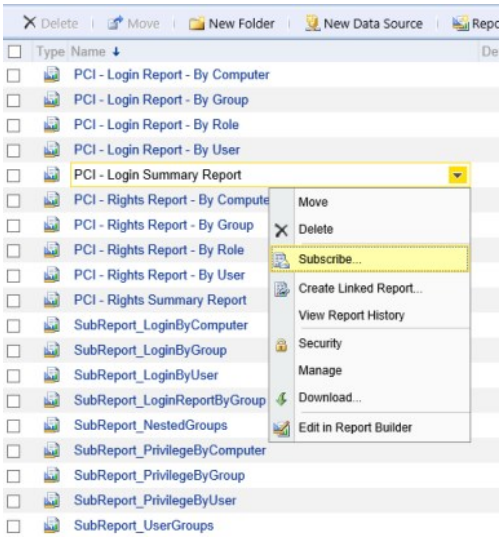
   For example, if you want the specified users to only view the report, select the Browser role.

6. Click OK to save the changes.

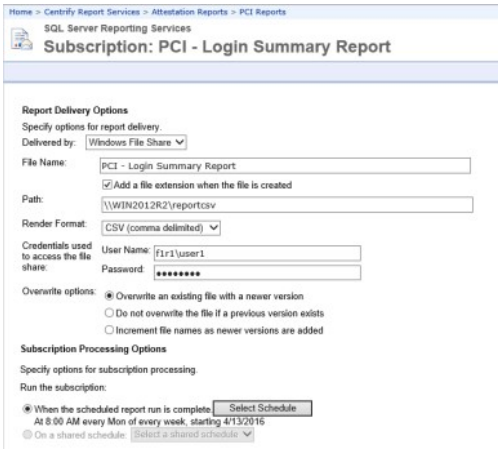
Creating A CSV Report Subscription

To configure a report subscription in SSRS for CSV export and skip the chart data in the export:

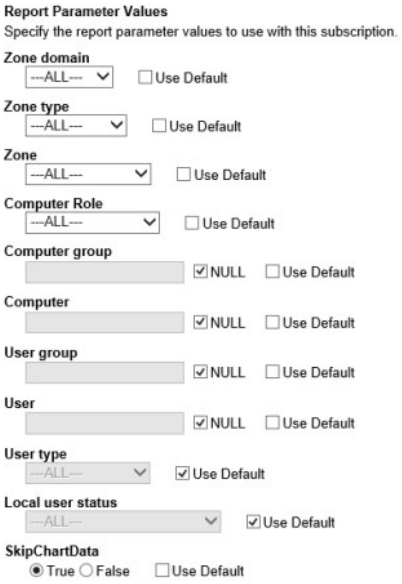
1. In the list of reports, select the report that you want to export to CSV.
2. Click the context menu and click **Subscribe**.



3. In the **Subscription** page, set the options according to the following screenshot.
   1. To specify when the scheduled report runs, click **Select Schedule**.
   2. When you specify the file path, the path must conform to the Uniform Naming Convention format.



3. In the lower area of the subscription page, set the Zone domain parameter to **ALL** in order to export report data for all zone domains.



4. After setting the options, click **OK** to create this subscription.

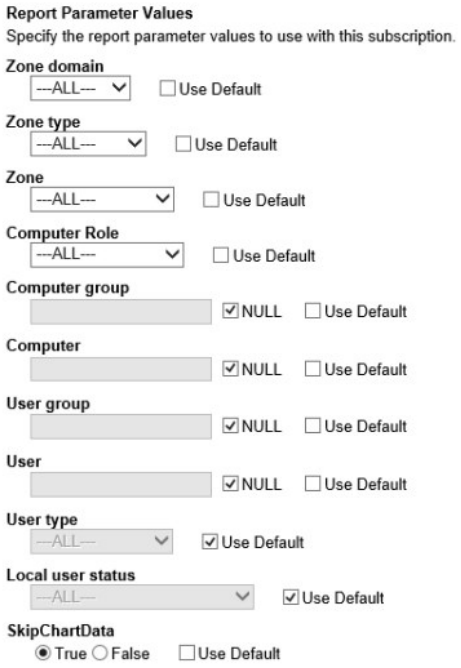
Skipping Chart Data From CSV Report Subscriptions

You can skip exporting the chart data to CSV for the following reports:

- PCI – Login Summary Report
- PCI – Right Summary Report
- SOX – Login Summary Report
- SOX – Right Summary Report

To configure a report subscription in SSRS for CSV export and skip the chart data in the export:

1. Open the report subscription. (From the report's context menu, click Manage, and then click the **Subscription** page.)
2. In the lower area of the subscription page, set the **SkipChartData** parameter to **True**.



3. After setting the options, click **OK** to save the subscription.

In general, if something doesn't work the way that you think it should, try the following to troubleshoot your reporting environment:

- View the log files
- Rebuild or refresh the reporting data
- Validate that the reporting service has the correct permissions to read data from the monitored domains and replicate the data.
- Export diagnostics data for use by Delinea Technical Support (if technical support requests that you do so).

This section describes some situations that you might encounter, along with some suggested solutions or workarounds.

You Don't See Any data When You Open a Report

Problem: You've installed everything and you can open a report, but you don't see any data.

Solution: Make sure that there has been at least one synchronization between Active Directory and the reporting database. Use the Report Configuration wizard to do this.

You Don't See the Report Builder Link in Internet Explorer

Problem: You go the Home page in Internet Explorer, the home page for your deployed reports in SSRS, and you do not see the Report Builder link. But you're fairly sure that you have the required permissions to create reports.

Solution: Here are some things for you to check:

1. Make sure that you are logging in within the same domain that SSRS is installed within. For example, if you're creating an evaluation version that uses a different domain, there may be issues.
2. Go download the Report Builder for your SQL Server version. For now, it's a separate download.

You Can't Log in to Report Services in Internet Explorer

Problem: When you log in to Delinea Report Services in Internet Explorer, you cannot successfully log in. You see an error message like this: "User domain\user does not have required permissions. Verify that sufficient permissions have been granted and Windows User Account Control (UAC) restrictions have been addressed."

Explanation: If you're seeing this issue, it may have happened after your first installation or an upgrade in which you created a new SQL Server instance.

Solution: Here are some things for you to try:

- When you go to launch Report Services, right-click it and select Run as Administrator. This may allow you to log in to Report Services, and from there you can edit the Site Settings for security.
- Log in to Report Services as an administrator, and go to Site Settings to add your users by way of adding the domain and assign the group or user a role. For details, see Granting access in SSRS to reports.
- Make sure that you also set permissions for the home folder, as mentioned in the topic mentioned above.

You Get a Server Error When You Try to Synchronize with Active Directory

Problem: In the Report Services control panel, when you go to synchronize data for report services, the following error displays: "The server is unwilling to process the request." (KB-6350)

You also see a similar error in the report services log file. Here's an example of what the error looks like:

[2015-08-21 10:53:25.714 +0800] Centrify.Report.Service.exe[3596,10] Error: SyncServer.DoSynchronization: Failure during synchronize domain a9f1r1.test, DC: a9d1-w2k12r2.a9f1r1.test.

[2015-08-21 10:53:25.714 +0800] Centrify.Report.Service.exe[3596,10] Error: SyncServer.DoSynchronization: Reason: The server is unwilling to process the request.

Explanation: The issue is due to insufficient memory on the domain controller. The domain controller is unable to allocate enough memory for Active Directory caching.

Solution: Adjust the memory allocated to the domain controller, according to Memory requirements.

Port Conflicts

Problem: Delinea Report Services not install correctly when port 80 is used by another application, such as Apache Tomcat. The following error displays during the report services configuration wizard: "The service was unable to access Report Services." (KB-7443)

Explanation: By default, Microsoft SQL Server Reporting Services (SSRS) use port 80, and it is not recommended to run it with a third party software that also uses port 80 or 443.

Solution: For port conflict situations, you can configure SSRS to use another port.

To change the port that SQL Server Reporting Services (SSRS) uses:

1. Open the SQL Server Reporting Services Configuration Manager.
2. Navigate to the **Web Service URL**.
3. Change the TCP port to an unused port other than 80.

For example, port 8080.

4. Navigate to the **Report Manager URL**, and click **Advanced**.
5. Change the TCP port to the same port number that you specified in Step 3.
6. Run the Delinea Report Services Configuration Wizard and specify URLs with the new port number.

For example, http://reportservice:8080/ReportServer_CssREPORTS2

7. Verify that you can access reports through the specified port.

You may also need to modify your firewall rules for access to the specified port.

SSRS Fails to Start on Windows 2008 R2 Systems

Problem: SQL Server Reporting Services (SSRS) fails to start, due to a timeout issue. This issue occurs only on Windows 2008 R2 systems. (KB-8065)

SSRS Produces the Following Error

Windows could not start the SQL Server Reporting Services (MSSQLSERVER) service on local computer. Error 1053: The service did not respond to the start or control request in a timely fashion.

Explanation: This happens due to SSRS checking for certificate revocation lists (CRL), and this is a Microsoft known issue, as detailed here: http://support.microsoft.com/kb/2745448.

> **Note**: Delinea does not take any responsibility for the content or availability of this link, it is provided as a courtesy. You should contact Microsoft if there are any further questions.

Solution: You can perform one of the following tasks to try and resolve this issue:

- Disable certificate revocation lists checking. For details, see http://tech.lanesnotes.com/2014/02/sql-server-reporting-services-service.html
- Change the default revocation checking behavior using group policy. For details, see https://technet.microsoft.com/en-us/library/ee619786(v=ws.10).aspx

SQL Server 2008 R2 Express Edition Produces an Installation Error

Problem: When you run the installer, you get an error when it tries to install the SQL Server 2008 R2 Express edition for report services. The installer produces the following error: (KB-8172)

The Report Services Configuration Wizard Cannot be Completed Due to an Error that Occurred

The program was unable to install SQL Server on this computer, exit code: 0x851A0017. Please refer to the Delinea Knowledge Base article (KB-4589) for more information on the error code you received. Please fix the issue and run Setup again.

You might also see something like the following errors in the SQL Server log file, which you can locate in a directory such as C:\Program Files\Microsoft SQL Server\100\Setup Bootstrap\Log\<number>\Detail.txt.

2017-01-25 12:41:31 Slp: Configuration action failed for feature SQL_Engine_Core_Inst during timing ConfigRC and scenario ConfigRC. 2017-01-25 12:41:31 Slp: Could not find the Database Engine startup handle. 2017-01-25 12:41:31 Slp: The configuration failure category of current exception is ConfigurationFailure 2017-01-25 12:41:31 Slp: Configuration action failed for feature SQL_Engine_Core_Inst during timing ConfigRC and scenario ConfigRC. 2017-01-25 12:41:31 Slp: Microsoft.SqlServer.Configuration.SqlEngine.SqlEngineConfigException: Could not find the Database Engine startup handle. 2017-01-25 12:41:31 Slp: at Microsoft.SqlServer.Configuration.SqlEngine.SqlServerServiceBase.WaitSqlServerStart(Process processSql) 2017-01-25 12:41:31 Slp: at Microsoft.SqlServer.Configuration.SqlEngine.SqlEngineDBStartConfig.ConfigSQLServerSystemDatabases(EffectiveProperties properties, Boolean isConfiguringTemplateDBs, Boolean useInstallInputs) 2017-01-25 12:41:31 Slp: at Microsoft.SqlServer.Configuration.SqlEngine.SqlEngineDBStartConfig.DoCommonDBStartConfig(ConfigActionTiming timing) 2017-01-25 12:41:31 Slp: at Microsoft.SqlServer.Configuration.SqlConfigBase.SlpConfigAction.ExecuteAction(String actionId) 2017-01-25 12:41:31 Slp: at Microsoft.SqlServer.Configuration.SqlConfigBase.SlpConfigAction.Execute(String actionId, TextWriter errorStream) 2017-01-25 12:41:31 Slp: Exception: Microsoft.SqlServer.Configuration.SqlEngine.SqlEngineConfigException. 2017-01-25 12:41:31 Slp: Source: Microsoft.SqlServer.Configuration.SqlServer_ConfigExtension. 2017-01-25 12:41:31 Slp: Message: Could not find the Database Engine startup handle.

Explanation: The SQL Server Express edition isn't able to use the encryption protocols provided by the server.

The installation error occurs because TLS1.0/1.1 and SSL 3.0 protocols and some ciphers have been disabled on the server, due to customer security concerns. SQL Server 2008 R2 Express Edition does not support the newer version of cipher suites (such as TLS1.2 with SHA256), while the regular versions of SQL Server with the latest updates or support packs (SP) do.

Solution: Restore the server settings back to the system defaults that allow TLS1.0/1.1, SSL 3.0 protocols and ciphers. After you do that, the installer will successfully complete a report services installation with SQL Server Express edition.

Installing SQL Server from the Delinea Management Services Installer Generates Error Codes

Problem: When you install the SQL Server version that is bundled with the Delinea Management Services installer, there are errors. (KB-4589)

0x84B40000 - full text service cannot run under local system account on DC.	This means user is trying to install SQL Server on a Domain Controller with Full Text Search service configured under a local system account. This is not supported by Microsoft. Workaround is to either install SQL on a member server, or manually install SQL and select a different account to run it as Full Text Search service.
	For this error code, more information is needed, see below on how to collect logs.
0X6AA	If SQL server is already installed on a machine with default SQL server instance (with advanced services), the SQL server setup will fail with the above error code. To workaround this issue, reinstall SQL Native Client (SNAC) before installing the second instance of SQL Server 2005 Express Edition with Advanced Services. - http://msdn.microsoft.com/en-us/sqlserver/ff658533 (Provided as a courtesy)
	This means a hyphen (-) in the SQL server's instance name has been specified and is not allowed.
	SQL Server Management Studio 2005 has been installed on the system and there is an attempt to install SQL 2008 on top of it. To workaround this issue, manually uninstall SQL Server Management Studio and then install the later version.
	PowerShell 2.0, which is a prerequisite for Microsoft SQL server 2014, is not installed. Install Windows Management Framework 2.0 first before run Report Services Configuration Wizard
	SQL Server 2008 R2 express edition with advanced features will fail to install an new instance when TLS 1.0/1.1 and SSL 3.0 protocols are disabled. It fails with a message like: SQL Server installation failed. To continue, investigate the reason for the failure, correct the problem, uninstall SQL Server, and then rerun SQL Server Setup. To work around this issue, re-enable the protocols (Update corresponding values to 1.) The SQL Server instance then can be installed successfully. Refer to: https://blogs.msdn.microsoft.com/friis/2016/07/25/disabling-tls-1-0-on-your-windows-2008-r2-server-just-because-you-still-have-one/

If the SQL Server installation fails for any other reason, send the installation log files to Delinea support. You can locate the installation log files in the following locations:

- SQL Server 2008 and 2008 R2:

%ProgramFiles%\Microsoft SQL Server\100\Setup Bootstrap\LOG

- SQL Server 2012:

%ProgramFiles%\Microsoft SQL Server\110\Setup Bootstrap\Log\.

- SQL Server 2014:

%ProgramFiles%\MicrosoftSQL Server\120\Setup Bootstrap\Log\.

- SQL Server 2016:

%ProgramFiles%\ Microsoft SQL Server\130\Setup Bootstrap\Log\

Can't install SQL Server 2012 or 2014 instance on Windows 2008 SP2

Problem: If you use the Report Services Configuration wizard to install a new instance of SQL Server version 2012 or 2014 on Windows Server 2008 SP2, the installation fails if Windows Powershell 2.0+ or Windows Management Framework 2.0 is not already installed. The installation failure has an exit code of 0x84BE0260 (KB-7096).

Explanation: Windows Server 2008 SP2 doesn't include PowerShell 2.0 or Windows Management Framework 2.0 by default. Later versions of Windows Server do include these components by default.

Solution: Install PowerShell 2.0 or higher and Windows Management Framework 2.0 before you run the Report Services Configuration Wizard to install a new instance of Microsoft SQL Server 2012 or 2014.

You can download Windows Management Framework 2.0 from https://support.microsoft.com/en-us/kb/968930.

Report Services computation takes longer than it used to

Problem: If Report Services uses SQL Server 2014 or above, you might notice that Report Services spends more time on computation.

Explanation: In SQL Server 2014, Microsoft introduced a new cardinality estimator (CE). This cardinality estimator was redesigned to improve query performance, and there may be some performance degradation for some SQL statements.

Solution: If you notice some report services computation performance issues, set the database compatibility level to 110 to force SQL Server to use the old cardinality estimator.

To set the database compatibility level to 110:

1. In SQL Server Management studio, run the following before Report Services synchronizes with Active Directory:

ALTER DATABASE <the database name deployed by Report Services> SET COMPATIBILITY_LEVEL = 110

Frequently asked questions about report services

Question: Is it possible for report services to use an existing database that's already been created according to our organization's standards?

Answer: Report services cannot use an existing database, the Configuration Wizard creates a new database.

Question: Does report services create just one database?

Answer: Yes. If you reconfigure report services, the Configuration Wizard creates a new database.

Question: Does the report services installation make any other modifications to database objects other than in the database it creates?

Answer: No.

Delinea

This section covers which Active Directory attributes that report services synchronizes for use in reports. Report services synchronizes these attributes from Active Directory to the reports database in a one-way synchronization process.

Auditing Guides

- Auditing Administrator Guide
- Audit Database Management Guide
- Find Sessions Guide

Overview of the Auditing Infrastructure

Auditing is a key feature of Server Suite. If you choose to enable auditing in your organization, you can capture detailed information about user activity on Linux, UNIX, and Windows computers and store that activity to improve regulatory compliance and accountability and mitigate security risks. This section provides an overview of the auditing infrastructure, including key components and terminology.

The following topics are covered:

Delinea

Deciding Whether to Audit User Activity

Just as it is important to protect assets and resources from unauthorized access, it is equally important to track what users who have permission to access those resources are doing or have done in the past. For users who have privileged access to computers and applications with sensitive information, auditing their actions helps ensure accountability and improve regulatory compliance.

There are many reasons for organizations to establish auditing policies and enable auditing of user activity. For example, you might want to audit activity for any of the following reasons:

- To prove certain computers or applications are secure in order to comply with government or industry regulatory requirements.
- To report on actions taken by users with elevated privileges.
- To prevent the use of shared passwords when more than one person needs administrative access to a computer or an application.
- To improve accountability when users with elevated permissions have access to privileged resources.
- To detect suspicious activity and mitigate the threat posed by malicious insiders or third parties who have access to sensitive systems.
- To pinpoint actions that may have caused failures and simplify troubleshooting procedures.
- To capture information, such as the steps that resolved an open case, that can be used to help your organization improve its helpdesk operations or security procedures.

Capturing Detailed and Summary Information for User Sessions

After you deploy the auditing infrastructure, you can capture detailed information about user activity and the events that occurred on the computers you choose to audit. On those computers, an agent starts recording user activity when a user selects an audited role or starts a login shell locally, using a remote shell, or through a virtual network connection such as Citrix or VNC.

Each record of continuous user activity is called a **session**. A session ends when the user logs out, disconnects, or is inactive long enough to lock the desktop. If the user reconnects or unlocks the desktop, the agent resumes recording the user's activity as a new session. When users start a new session on an audited computer, they can be notified that their session is being audited but they cannot turn off auditing except by logging off, so you have a complete record of what happened, includes an audit trail of the actions a user has taken.

You can choose whether to record only summaries of user activity or a full visual record of user activity.

Sessions include different kinds of information depending on the audited system's operating system:

- **Windows**: When auditing Windows computers, each session is a video capture of everything that takes place on the desktop, including the applications opened, text that was entered, and the results that were displayed.
- **Linux:** When auditing Linux computers, the agent records shell activity, such as the commands a user runs or the changes made to key files and data. On some versions of Linux computers, actions performed using a display manager, such as GNOME or KDE, are also recorded. Consult the Delinea release notes for supported platform details.

In addition to capturing detailed information about user activity, sessions provide a summary of actions taken so that you can scan the applications opened or commands executed for potentially interesting or damaging actions without playing back a complete session. After you select a session of interest in the Audit Analyzer, the console displays an indexed list of actions taken in the order in which they occurred. You can then select any entry in the list to start viewing the session beginning with that action. For example, if a user opened an application that stores credit card information, you can scan the list of actions for that event and begin reviewing what happened in the session from the time the user opened that particular application.

If users change their account permissions to take any action with elevated privileges, the change is recorded as an audit trail event. You can also search for these events to find sessions of interest.

Reviewing Recorded Activity

The information recorded in each session is transferred to a Microsoft SQL Server database so that it is available for querying and playback. Because the information is collected as it happens, you can monitor computers for suspicious activity or troubleshoot problems immediately after they occur.

You can also search for and play back sessions to locate past events that occurred on specific computers or that affected particular users. For example, you might be interested in activity that occurred immediately before a security breach or want to investigate the cause of an application failure. Similarly, a security expert might want to see who had access to computers with sensitive data, such as payroll information or medical records, during a particular period of time, such as the last 72 hours.

Auditing Requires a Scalable Architecture

To ensure scalability for large organizations and provide fault tolerance, the auditing infrastructure has a multi-tier architecture that consists of the following layers:

- **Audited computers** are the computers on which you want to monitor activity. To be audited, the computer must have an agent installed, audit features enabled, and be joined to an Active Directory domain.
- **Collectors** are intermediate services that receive and compress the captured activity from the agents on audited computers as the activity occurs. You should establish at least two collectors to ensure that auditing is not interrupted. You can add collectors to your installation at any time and it is common to have multiple collectors to provide load balancing and redundancy.
- **Audit stores** define a scope for auditing and include the audit store databases that receive captured activity and audit trail records from the collectors and store it for querying and playback. Audit store databases also keep track of all the agents and collectors you deploy. For scalability and network efficiency, you can have multiple audit stores each with multiple databases.
- A **management database server** is a computer that hosts the Microsoft SQL Server instance with the audit management database. The management database stores information about the overall installation, such as the scope of each audit store, which audit store database is active and where there are attached databases, the audit roles you create, and the permissions you define. The management database enables centralized monitoring and reporting across all audit stores, collectors, and audited computers.
- The **Audit Manager** and **Audit Analyzer consoles** are the graphical user interfaces which administrators can use to configure and manage the deployment of audit components, such as agents and collectors, or to query and review captured user sessions.

To ensure that audit data transferred over the network is secure, communication between components is authenticated and encrypted.

In addition to these core components of the auditing infrastructure, there is a separate Windows service that collects audit trail events when there are audit store databases that are not accessible, for example, because of network issues or the database server is shut down. This audit management server runs as a Windows service and spools the events on the management database, then sends them to the audit store database when the inaccessible database comes back online.

In addition to spooling audit trail events, the audit management server automatically calculates the approximate disk space used by audited sessions on the database server. The audit management server will calculate the session size for all completed audited sessions. The session size is not calculated for in-progress or disconnected sessions. You can view the session size for all completed sessions in the Audit Analyzer console's query results.

How Audited Sessions are Collected and Stored

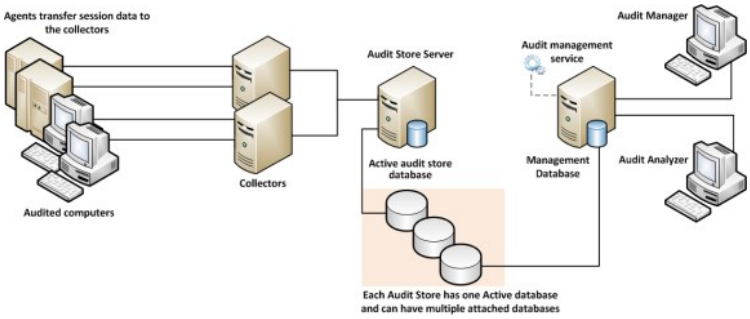
The agent on each audited computer captures user activity and forwards it to a collector on a Windows computer. If the agent cannot connect to a collector—for example, because all of the computers hosting the collector service for the agent are shut down for maintenance—the agent spools the session data locally and transfers it to a collector later.

The collector sends the data to an audit store server, where the audit data is stored in the Microsoft SQL Server database that you have designated as the **active audit store database**. As you accumulate data, you can add more SQL Server databases to the audit store to hold historical information or to change the database designated as the active audit store database.

After the audit data is transferred to the audit store database, you can use the Audit Analyzer console to request session data. The audit management database, which stores information about all of the components that make up the auditing infrastructure, retrieves the session data from the appropriate audit store database.

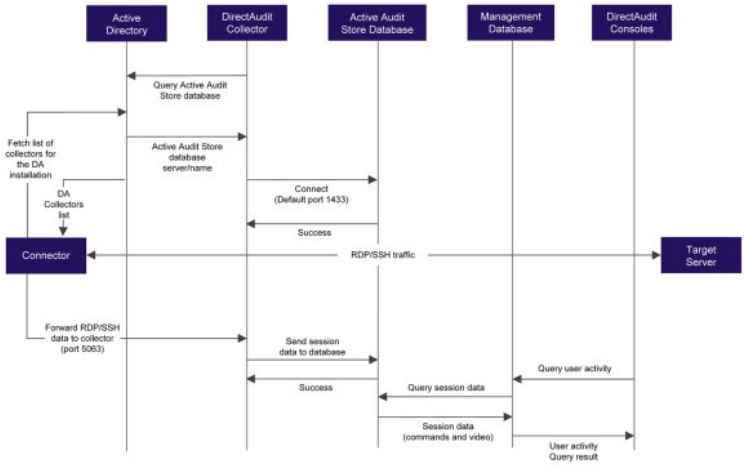
Auditing Architecture and Dataflow

The following figure illustrates the basic architecture and flow of data with a minimum number of auditing components installed.

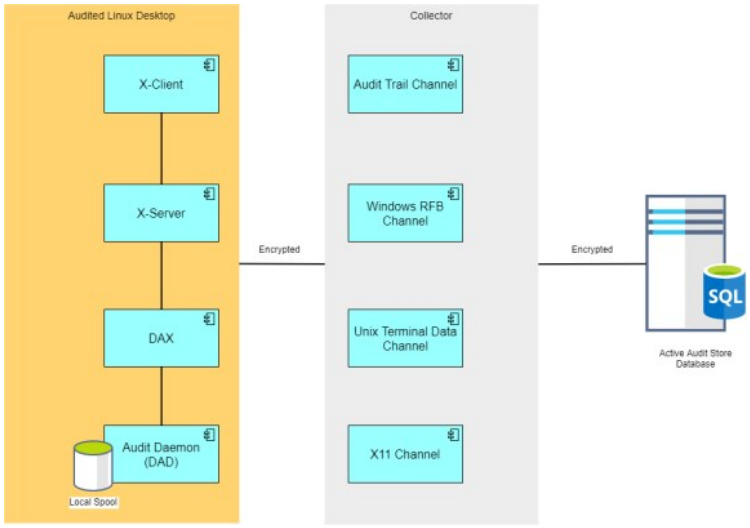


In the illustration, each agent connects to one collector. In a production environment, you can configure agents to allow connections to additional collectors for redundancy and load balancing or to prevent connections between specific agents and collectors. You can also add audit stores and configure which connections are allowed or restricted. The size and complexity of the auditing infrastructure depends on how you want to optimize your network topology, how many computers you are auditing, how much audit data you want to collect and store, and how long you plan to retain audit records.

The following figure illustrates the data flow details. You can see which components communicate to other components and in what order. The diagram also includes some port details.



The following diagram shows how the Linux Desktop auditing session data is collected.



Within the Linux Desktop, there's a component called DAX that generates the recorded session data and passes it to the audit daemon. The audit daemon encrypts and passes the recorded session data to the collector. The collector channels session data of different types together and passes that encrypted session data along to the active audit store database.

Deploying Auditing Components in an Audit Installation

The multi-tiered architecture of the auditing infrastructure is referred to collectively as a **DirectAudit installation**. The DirectAudit installation represents a logical object similar to an Active Directory forest or site. It encompasses all of the auditing components you deploy—agents, collectors, audit stores, management database, and consoles—regardless of how they are distributed on your network. The installation also defines the scope of audit data available. All queries and reports are against the audit data contained within the installation boundary.

The most common deployment scenario is to have a single audit installation for an entire organization so that all audit data and management of the audit data is centralized. Within a single installation, you can have components wherever they are needed, as long as you have the appropriate network connections that allow them to communicate with each other. The audit data for the entire installation is available to users who have permission to query and view it using a console. For most organizations, having a single installation is a scalable solution that allows a "separation of duties" security model through the use of audit roles. If you establish a single installation, there will be one Master Auditor role for the entire organization, and that Master Auditor can control the audit data that other users and groups can see or respond to by defining roles that limit access rights and privileges.

However, if you have different lines of business with different audit policies—in different geographic locations, or with different administrative groups—you can configure them as separate audit installations. For example, if you have offices in North America and Hong Kong managed by two different IT teams—IT-US and IT-HK—you might want to create two DirectAudit installations to maintain your existing separation of duties for the ITUS and IT-HK teams.

Planning Where to Install Auditing Components

Before you install Centrify Audit & Monitoring Service, you should develop a basic deployment plan for how you will distribute and manage the components that make up an installation. For example, you should decide how many collectors and audit stores to create and where to put them. You should also consider the network connections required and how many computers you plan to audit. For example, you can have multiple agents using the same set of collectors, but you should keep the collectors within one hop of the agents they serve and within one hop of the audit stores to which they transfer data.

By planning where to install components initially, you can determine the number of collectors you should have for load balancing or redundancy. After the initial deployment, you can add collectors and audit stores whenever and wherever they are needed.

Using Multiple Databases in an Audit Store

Each audit store uses Microsoft SQL Server to provide database services to the audit installation. When you install the first audit store, you configure the database instance you want to use and that database becomes the active database for storing incoming audit data. A single audit store, however, can have several databases attached to it. Attached databases store historical information and respond to queries from the management database. You can use the Audit Manager console to control the databases that are attached to the audit store and to designate which database is active. Only one database can be active in an audit store at any given time.

Although the audit store can use multiple databases, the presentation of session data is not affected. If a session spans two or more databases that are attached to the audit store, the Audit Analyzer console presents the data as a single, unbroken session. For example, if you change the active database during a session, some of the session data is stored in the attached database that is no longer active and some of it stored in the newly activated database, but the session data plays back as a single session to the auditor.

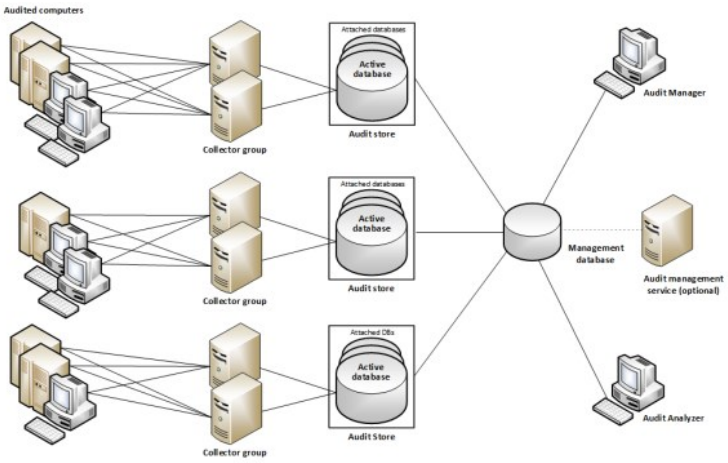
Using Multiple Consoles in an Installation

A single installation always has a single audit management database. In most cases, however, you use more than one console to request data from the audit management database. The two most important consoles in an installation are the Audit Manager console and the Audit Analyzer console.

- As the audit installation owner, you use the Audit Manager console to configure and manage the auditing components in your installation. In most organizations, there is only one Audit Manager console installed.
- Auditors use the Audit Analyzer console to search, retrieve, and play back sessions. The auditor can use predefined queries to find sessions or define new queries. Auditors can also choose whether to share their queries with other auditors or keep them private. In most organizations, there are multiple Audit Analyzer consoles installed.

In addition to the Audit Manager and Audit Analyzer consoles, you can use the Agent Control Panel and the Collector Control Panel to configure and manage agents and collectors.

The following figure shows the architecture of a medium-size installation.



Audit Installation

Agent Components

On Audited UNIX computers

To enable auditing for Linux and UNIX computers, you must install the Centrify Agent for *NIX on the computers you want to audit and make sure the computers are joined to an Active Directory domain. Joining a domain is required to ensure that authentication and authorization services are provided by Active Directory. To enable auditing on a computer, the Centrify Agent for *NIX includes the following components:

- dad—the core auditing service that collects the audit data and either sends it to a collector or spools it locally until a collector is available.
- cdash—the UNIX shell wrapper that intercepts all user traffic and sends it to the dad process.
- dacontrol, dainfo, dareload, and other command-line programs that enable you to manage agent operations from a login shell.
- dax—the audit service that records graphical user interface sessions on xWindows computers. Consult the release notes for which xWindows versions are supported.

If you're auditing only shell sessions on a UNIX computer: after you enable auditing on a computer, the agent captures all output (stdout), error messages (stderr), and user input (stdin) except for passwords. By default, the agent captures user input even if a user runs commands with echo turned off. For example, if a user logs on, then runs echo off before typing the sudo command, the auditing service captures the sudo entry as part of the user's session.

If you're auditing xWindows sessions: the agent captures all windows that a user opens and which user interface items the user interacts with. For web browser applications, the agent captures the title of the web page but not any activity within the web page.

On Audited Windows Computers

To enable auditing for Windows computers, you must install the Centrify Agent for Windows on the computers you want to audit and make sure the computers are joined to an Active Directory domain. Joining a domain is required to ensure that authentication and authorization services are provided by Active Directory. If you enable auditing for the Centrify Agent for Windows, the agent includes the following components:

- wdad—the Windows audit data collection service.
- wash—the Windows service that intercepts all user traffic and sends it to the Windows audit data collection service.
- The Agent Control Panel—an applet that enables you to configure and manage the agent.

For example, you can use the Agent Control Panel to configure the color depth of audit data to achieve the desired balance between playback screen resolution and audit store database size.

Planning an Audit Installation

This section describes the decisions you need to make during the planning phase of a deployment and summarizes what's involved in deploying audit and monitoring service components and auditing-related services on the computers to be audited. It includes simplified diagrams that highlight the steps involved.

The following topics are covered:

- Deciding on the scope of the installation
- Deciding where to install the management database
- Deciding where to install collectors and audit stores
- Deciding where to install agents
- Deciding where to install consoles

- Supported SQL Server editions
- Checking SQL Server logins for auditing
- Determining storage requirements for auditing
- What's involved in the deployment process

Deciding on the Scope of the Installation

Before you deploy any part of the auditing infrastructure, you should decide on the scope of the audit installation and whether you want to use a single installation for your entire Active Directory site, or separate audit installations for different geographical areas or functional groups.

The most common deployment scenario is a single installation for each Active Directory forest, so that auditors can query and review information for the entire organization. However, if your Active Directory site has more than one forest, you might want to use more than one installation. If you want to use more than one installation, you should determine the subnetwork segments that will define the scope of each installation.

In Active Directory, a site represents the collection of Internet Protocol (IP) addresses that describe the physical structure of your network. If you are not familiar with how Active Directory sites are defined, you should consult Microsoft documentation for more information.

Delinea

Deciding Where to Install Different Audit Components

It is important to plan the installation of all the different audit and monitoring services components.

- Deciding where to install the management database
- Deciding where to install collectors and audit stores
- Deciding where to install agents
- Deciding where to install consoles

Deciding Where to Install the Management DDatabase

Each audit installation has a single audit management server and audit management database. The management database is a Microsoft SQL Server database that stores information about the installation such as the Active Directory sites or subnets associated with each audit store.

The computer you use for the audit management database should have reliable, high-speed network connectivity. The management database does not store the captured sessions, and is, therefore, much smaller than the audit store databases. There are no specific sizing requirements or recommendations for the management database.

You can use the following guideline as the recommended minimum hardware configuration for the computer you use as the management database:

Management database	Any	1 to 2	2.33 GHz	8 GB

The audit management server is a Windows service that performs two main tasks:

- The service collects audit trail events on the management database, then sends them to the audit store database.
- The service automatically calculates the approximate disk space used by audited sessions.

Deciding Where to Install Collectors and Audit Stores

Although a collector and an audit store database can be installed on the same computer for evaluation, you should avoid doing so in a production environment. As part of the planning process, therefore, you need to decide where to install collectors and audit store databases. In designing the network topology for the installation, there are several factors to consider. For example, you should consider the following:

- Database load and capacity
- Network connectivity
- Port requirements
- Active Directory requirements

The next sections provide guidelines and recommendations to help you decide where to install the collectors and audit store databases required to support the number of computers you plan to audit.

Use Separate Computers for Collectors and Audit Store Databases

To avoid overloading the computers that host collectors and audit store databases, you should install collectors and audit store SQL Server databases on separate computers. Because SQL Server uses physical memory to store database information for fast query results, you should use a dedicated computer for the audit store database, and allocate up to 80% of the computer's memory to SQL Server. In most installations, you also need to plan for more than one audit store database and to periodically rotate from one database to another to prevent any one database from getting too large. For more information about managing audit store databases, see Managing audit store databases.

Plan for Network Traffic and Default Ports

You should minimize the distance network packets have to travel between an agent and its collector. You should also minimize the distance between collectors and their audit stores. If possible, you should not have more than one gateway or router hop between an agent and its collector.

To help you plan for network traffic, the following ports are used in the initial set of network transactions:

- Directory Service - Global Catalog lookup request on port 3268.
- Authentication Services - LDAP sealed request on port 389.
- Kerberos - Ticket Granting Ticket (TGT) request on port 88.
- Network Time Protocol (NTP) Server - Time synchronized for Kerberos on port 123.
- Domain Name Service (DNS) - Host (A), Pointer (PTR), Service Location (SRV) records on port 53.

Depending on the specific components you deploy and operations performed, you might need to open additional ports. The following table summarizes the ports used for Server Suite software.

23	TCP communication for Telnet connections	Server Suite authentication service, privilege elevation service, and audit and monitoring service. By default, telnet connections are not allowed because passwords are transferred over the network as plain text.
53	TCP/UDP communication	Clients use the Active Directory DNS server for DNS lookup requests.
88	Encrypted UDP communication	Kerberos ticket validation and authentication, agents, Server Suite PuTTY
123	UDP communication for simple network time protocol (NTP)	Keeps time synchronized between clients and Active Directory for Kerberos ticketing.
389	Encrypted TCP/UDP communication	Active Directory authentication and client LDAP service.
443	Cloud Connector communication with Privileged Access Service	Cloud Connector
445	Encrypted TCP/UDP communication for delivery of group policies	The adclient and adgpupdate use Samba (SMB) and Windows file sharing to download and update group policies, if applicable.

464	Encrypted TCP/UDP communication for Kerberos password changes	Kerberos ticket validation and authentication for agents, Server Suite PuTTY, adpasswd, and passwd.
1433	Encrypted TCP communication for the collector connection to Microsoft SQL Server	The collector service sends audited activity to the database
3268	Encrypted TCP communication	Active Directory authentication and LDAP global catalog updates.
5063	Encrypted TCP/RPC communication for the agent connection to collectors	The auditing service records user activity on an audited computer.
5064	Encrypted SSL/TLS communication for the agent connection to collectors for systems that are not joined to Active Directory.	The auditing service records user activity on an audited computer outside of Active Directory.
none	ICMP (ping) connections	To determine whether if a remote computer is reachable.

Identify an Active Directory Site or Subnets

Depending on the size and distribution of your Active Directory site, an audit store might cover an entire site or specific subnet segments. If you have a large, widely distributed site, you should consider network connectivity and latency issues in determining which subnets each audit store should serve. In addition, you should always place collectors in the same site as the agents from which they receive data. Collectors and agents must always be in the same Active Directory forest. If possible, you should put collectors and agents in the same domain.

> **Note**: If you deploy agents in a perimeter network, such as a demilitarized zone (DMZ), that is separated from your main network by a firewall, put the collectors in the same Active Directory domain as the audited computers. The collectors can communicate with the audit store database through a firewall.

Determining How Many Collectors and Audit Stores to Install

Although you can add collectors and audit stores to your audit installation after the initial deployment, you might want to calculate how many you will need before you begin deploying components. You should always have at least two collectors to provide redundancy. As you increase the number of agents deployed, you should consider adding collectors.

Estimate the Number of Agents and Sessions Audited

If you plan to use more than the minimum number of collectors, the most important factor to consider is the number of concurrent sessions you expect to monitor on audited computers. The number of concurrent sessions represents the number of agents that are actively capturing user sessions in a site at the same time.

Guidelines for Linux and UNIX Computers

You can use the following guidelines as a starting point and adjust after you have observed how much audit data you are collecting and storing for Linux and UNIX computers:

500 (or less) agents	2	1
up to 1000 agents	4	1
more than 1000 agents	2 for every 500 agents	1 for every 1000 agents

Guidelines for Windows Computers or Mixed Environments

You can use the following guidelines as a starting point and adjust after you have observed how much audit data you are collecting and storing for Windows computers:

100 (or less) agents	2	1
more than 100 agents	2 for every 100 agents	1 for every 100 agents

If you auditing Linux, UNIX, and Windows computers, use the numbers of collectors and audit stores recommended for Windows agents unless you have significantly fewer Windows agents.

Determine the Recommended Hardware Configuration

The hardware requirements for collectors and audit store servers depend on the size of the installation and where the components are installed on the network. For example, the requirements for a computer that hosts the collector service are determined by the number of audited computers the collector supports, the level of user activity being captured and transferred, and the speed of the network connection between the agents and the collector and between the collector and its audit store.

Guidelines for Linux and UNIX Computers

You can use the following guidelines as the recommended hardware configuration for the computers you use for collectors and audit store servers when auditing Linux and UNIX computers:

Collectors	Up to 250 active UNIX agents	2	2.33 GHz	8 GB
	250 to 500 active UNIX agents	4	2.33 GHz	16 GB
Audit store	Up to 250 active UNIX agents	2	2.33 GHz	8 GB
	250 to 500 active UNIX agents	4	2.33 GHz	16 GB
	500 to 1000 active UNIX agents	4	2.33 GHz	32 GB

Guidelines for Windows Computers

You can use the following guidelines as the recommended hardware configuration for the computers you use as collectors and audit store servers when auditing Windows computers:

Collectors	Up to 100 active Windows agents	2	2.33 GHz	8 GB
Audit store	Up to 200 active Windows agents	2	2.33 GHz	8 GB
	200 to 500 active Windows agents	4	2.33 GHz	32 GB

Guidelines for Storage

Because audit and monitoring service collectors send captured user sessions to the active SQL Server database, you should optimize SQL Server storage for fast data logging, if possible. For the active database, you get the most benefit from improvements to disk write performance. Read performance is secondary. Fibre Attached Storage (FAS) and Storage Area Network (SAN) solutions can provide 2 to 10 times better performance than Direct Attached Storage (DAS), but at a higher cost. For attached databases that are only used to store information for queries, you can use lower-cost storage options.

Guidelines for Disk Layout

The following table outlines the recommended disk arrays:

Operating system	C: RAID 1	Operating system files, page file, and SQL Server binaries.
Microsoft SQL Server	D: RAID 10 (1+0)	Audit store database.
	E: RAID 10 (1+0)	Audit store database log files.
	F: RAID 1 or 10 (1+0)	Temporary database space (tempdb) for large queries for reports.
	G: RAID 1	Database dump files.

The size of disk needed depends on the number, length, and types of sessions recorded each day, the selected recovery model, and your data retention policies. For more information about managing audit store databases, see Managing audit store databases.

Deciding where to install agents

The Centrify Agent must be installed on all of the computers you want to audit. Therefore, as part of your planning process, you should decide whether you want to audit every computer on the network or specific computers, such as the computers used as servers or used to run administrative software.

Before installing the Centrify Agent for Windows, verify the following:

- The computer is joined to Active Directory.
- The computer has .NET 4.6.2 or later installed.
- The computer has Microsoft Windows Installer version 3.1 or newer.

Agents can communicate with a collector only if the agents and collector are in the same Active Directory forest.

For UNIX and Linux systems, be aware that desktop auditing is available only for some Linux distributions. Please see the release notes for the supported platform details.

Linux desktop auditing workings independently from shell session auditing. For platforms that support both, you can enable either one or both.

Deciding where to install consoles

You can install and run the Audit Manager console and the Audit Analyzer console on the same computer or on different computers. The computers where you install the consoles must be joined to the Active Directory domain and be able to access the management database that serves the installation.

You can also use the Audit Analyzer console to run queries from any additional computers with network access to the management database. Therefore, you should decide where it would be convenient to have this capability.

Audit and Monitoring Deployment Checklist

The following checklist provides an overview of each of the main steps that are involved when you deploy the Audit & Monitoring Service. For any tasks related to other Delinea software, there are links to more information and procedures.

For authentication and privilege elevation deployment steps, please see Authentication and Privilege Elevation services deployment checklist.

	Preparation and Planning		
1	Analyze your network topology to determine where to install components and services and any hardware or software updates required.		Overview of the Auditing Infrastructure
2	Create a list of the computers where you plan to install different components.		Planning an Audit Installation
3	Determine the scope of the audit installation.		Deciding on the Scope of the Installation
4	Determine the size of your database storage.		Sizing Recommendations for Audit Installations
	Pre-Requisite Tasks		
5	Create Active Directory security groups for managing the permissions required for the auditing and monitoring service infrastructure.		Creating Security Groups for Auditing
6	Install Microsoft SQL Server and create a database instance for use with the audit and monitoring service.		Installing and Configuring Microsoft SQL Server for Auditing
7	Prepare SQL Server for auditing.	This includes creating a backend service account that will run stored procedures.	Configuring SQL Server to Prepare for Auditing
8	Create a setup user account and give it database administrator (DBA) privileges.	You'll use this account and password to run the installers.	Creating a Setup User Account for Installation
	Install Tasks		
9	Install the Audit Manager and Audit Analyzer consoles.		Installing the Audit Manager and Audit Analyzer Consoles
10	In Audit Manager, create a new installation for auditing.		Creating a New Installation
11	In Audit Manager, set up the Audit Stores and Audit Store databases.		Creating the First Audit Store, Creating the First Audit Store Database
12	Install and configure the audit collector service on at least two Windows computers.		Installing the Audit Collectors
13	Install a Server Suite Agent for Windows on each Windows computer that you want to audit.		Installing the Server Suite Agent for Windows
14	Install a Server Suite Agent for *NIX on each UNIX or Linux computer that you want to audit.		Installing an Server Suite Agent for

15	Install and configure the Audit Management Server component on a Windows server computer.	For this task, run the installer using the setup user account that you created in step 8.	Installing the Audit Management Server and Configuring the Audit Management Server
16	Configure and enable auditing on the Windows computers, if they're not already enabled.		Enabling or Disabling Auditing on Windows Computers
17	Configure and enable auditing on the UNIX or Linux computers.		Enabling or Disabling Auditing on Linux and UNIX Computers
18	Install additional Audit Manager or Audit Analyzer consoles on any Windows computer that you want to use for the auditing and monitoring service.		Installing Additional Audit Manager or Audit Analyzer Consoles
	Verification Tasks		
19	Verify that data is being collected and agents are working correctly: Run dainfo on audited UNIX computers. Use Audit Analyzer to verify that data is being collected.		Checking the Status of the UNIX Agent

Supported SQL Server Editions

The current release of the Audit & Monitoring Service supports 64-bit versions of the following SQL Server editions:

- SQL Server 2008 Express with Advanced Services
- SQL Server 2008
- SQL Server 2008 R2 Express with Advanced Services (Service Pack 2 or higher recommended)
- SQL Server 2008 R2 (Service Pack 2 or higher recommended)
- SQL Server 2012 Express with Advanced Services
- SQL Server 2012 (All SP levels)
- SQL Server 2014 Express with Advanced Services
- SQL Server 2014 (All SP levels)
- SQL Server 2016 -- all SP levels for SQL Server 2016 Standard and Enterprise including the latest 2016 SP2 CU7 version.
- SQL Server 2017
- SQL Server 2017 Express Advanced
- SQL Server 2019
- SQL Server 2019 Express Advanced

  Note: SQL Server 2008 and 2008 R2 are not compatible with Windows 10

Checking SQL Server Logins for Auditing

An audit installation requires at least two Microsoft SQL Server databases: one for the management database and at least one for the first audit store database. To successfully connect to these databases, you must ensure that the appropriate users and computers have permission to read or to read and write for the databases that store audit-related information.

The simplest way to manage SQL Server logins for auditors and administrators is to do the following:

- Ensure you have a SQL Server login account for the NT Authority\System built-in account.
- Add the NT Authority\System account to the sysadmin fixed server role.
- Use the Audit Manager console to add Active Directory users and groups to the Auditor roles and/or assign them administrative rights over the audit installation.

If you use Audit Manager to manage SQL Server logins, you can use Active Directory membership to automatically add and remove the permissions required for auditing activity. There is no requirement to use the SQL Server Management Studio to manage logins or permissions. Since it is recommended that you have a dedicated SQL Server instance for auditing, giving the NT Authority\System account a SQL Server login and system administrator role is an acceptable solution for most organizations.

Auditing Permissions for SQL Server

NT Authority\System	machine account	SQL Server Roles: sysadmin role

Creating Security Groups for Auditing

Depending on whether you configure Microsoft SQL Server to use Windows only authentication or Windows or SQL Server authentication, your SQL Server login credentials might be a Windows account or a SQL Server login account that is not associated with a Windows account.

To facilitate communication and the management of SQL Server logins, you can create Active Directory security groups for the following users and computers:

- **Centrify-Admins** for the user accounts that perform administrative tasks using Audit Manager.
- **Centrify-Auditors** for the user accounts that use Audit Analyzer.
- **Centrify-TrustedCollectors** for the computers accounts that host the collector service.

If you create these Active Directory security groups, you can then use Audit Manager to grant Manage SQL Login permissions for each group to allow its members to connect to the appropriate SQL Server database. Creating Active Directory security groups with SQL Server logins enables you to manage access to the databases required for auditing through Active Directory group membership without the help of the database administrator.

Any time you want to add an administrator, auditor, or collector computer to the installation, you simply add that user account or computer object to the appropriate Active Directory group. If an administrator or auditor leaves or if you want to stop using the collector on a particular computer, you can remove that user or computer from its Active Directory security group to prevent it from accessing the database.

Auditing Security Groups

Centrify-Admins for the user accounts that perform administrative tasks using Audit Manager.	Active Directory	no explicit SQL Server permissions needed — Audit Manager handles the SQL Server permissions	Creating Active Directory security groups with SQL Server logins enables you to manage access to the databases required for auditing through Active Directory group membership without the help of the database administrator.
Centrify-Auditors for the user accounts that use Audit Analyzer.			
Centrify-Collectors for the			

computer accounts that host the collector service.

Determining Storage Requirements for Auditing

There are two important policy decisions your organization must make to determine how much disk space you need for storing audit data and how frequently you should plan to rotate the active database. Early on in the deployment, your organization should consider the following policy decisions:

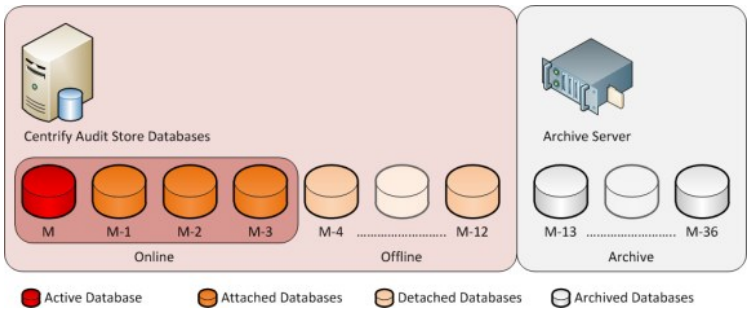
- What is your rotation policy?

  To answer this question, you should decide the period of time audited sessions should be available in the active and attached database for auditors to review using the Audit Analyzer console. For example, you might decide that you want to be able to query audited activity for a minimum of 90 days. Alternatively, you might want to define a rotation policy that is based on the size of the database, so that the active database is not allowed to exceed a specific size. For example, you might decide that the database should not exceed 4GB to optimize performance for archiving.

- What is your retention policy?

  To answer this question, you should decide the period of time to keep audited data available in attached databases and the maximum period of time to keep archived audit data available before purging data that's no longer needed.

To illustrate how these policies affect database management, consider a rotation policy based on a monthly schedule. In this example, an organization decides that audit data must be available for querying for a minimum of 90 days. On the first of each month, a new active database is brought online and the previous 3 months remain available as attached databases to support querying 90 to 120 days of audit data.



In this model, there are four databases online at the same time. This example organization has also decided on a two-stage retention policy. In the first stage, older databases are detached from Audit Analyzer, but remain stored on the SQL Server instance for up to one year. The detached databases provide up to a year of audit history and can be reattached, if that data is needed. In the second stage of the retention policy, the organization archives the audit store databases for up to 3 years. After three years, the oldest data is permanently purged.

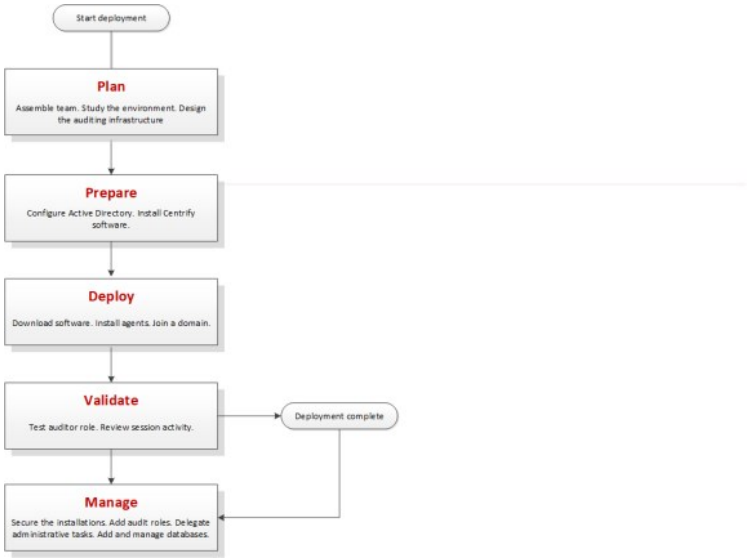
Depending on your requirements, you might use a similar retention policy or have different policies based on the session activity you are capturing. For example, you might keep sessions that capture normal user activity for three years, but keep sessions that capture SOX compliance for ten years.

To project your storage requirements, you will need additional information that is specific to your organization, including the number of computers you plan to audit, the number of sessions that are active on audited computers, and whether you record all activity using video capture or only summaries of user activity. To collect this information, you should monitor a pilot deployment. You can then use the information from the pilot deployment as described in Estimating database requirements based on the data you collect to estimate your storage requirements based on how much audit data you are generating. The decisions you make for the rotation and retention policies will help you further refine those estimations as you expand the deployment.

> **Note**: If you define a rotation policy similar to this example, you can automate the monthly database rotation using Centrify application programming interfaces or using scheduled SQL Server jobs or scripts that perform database maintenance operations. For more information, see the Database Management Guide.

What's Involved in the Deployment Process

Most of the planning in this chapter has focused on designing the auditing infrastructure and deciding where to install components. The following illustration provides a visual summary of the complete deployment process and highlights the keys to success. The sections after the flowchart provide additional details about what's involved in each phase or the decisions you will need to make, such as who should be part of the deployment team, where to install the software, and who has permission to do what.



Plan

During the first phase of the deployment, you collect and analyze details about your organization's requirements and goals. You can then also make preliminary decisions about sizing, network communication, and where to install components.

Here are the key steps involved:

- Identify the goals of the deployment.
  - Is auditing important for specific computers?
  - Is auditing important for computers used to perform administrative tasks?
  - Is auditing important for computers that host specific applications or sensitive information?
  - Should auditing be required for users in specific groups or with specific roles?
- Assemble a deployment team with Active Directory, UNIX, and other expertise, including at least one Microsoft SQL Server database administrator.
- Provide basic training on Centrify architecture, concepts, and terminology.
- Analyze the existing environment to identify target computers where you plan to install Centrify auditing infrastructure components.
  - Plan for permissions and the appropriate separation of duties for your organization.
  - Review network connections, port requirements, firewall configuration.
  - Identify computers for Audit Manager and Audit Analyzer consoles.
  - Identify computers to be used as collectors, audit stores, and the management Database.
  - Verify that you have reliable, high-speed network connections between components that collect and transfer audit data and sufficient disk storage for the first audit store database.
  - Identify the initial target group of computers to be audited.
- Define and document your data archiving and data retention policies.

Prepare

After you have analyzed the environment, you should prepare the Active Directory groups to use. You can then install administrative consoles and the auditing infrastructure.

Here are the key steps involved:

- (Optional) Create the additional Active Directory security groups for your organization.

- Groups can simplify permission management and the separation-of-duties security model.
- Install Audit Manager and Audit Analyzer on at least one administrative Windows computer.
- Create a new audit installation and a management database on one computer.
- Create an audit store and audit store database on at least one computer.
- Install a collector on at least two computers.

Deploy

After you have prepared Active Directory, installed administrative consoles on at least one computer, and created at least one installation, you are ready to deploy agents on the computers to be audited.

Here are the key steps involved:

- Install the agent on the computers you want to audit.
- Join the appropriate domains and zones.
- Prepare a Group Policy Object for deploying agents remotely using a group policy.
- Assign the appropriate permissions to the users and groups who should have access to audit data.

Validate

After you have deployed agents on target computers, you should test and verify operations before deploying on additional computers.

Here are the key steps involved:

- Log on locally to a target computer using an Active Directory user account and password to verify Active Directory authentication.
- Open Audit Analyzer and query for your user session.

Manage

After you have tested and verified auditing operations, you are ready to begin managing your audit installation.

Here are the key steps involved:

- Secure the installation.
- Add auditor roles and assign permissions to the appropriate users and groups.
- Create new databases and rotate the active database.
- Archive and delete old audit data.

Installing the Audit and Monitoring Service

This chapter describes how to install Delinea Audit & Monitoring Service in a production environment. In production environments, you should use a different computer for each component. For example, you should install the collector on its own computer separate from the computer used for the audit store database, and on a separate computer from the audit management database.

To create a simpler installation with all components on the same computer for evaluation purposes, see the Evaluation Guide for Linux and UNIX. For evaluation of auditing features in a Windows-only environment, see the Evaluation Guide for Windows.

Delinea

Installation Preview

As a preview of what's involved in the installation process, the following steps summarize what you need to do and the information you should have on hand for a successful deployment of Centrify software.

To prepare for deployment:

1. Analyze your network topology to determine where to install components and services and any hardware or software updates required.

   For a review of the decisions to make and recommended hardware configuration, see Planning an audit installation.

2. Create a list of the computers where you plan to install different components.

   For example, list the computers where you plan to install agents, collectors, audit store databases, and consoles.

   For a review of the requirements associated with each component, see Planning an audit installation.

3. Determine the scope of the audit installation.

   The most common deployment scenario is a single installation for an Active Directory site, but you can have more than one installation, if needed, and use subnets to limit the scope of the installation.

   For a review of what constitutes an installation, see Deploying auditing components in an audit installation and Deciding on the scope of the installation.

4. Create Active Directory security groups for managing the permissions that are required for accessing the databases that store audit-related information.

   For a review of the Active Directory security groups to create, see Checking SQL Server logins for auditing.

5. Install Microsoft SQL Server.

   If you are not a database administrator in your organization, you should submit a service request or contact an administrator who has permission to create databases.

   For more information about preparing a SQL Server database engine for auditing, see Installing and configuring Microsoft SQL Server for auditing.

6. Install the Audit Manager and Audit Analyzer consoles.

   For more information about installing the consoles, see Installing the Audit Manager and Audit Analyzer consoles.

7. Create a service account with the permissions to create a new installation. For details, see Creating a setup user account for installation.

8. Open Audit Manager to create a new installation.

   For more information about using Audit Manager to create a new installation and audit store, see Creating a new installation.

9. Install the audit collector service on at least two Windows computers.

   You can add collectors to the installation at any time. For more information about installing and configuring collectors, see Installing the audit collectors.

10. Install the Audit Management Server on a Windows computer.

    For more information, see Installing the Audit Management Server.

11. Install a Centrify Agent on each Windows, Linux, or UNIX computer you want to audit.

    For more information about installing Centrify Agents, see Installing the Centrify Agent for Windows and Installing an Centrify Agent for *NIX.

12. Make sure agents are enabled for auditing. For details, see Enabling or disabling auditing on Windows computers and Enabling or disabling auditing on Linux and UNIX computers.

13. Install additional Audit Manager or Audit Analyzer consoles on any Windows computer that you want to use to manage the installation or query and play back session data.

After the initial deployment, you can add new agents, collectors, audit stores, and audit store databases to the installation or create additional installations.

Delinea

Installing and configuring Microsoft SQL Server for Auditing

If you want to audit user activity on Windows, you must have at least one Microsoft SQL Server database instance for the audit management database and audit store databases. Centrify recommends that you use a dedicated instance of SQL Server for the audit management database. A dedicated SQL Server instance is an instance that does not share resources with other applications. The audit store databases can use the same dedicated instance of SQL Server or their own dedicated instances.

There are three database deployment scenarios for your audit installation:

- **Evaluation**—You can install Microsoft SQL Server Express with Advanced features directly from the configuration wizard or by running the SQLEXPRADV_x64_ENU.exe setup program to create a new Microsoft SQL Server Express database instance for testing. However, if you are auditing a production environment*,* you should not use Microsoft SQL Server Express.

  If you choose to install a different version of Microsoft SQL Server Express for an evaluation and the version requires .NET version 3.5 SP1, you will need to manually install the .NET files yourself (the installer doesn't include these files)..

- **Manual installation with system administrator privileges**—Install a Microsoft SQL Server database instance for which you are a system administrator or have been added to the system administrator role.

- **Manual installation without system administrator privileges**—Have the database administrator (DBA) install an instance of Microsoft SQL Server and provide you with system administrator credentials or information about the database instance so that you can create the management database and audit store databases.

Downloading and installing SQL Server manually

You can use an existing instance of Microsoft SQL Server or install a new instance. You can install Microsoft SQL Server directly from the Centrify ISO or ZIP, or download it from the Microsoft web site. In selecting a version of SQL Server to download, you should be sure it includes Advanced Services. Advanced Services are required to support querying using SQL Server full-text search.

After downloading an appropriate software package, run the setup program using your Active Directory domain account and follow the instructions displayed to complete the installation of the Microsoft SQL Server instance.

When selecting the components to install in the setup program, expand the Database Services and select Full Text Search as a feature to be installed. For the authentication mode, select Windows authentication if all connections between auditing components will be in the same forest. If any communication will be outside of the forest, use Mixed Mode authentication and select the option to add the current user to the SQL Server Administrator role.

> **Note**: Centrify does not recommend running SQL Server under a high privilege account such as a LocalSystem account.

Configuring SQL Server to prepare for auditing

After you install the SQL Server database engine and management tools, you should configure the SQL Server instance for auditing. For example, depending on the version of SQL Server you install, you might need to manually enable fulltext search.

To prepare a Microsoft SQL Server database instance for storing audit data:

- Use SQL Server Surface Area Configuration for Services and Connections to check the status and start the database engine, full-text search, and SQL Server Browser services.
- Use SQL Server Surface Area Configuration for Services and Connections or SQL Server Configuration Manager to enable remote connections for TCP/IP.
- Verify whether SQL Native Client Configuration Client Protocol is using the default TCP port 1433 for network communications. If you use a different port, you should note the port number because you will need to specify it in the server name when you create the management and audit store databases.
- Use SQL Server Configuration Manager to restart the SQL Server and SQL Server Browser services.
- Create a database backend service account in the system administrator (sa) fixed server role on the selected database server; you'll specify this account when you create the audit installation. This account is used to run backend stored procedures. If desired, this can be the same account that you use the create the audit installation, as mentioned in Creating a setup user account for installation.

Configuring Amazon RDS for SQL Server for auditing

You can deploy audit store databases on Amazon RDS instances, if desired. Centrify supports Amazon RDS for 2016 and earlier versions (not 2017).

You must host the audit management database on a traditional SQL Server, such as SQL Server Express, Standard, or Enterprise.

If you want to use an instance of Amazon RDS for SQL Server for audit store databases you need to do the following configurations:

- After you set up your Amazon RDS for SQL Server, join the RDS SQL server to AWS Microsoft Active Directory.
- Enable these DB Parameter Group settings on RDS SQL Server:
  - clr enabled
  - show advanced options

    You can use the AWS Management Console, API, or the AWS command line interface to enable these settings.

    For more details, see <http://docs.aws.amazon.com/AmazonRDS/latest/UserGuide/USER_WorkingWithParamGroups.html>.
- Set up a one-way or two-way forest trust between the AWS Microsoft Active Directory and your on-premise Active Directory forest so that users of your on-premise Active Directory forest can access resources in the AWS Microsoft Active Directory.

  Note: Amazon RDS for SQL Server with High Availability is supported.

Amazon RDS for SQL Server required permissions

The permissions for Amazon RDS for SQL Server vary a little from the permissions for local or network instances of SQL Server. This section covers the Amazon RDS for SQL Server permission required or granted for each auditing component.

Permissions to the audit store database stored procedures service account

The stored procedures service account (in other words, the 'execute as' account) no longer requires the sysadmin server role permission if the audit store database is on Amazon RDS for SQL Server.

The service account requires only the db_owner database role permission and the account will be added to be member of db_owner database role by Add Audit Store Database wizard.

> **Note**:You do not need to grant the permissions manually. The Audit Manager console, Powershell cmdlet, or SDK grants the permissions to the service account.

Collector account permissions for audit store databases on Amazon RDS for SQL Server

The collector account requires the following server level permissions on the Amazon RDS for SQL Server:

- 'View Any Definition' server level permission
- 'View Server State' server level permission

The collector account requires the following database level permissions on the audit store database:

- A member of the 'collector' database role

  > **Note**:You do not need to grant the permissions manually. The Audit Manager console, Powershell cmdlet, SDK, or the Collector Configuration wizard grants the permissions to the collector account.

Management Database Account permissions for audit store databases on Amazon RDS for SQL Server

The management database account requires the following server level permissions on the RDS SQL server:

- 'Alter Trace' server level permission
- 'Alter Any Login' server level permission
- Grant permission of 'Alter Any Login' server level permission
- Grant permission of 'View Any Definition' server level permission
- Grant permission of 'View Server State' server level permission

The management database account requires the following database level permissions on the audit store database:

- A member of 'managementdb' database role

Note:You do not need to grant the permissions manually. The Audit Manager console, Powershell cmdlet, or SDK grants the permissions to the management database account.

Permissions to create the audit store database on Amazon RDS for SQL Server

In order to create an audit store database on Amazon RDS for SQL Server, you must have the following permissions:

- 'Create Any Database' server level permission to create the database on the server
- 'Alter Any Login' server level permission to create the login for the management database account and the collector account
- Alter Any Login' server level permission to grant the 'Alter Any Login' permission to the management database account
- 'Alter Trace' server level permission to grant the 'Alter Trace' permission to the management database account
- 'View Any Definition' server level permission to grant the 'View Any Definition' (with grant) permission to the management database account and also to grant the 'View Any Definition' permission to the collector account
- Grant permission of 'View Server State' server level permission to grant the 'View Server State' (with grant) permission to the management database account and also to grant the 'View Server State' permission to the collector account

Permissions to upgrade the audit store database on Amazon RDS for SQL Server

The required permission to upgrade the audit store database on Amazon RDS for SQL Server is the 'db owner' permission on the database. No server level permissions are required

Installing the Audit Manager and Audit Analyzer Consoles

You can install Audit Manager and Audit Analyzer on the same computer or on different computers. The computers where you install the consoles must be joined to the Active Directory domain and be able to access the management database.

In most cases, the consoles are installed together on at least one computer.

You can use either the individual console installers or the main installer.

- Install Audit Manager using the console installer
- Install Audit Analyzer using the console installer
- Install both consoles using the main installer

Install Audit Manager Using the Individual Console Installer

1. Log on using an Active Directory domain account.
2. Open the ISO file, and navigate to the following folder:

   \DirectAudit\Console\
3. Run the Audit Manager installer : Centrify DirectAudit Administrator Console64.exe.
4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I accept the terms in the license agreement**, then click **Next**.
6. On the Destination Folder page, review the installation location and click **Next** to continue.
7. If you want to install the console in a different location, click **Change** and navigate to the desired folder.
8. Click **Install** to begin the installation.
9. The installer installs the necessary files. To open the console, keep the **Launch Centrify Audit Manager** option selected. Otherwise, deselect the option.
10. Click **Finish** to close the installer.

After you install Audit Manager, you can open Audit Manager to create a new installation.

Install Audit Analyzer Using the Individual Console Installer

1. Log on using an Active Directory domain account.
2. Open the ISO file, and navigate to the following folder:

   \DirectAudit\Console\
3. Run the Audit Manager installer : Centrify DirectAudit Auditor Console64.exe.
4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I accept the terms in the license agreement**, then click **Next**.
6. On the Destination Folder page, review the installation location and click **Next** to continue.
7. If you want to install the console in a different location, click **Change** and navigate to the desired folder.
8. Click **Install** to begin the installation.
9. The installer installs the necessary file. To open the console, keep the **Launch Centrify Audit Analyzer** option selected. Otherwise, deselect the option.
10. Click **Finish** to close the installer.

Install Audit Manager and Audit Analyzer on the Same Computer Using the Main Installer

1. Log on using an Active Directory domain account.
2. Open the ISO file.

   If you created a physical CD from the ISO file that you downloaded, the Getting Started page is displayed automatically. If the page is not displayed, open the autorun.exe file to start the installation.
3. On the Getting Started page, click **Audit & Monitor** to start the setup program for audit and monitoring service components.
4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I accept the terms in the license agreement**, then click **Next**.
6. Select **Centrify Administration** to install both Audit Manager and Audit Analyzer, then click **Next**.
7. In the rare case where the administrator should not have access to the Audit Analyzer, select Audit Manager, then click **Next**.
8. After you install Audit Manager, you are prompted to create a new installation. If you want to create the installation at a later time, you can run the setup program again to create a new installation.

Creating a Setup User Account for Installation

You'll need to create an account to use when you create the audit installation, set up audit stores, and so forth. This account needs to have the following permissions:

- Active Directory:
  - Permission to create serviceConnectionPoint objects on the container or organizational unit you select for publishing installation information
- SQL Server:
  - Be a member of the system administrator (sa) fixed server role

This user account needs these permissions for the initial installation and some maintenance tasks. It's a good practice to add this account to your Centrify-admins security group, as mentioned in Creating security groups for auditing.

Creating a New Installation

Before you can begin auditing, you must create at least one audit installation and a management database. Creating the management database, however, requires SQL Server system administrator privileges on the computer that hosts the SQL Server instance. If possible, you should have a database administrator add your Active Directory domain account to the SQL Server system administrators role.

If you have not been added to the system administrators role, you should contact a database administrator to assist you. For more information about creating a new installation when you don't have system administrator privileges, see How to create an installation without system administrator privileges.

To Create a New Installation and Management Database as a System Administrator

1. Log on using an Active Directory account with permission to install software on the local computer and permissions listed in Creating a setup user account for installation.
2. Open Audit Manager.

   Note:If you haven't configured an audit installation yet, the New Installation wizard opens automatically.
3. If this isn't your first audit installation: in Audit Manager, right-click **Centrify Audit Manager** and select **New Installation** to open the New Installation wizard.
4. Enter a name for the new installation, then click **Next**.

   Tip: Name the installation to reflect its administrative scope. For example, if you are using one installation for your entire organization, you might include the organization name and All or Global in the installation name, such as AcmeAll. If you plan to use separate installations for different regions or divisions, you might include that information in the name, for example AcmeBrazil for a regional installation or AcmeFinance for an installation that audits computers in the Finance department.
5. Select the option to create a new management database and verify the SQL Server computer name, instance name, and database name are correct.

   If the server does not use the default TCP port (1433), you must provide the server and instance names separated by a backslash, then type a comma and the appropriate port number. For example, if the server name is ACME, the instance name is BOSTON, and the port number is 1234, the server name would be ACME\BOSTON,1234.

   If you're installing on a SQL cluster, enter the SQL cluster name in the SQL Server computer name field.

   If you're connecting to a SQL Server availability group listener, click Options (next to the Server Name) and enter the following connection string parameters:

   MultiSubnetFailover=Yes

   Click **Next** to continue.
6. Select **Use the default NT AUTHORITY\SYSTEM account** to use the internal account or select a specific SQL login account with sufficient privileges, then click **Next**.

   A SQL login account is required to run the stored procedures that read and write information to the management database. The account must a member of the system administrator (sa) fixed server role on the selected database server, as mentioned in Configuring SQL Server to prepare for auditing.
7. Type the license key you received, then click **Add** or click **Import** to import the keys directly from a file, then click **Next**.
8. Accept the default location or click **Browse** to select a different Active Directory location for publishing installation information, then click **Next**.

   You must have the Active Directory permission to Create serviceConnectionPoint objects on the container or organizational unit you select for publishing installation information.
9. Select the installation-wide auditing options you want to enable, then click **Next**.
   - Select **Enable video capture recording of user activity** if you want to capture shell or desktop activity on computers when users are audited, then click **Next**.

   Selecting this option enables you to review everything displayed during an audited user session, but will increase the audit store database storage

requirements for the installation. You can deselect this option if you are only interested in a summary of user activity in the form of audit trail events. Audit trail events are recorded when users log on, open applications, and select and use role assignments with elevated rights.

- Select **Do not allow any users to review their own sessions** to prevent all users from updating the review status for their own sessions or adding comments to their own sessions.
- Select **Do not allow any users to delete their own sessions** to prevent all users from deleting their own sessions.

If you set either of the installationwide policies disallowing user activity, the policy takes precedence over any rights provided by a user's audit role.

10. Review details about the installation and management database, then click **Next**.

If you have SQL Server system administrator (sa) privileges and can connect to the SQL Server instance, the wizard automatically creates the management database.

11. Select the **Launch Add Audit Store Wizard** option if you want to start the Add Audit Store wizard, then click **Finish**

If you want to create the first audit store database on a different SQL Server instance, you should deselect the **Launch Add Audit Store Wizard** option and click **Finish**.

For more information about adding the first audit store database, see Creating the first audit store.

How to Create an Installation without System Administrator Privileges

If you do not have the appropriate permission to create SQL Server databases, you cannot use the New Installation wizard to create the management database without the assistance of a database administrator.

If you do not have system administrator privileges, the wizard prompts you to specify another set of credentials or generate SQL scripts to give to a database administrator. For example:

If you don't have a database administrator immediately available who can enter the credentials for you, you cannot continue with the installation.

To Create an Installation when you don't have System Administrator Privileges

1. Select the option to generate the SQL scripts, then click **Next**.
2. Select the folder location for the scripts, then click **Next**.
3. Review details about the installation and management database you want created, then click **Next**.

   The wizard generates two scripts: Script1 prepares the SQL Server instance for the management database and Script2 creates the database.
4. Click **Finish** to exit the New Installation wizard.
5. Send the scripts to a database administrator with a service or change-control request.

   Note:You should notify the database administrator that the scripts must be run in the proper sequence and not modified in any way. Changes to the scripts could render the database unusable.
6. After the database administrator creates the database using the scripts, open the Audit Manager console to run the New Installation wizard again.
7. Type the name of the installation, then click **Next**.
8. Select **Use an existing database** and verify the database server and instance name, then click the Database name list to browse for the database

name that the database administrator created for you.

If the server does not use the default TCP port, specify the port number as part of the server name. For example, if the port number is 1234, the server name would be similar to ACME\BOSTON,1234.

If you're installing on a SQL cluster, enter the SQL cluster name in the SQL Server computer name field.

9. Select the database name from the list of available databases, click **OK**, then click **Next**.

   You should only select an existing database if the database was created using scripts provided by Centrify.

10. Select **Use the default NT AUTHORITY\SYSTEM account** to use the internal account or select a specific SQL login account with sufficient privileges, then click **Next**.

A SQL login account is required to run the stored procedures that read and write information to the management database. The account must a member of the system administrator (sa) fixed server role on the selected database server.

11. Type a license key or import licenses from a file, then click **Next**.
12. Review details about the management database to be installed, then click **Next**.
13. Select the **Launch Add Audit Store Wizard** option if you want to start the Add Audit Store wizard, then click **Finish**.

Creating the First Audit Store

If you selected the Launch Add Audit Store Wizard check box at the end of the New Installation Wizard, the Add Audit Store Wizard opens automatically. You can also open the wizard at any time by right-clicking the Audit Stores node in the Audit Manager console and choosing Add Audit Store.

To create the first audit store:

1. Type a display name for the audit store, then click **Next**.

   Tip: If your plan specifies multiple audit stores, use the name to reflect the sites or subnets serviced by this audit store. Note that an audit store is actually a record in the management database. It is not a separate process running on any computer. You use a separate wizard to create the databases for an audit store.

2. Select the type of systems that the audit store will serve.

   You can choose to separate Windows traffic from UNIX traffic if both types of agents belong to the same site or subnet.

   The options are:

   - Windows and UNIX
   - Windows
   - UNIX

   Click **Next** to continue.

3. Click **Add Site** or **Add Subnet** to specify the sites or subnets in this audit store.

   - If you select Add Site, you are prompted to select an Active Directory site.
   - If you select Add Subnet, you are prompted to type the network address and subnet mask.

   After you make a selection or type the address, click **OK**. You can then add more sites or subnets to the audit store. When you are finished adding sites or subnets, click **Next** to continue.

   The computer you use to host the audit store database should be no more than one gateway or router away from the computers being audited. If your Active Directory sites are too broad, you can use standard network subnets to limit the scope of the audit store.

4. Review information about the audit store display name and sites or subnets, then click **Next**.

5. Select the **Launch Add Audit Store Database Wizard** option if you want to create the first audit store database, then click **Finish**.

Creating the First Audit Store Database

If you selected the Launch Add Audit Store Database Wizard check box at the end of the Launch Add Audit Store Wizard, the Add Audit Store Database Wizard

opens automatically. You can also open the wizard at any time from the Audit Manager console by expanding an audit store, right-clicking the Databases node, and choosing Add Audit Store Database.

To create the first audit store database:

1. Type a display name for the audit store database, then click **Next**.

   The default name is based on the name of the audit store and the date the database is created.

2. Select the option to create a new database and verify that the SQL Server computer name, instance name, and database name are correct.

   The default database name is the same as the display name. You can change the database name to be different from the display name, if you want to use another name.

   If the server does not use the default TCP port, specify the port number as part of the server name. For example, if the port number is 1234, the server name would be similar to ACME\BOSTON,1234.

   If you're installing on a SQL cluster, enter the SQL cluster name in the SQL Server computer name field.

   When entering the SQL Server host computer name, note that you can enter either the server short name (which is automatically resolved to its fully qualified domain name, or FQDN) or the actual server FQDN or the CNAME alias for the server.

   If the database is an Amazon RDS SQL Server:

   1. Select the **This is an Amazon RDS SQL Server** option.
   2. In the Server Name field, enter the RDS SQL Server database instance endpoint name used for Kerberos authentication.

   For example, if the database host name is northwest1 and the domain name is sales.acme.com, then the endpoint name would be northwest1.sales.acme.com.

   Click **Options** to enter additional connection string parameters or to enable data integrity checking.

   - If you're connecting to a SQL Server availability group listener, click Options (next to the Server Name) and enter the following connection string parameters:

   MultiSubnetFailover=Yes

   - You can enable or disable data integrity checking once, when you create the audit store database. To change the state, you must rotate to a new audit store database.

   When you create your audit store database, you have the option to enable data integrity checking. Data integrity checking provides the ability to detect if auditing data has been tampered. For example, data integrity checking can detect if a user who has write privileges over the Audit Store database directly manipulates the audited session data by making a direct connection to the Microsoft SQL Server database. Data integrity checking cannot detect tampering if a database administrator deletes an entire session or database.

   Click **Next** to continue.

3. Because this is the first audit store database, you also want to make it the active database. This option is selected by default. If you are creating the database for future use and don't want to use it immediately, you can deselect the **Set as active database** option. The option to create a new database is also selected by default.

   Click **Next** to continue.

4. Specify the stored procedures services account:

   - Select **Use the default NT AUTHORITY\SYSTEM account** to use the internal account
   - Or, select **Specify a SQL Login account** and enter a specific SQL login account with sufficient privileges.

   A SQL Server login account is required to run the stored procedures that read and write information to the management database.

   For local or network databases, the account must a member of the system administrator (sa) fixed server role on the selected database server.

   If the database is an Amazon RDS for SQL Server, the account you specify will be added as a member of the db_owner fixed database role in Amazon RDS for SQL Server.

Click **Next** to continue.

5. Review details about the audit store database, then click **Next**.

   If you have the correct privileges and can connect to the SQL Server instance, the wizard automatically creates the audit store database.

Installing the Audit Collectors

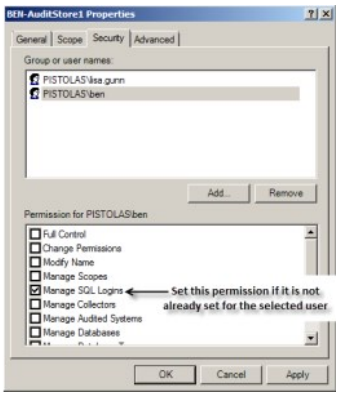
After you have created a new installation, with an audit management database and at least one audit store and audit store database, you must add the collectors that will receive audit records from the agents and forward those records to the audit store. For redundancy and scalability, you should have at least two collectors. For more information about planning how many collectors to use and the recommended hardware and network configuration for the collector computers, see Deciding where to install collectors and audit stores.

Set the Required Permission

Before you configure a collector, you should check whether your user account has sufficient permissions to add new collector accounts to the audit store database. If you are a database administrator or logged on with an account that has system administrator privileges, you should be able to configure the collector without modifying your account permissions. If you have administrative rights on the computer that hosts Audit Manager but are not a database administrator, you can set the appropriate permission before continuing.

To set the permission required to add accounts to the audit store database:

1. Open Audit Manager.
2. Expand the installation, then expand Audit Stores.
3. Select the audit store that the collector will connect to, right-click, then click **Properties**.
4. Click the **Security** tab.
5. Click **Add** to search for and select the user who will configure the collector.
6. Select the **Manage SQL Logins** right, then click **OK**.



Install the Collector Service using the Setup Program

If your user account has sufficient permissions to add new collector accounts to the audit store database, you can install a collector by running the setup program on the computer on which you want to install the collector. When you are prompted to select components, select Audit Collector and deselect all of the other components, then click **Next**. Follow the instructions in the wizard to select the location for installing files and to confirm your selections, then click **Finish** to complete the installation.

The collector installer is in the \DirectAudit\Collector folder in your installation media.

Configure the Audit Collector Service

By default, when you click **Finish**, the setup program opens the Collector Configuration Wizard. Alternatively, you can launch the configuration wizard at any time by clicking **Configure** in the Collector Control Panel.

To configure the collector service:

1. On the first screen of the Collector Configuration Wizard, select the DirectAuditinstallation to assign this collector to.

   If the computer is also enrolled in the Centrify Cloud Platform and you have already enabled auditing in the Admin Portal, you can choose which kind of

audit installation to assign the collector to:

- **Automatic**: This option configures the collector to receive audit data from systems that are enrolled in the Centrify Cloud Platform and systems that are joined to Active Directory.

  You use the Admin Portal to configure which installation is used by these systems. The systems have either the Centrify Client for Linux or Centrify Client for Windows and the audit packages installed so that auditing is enabled. These systems do not have to be joined to Active Directory.

- **Manual**: This option configures the collector to receive audit data from systems that are joined to Active Directory and have either the Centrify Agent for *NIX or Centrify Agent for Windows installed and the system is enabled for auditing. For this option, select the audit installation.

  Computers that are not enrolled in the Centrify Cloud Platform have a single list of audit installations to pick from.

Click **Next** to continue.

The configuration wizard verifies that the specified installation has an audit store that services the site that the collector is in and that the collector and its audit store database are compatible.

2. Enter the port number(s) that the collector will use to communicate with the audited systems.
   - The default port is 5063 for systems that have either the Centrify Agent for *NIX or Centrify Agent for Windows installed.
   - If the computer is also enrolled in the Centrify Cloud Platform, the default port is 5064 for systems that have either the Centrify Client for Linux or Centrify Client for Windows installed.
   - If you set the installation to Manual in the previous step, Centrify Client System port is greyed out.

     For either port, if you specify a different port and have the default Windows firewall turned on, the wizard checks whether the port is open. If the port isn't open, the wizard offers to open it for you.

     If you are using another vendor's firewall, open the port with the tools provided by that vendor. If there's an upstream firewall—such as a dedicated firewall appliance—between the collector and the computers to be audited, contact the appropriate personnel to open the port on that firewall.

   Click **Next** to continue.
3. If the computer where you're configuring a collector belongs to multiple audit stores in the auditing installation, choose which audit store this collector will connect to, then click **Next**.

   For example, two audit stores can have an overlapping scope if one audit store scope is configured for Active Directory sites and another one is set by subnets.
4. Select whether you want to use Windows authentication or SQL Server authentication when the collector authenticates to the audit store database, then click **Next**.

   In most cases, you should choose Windows authentication to add the computer account to the audit store database as a trusted, incoming user.

   If Microsoft SQL Server is in a different forest or in an untrusted forest, you should use SQL Server Management Studio to set up one or more SQL Server login accounts for the collector. After you create the SQL Server login account for the collector to use, you can select SQL Server authentication, then type the SQL Server login name and password in the wizard.
5. Type the maximum number of connections for the Microsoft SQL Server connection pool, then click **Next**.
6. Review the settings for the collector, then click **Next**.
7. Click **Finish** to close the wizard and start the collector service.

Installing the Audit Management Server

It's a best practice to install the Audit Management Server after you've installed your audit stores, audit store databases, and installed your collectors. You can install the Audit Management Server either on a new computer or one where you've installed a collector.

To install the Audit Manager Server:

1. Log on using an Active Directory domain account.
2. Open the ISO file, and navigate to the following folder:

   \DirectAudit\Audit Management Server\
3. Run the Audit Management Server installer : Centrify DirectAudit Audit Management Server64.exe.
4. At the Welcome page, click **Next**.
5. Review the terms of the license agreement, click **I accept the terms in the license agreement**, then click **Next**.
6. On the Destination Folder page, review the installation location and click **Next** to continue.
7. If you want to install the console in a different location, click **Change** and navigate to the desired folder.
8. Click **Install** to begin the installation.
9. The installer installs the necessary files. To open the console, keep the **Run Audit Management Configuration Wizard** option selected. Otherwise, deselect the option.
10. Click **Finish** to close the installer.

Configuring the Audit Management Server

By default, when you finish installing the Audit Management Server, the installer opens the Audit Management Server Configuration Wizard.

To configure the Audit Management Server:

1. On the first page, select the installation for which you want to configure the Audit Management Server.

   If you have one installation, it's already selected.

   Click **Next** to continue.
2. On the Authentication Type page, specify which kind of authentication that the Audit Management Server will use. The choices are:

   - **Windows Authentication:** Specify the computer account that will run the Audit Management Server.
   - **SQL Server Authentication**: Specify the SQL Server user name and password to use. Click Test Connection to make sure that the login credentials work.

   Click **Next** to continue.
3. On the Summary page, review the Audit Management Server configuration details, and click **Next** to continue.
4. Click **Finish** to close the configuration wizard.

Installing the Centrify Agent for Windows

You must install an agent on every Windows computer that you want audit. You can install the agent in the following ways:

- **Interactively**, by running the Centrify setup program on each computer.

  When the installation finishes, the agent configuration wizard launches automatically. You can configure the agent right away, or exit the configuration wizard and configure the agent later. See Installing interactively using the setup program for details.

- **Silently**, by executing appropriate commands in a terminal window on each computer.

  You can installation silently on a local computer or use a software distribution product, such as Microsoft System Center Configuration Manager (SCCM), to execute the appropriate commands remotely to deploy agents on remote computers. After installation, you can change the default agent settings, if needed. See Installing silently by using the Microsoft Windows Installer for details.

- **Silently and centrally**, by using a group policy to execute commands remotely on the computers in a domain or organizational unit.

  If you use the Centrify Group Policy Deployment files, you can both install and configure the registry on remote computers from a central location without a separate software distribution product. However, you must configure the Windows agent registry settings in a file before deploying. See Installing from a central location by using group policy for details.

Regardless of the deployment method you choose, you should first make sure that the computers where you plan to deploy meet all of the installation prerequisites.

Delinea

Verify Prerequisites

Before installing the Windows agent, verify the computer on which you plan to install meets the following requirements:

- The computer is running a supported Windows operating system version.
- The computer is joined to Active Directory.
- The computer has sufficient processing power, memory, and disk space for the agent to use.
- The computer has the .NET Framework, version 4.5.2 or later.
- The computer has Windows Installer version 3.1, or later.

If you are installing interactively using the setup program, the setup program can check that the local computer meets these requirements and install any missing software. If you are installing silently from the command line or by using a Group Policy Object, you should verify the computers where you plan to install meet these requirements. If you are installing silently and a computer does not meet these requirements, the installation will fail.

Installing Interactively Using the Setup Program

If you select auditing when you install the Windows agent, the agent starts capturing user session activity immediately after it is installed. Therefore, you should be sure that you have an installation, audit store database, and collector prepared and available before installing an agent. If the agent cannot connect to an installation, it stores the captured session data locally and can quickly overload the local computer's resources.

To install the agent on Windows using the setup program:

1. Log on to the computer and insert the CD or browse to the location where you have saved downloaded Centrify files.

   If the Getting Started page is not displayed automatically, open the autorun.exe file.
2. On the Getting Started page, click **Agent** to start the setup program for the Windows agent.
3. At the Welcome page, click **Next**.
4. Review the terms of the license agreement, click **I accept the terms in the License Agreement**, then click **Next**.
5. Verify the location where files will be installed, then click **Next**.

   If you want to install in a location other than the default location, click Browse, select a different location, then click **Next**.
6. Click **Install**.
7. Click **Finish** to complete the installation and start the agent configuration wizard.
8. In the Centrify Agent Configuration window, click **Add Service**.

9. In the dialog box that opens, select the Centrify Auditing and Monitoring Service option and click **OK**.
10. In the Enable session capture and replay window, select the auditing installation to which you want the agent on this computer to connect.

    Click **Next** to continue.

    The Centrify Auditing and Monitoring Service is now listed as an enabled service.
11. Close the Agent configuration window and click **Exit** in the installer window.

Configuring the Agent Settings for Auditing

The agent configuration wizard automatically configures several default settings in the agent registry. If you want to view or change the agent settings for auditing on a Windows computer after running the configuration wizard—or if you did not use the configuration wizard immediately after installation—you can use the Agent Configuration Wizard.

To configure the agent settings for auditing:

1. Click **Start > All Programs > Centrify Server Suite 2021.1 > Centrify Agent for Windows Configuration > Agent Configuration**.
2. In the Centrify Agent Configuration window, locate the Centrify Auditing and Monitoring Service option, and click **Settings**.

   The Centrify Auditing and Monitoring Service Settings window opens.
3. On the General tab, click **Configure**.
4. Select the maximum color quality for recorded sessions, then click **Next**.

   If your audit installation has video capture auditing enabled, you can configure the color depth of the sessions to control the size of data that must be transferred over the network and stored in the database. A higher color depth increases the CPU overhead on audited computers but improves resolution when the session is played back. A lower color depth decreases network traffic and database storage requirements, but reduces the resolution of recorded sessions.

   The default color quality is Low (8-bit).
5. Specify the offline data location and the maximum percentage of disk that the offline data file should be allowed to occupy, then click **Next**.

If the agent cannot connect to a collector, it saves session activity in the offline data location you specify until it can contact a collector.

The spool threshold defines the minimum percentage of disk space that should be available to continue auditing. It is intended to prevent audited computers from running out of disk space if the agent is sending data to its offline data storage location because no collectors are available.

For example, if you set this threshold to 10%, auditing will continue while spooling data to the offline file location as long as there's at least 10% disk space is available on the spool partition. When the disk space available reaches the threshold, auditing will stop until a collector is available.

The agent checks the spool disk space by periodically running a background process. By default, the background process runs every 15 seconds. Because of the delay between background checks, it is possible for the actual disk space available to fall below the threshold setting. If this were to occur, auditing would stop at the next interval. You can configure the interval for the background process to run by editing the HKLM\Software\Centrify\DirectAudit\Agent\DiskCheckInterval registry setting.

6. Select the installation that the agent belongs to, then click **Next**.
7. If the computer where you're configuring an agent belongs to multiple audit stores in the auditing installation, choose which audit store this agent will connect to, then click **Next**.
8. In the Summary page, review your settings, then click **Next**.

   The agent is now configured and enabled for auditing.
9. Click **Finish** to close the agent configuration wizard, then click **Close** to exit the Centrify Auditing and Monitoring Service Settings window.

Deciding to Install With or Without Joining the Computer to a Zone

Before you begin a silent installation, you should decide whether you will wait until later to join the computer to a zone, or join the computer to a zone as part of the installation procedure.

If you install without joining a zone during installation:

- See Installing silently by using the Microsoft Windows Installer for details about the registry settings that you can configure manually after the installation finishes.
- See Installing silently without joining a zone for details about performing the installation.

If you install and join a zone during installation:

- You use a transform (MST) file that is provided with Server Suite to configure a default set of agent-specific registry keys during the silent installation.
- You can optionally edit the MST file before performing the installation to customize agent-specific registry settings for your environment.
- You can optionally use the agent configuration control panel or the registry editor to configure registry settings after the installation finishes.
- See Installing silently by using the Microsoft Windows Installer for details about the registry settings that you can configure by editing the MST file.
- See Installing silently by using the Microsoft Windows Installer for details about how to edit the MST file before you perform the installation.
- See Installing and joining a zone silently for details about performing the installation.

Installing Silently Without Joining a Zone

This section describes how to install the agent silently without joining the computer to a zone. This procedure includes configuring registry settings manually using the registry editor or a third-party tool.

> **Note**:To install the agent and join the computer to a zone during installation, see Installing and joining a zone silently for more information.

Check prerequisites:

1. Verify that the computers where you plan to install meet the prerequisites described in Verify prerequisites. If prerequisites are not met, the silent installation will fail.
2. If you are installing audit and monitoring service, verify that the following tasks have been completed:
    1. Installed and configured the SQL Server management database and the SQL Server audit store database.
    2. Installed and configured one or more collectors.
    3. Configured and applied the Centrify DirectAudit Settings group policy that specifies the installation name.

To install the Centrify Agent for Windows silently without joining the computer to a zone:

1. Open a Command Prompt window or prepare a software distribution package for deployment on remote computers.

    For information about preparing to deploy software on remote computers, see the documentation for the specific software distribution product you are using. For example, if you are using Microsoft System Center Configuration Manager (SCCM), see the Configuration Manager documentation.

2. Run the installer for the Centrify Agent for Windows package. For example:

    msiexec /qn /i "Centrify Agent for Windows64.msi"

    By default, none of the services are enabled.

3. Use the registry editor or a configuration management product to configure the registry settings for each agent.

    For example, under HKEY_LOCAL_MACHINE\Software\Centrify\DirectAudit\Agent, you could set the DiskCheckThreshold key to a value other than the default value of 10%.

To install the Centrify Agent for Windows and add a computer to a zone during installation:

1. Prepare a computer account in the appropriate zone using Access Manager or the PowerShell command New-CdmManagedComputer.

2. You will use the default transform file Group Policy Deployment.mst in Step 3 to update the MSI installation file so that the computer is joined to the zone in which it was pre-created in Step 1. You can optionally modify Group Policy Deployment.mst to change or add additional registry settings during installation.

    If you want to edit Group Policy Deployment.mst to change or add additional registry settings and have not yet done so, edit it now as described in

Installing silently by using the Microsoft Windows Installer.

In order for the computer to join the zone from Step 1, the Group Policy Deployment.mst file *must* specify the GPDeployment property with a value of 1.

3. Run the following command:

   msiexec /i "Centrify Agent for Windows64.msi" /qn TRANSFORMS="Group Policy Deployment.mst"

Installing and Joining a Zone Silently

This section describes how to install the agent and join the computer to a zone at the same time. The procedure described here includes the following steps in addition to executing the MSI file:

- You first prepare (pre-create) the Windows computer account in the appropriate zone.

You execute an MST file together with the MSI file to join the computer to a zone and configure registry settings during the installation.

Installing silently by Using the Microsoft Windows Installer

If you want to perform a "silent" (also called *unattended*) installation of the Centrify Agent for Windows, you can do so by specifying the appropriate command line options and Microsoft Windows Installer (MSI) file to deploy. You must execute the commands on every Windows computer that you want to audit.

You can also use silent installation commands to automate the installation or upgrade of the Windows agent on remote computers if you use a software distribution product, such as Microsoft System Center Configuration Manager (SCCM), that enables you to run commands remotely to deploy software packages. However, only the command-line instructions are covered in this guide.

Configuring Registry Settings

When you perform a silent installation, several registry settings specific to the agent are configured by the default MSI file. In addition, a default transform (MST) file is provided for you to use if you join the computer to a zone as part of the installation procedure. When executed together, the default MSI and MST files ensure that the computer is joined to a zone, and that a default set of agent-specific registry keys is configured.

If your environment requires different or additional registry settings, you can edit the MST file before performing an installation. Then, when you execute the MSI and MST files to perform an installation, your customized registry settings are implemented. For details about how to edit the MST file, see Editing the default transform (MST) file.

> **Note**:If you do not join the computer to a zone during installation, you do not use the MST file. In this situation, you can create or edit registry keys manually after the installation finishes by using the , or the registry editor.

The following table describes the agent-specific registry settings that are available for you to configure during installation (by using the MST file) or after installation (by using the or the registry editor). Use the information in this table if you need to configure registry settings differently than how they are configured by the default MSI and MST files. Keep the following in mind as you review the information in the table:

- The default MSI file is named Centrify Agent for Windows64.msi, and is located in the **Agent** folder in the Centrify download location.
- The default MST file is named Group Policy Deployment.mst, and is located in the **Agent** folder in the Centrify download location.
- All of the settings in the following table are optional, although some are included in the default MSI and MST files so that they are configured when the MSI and MST files execute during an installation.
- Settings that are included in the default MSI and MST files are noted in the table.
- Some settings are environment-specific, and therefore do not have a default value. Others are not environment-specific, and do have a default value.
- The settings described in the table are located in the MSI file's Property table.
- The **Setting** column shows both the property name in the MSI file, and the name (in parentheses) of the registry key in the Windows registry.

Auditing and Monitoring	REG_MAX_FORMAT (MaxFormat)	Specifies the color depth of sessions recorded by the agent. The color depth affects the resolution of the activity recorded and the size of the records stored in the audit store database when you have video capture auditing enabled. You can set the color depth to one of the following values: 0 to use the native color depth on an audited computer. 1 for a low resolution with an 8-bit color depth 2 for medium resolution with a 16-bit color depth (default) 4 for highest resolution with a 32-bit color **This setting is included in the default MSI file.** In the registry, this setting is specified by a numeral (for

		example, 1). In the MSI file Property table, it is specified by the # character and a numeral (such as #1). The default value is 1.
Auditing and Monitoring	REG_DISK_CHECK_THRESHOLD (DiskCheckThreshold)	Specifies the minimum amount of disk space that must be available on the disk volume that contains the offline data storage file. You can change the percentage required to be available by modifying this registry key value. **This setting is included in the default MSI file.** In the registry, this setting is specified by a numeral (for example, 1). In the MSI file Property table, it is specified by the # character and a numeral (such as #10). The default value is 10, meaning that at least 10% of the disk space on the volume that contains the offline data storage file must be available. If this threshold is reached and there are no collectors available, the agent stops spooling data and audit data is lost.
Auditing and Monitoring	REG_SPOOL_DIR (SpoolDir)	Specifies the offline data storage location. The folder location you specify will be where the agent saves ("spools") data when it cannot connect to a collector. **This setting is not included in the default MSI file.** To use it, you must edit the default transform (MST) file so that it is processed together with the MSI file during installation, or create it manually in the registry after the installation finishes.
Auditing and Monitoring	REG_INSTALLATION_ID (InstallationId)	Specifies the unique global identifier (GUID) associated with the installation service connection point. **This setting is not included in the default MSI file.** To use it, you must edit the default transform (MST) file so that it is processed together with the MSI file during installation, or create it manually in the registry after the installation finishes.
Auditing and Monitoring	REG_LOG_LEVEL_DA (LogLevel)	Specifies what level of information, if any, is logged. Possible values are: off information warning error verbose **This setting is included in the default MSI file.** The default value is information.
Authentication & Privilege	REG_RESCUEUSERSIDS (RescueUserSids)	Specifies which users have rescue rights. Type user SID strings in a comma separated list. For example: *user1SID*,*user2SID*,*usernSID* **This setting is not included in the default MSI file.** To use it, you must edit the default transform (MST) file so that the setting is processed together with the MSI file during installation, or create it manually in the registry after the installation finishes.
Authentication & Privilege	REG_LOG_LEVEL_DZ (LoggingLevel)	Specifies what level of information, if any, is logged. Possible values are: off information warning error verbose **This setting is included in the default MSI file.** The default value is information.
Authentication & Privilege	GPDeployment	Specifies whether the computer is joined to the zone where the computer was pre-created. This setting is used only during installation and does not have a corresponding registry key. Possible values are: 0 - The computer is not joined to the zone. 1 - The computer is joined to the zone. **This setting is included in the default transform (MST) file.** To use it, you must execute the MST file when you execute the default MSI file. The default value is 1, meaning that the pre-created computer is joined to the zone.

Editing the Default Transform (MST) File

The default transform file, Group Policy Deployment.mst, enables you to specify registry key settings that are different from the default settings that are defined in the MSI file. You can use the Group Policy Deployment.mst file to customize a silent installation for a specific environment.

If you want to customize the agent settings for your environment, you should edit the Group Policy Deployment.mst file before executing the command to perform a silent installation. If you want to use the default settings specified in the MSI file, you can skip this section and go directly to Installing silently from the command line.

You must use the Orca MSI editor to edit the Group Policy Deployment.mst file. Orca is one of the tools available in the Windows SDK. If you do not have the Windows SDK or Orca installed on your computer, you can download and install it from this location: http://msdn.microsoft.com/en-us/library/aa370557(v=vs.85).aspx.

To edit the default MST file:

1. In the Agent folder in the Centrify download location, create a backup copy of the default Group Policy Deployment.mst file.

2. Open a Command Prompt window and execute the following command to launch Orca:

   Orca.exe

3. In Orca, select **File > Open** and open the Centrify Agent for Windows64.msi file located in the Agent folder in the Centrify download location.
4. In Orca, select **Transform > Apply Transform**.
5. In Orca, navigate to the Agent folder in the Centrify download location and open Group Policy Deployment.mst. The file is now in transform edit mode, and you can modify data rows in it.
6. In the Orca left pane, select the Property table. Notice that a green bar displays to the left of "Property" in the left pane. This indicates that the Property table will be modified by the MST file. The right pane displays the properties that configure registry keys when you execute the command to install the agent using the MSI file. Notice that the last property in the table, GPDeployment, is highlighted in a green box. This indicates that the GPDeployment property will be added to the MSI file by the MST file.
7. In the right pane, edit or add properties as necessary to configure registry keys for your environment.

REG_MAX_FORMAT	Sets the MaxFormat registry key to specify the color depth of sessions recorded by the agent. The color depth affects the resolution of the activity recorded and the size of the records stored in the audit store database when you have video capture auditing enabled. In the MSI file Property table, you can set the color depth to one of the following values: #0 to use the native color depth on an audited computer. #1 for a low resolution with an 8-bit color depth. #2 for medium resolution with a 16-bit color depth. #4 for highest resolution with a 32-bit color. The default value is #1. To edit this property, double-click the Value column and type a new value.
REG_DISK_CHECK_THRESHOLD	Sets the DiskCheckThreshold registry key to specify the minimum amount of disk space that must be available on the disk volume that contains the offline data storage file. In the MSI file Property table, the default value is #10, meaning that at least 10% of the disk space on the volume that contains the offline data storage file must be available. You can change the percentage required to be available. To edit this property, double-click the Value column and type a new value.
REG_SPOOL_DIR	Sets the SpoolDir registry key to specify the offline data storage location. The folder location you specify will be where the agent saves data when it cannot connect to a collector. To add a this property to the transform file, right-click anywhere in the property table, then select **Add Row**.
REG_INSTALLATION_ID	Sets the InstallationId registry key to specify the unique global identifier (GUID) associated with the installation service connection point. This property is not required if you are using the Installation group policy to identify the audit installation to use. If you are not using group policy to identify the audit installation, you can add a this property to the transform file. Right-click anywhere in the property table, then select **Add Row** to add the property and value to the file.
REG_LOG_LEVEL_DA	Sets the LogLevel registry key to specifies what level of information, if any, is logged. Possible values are: off information warning error verbose The default value is information. To edit this property, double-click the Value column and type a new value.

8. After you have made the necessary modifications, select **Transform > Generate Transform** to save your modifications to the default MST file. Be sure to save the MST file in the same folder as the MSI file. If the MST and MSI files are in different folders, the MST file will not execute when you execute the MSI file.

The MST file is now ready to be used as described in Installing silently from the command line.

Installing Silently from the Command Line

If you want to perform a "silent" or unattended installation of the Centrify Agent for Windows, you can do so by specifying the appropriate command line options and Microsoft Windows Installer (MSI) file to deploy.

Before running the installation command, you should verify the computers where you plan to install meet the prerequisites described in Verify prerequisites. If the prerequisites are not met, the silent installation will fail. You should have also completed the following tasks:

- Installed and configured the SQL Server management database and the SQL Server audit store database.
- Installed and configured one or more collectors.
- Configured and applied the Centrify DirectAudit Settings group policy that specifies the installation name.

You can use similar steps to install the Centrify Common Component using the Centrify Common Component64.msi file before you install the agent. If you install the common component first, information about the agent installation is recorded in a log file for troubleshooting purposes. However, you are not required to install the common component separately from the agent.

To install the Centrify Agent for Windows silently:

1. Open a Command Prompt window or prepare a software distribution package for deployment on remote computers.
2. Run the installer for the Centrify Agent for Windows package for a 64-bit architecture with the appropriate command line options. For example, to install the Centrify Common Component on a computer with 64-bit architecture, run the following command: msiexec /i "Centrify Common Component64.msi" /qn If you want to enable both auditing and access control features on a computer with a 64bit operating system and use the values defined in the Group Policy Deployment.mst file, you would run the following command: msiexec /i "Centrify Agent for Windows64.msi" /qn TRANSFORMS="Group Policy Deployment.mst"

Installing from a Central Location by Using Group Policy

You can use a Group Policy Object (GPO) to automate the deployment of Centrify Agent for Windows. Because automated installation fails if all the prerequisites are not met, be sure that all the computers on which you intend to install meet the requirements described in Verify prerequisites.

You can use similar steps to install the Centrify Common Component using the Centrify Common Component64.msi file before you install the agent. If you install the common component first, information about the agent installation is recorded in a log file for troubleshooting purposes. However, you are not required to install the common component separately from the agent.

In most cases, you can use the default agent settings defined in the Group Policy Deployment.mst transform file. If you want to modify the default settings prior to installation, see the instructions in Installing silently by using the Microsoft Windows Installer.

To create a Group Policy Object for the deployment of Centrify Agents for Windows:

1. Copy the Centrify Agent for Windows64.msi and Group Policy Deployment.mst files to a shared folder on the domain controller or a location accessible from the domain controller. When you select a folder for the files, right-click and select **Share with > Specific people** to verify that the folder is shared with Everyone or with appropriate users and groups.
2. On the domain controller, click **Start > Administrative Tools > Group Policy Management**.
3. Select the domain or organizational unit that has the Windows computers where you want to deploy the Centrify Agent, right-click, then select **Create a GPO in this domain, and Link it here**. For example, you might have an organizational unit specifically for Centrify-managed Windows computers. You can create a group policy object and link it to that specific organizational unit.
4. Type a name for the new Group Policy Object, for example, Centrify Agent Deployment, and click **OK**.
5. Right-click the new Group Policy Object and click **Edit**.
6. Expand **Computer Configuration > Policies > Software Settings**.
7. Select **Software installation**, right-click, and select **New > Package**.
8. Navigate to the folder you selected in Step 1, select the Centrify Agent for Windows64.msi file, and click **Open**.
9. Select **Advanced** and click **OK**.
10. Click the **Modifications** tab and click **Add**.
11. Select the Group Policy Deployment.mst file, click **Open**, and click **OK**.
12. Close the Group Policy Management Editor, right-click the Centrify Agent Deployment group policy object, and verify that **Link Enabled** is selected.

By default, when computers in the selected domain or organizational unit receive the next group policy update or are restarted, the agent will be deployed and the computer will be automatically rebooted to complete the deployment of the agent.

If you want to test deployment or deploy immediately, you can open a Command Prompt window to log on to a Windows client as a domain administrator and

force group policies to be updated immediately by running the following command:

gpupdate /force

After installation, all of the registry settings that were specified in the MSI and MST files are configured. If you need to change any of the default agent settings, open the DirectAudit Agent Control Panel or the Registry Editor.

For more information about how to configure and use Group Policy Objects, see the documentation on the Microsoft Windows website.

Enabling or Disabling Auditing on Windows Computers

You enable or disabling auditing for a Windows computer by adding or removing the audit and monitoring service from the agent configuration.

To enable auditing on a Windows computer:

- Use the Agent Configuration wizard to configure the Centrify Agent for Windows to connect to the Centrify Audit & Monitoring Service.

  The agent configuration wizard runs automatically after you've installed the Centrify Agent for Windows.

To disable auditing on a Windows computer:

- In the Centrify Agent Configuration window, select Centrify Audit & Monitoring Service and click **Remove**.

To enable or disable video capture editing for an entire installation, see Enabling or disabling video capture auditing . To enable or disable auditing on a per-user basis you can use a group policy and the audited user list and non-audited user lists. For details, see the Group Policy Guide.

Enabling or Disabling Auditing on Linux and UNIX Computers

After you install the agent, you can enable auditing with the dacontrol command. The dacontrol command links all shells to the cdash shell wrapper by way of NSS. When a user opens a terminal, cdash is automatically loaded instead of the user's shell, then cdash loads the appropriate shell for the user and begins auditing the session.

You can also choose to enable video capture editing for an installation but disable it for specific computers. You disable or enable video capture auditing for a specific computer or set of computers by using group policy settings or by modifying the agent.video.capture setting. For details, see the *Group Policy Guide* or the *Configuration and Tuning Reference Guide*.

Shell or Terminal Window Auditing

To enable auditing on a Linux or UNIX computer:

1. Log on as a user with root privileges.
2. Run dacontrol with the -e option:

   dacontrol -e
3. Run dacontrol again to verify that auditing has been enabled or run dainfo.

   For example, the output of the dacontrol command shows something like this:

   dacontrol --query

   This machine has been configured through group policy to use installation 'DefaultInstallation'

   DirectAudit NSS module: Active

   DirectAudit is not configured to audit individual commands.

   When you enable auditing, the NSS module shows as active. You can also see if auditing is enabled or not for a system in the Audit Manager console.

After you enable auditing on a Linux or UNIX computer, you can control whether the auditing of shell activity applies for all users or for selected users by using role assignments. If auditing is enabled and the agent is not running, users with an active role assignment that requires logging are not allowed to log in.

For more information about configuring and assigning roles, see the *Administrator's Guide for Linux and UNIX*.

To disable auditing on a Linux or UNIX computer:

1. Log on as a user with root privileges.
2. Run dacontrol with the -d option or the --disable option:

   dacontrol -d

   dacontrol --disable
3. Run dacontrol again to verify that auditing has been disabled or run dainfo.

   For example:

   dacontrol --query

   This machine has been configured through group policy to use installation 'DefaultInstallation'

   DirectAudit NSS module: Inactive

   DirectAudit is not configured to audit individual commands

   When you disable auditing, the NSS module shows as inactive. You can also see if auditing is enabled or not for a system in the Audit Manager console.

Linux Desktop Auditing

In addition to shell auditing, for some Linux systems you can also enable desktop auditing. When desktop auditing is enabled, the user's entire screen is continuously monitored to record all graphical interactions. More specifically, desktop auditing captures the following:

- The application name and window title when the user switches the focus to that application. For example, if a user opens a web browser or a terminal window.
- Changes to the application window title that currently has focus. For example, if a user opens a web browser and goes to a new web page, desktop auditing records the title of a web page.

The supported platforms for Linux desktop auditing are as follows:

- RHEL 6, 7, and 8 with GNOME v3
- CentOS 6, 7, and 8 with GNOME v3

Linux sessions must be running X as the primary display manager (not Wayland).

Linux desktop auditing requires shell session auditing.

To enable desktop auditing on a Linux computer:

1. Log on as a user with root privileges.
2. Run dacontrol with the -x option or the --desktop-audit option:

   dacontrol -x

   dacontrol --desktop-audit

   To enable both shell and desktop auditing at the same time, use both the -e and -x options:

   dacontrol -e -x
3. Run dainfo to verify that desktop auditing has been enabled.

   For example, the relevant information from the dainfo command looks like this:

   Pinging adclient: adclient is available
   Daemon status: Online
   Current installation: 'DirectAudit' (configured locally)
   Current collector: test.acme.com:5063:HOST/test.acme.com@acme.com
   DirectAudit NSS module: Active
   ... DirectAudit desktop auditing: Enabled
   User (root) audited status: Yes

   When you enable auditing, the desktop auditing module shows as Enabled. You can also see if auditing is enabled or not for a system in the Audit Manager console.

To disable desktop auditing on a Linux computer:

1. Log on as a user with root privileges.
2. Run dacontrol with the -z option or the --no-desktop-audit option:

   dacontrol -z

   dacontrol --no-desktop-audit
3. Run dainfo to verify that desktop auditing has been disabled.

   For example, the relevant information from the dainfo command looks like this:

   Pinging adclient: adclient is available
   Daemon status: Online

   Current installation: 'DirectAudit' (configured locally)
   Current collector: test.acme.com:5063:HOST/test.acme.com@acme.com

DirectAudit NSS module: Inactive
... DirectAudit desktop auditing: Disabled
User (root) audited status: No

When you disable auditing, the desktop auditing module shows as Disabled. You can also see if auditing is enabled or not for a system in the Audit Manager console.

Installing an Centrify Agent for Unix/Linux

You can install the auditing services for Linux or UNIX computers interactively the agent installation script, install.sh. If you want to run the installation script silently or use a native package manager to install UNIX agents, see Installing the UNIX agent on remote computers.

The steps in this section describe how to install interactively using the install.sh script, which automatically installs platform specific software packages and invokes the proper installation mechanism and options for a computer's operating system.

To install the agent using the installation script:

1. Log on as a user with root privileges.
2. Mount the cdrom device using the appropriate command for the local computer's operating environment, if necessary.

   Note:If you are not using the CD, verify the location and go on to the next step.
3. Change to the appropriate directory.

   For example, to install on an AIX computer from the Centrify CD or ISO file, change to the UNIX directory:

   cd Agent_Unix22
4. Run the installer and respond to its questions:

   ./install.sh

   If there is an installation with the name DefaultInstallation, the UNIX agent uses it by default. If you are using an installation with a name other than DefaultInstallation, you must identify the installation by using dacontrol or group policy after installing the agent. For more information, see Checking the status of the UNIX agent.
5. After installing the package, use dainfo to verify that the agent is installed and running. You should see output similar to the following that indicates the agent is Online:

   Pinging adclient: adclient is available

   Daemon status: Online

   Current installation: 'PistolasSF' (configured locally)

   Current collector: DC2008r2-LG.pistolas.org:5063:HOST/dc2008r2-lg@PISTOLAS.ORG ...

   If the output of dainfo indicates that the agent is Offline or that auditing is not enabled, verify your network connections and try restarting the auditing service or run the command to enable auditing manually as described in Enabling or disabling auditing on Linux and UNIX computers.

You must adjust the disk space requirements higher if you allocate a large amount of offline storage to use when none of the collectors servicing the audit store can be reached. This and other parameters are in a text file named centrifyda.conf in /etc/centrifyda on each audited computer that has the UNIX agent installed. For more information about setting configuration parameters, see Configuring the UNIX agent off-line database. For information about all of the configuration parameters available to customize auditing, see the *Configuration and Tuning Reference Guide*.

Enabling or Disabling Video Capture Auditing

In most cases, you decide whether to enable video capture auditing when you create a new installation. You can, however, choose to enable or disable video capture auditing for an installation at any time. For example, you might enable full video capture auditing of user activity during your initial deployment and later find that you are capturing user activity that is of no interest or requires too much database management to store. Conversely, you might initially decide not to enable video capture and later discover that you want to record complete information about user activity when users run privileged commands or open certain applications.

You can also choose to enable video capture editing for an installation but disable it for specific computers. You disable or enable video capture auditing for a specific computer or set of computers by using group policy settings or by modifying the agent.video.capture setting. For details, see the *Group Policy Guide* or the *Configuration and Tuning Reference Guide*.

For information about enabling or disabling auditing on Windows or Linux/UNIX computers, see Enabling or disabling auditing on Windows computers and Enabling or disabling auditing on Linux and UNIX computers

To enable or disable video capture auditing for an installation:

1. In the Audit Manager console, right-click the installation name, then select **Properties**.
2. Click the **Audit Options** tab.
3. Select **Enable video capture auditing of user activity** if it is not selected to start capturing a visual record of all user activity when users perform tasks using a role that is configured to be audited.

   Deselect this option to stop all video capture auditing. If you disable video capture auditing, you will not be able to replay session activity.
4. Click **OK** or **Apply**.

Installing Additional Audit Manager or Audit Analyzer Consoles

If you need to make Audit Manager or Audit Analyzer consoles available to other users, you can install additional consoles on other computers. For example, install Audit Analyzer on computers used by auditors in your organization.

Delinea

Checklist for Auditing Systems Outside of Active Directory

Here is the overall process for auditing a computer that isn't joined to Active Directory, including links to documented procedures.

	Create the audit installation	
1	For the audit store that includes the collector that you will enroll to the Privileged Access Service, edit the audit store scope so that it includes the following: The site or subnet that the collector is in The IP address or subnet of the system to be audited (the one that isn't in Active Directory)	Creating a new installation
	Add the audit installation to the Admin Portal and enable auditing	
2	Install a connector on a Windows computer in the Active Directory domain Note: For now, do not install a connector on the same computer as a collector.	"How to install a connector" in the Privileged Access Service help (docs.centrify.com)
3	In the Admin Portal, enable auditing for the audit installation.	"Enabling auditing for remote sessions" in the Privileged Access Service help (docs.centrify.com)
4	Verify the connector status in the Admin Portal. **Note**: If your deployment is across multiple Active Directory forests or you have multiple DirectAudit installations, your deployment will include multiple cloud connectors. In this kind of deployment, you should configure each non-Active Directory system to use only the cloud connectors that are in the same Active Directory forest as the desired DirectAudit installation. You can configure which connectors should be used in the system's Connector settings in the Admin Portal. For details, see the "Selecting the connectors to use" topic in the Privileged Access Service help (docs.centrify.com).	"Reference content - Connector configuration program" in the Privileged Access Service help (docs.centrify.com)
	Configure the collector	
5	On the computer where the collector is or will be, install the Centrify Client and enroll the computer in the Privileged Access Service. The collector needs to be joined to Active Directory and enrolled in the Privileged Access Service.	"Installing and using the Centrify Client for Windows" in the Privileged Access Service help (docs.centrify.com)
6	Install a new collector or reconfigure an existing collector so that the collector receives audit data according to the cloud settings.	Configure the audit collector service
	Configure the computer to be audited	
7	In the Admin Portal, download the Centrify Client installers and get an enrollment code	"Installing and using the Centrify Client for Windows" in the Privileged Access Service help (docs.centrify.com) "Enrolling and managing computers using Centrify Client for Linux" in the Privileged Access Service help (docs.centrify.com) "Enrolling a computer" in the Privileged Access Service help (docs.centrify.com)
8	In the Admin Portal, make sure that the user account you'll use to run the installer has the permissions to enroll the system.	"Admin Portal administrative rights" in the Privileged Access Service help (docs.centrify.com)
		On the computer to be audited, make sure that its

9	On the computer to be audited, make sure that its DNS setting are set so that it can contact and be contacted by the collector computer.	DNS settings are set so that it can contact the collector computer by its fully qualified domain name (FQDN).
10	Install the client and enroll the computer in the Privileged Access Service. Auditing Systems That are Inside a DMZ

If you have Windows or UNIX/Linux systems that are deployed inside of a networking DMZ, you can audit those systems without having to set up a separate audit installation.

Organizations often use a DMZ to host a group of systems in a section of the corporate network in between the intranet and the public internet access. Firewall settings define the perimeter of the DMZ; the firewall helps limit access to internal networks from the outside network.

In order to audit systems inside of a DMZ, the following must be true for your deployment:

- All the Windows or UNIX/Linux systems in the DMZ are joined to the DMZ domain (for example, acme.dmz).
- You've already set up the audit installation in your main domain for your organization (for example, acme.corp) and you're auditing systems in that domain.
- The SQL Server that hosts the audit databases is also joined to the main domain.
- There's either no Active Directory trust between the main and DMZ domains or there's a one-way trust where the DMZ domain trusts the main domain (for example, acme.dmz trusts acme.corp).
- All the audit administrator and auditor accounts belong to the main domain.

Before you go to set up auditing on DMZ systems, be sure to do the following:

- Deploy at least one audit collector on a system that's joined to the DMZ domain. This is because an audited system can only look for audit collectors in its own forest.
- Configure the SQL Server to use mixed-mode authentication. This is because a collector in a DMZ cannot authenticate with SQL Server in the main domain using Windows authentication.
- Configure the necessary firewall exceptions for the SQL Server deployed in the main domain so that the audit collector in the DMZ can connect to the SQL Server. This includes the firewall exceptions for the SQL Server listener port as well as other ports, such as UDP 1434 (which is used by the SQL browser service).

To audit systems in a DMZ:

1. Prepare the audit store:

    1. Set up an audit store that contains the audited data for the systems in the DMZ. You can either create a new audit store or modify an existing one so that the audit store scope includes the sites or subnets of the systems in the DMZ.
    2. Add a new audit store database to the DMZ audit store and mark the database as active.

    For more information, see Creating the first audit store.

2. Prepare the SQL authentication account:

    1. In Audit Manager, right-click the audit store database that you just created and select **Properties**.
    2. In the Advanced tab, under the Allowed incoming collectors, click **Add**.
    3. For the authentication, select **SQL Server authentication**. Select an existing account or click the list to create a new SQL Login account.

    This SQL Login account is what the collectors in the DMZ domain will use to authentication with the SQL Server in the main domain. As a best practice, it's recommended to create a dedicated incoming collector account for all collectors in the DMZ.

3. Publish the audit installation information to the DMZ domain:

    - If there's a one-way trust between the DMZ and main domains:
        1. In Audit Manager, right click the installation name and click **Properties**.
        2. In the Publication tab, click **Add**.
        3. Select an OU or container in the DMZ domain to which you'll publish the audit installation information. Click **OK** to continue, and click **OK** again to close the dialog box and publish the audit installation information to the DMZ.

    For more information, see Publishing installation information.

    - If there's no trust between the DMZ and main domains:
        1. In Audit Manager, right-click the installation name and click **Properties**.
        2. In the Publication tab, click **Export** to export the audit installation information to an LDIF file.
        3. Provide the LDIF file to the Active Directory administrator of the DMZ domain and request that they manually import the file into an OU or container in the DMZ domain. They can import the LDIF file using the LDIFDE.exe utility.

For more information, see Exporting installation information.

4. Install a collector on at least one Windows system in the DMZ:

    1. Run the Collector Configuration wizard, and select the audit installation and specify the port number.
    2. In the Authentication type screen, select **SQL Server authentication** and enter the credentials for the SQL authentication account that you created earlier.
    3. Click **Test Connection** to ensure that the credentials work and the SQL Server is reachable.
    4. Finish the rest of the wizard. If there are any warnings when validating the permissions, you can safely ignore them.

    If you login to the collector computer as a user from your DMZ domain, that user will most certainly not have the permissions to connect to the audit installation and, as a result, the Collector Configuration wizard (which runs in context of the logged-in user) may fail to validate certain permissions and show warning messages instead.

    For details about configuring a collector, see Installing the audit collectors.

5. Install and configure the agent on the systems in the DMZ.

    For details, see Installing the Centrify Agent for Windows.

Managing an Installation

This section describes how to secure and manage an audit installation after the initial deployment of Centrify software. It includes tasks that are done by users assigned the Master Auditor role for an installation and users who are Microsoft SQL Server database administrators.

Topics available:

Securing an Installation

For production deployments, you can take the following steps to secure the installation:

- Use the Installation group policy to specify which installation agents and collectors are part of. By enabling the Installation group policy you can prevent local administrators from configuring a computer to be part of an unauthorized installation.
- Configure a trusted group of collectors to prevent a hacker from creating a rogue collector to collect data from agents.
- Configure a trusted group of agents to prevent a hacker from performing a Denial of Service attack on the collector and database by flooding a collector with bogus audit data.
- Encrypt all data sent from the collector to the database.

Before you can follow these steps to secure an installation, you must have access to an Active Directory user account with permission to create Active Directory security groups, enable group policies, and edit Group Policy Objects.

To secure an installation using Windows group policy:

1. Open the Group Policy Management console.
2. Expand the forest and domains to select the Default Domain Policy object.
3. Right-click, then click **Edit** to open Group Policy Management Editor.
4. Expand **Computer Configuration > Policies > Centrify Audit Settings**, then select **Common Settings**.
5. Double-click the **Installation** policy in the right pane.
6. On the Policy tab, select **Enabled**.
7. Click **Browse** to select the installation you want to secure, then click **OK**.
8. Click **OK** to close the Installation properties.

Securing an Audit Store with Trusted Collectors and Agents

By default, audit stores are configured to trust all audited computers and collectors in the installation. Trusting all computers by default makes it easier to deploy and test auditing in an evaluation or demonstration environment. For a production environment, however, you should secure the audit store by explicitly defining the computers the audit store can trust.

You can define two lists of trusted computers:

- Audited computers that can be trusted.
- Collector computers that can be trusted.

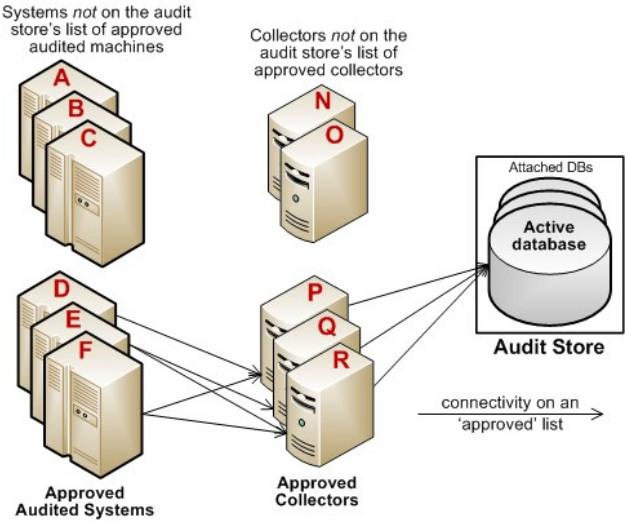
To secure an audit store:

1. Open the Audit Manager console.
2. Expand the installation and Audit Stores nodes.
3. Select the audit store you want to secure, right-click, then select **Properties**.
4. Click the **Advanced** tab.
5. Select **Define trusted Collector list**, then click **Add**.
6. Select a domain, click **OK**, then search for and select the collectors to trust and click **OK** to add the selected computers to the list.

   Only the collectors you add to the trusted list are allowed to connect to the audit store database. All other collectors are considered untrusted and cannot write to the audit store database.
7. Select **Define trusted Audited System list**, then click **Add**.
8. Select a domain, click **OK**, then search for and select the audited computers to trust and click **OK** to add the selected computers to the list.

   Only the audited computers you add to the trusted list are allowed to connect to the trusted collectors. All other computers are considered untrusted and cannot send audit data to trusted collectors.
9. Click **OK** to close the audit store properties dialog box.

The following example illustrates the configuration of trusted collectors and trusted audited computers.



In this example, the audit store trusts the computers represented by P, Q, and R.Those are the only computers that have been identified as trusted collectors in the audit store Properties. list. The audit store has been configured to trust the audited computers represented by D, E, and F. As a result of this configuration:

- Audited computers D, E, and F only send audit data to the trusted collectors P, Q, and R.
- Trusted collectors P, Q, and R only accept audit data from the trusted audited computers D, E, and F.
- The audit store database only accepts data for its trusted collectors P, Q, and R, and therefore only stores audit data that originated on the trusted audited computers D, E, and F.

Disabling a Trusted List

After you have added trusted collectors and audited computers to these lists, you can disable either one or both lists at any time to remove the security restrictions. For example, if you decide to allow auditing data from all audited computers, you can open the audit store properties, click the Advanced tab, and deselect the **Define trusted Audited System list** option. You don't have to remove any computers from the list. The audit store continues to only accept data from trusted collectors.

Using Security Groups to Define Trusted Computers

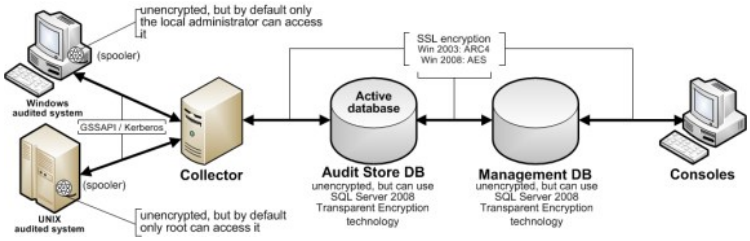
You can use Active Directory security groups to manage trusted computer accounts. For example, if you create a group for trusted audited computers and a group for trusted collectors, you can use those groups to define the list of trusted collectors and audited computers for the audit store. Any time you add a new computer to one of those groups, thereafter, it is automatically trusted, without requiring any update to the audit store properties.

Securing Network Traffic with Encryption

The last step in securing an installation is to secure the data collected and stored through encryption. The following summarizes how data is secured as it moves from component to component:

- Between an audited computer and the spooler that stores the data locally when no collectors are available, audit data is not encrypted. Only the root user or local Administrator account can access the data by default.
- Between the audited computer's data collection service (dad on UNIX or wdad on Windows) and the collector, data is secured using Generic Security Services Application Program Interface (GSSAPI) with Kerberos encryption.
- Between the collector and the audit store database, data can be secured using Secure Socket Layer (SSL) connections and ARC4 or AES encryption if the database is configured to use SSL connections.
- Between the audit store and management databases, data can be secured using Secure Socket Layer (SSL) connections and ARC4 or AES encryption if the database is configured to use SSL connections.
- Between the management database and the Audit Manager console, data can be secured using Secure Socket Layer (SSL) connections and ARC4 or AES encryption if the database is configured to use SSL connections.

The following illustration summarizes the flow of data and how network traffic is secured from one component to the next.



Enabling Secure Socket Layer (SSL) communication

Although the database connections can be secured using SSL, you must configure SSL support for Microsoft SQL Server as part of SQL Server administration. You must also have valid certificates installed on clients and the database server. If you are not the database administrator, you should contact the database administrator to determine whether encryption has been enabled and appropriate certificates have been installed. For more information about enabling SSL encryption for SQL Server and installing the required certificates, see the following Microsoft support article:

https://support.microsoft.com/en-us/help/316898/how-to-enable-ssl-encryption-for-an-instance-of-sql-server-by-using-mi

Enabling Encryption for Microsoft SQL Server Express

If you use Microsoft SQL Server Express, encryption is turned off by default. To secure the data transferred to the database server, you should turn encryption on.

To enable encryption for each audit store and management database:

1. Log on to the computer hosting an audit store or management database with an account that has database administrator authority.
2. Open **SQL Server Configuration Manager**.
3. Select the SQL Server Network Configuration node, right-click **Protocols for DBINSTANCE**, then select **Properties**.
4. On the **Flags** tab, select **Yes** for the **Force Encryption** option, then click **OK** to save the setting.

Using a Service Account for Microsoft SQL Server

When you install Microsoft SQL Server, you specify whether to use Windows authentication or a mix of Windows and SQL Server authentication. You also specify the accounts that the database services should use. By default, system accounts are used. If SQL Server uses a domain user account instead of a system account, you should ensure that the account has permission to update the SQL Server computer object in Active Directory. If the account has permission to update the computer where SQL Server is running, SQL Server can publish its service principal name (SPN) automatically. Getting the correct service principal name is important because Windows authentication relies on the SPN to find services and audit and monitoring service uses Windows authentication for console-to-audit management database connections. If the SPN is not found, the connection between the console and audit management database fails.

The audit management database-to-audit store connection and the collector-to-audit store connection can use either Windows authentication or SQL Server authentication. If SQL Server authentication is used, it does not matter whether the SQL Server instance uses a system account or a service account.

If you have configured SQL Server to use Windows authentication only, be sure that the Windows account is allowed to connect to the audit management database and to the audit store database.

If the domain user account running SQL Server services does not have permission to update the computer object, see the following Microsoft knowledge base article for information about how to manually register the SPN for SQL Server:

https://support.microsoft.com/en-us/help/909801/how-to-make-sure-that-you-are-using-kerberos-authentication-when-you-c

Configuring Selective Auditing

By default, the agent captures activity for all users on audited computers, but you can limit auditing to specified users. If you are using authentication and privilege elevation, you can control auditing by configuring role definitions with different audit requirements then assigning those role definitions to different sets of Active Directory users.

If you are using the Centrify Audit & Monitoring Service without access management:

- You can use group policies to specify which Windows users to audit and which Windows users should not be audited.

  For information about configuring group policies to customize auditing, see the *Group Policy Guide*.

- For UNIX users, you can use the dash.user.skiplist configuration parameter to specify the UNIX user accounts and Active Directory UNIX names that you don't want to audit.

  For more information about setting the dash.user.skiplist parameter, see the comments in the /etc/centrifyda/centrifyda.conf file. For information about all of the configuration parameters available to customize auditing, see the *Configuration and Tuning Reference Guide*.

Controlling Auditing by Using Group Policies

1. Open the Group Policy Management console.
2. Expand the forest and domains to select the Default Domain Policy object.
3. Right-click, then click **Edit** to open Group Policy Management Editor.
4. Expand **Computer Configuration > Policies > Centrify Audit Settings**, then select **Windows Agent Settings**.
5. Select the Audited user list policy and change the policy setting from Not Configured to **Enabled**, then click **Add** if you want to identify specific users to audit.

   When you enable this group policy, only the users you specify in the policy are audited. If this policy is not configured, all users are audited.
6. Select the Non-audited user list policy and change the policy setting from Not Configured to **Enabled**, then click **Add** if you want to identify specific users that should not be audited.

   When you enable this group policy, only the users you specify are not audited. If this policy is not configured, all users are audited. If you enable both the Audited user list and the Non-audited user list policies, the users you include in the Non-audited user list take precedence over the Audited user list.

The following table details the effect of choosing to enable the Audited user list policy, the Non-audited user list policy, or a combination of both policies.

Not configured	Not configured	No users are defined for either policy, so all users accessing audited computers are audited.
Not configured	Enabled	Only the users you specify in the Audited user list policy are audited. If you do not specify any users when you enable this policy, no users are audited.
Enabled	Not configured	Only the users you specify in the Non-audited user list are exempt from auditing. If you enable this policy but do not specify any users, no users are exempt from auditing. All users are audited.
Enabled	Enabled	If both policies are enabled, the non-audited user takes precedence over the audited list of users. If a user is specified in the audited list, that user is explicitly audited. If a user is specified in the non-audited list, that user is explicitly not audited. If the same user is specified in both lists or no users are specified for either policy, no users are audited because the non-audited user takes precedence.

Configuring agents to prefer collectors

If desired, you can specify that agents first use the collectors that are in the same site as the agent. You configure this option for each audit store.

For example, consider the following installation setup:

- One audit store
- Two sites (SantaClara and SanDiego)
- Two collectors in SantaClara, and two collectors in SanDiego

If you enable the option for the agents to prefer collectors in the same site as the agent, the agents in the SantaClara site use the collectors in that site, and the agents in the SanDiego site use the collectors there.

If for some reason all collectors in a site are down, the agents use collectors in another site or configured subnet.

Once an agent fails over and uses a collector in another site, the agent continues to use that collector until a rebinding occurs. You can do a rebinding with the dareload -b command. During the time that the agent is using a collector in another site, dadiag displays a warning message.

If your installation uses agents older than version 2017, those older agents ignore the collector preference setting.

Specify Agents Use Collectors in the Same Site

1. Open the Audit Manager console window.
2. Expand **Audit Stores**, and right-click the desired audit store and select **Properties**.
3. In the Audit Store Properties dialog box, click **Advanced**.
4. Select **Agents must prefer collectors in the same site as the agent**.

   By default, this option is not enabled.
5. Click **OK** to save the changes.

It may take several minutes for the changes to take effect, depending on Active Directory replication delays and policy sets.

Audit License Enforcement

Any time you open the Audit Manager console, Audit Analyzer console, or the session player, a background process determines the availability of audit licenses. Only the audited computers that are currently connected to a collector are included in the license count to determine license usage and compliance. Computers that have been previously audited and have data in the audit store database but are not currently connected to a collector and haven't been connected to a collector for over 45 days are not included in the license count.

As you increase the number of licenses in use, license enforcement is progressive. If the number of audited computers is less than 90% of the number of licenses you have purchased, there's no affect on any auditing features. If the number of audited computers is more than 90% of the licenses purchased, enforcement depends on the number of licenses in use:

- 90-100% of the licensing limit displays a warning message that you are close to over deployment, but you can continue to use all auditing features.
- 100-120% of the licensing limit displays a warning message that you must acknowledge by clicking **OK** when you open any console, after which you can resume using the console or session player.
- Over 120% of the licensing limit displays a warning message for 60 seconds when you open any console. If you see the 60 second warning message, use the License dialog box to add license keys to continue using auditing features.

You can contact Centrify to purchase additional licenses or remove some audited computers from the installation to bring the number of licenses used into compliance.

Agents and Licenses from Previous Versions

An installation can include agents and licenses from previous versions of Server Suite. For example, an installation might include a mix of UNIX and Windows agents from DirectAudit 2.x, or DirectAudit 3.x, or all new agents on the computers you want to audit.

Enabling Audit Notification on Windows

If you enable audit notification, users see a message informing them that their actions are being auditing when they log on. After you enable notification, the message is always displayed on audited computers if the session activity is being recorded.

> **Note**: This audit notification banner mentioned below displays on Windows systems. For notifying users on UNIX or Linux systems, the messages specified in the dash.prompt.message.file parameter apply. For details, see the *Configuration and Tuning Reference Guide*.

To enable audit notification for an installation:

1. In the Audit Manager console, right-click the installation name, then select **Properties**.
2. Click the **Notification** tab.
3. Select **Enable notification**.

   Deselect this option to turn off notification.
4. Click the browse button to locate and select a text file that contains the message you want to display.

   A notification message is required if you select the Enable notification option. The contents of the file you select are displayed below the file location. The maximum text file size is 30 KB.
5. Click the browse button to locate and select an image to appear as a banner across the top of the audit notification.

   Displaying a banner image is optional when you enable notification. The maximum image file size is 15 KB. For the best image display, use an image that is 468 pixels wide by 60 pixels high.

   > **Note**: Animated GIF files are not supported for use as audit notifications. If you do specify an animated GIF, the image displays as a static image.
6. Click **OK** or **Apply**.

   Users will see the notification message the next time they log in.
7. If you enable notification after you have deployed agents, update the local policy on the audited computers by running the following command:

   gpupdate /FORCE

Preventing Users from Reviewing or Deleting Sessions

By default, users can update the review status, add comments, and delete their own sessions if they have an audit role with the appropriate permissions. However, there are installationwide options to prevent any users from updating the review status or deleting their own sessions. These installation-wide options take precedence over audit role permissions for all users.

To prevent all users from updating the review status or deleting their own sessions in an installation:

1. In the Audit Manager console, right-click the installation name, then select **Properties**.
2. Click the **Audit Options** tab.
3. Select the appropriate settings for your installation.
    - Select **Do not allow any users to review their own sessions** if you to prevent all users from updating the review status or adding comments to their own sessions in Audit Analyzer.
    - Select **Do not allow any users to delete their own sessions** if you to prevent all users from deleting their own sessions in Audit Analyzer.
4. Click **OK** or **Apply**.

Adding an Installation

Although a single installation is the most common deployment scenario, you can configure multiple installations. For example, you can use separate installations to provide concurrent production and test-bed deployments or to support multiple administrative domains within your organization.

To create a new installation:

1. Open Audit Manager.
2. Select the root node, right-click, then select **New Installation**.
3. Follow the prompts displayed.

   The steps are the same as the first installation. For more information, see Creating a new installation.
4. Choose the appropriate installation for each collector using the Collector Configuration wizard.
5. Choose the appropriate installation for each agent using the Agent Configuration wizard.

Once you have multiple installations, you can choose which one each collector is part of using the Collector Configuration wizard. You can choose which installation each agent is part of using the Agent Configuration wizard. You can also configure collectors and agents using group policy.

> **Note**: Agents can communicate with a collector only if the agents and collector are in the same Active Directory forest.

Delegating Administrative Tasks for a New Installation

The account you use to create a new installation is the default administrator and Master Auditor with full control over the entire installation and the ability to delegate administration tasks to other Active Directory users or groups. You can grant permission to perform administrative tasks to other users by opening the Properties for each component, then clicking the Security tab.

Opening an Installation in a New Console

If you create multiple installations at the same site, you can select the installation name, right-click, then select **New Window From Here** to keep consoles for different installations separate from each other. Creating a new window for each installation can help you avoid performing operations on one installation that you intended to perform on another.

Closing an Installation

The Audit Manager console allows you to manage multiple installations. To remove the current installation from the console, but not physically remove the database or the information published to Active Directory, you can select the installation name, right-click, then select **Close**.

Publishing Installation Information

Centrify Audit & Monitoring Service publishes installation information to a service connection point (SCP) object in Active Directory so that audited computers and collectors can look up the information. If the published locations for multiple SCPs in the same installation are not the same, or if collectors cannot read from at least one of the published locations, the collectors are unable to determine which audit store is the best match for the sites and subnets, and so they do not attempt to connect to an audit store.

Permission to Publish to Active Directory

Only administrators who have been delegated permission to modify various attributes of the installation can publish those attributes to Active Directory.

At a minimum, you must have the Active Directory permission to Create serviceConnectionPoint objects on the container or organizational unit that you have identified for publishing installation information.

If you do *not* have Active Directory permission to modify the installation, the updates are kept in the audit management database, and a message is issued to notify you that the installation information could not be updated in Active Directory.

Synchronizing Installation Information

If you have an Active Directory account with permission to publish information about the installation, you can update the service connection point.

To publish the service connection point for an installation:

1. Open Audit Manager.
2. Select the installation name, right-click, then click **Properties**.
3. Click the **Publication** tab, then click **Synchronize** to publish the information.

   In a multi-forest or DMZ environment, this tab lists multiple Active Directory locations to which to publish.
4. Click **OK** to close the installation properties.

Exporting Installation Information

If you have an Active Directory account with permission to access installation information, you can export the service connection point that contains the installation information to a file in LDAP Data Interchange Format (LDIF). Exporting installation information can be useful if you want to add the domain for a perimeter network to an existing installation. After exporting installation information to a file, you can modify the file—for example, to use a different domain component—then import the modified file using the ldifde command.

To export and import installation information:

1. Open Audit Manager.
2. Select the installation name, right-click, then click **Properties**.
3. Click the **Publication** tab.
4. Select the Active Directory location, then click **Export**.
5. Select a file location and type a file name, then click **Save**.
6. Click **OK** to close the installation properties.
7. Use a text editor to modify the file, as needed.

   For example, you might use a different domain component—such as DC=dmz1,DC=ajax, DC=org in place of DC=internal, DC=ajax, DC=org—to differentiate between the perimeter and internal networks.
8. Import the modified file using a command similar to the following in a Command Prompt window:

   ldifde -i -f C:\Users\Administrator\Desktop\sample-dmz.ldif

Removing or Deleting an Installation

Before you can remove or delete an installation, you must do the following:

- Run the setup program to remove all agents and collectors and collector service connection points (SCPs).
- Detach and remove all audit store databases.
- Open the Installation Properties and click the **Publications** tab to make sure only one installation service connection point (SCP) is listed.

  Note: To remove service connection points on other sites, contact an administrator with publication permission on those sites.

To remove or delete an installation, select the installation in the Audit Manager console, right-click, then select **Remove** to open the Remove installation dialog box.

- Click **Remove** to remove the installation but *not* delete the management database from the SQL Server instance.
- Click **Delete** to remove the installation *and* delete the management database from the installation of SQL Server.

  Note: All the publications published to Active Directory are removed when you remove or delete an installation.

Managing Audit Store Databases

During the initial deployment, your installation only has one audit store database. As you begin collecting audit data, however, that database can quickly increase in size and degrade performance. Over time, an installation typically requires several Microsoft SQL Server databases to store the data being captured and historical records of session activity, login and role change events, and other information. As part of managing an installation, you must manage these databases to prevent overloading any one database and to avoid corrupting or losing data that you want to keep.

One of the biggest challenges in preparing and managing Microsoft SQL Server databases for storing audit data is that it is difficult to estimate the level of activity and how much data will need to be stored. There are several factors to consider that affect how you configure Microsoft SQL Server databases for auditing data, including the recovery method, memory allocation, and your backup and archiving policies.

The sections below provide guidelines for sizing and managing the Microsoft SQL Server databases you use for audit data. For more complete information about managing and configuring SQL Server, however, you should refer to your Microsoft SQL Server documentation.

Selecting a recovery model

Standard backup and restore procedures come in three recovery models:

- **Simple**—The Simple recovery model allows high-performance bulk copy operations, minimizes the disk space required, and requires the least administration. The Simple Recovery model does not provide transaction log backups, so you can only recover data to the point of the most recent full or differential backup. The default recovery model is Simple, but is not appropriate in cases where the loss of recent changes is not acceptable.
- **Full**—The Full recovery model has no work-loss exposure, limits log loss to changes since the most recent log backup, and provides recovery to an arbitrary time point. However, the Full recovery model uses much more disk space.
- **Bulk-logged**—The Bulk-logged recovery model provides higher performance and minimizes the log space used by disk-intensive operations, such as create index or bulk copy. With the Bulk-logged recovery model, you can only recover data to the point of the most recent full or differential backup. However, because most databases undergo periods of bulk loading or index creation, you can switch between Bulk-logged and Full recovery models to minimize the disk space used to log bulk operations.

When a database is created, it has the same recovery model as the **model** database. Although the Simple recovery model is the default, the Full and Bulk-Logged recovery models provide the greatest protection for data, and the Full recovery model provides the most flexibility for recovering databases to an earlier point in time. To change the recovery model for a database, use the ALTER DATABASE statement with a RECOVERY clause.

Regardless of the recovery model you choose, you should keep in mind that backup, restore, and archive operations involve heavy disk I/O activity. You should schedule these operations to take place in off-peak hours. If you use the Simple recovery model, you should set the backup schedule long enough to prevent backup operations from affecting production work, but short enough to prevent the loss of significant amounts of data.

Configuring the Maximum Memory for Audit Store Databases

Because Microsoft SQL Server uses physical memory to hold database information for fast query results, you should use a dedicated instance to store auditing data. Because SQL Server dynamically acquires memory whenever it needs it until it reaches the maximum server memory you have configured, you should set constraints on how much physical memory it should be allowed to consume.

The maximum server memory (max server memory) setting controls the maximum amount of physical memory that can be consumed by the Microsoft SQL Server buffer pool. The default value for this setting is such a high number that the default maximum server memory is virtually unlimited. Because of this default value, SQL Server will try to consume as much memory as possible to improve query performance by caching data in memory.

Processes that run outside SQL Server, such as operating system processes, thread stacks, socket connections and Common Language Runtime (CLR) stored procedures are not allowed to use the memory allocated to the Microsoft SQL Server buffer pool. Because those other processes can only use the remaining available memory, they might not have enough physical memory to perform their operations. In most casts, the lack of physical memory forces the operating system to read and write to disk frequently and reduces overall performance.

To prevent Microsoft SQL Server from consuming too much memory, you can use the following formula to determine the recommended maximum server memory:

- Reserve 4GB from the first 16GB of RAM and then 1GB from each additional 8GB of RAM for the operating system and other applications.
- Configure the remaining memory as the maximum server memory allocated for the Microsoft SQL Server buffer pool.

For example, if the computer hosting the Microsoft SQL Server instance has 32GB of total physical memory, you would reserve 4GB (from first 16 GB) + 1GB (from next 8 GB) + 1 GB (from next 8 GB) for the operating system, then set the Maximum server memory for Microsoft SQL server to 26GB (32GB – 4GB – 1GB – 1GB = 26).

For more information about how to configure Microsoft SQL Server maximum memory setting and other memory options, see the following Microsoft article:

http://msdn.microsoft.com/en-us/librms178067(v=sql.105).aspxary/ms178067(v=sql.105).aspx

You should configure the maximum memory allowed for the Microsoft SQL Server instances hosting audit store databases and the management database. However, this setting is especially important to configure on the Microsoft SQL Server instance hosting the active audit store database.

Using Transact-SQL to Configure Minimum and Maximum Memory

You can control the minimum and maximum memory that the SQL Server buffer manager uses by issuing Transact-SQL commands. For example:

```
sp_configure 'show advanced options', 1
reconfigure
go
sp_configure 'min server memory', 60
reconfigure
go
sp_configure 'max server memory', 100
reconfigure
go
```

For more information about configuring SQL Server and setting minimum and maximum server memory using T-SQL, see https://docs.microsoft.com/en-us/sql/database-engine/configure-windows/server-memory-server-configuration-options?view=sql-server-2017

Estimating Database Requirements Based on the Data You Collect

To determine how auditing will affect database capacity, you should monitor a pilot deployment of 20 to 25 agents with representative activity to see how much data is produced daily. For example, some audited computers might have few interactive user sessions or only short periods of activity. Other audited computers might have many interactive user sessions or long sessions of activity on average.

During the pilot deployment, you want to the following information:

- How many interactive user sessions occur daily on each computer?
- How long do sessions last on average?
- What are the activities being captured, and what is the average size of each session being captured?
- How long do you need to store the captured data to balance performance and storage?
- What is the data retention period for audited data?

From the information you collect in the pilot deployment and the data retention policy for your organization, you can estimate the database size using the following guideline:

(number of agents) x (number of sessions per agent) x (average data size per session) x (retention days)

Results in the estimated size of the Microsoft SQL Server database for the number of days in the retention policy

For example, if an average session generated 100 KB in the database and the installation had 250 agents, 10 sessions per agent, and a six-month retention period (about 130 working days), the storage requirement for the audit store database would be 36.9 GB:

250 agents x 10 sessions/agent each day x 100 KB/session x 130 days = 32,500,000 KB

The following table shows examples of the data storage requirement in an installation with Windows agents, typical levels of activity with an average of one session per day on each audited computer, and the recovery mode set to Simple:

100	20 minutes	806 KB - low activity	79 MB	394 MB	10 GB
50	25 minutes	11.56 MB - high activity	578 MB	2.81 GB	73.36 GB
100	20 minutes	9.05 MB - high activity	905 MB	4.42 GB	115 GB

In this example, an installation with 100 Windows agents with low activity would require approximately 10 GB for the audit store database to keep audit data for 6 months. An increase in the number of interactive sessions, session length, or average session size would increase the database storage required.

If SQL Server requires more space to accommodate the new data, it expands the database file immediately, which can cause degraded performance. To reduce the effect of database expansion on performance, allocate sufficient space to support database growth. In addition, monitor database space and when space is low, schedule a database expand operation for an off-peak time.

Reducing Color Depth to Decrease Disk Usage

If you enable video capture auditing of user activity for an installation, the color depth setting affects the size of sessions stored in the audit store database. Depending on whether you want higher quality video playback or lower disk consumption, you can modify this setting. The growth rate is linear as you increase or decrease the color depth.

Based on a simulation of user activity, changing the color depth from 16-bit to 8-bit reduces disk space by 42%. Changing the color depth from 32-bit to 16-bit reduces disk space by 34 to 39%. If you can accept the lower quality video playback, changing the color depth from 32-bit to 8-bit reduces disk space by 62 to 65%.

Using SQL Server availability groups with multi-subnet failover for audit store databases

If you add an audit store database to a SQL Server availability group that has multiple subnet failover functionality, the SQL Server that hosts the management database must be SQL Server 2012 or above. This restriction applies only to availability groups that have multi-subnet failover configured.

For details about availability group multi-subnet failovers, see https://msdn.microsoft.com/en-us/library/hh213417.aspx#SupportAgMultiSubnetFailover.

Adding New Audit Store Databases to an Installation

When you first set up an installation, you also create the first audit store and audit store database. By default, that first database is the active database. As you begin collecting audit data, you might want to add databases to the audit store to support a rolling data retention policy and to prevent any one database from becoming a bottleneck and degrading performance.

Only one database can be the active database in an audit store at any given time. The computer hosting the active database should be optimized for read/write performance. As you add databases, you can change the older database from active to attached. Attached databases are only used for querying stored information and can use lower cost storage options.

> **Note**: A single instance of Microsoft SQL Server can host multiple databases. Those databases can support different versions of the agent.

Audit store databases have the following characteristics:

- A database can be active, attached, or detached.
- Only one database can be actively receiving audit data from collectors.
- A database cannot be detached while it is the active database.
- A database that was previously the active database cannot again be the active database.
- If a detached database contains parts of sessions presented to the Audit Analyzer, a warning is displayed when the auditor replays those sessions.

Rotating the Active Database

Database rotation is a management policy to help you control the size of the audit store database and the performance of database operations. There are several reasons to do database rotation:

- It is more difficult to manage one large database than multiple small databases.
- Performance is better with multiple small databases.
- Backing up, restoring, archiving, and deleting data all take significantly more time if you work with one large database.
- Database operations take very little time when you work with multiple small databases.

For audit and monitoring service, you can implement a database rotation policy by having the collector write data to a new database after a certain period of time. For example, the collector in site A writes data to the database siteA-2015-11 in November, then write data to database siteA-2015-12 in December and to the database siteA-2016-01 in January. By rotating from one active database to another, each database stays more compact and manageable.

Creating a New Database for Rotation

You can rotate from one active database to another at any time using the Audit Manager console.

To create a new database for rotation:

1. Open Audit Manager.
2. Expand the installation node, then expand Audit Stores and a specific audit store name.
3. Select **Databases**, right-click, then select **Add Audit Store Database** to create a new database.

   For details on setting up the database, see Creating the first audit store database.
4. Select the **Set as Active database** option so collectors start writing to the newly created database.

You can also use Centrify application programming interfaces (APIs) to write a script that automates the database rotation process. For API details and sample code, see the Centrify SDK documentation.

Database Archiving

To implement periodic archiving, add a new active database, leave one or more previous databases attached, and take the oldest database off-line for archiving.

Queries During Rotation and Archiving

If the database backup program supports online backups, the Audit Analyzer can still query the database while the backup is in progress. However, the backup program may block updates to the session review status. If the backup program does not support online backup, the database will be offline until the backup is complete.

Database Backups

You can back up a database whether it is attached to the audit store or detached from the audit store.

Reattaching a Restored Backup of a Database

If you need to query sessions from an older database that is offline and detached, you can restore the database from a backup and reattach it to your auditing installation. You might need to do this is your auditing installation is large, you do frequent database rotation, and you don't keep many databases attached and online.

Understand that after you restore a database from a backup, you need to fix a couple of settings in the database before you can reattach it to your auditing installation. During the backup operation, the database owner and trustworthy properties get set in such a way that prevents you from reattaching the database to your auditing installation unless you fix these properties.

To reattach a restored database to your auditing installation:

1. Run the following command to reset the database owner to [sa]:

   ALTER AUTHORIZATION ON DATABASE:: *<db_name>* TO [sa]
2. Run the following command to reset the trustworthy property:

   ALTER DATABASE *<db_name>* SET TRUSTWORTHY ON

   You can now reattach the database to your auditing installation.

Allowed Incoming Accounts

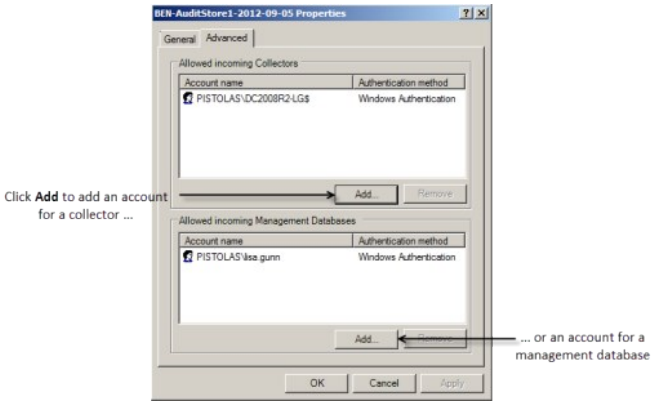
You can specify the accounts that are allowed to access the audit store database. By configuring these accounts, you can control which collector computers can connect to the audit store database and which management databases have access to the data stored in the audit store database.

Your account must have Manage SQL Login permission to configure the incoming accounts.

To configure allowed accounts:

1. Open Audit Manager.

2. Expand the installation node, then expand Audit Stores and select a specific audit store name.
3. Select a database under the audit store, right-click, then select **Properties**.
4. Click the **Advanced** tab.
5. Click **Add** to add a collector or management database account. For example:



6. Select an authentication type.
    - If you select Windows authentication, you can browse to select a computer, user, or group to add.
    - If you select SQL Server authentication, you can select an existing SQL Server login or create a new login.

Connections should use Windows authentication whenever possible. However, computers in an untrusted forest cannot connect to an audit management database using Windows authentication. To allow connections from an untrusted forest, add a SQL Server login account as the incoming account for the management database.

Detecting Data Tampering and Verifying Session Integrity

When you create your audit store database, you have the option to enable data integrity checking. Data integrity checking provides the ability to detect if auditing data has been tampered with.

For example, data integrity checking can detect if a user who has write privileges over the Audit Store database directly manipulates the audited session data by making a direct connection to the Microsoft SQL Server database.

Session data that is stored in audit store databases is typically accessible to database administrators and/or database owners in an unrestricted fashion. For these users with write privileges on the audit store database, it's fairly easy to tamper with data in such a way that it can help manipulate the outcome of an AQL query.

For example, someone could change the searchable tags in such a way so that the session is never returned by a query. Or, someone could remove suspicious activity from a recorded session, such as by changing the list of commands that are executed or changing the command output.

> **Note**: Data integrity checking cannot detect tampering if a database administrator deletes an entire session or database. Also, data integrity checking is not yet available for audit trail events.

Once you enable data integrity checking, you can do the following:

- Use the Audit Analyzer console or a PowerShell cmdlet to check the integrity of audited sessions.
- Determine if any data in the following tables has been modified and where it was modified:
    - Session
    - RawData
    - Command
    - SyscallCommand
    - SyscallFilemon
    - WashData
    - WashEvent
- Determine if any database rows belonging to an audited session were permanently deleted.

If you have not enabled an audit store database for data integrity checking and you try to check session integrity in Audit Analyzer, an error message appears.

Managing Audit Stores

An audit store is a collection of databases that contain audit data. All attached databases in the audit store are available to the audit management database. Typically each site has one audit store, but you can add audit stores as required for large or multi-site installations. For details, see Adding more audit stores to an installation.

Configuring Audit Store Scope

The scope of an audit store defines which audited computers send their audit data to the audit store, and which collectors are assigned to the audit store. The scope is a set of Active Directory sites and/or subnets. To configure the scope for an audit store, open its **Properties** page and select the **Scope** tab. To add a site, click **Add Site** and select the site from the list. To add a subnet, click **Add Subnet** and type a subnet address and mask.

Configuring Permissions for an Audit Store

To configure audit store security, open the audit store's **Properties** page and select the **Security** tab.

Only users with Change Permission permission on the audit store are allowed to modify the user rights on the Security tab of the audit store's Properties page.

The following table lists the rights that can be granted to active Directory users or groups, and the operations that the users granted such rights ("trustees") are allowed to perform.

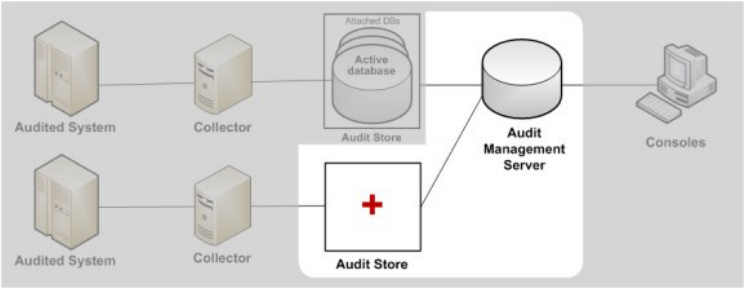
The audit store administrator by definition has all of these user rights (Full Control).

Full Control	All of the operations listed in the following rows of this table
Change Permissions	Modify permissions on this audit store
Modify Name	Modify display name for this audit store
Manage Scopes	Add a subnet or active Directory site Remove a subnet or active Directory site
Manage SQL Logins	Set the allowed incoming accounts for this audit store's databases Set the allowed incoming accounts for collectors
Manage collectors	Enable collector trusted group for this audit store Add collector to the trusted collector group in this audit store Remove collector from the trusted collector group in this audit store Remove disconnected collector record from this audit store
Manage Audited Systems	Enable audited computers trusted group for this audit store Add audited computer to the trusted audited computer group in this audit store Remove audited computer from the trusted audited computer list in this audit store Remove disconnected audited computer record from this audit store
Manage Databases	Add audit store database to this audit store Attach audit store database to this audit store Detach an audit store database from this audit store Change active database in this audit store Modify the display name of a version 2 audit store database
Manage Database Trace	Enable or disable database trace Export database trace

Adding More Audit Stores to an Installation

The audit store typically maps one-to-one with an Active Directory site. However, in some situations it is desirable to define the scope of an audit store differently:

- A subnet that Active Directory considers part of a site may be connected over a slow link. In this situation, you probably want to configure another audit store and collectors that service audited computers in the remote subnet.
- A very large site may require multiple audit stores for load distribution. You can accomplish this by partitioning an Active Directory site into multiple audit stores based on subnets. Each subnet has its own audit store and set of collectors and audited computers.



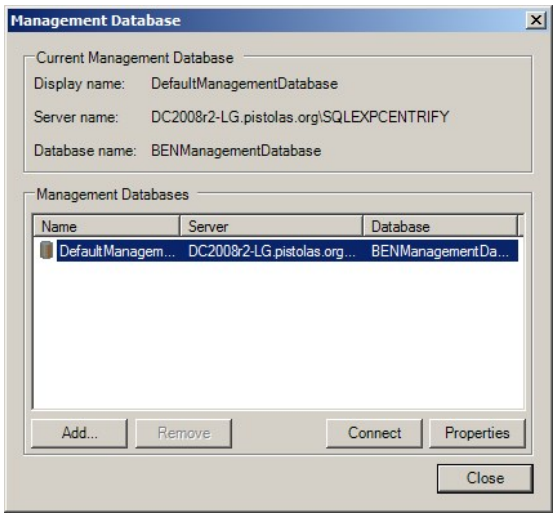
Two common audit store actions are:

- Adding a new audit store in a new site, and using the **Select Scope** page in the **Add Audit Store Wizard** to configure the site settings.
- Splitting an audit store in two, using the audit store's **Property** page to adjust the scope of the existing audit store, and then adding a new audit store.

To configure the audit store to support a particular subnet, click the **Subnet** radio button, and fill in the subnet IP address and mask.

Managing the Audit Management Database

The audit management database keeps track of where components are installed and information about the installation. To connect to the database or manage its properties, select a specific installation name in Audit Manager, right-click, then select **Management Databases**. From this dialog box, you can view information about the current audit management database, remove or connect to a management database, or change the properties for a management database.



Configuring Audit Management Database Scope

Select the audit management database you want to configure, then click **Properties**. From the Properties, click the **Scope** tab to configure audit management database scope. Click Add Site if you want to add a new Active Directory site to the management database or click Add Subnets to add a subnet for the management database to serve. Select the site or subnet from the list of sites or subnets found, then click **OK**. You can add or remove sites and subnets from the management database at any time using the Scope tab.

> **Note**: All components use Windows authentication whenever possible. However, an audit management database in another forest cannot connect to an audit store database using Windows authentication.

Setting Audit Management Database Security

Select the audit management database you want to configure, then click **Properties**. From the Properties, click the **Security** tab to configure security settings for the management database. Click the **Add** page to add groups or users to the list of trustees who can manage, modify, or remove installation-wide components. Type all or part of the user or group name, select the appropriate user or group from the results, then click **OK**.

Select the appropriate rights you want to grant to the selected Active Directory users or groups, and the operations that the users granted such rights ("trustees") are allowed to perform.

Full Control	All of the operations listed in the following rows of this table.
Change Permissions	Modify permissions on this audit management database.
Modify Name	Modify display name for this audit management database.
Manage Sites	Add a subnet or Active Directory site. Remove a subnet or Active Directory site.
Remove Database	Remove this audit management database from the installation.
Manage SQL Logins	Set the allowed incoming accounts for this audit management database. Set the outgoing account for this audit management database.

Manage Database Trace	Enable or disable database trace Export database trace

Only users with Change Permission permission on the audit management database can modify the user rights on the Security tab. By definition, the management database administrator has Full Control over all of the user rights and is an allowed incoming user.

Configuring the Maximum Memory for the Management Database

Because SQL Server dynamically acquires memory whenever it needs it until it reaches the maximum server memory you have configured, you should set constraints on how much physical memory it should be allowed to consume. You can use the formula described in Configuring the maximum memory for audit store databases to determine the maximum memory you should allow for the Microsoft SQL Server instances hosting the management database.

For more information about how to configure Microsoft SQL Server maximum memory setting and other memory options, see the following Microsoft article:

https://docs.microsoft.com/en-us/sql/database-engine/configure-windows/server-memory-server-configuration-options

Removing an Audit Management Database

Select a specific installation name in Audit Manager, right-click, then select **Management Databases**. Select the audit management database you want to remove, then click **Remove**.

Because it is *not* recommended that you have multiple management databases in a single installation, you ordinarily would not separately remove an audit management database, but rather remove it as part of deleting an installation.

Maintaining Database Indexes

To ensure better performance and prevent database corruption, Centrify recommends you rebuild the database indexes for all the audit store databases and the management database as a regularly scheduled task that your run at least once a week. Rebuilding the indexes is especially important for the active audit store database to reduce fragmentation, but as a best practice you should rebuild indexes for all attached databases and the management database.

The following sample SQL statements illustrate how to rebuild all indexes on all the databases in one script:

```
=== BEGIN SQL statements ===
DECLARE @Database NVARCHAR(128)
DECLARE @Table NVARCHAR(128)
DECLARE @Command NVARCHAR(500)

-- To skip index rebuilding for a database, add its name to the list below
DECLARE DatabaseCursor CURSOR FOR
SELECT name FROM master.dbo.sysdatabases
WHERE name NOT IN ('master','msdb','tempdb','model')
ORDER BY 1

OPEN DatabaseCursor
FETCH NEXT FROM DatabaseCursor INTO @Database
WHILE @@FETCH_STATUS = 0
BEGIN
PRINT 'Processing database ' + @Database
SET @Command = 'DECLARE TableCursor CURSOR FOR SELECT
''['' + TABLE_CATALOG + '']."' + TABLE_SCHEMA

- ''].['' +
  TABLE_NAME + '']'' as TableName FROM [' + @Database
- '].INFORMATION_SCHEMA.TABLES
  WHERE TABLE_TYPE = ''BASE TABLE'''
  EXEC (@Command)
  OPEN TableCursor

FETCH NEXT FROM TableCursor INTO @Table
WHILE @@FETCH_STATUS = 0
BEGIN
PRINT 'Rebuilding all indexes on ' + @Table
SET @Command = 'ALTER INDEX ALL ON ' + @Table

- ' REBUILD'
  EXEC (@Command)
  FETCH NEXT FROM TableCursor INTO @Table
  END

CLOSE TableCursor
DEALLOCATE TableCursor

FETCH NEXT FROM DatabaseCursor INTO @Database
END
CLOSE DatabaseCursor
DEALLOCATE DatabaseCursor
=== END SQL statements ===
```

Managing Collectors

You can select the Collector node in Audit Manager to view details about each collector you have added to the installation. You can then expand the Collectors node and select an individual collector in the left pane to display information about the audited computers that send sessions to that collector in the right pane.

The following table describes the columns available in the right pane for collectors.

Collector	Name of the collector
IP Address	Location of the collector on the network
Status	Whether the collector is disconnected from or connected to the audit store. If a collector has never been successfully assigned to an audit store, it is not even shown in the left-pane list.
Uptime	How long a connected collector has been running since it was last booted
Last Update Time	The date and time of the last update received by the collector.
Port Number	The port through which the collector communicates with its assigned audited computers and audit store. Default is 5063.
Audit Store	The audit store to which this collector is assigned
Audit Store Database	The active database to which the collector is currently sending audit data
Connected Machines	The number of audited computers currently connected to this collector. Because agents can communicate with a collector only if the agents and collector are in the same Active Directory forest, this column only includes audited computers that are in the same forest as the collector.
Disconnected Machines	The number of audited computers of which the collector is aware but that are not currently connected to this collector. Note that the collector is only aware of audited computers that were at one time connected to it.
Collector Version	The version of the collector software installed on the computer.

Monitoring Collector Status

The Collector Control Panel is available from the Start menu on any Windows computer on which you have installed a collector.

The Collector Control Panel enables you to monitor the local collector by giving you an overview of collector connectivity and status, including the collector's current installation, audit store, audit store database, port number, and service status. To change the collector's port number, installation, or authentication, click **Configure**. If you change the collector configuration, it might take a minute for the change to be reflected in the Collector Control Panel.

You can also use the Collector Control Panel to start, stop, or restart the collector service, and to generate more detailed information about the status of the collector. To see detailed information about the installation, audit store, audit store database, trusted agents, and connectivity between components, click the **Troubleshooting** tab, then click **Diagnostics**. The collector will generate a report and display the information in a separate window.

Modifying the Command Prompt Recognized by the Collector

For the collector to identify the command events executed in a session, it must also be able to identify the command prompt. Although there are several characters that are commonly used and recognized by default, most computers also allow you to customize the command prompt. If a customized command prompt is not detected by the collector, commands will not be displayed properly in the session Events list, making it difficult for auditors to see the commands executed in a selected session.

To enable the collector to detect custom or unusual command prompts, you can add a registry key on the computer where the collector is installed and specify a text string or a regular expression that will match the command prompt.

To specify a regular expression for the command prompt:

1. Log on to the computer where the collector component is installed and running.
2. Open the Registry Editor.
3. Expand the **HKEY_LOCAL_MACHINE > SOFTWARE > Centrify > DirectAudit** registry.
4. Select the Collector component, right-click, then select **String Value**.
5. Type Prompt as the new key name.
6. Select the new Prompt key, right-click, then select **Modify**.
7. Type a text string or regular expression that will enable the collector to identify the command prompt you are using on computers you are auditing.

   If you don't define a registry value, the default regular expression ^[^#%›\$]*[#%›\$]\s* is used to detect the command prompt.

Removing Collectors

If you want to remove a collector, go to the installer and select the collector. The Collector Setup wizard Welcome page appears.

Because a collector is present on the computer, the next page enables you to select Change, Repair, or Remove the collector. Click **Remove**.

Managing Audited Computers and Agents

You can monitor agent status from the Audit Manager console. With audited computers selected in the left pane, Audit Manager displays the name and IP address for audited computers, whether the agent is currently connected or disconnected, and how long the agent has been running since last restarted. You can also see the collector to which the agent is sending data, the audit store and audit store database where the audit data is stored, and the version of the agent software installed on the computer.

Audited systems can be either a computer or a network device. Audit Manager displays two kinds of audited systems:

- **System-based**: A Windows or UNIX computer that is running an agent. You can access these systems either directly or from the Privileged Access Service Admin Portal.
- **Vault-based**: A Windows or UNIX computer or a network device that is not running an agent (agentless). You can access these systems from the Privileged Access Service Admin Portal.

Because agentless systems do not have an agent installed, the Audit Manager displays slightly different information for these kinds of systems. For these systems, you can see the name, IP address, the collector, audit store, and audit store database.

Monitoring Agent Status

You can use the dainfo -d command on audited Linux and UNIX computers to view information about the configuration, connectivity, and auditing status of the agent.

Configuring the UNIX Agent Off-line Database

If the UNIX agent is unable to connect to a collector, it spools the session data to local storage. When a collector becomes available, it then sends the spooled data to that collector.

By default, the minimum amount of allocated disk space that must be available to the offline database before spooling stops and warnings are posted to the agent error log is 10%. You can change this percentage by assigning a different value to spool.diskspace.min in the /etc/centrifyda/centrifyda.conf file. For example, to change the minimum to 15%, set the following value:

spool.diskspace.min: 15

If the threshold is reached and a collector is still not available, the agent stops spooling data, and further audit data is lost. If this happens frequently or unexpectedly, you may want to increase the disk space allocation.

Removing an Audited Computer

If an audited computer has been removed from the audit installation, the audited computer will continue to be listed on the Audit Manager as Disconnected. To remove the decommissioned audited computer, select Delete from its context menu.

Delegating Administrative Permissions

You can facilitate the administration of a large installation by delegating tasks and, if needed, setting up additional Audit Manager consoles.

Whoever creates the installation is the first administrator in the system, with full control of the entire installation and the ability to delegate administration tasks to any Active Directory user or group. You can grant permissions to other users on the Security tab of the Properties page for each component.

Publishing Installation Information

Audit Manager publishes information about your installation to a service connection point (SCP) object in Active Directory so that audited computers and collectors can look up the information. If the published locations for multiple SCPs in the same installation are not in synch, or if agents cannot read from at least one of the published locations, the agents are unable to determine which audit store is the best match for the sites and subnets, and so they do not attempt to connect to an audit store.

Permission to Publish to Active Directory

Only administrators who have been delegated permission to modify various attributes of the installation can publish those attributes to Active Directory.

If you do *not* have Active Directory permission to modify the installation, the updates are kept in the audit management database, and a message is issued to notify you that the installation information could not by updated in Active Directory.

Synchronizing Installation Information

If you have an Active Directory account with permission to modify the installation, you can click Synchronize the Installation Properties page Publication tab to publish the information.

In a multi-forest or DMZ environment, this tab lists multiple Active Directory locations to which to publish.

Managing Audit Roles

By default, each installation automatically has a Master Auditor role that has access to all audit data.The Master Auditor can read, replay, update review status, and delete all audit sessions in the installation. You cannot delete or change the permissions for the Master Auditor role itself. You can change the users or groups who are assigned to the Master Auditor role and the permissions granted to each role member, but you cannot make any other changes to this role. You can, however, create your own custom audit roles for the installation.

Creating Custom Audit Roles

Audit roles allow specific auditors to search and replay specific sessions, review specific events, or generate reports using the Audit Analyzer console based on the criteria you define. Each role specifies the criteria to use, the users and groups that are assigned to the role, and the specific permissions those users and groups have been granted.

For example, you might specify the criteria for filtering sessions to be only the session activity recorded on a particular audited computer or all UNIX sessions recorded after a specific date and time.

The collection of auditors is identified by specifying either explicit auditors, or an Active Directory group of auditors. Using Active Directory groups is recommended because this puts all of a user's privileges under the common Active Directory infrastructure.

For each audit role, you can also configure the specific permissions granted to each member of the role. For example, some audit roles might permit auditors to read and replay sessions but not update the status, add review comments, or delete the sessions to which they have access.

To create and assign audit roles:

1. Open Audit Manager and expand the audit installation to which you are connected.
2. Select Audit Roles, right-click, then select **Add Audit Role**.
3. Type a name and, optionally, a description of the audit role, then click **Next**.
4. Select the type of sessions—UNIX sessions, Windows sessions, or both UNIX and Windows sessions—to include for auditors assigned to this audit role, then click **Add** to specify filtering criteria for the role.
5. Select an attribute for filtering information from the list of Attributes.

   For example, you can match sessions based on the period of time in which they were active, based on a specific state, or based on Active Directory group membership. You can also match sessions based on the specific activity that took place during the session. For example, you can find sessions where specific UNIX commands or Windows applications were used.
6. Select the appropriate criteria for the attribute you have selected, then click **OK**.

   The specific selections you can make depend on the attribute selected. For example, if the attribute is **Review Status**, you can choose between "Equals" and "Not equals" and the specific review status you want to find, such as "To be Reviewed." If you select the attribute **Comment**, you can specify "Contains any of" and type the text string that you want to find any part of. If you select the attribute **Group**, you can select "Is (exactly)" and the user principal name (UPN) of an Active Directory group, such as adm-sf@acme.com.

   You can specify multiple attributes, by clicking Add and selecting additional attributes and criteria. You can test the filtering criteria you have added by clicking **Execute Query** and examining the results. When you have finished adding filters, click **Next**.
7. Select the privileges for the audit role, then click **Next**.
8. Review your settings for the audit role, click **Next**, then click **Finish**.

   You can assign users and groups to the audit role immediately by running the Assign users and Groups wizard or at a later time by rightclicking on the role name.
9. Type all or part of name to search for and select Active Directory users and groups to assign to the audit role.

Changing Audit Role Properties

After creating an audit role, you can modify its properties.

To change properties for an audit role:

1. Open Audit Manager and expand the audit installation to which you are connected.
2. Expand Audit Roles, select an audit role name and right-click, then select **Properties**.
3. Click the General tab to change the name or description of an audit role.
4. Click the Access tab to change the filtering attributes and criteria an audit role.
5. Click the Privilege tab to change what members of the audit role can do with the sessions matching the criteria you specify.
6. Click the Security tab to change permissions for the audit role itself.

   For example, you allow another user or group to change role membership for an audit role, you would click Security, then click Add to search for and select a user or group, the select the Change Role Membership permission to allow the selected user or group to modify the membership of the audit role.

Granting Permissions to Manage Audit Roles

Anyone you assign the Manage Audit Roles permission on an installation has full control over all of the audit roles for that installation. After you grant users or groups the Manage Audit Roles permission, they can create and remove roles, change the filtering criteria, modify audit role permissions for other users and group, and select the users or groups who are assigned to the role.

The following examples illustrate how users or groups granted the Manage Audit Roles permission might modify the audit roles for an installation:

- Assign the Master Auditor role to other users and groups.
- Create a UNIX Session Viewer role for UNIX auditors that allows them to view (read) UNIX sessions—but not replay, update, or delete—all UNIX sessions in the installation.
- Create a Finance Managers role that includes both UNIX and Windows sessions filtered by the Active Directory group Finance Operators, so that users assigned to the Finance Managers audit role can read, replay, update, and delete all of the session activity generated by members of the Finance Operators group, but no other groups.
- Create an audit role that enables investigators who are assigned to the role to read and replay only the activity captured when a specific command or application is used.

These are only a few examples of how you can use the Manage Audit Roles permission to define filtering criteria and privileges that control what different users or groups who are assigned to audit roles can see and do.

Querying and Reviewing Audited Activity

This section describes how to use Audit Analyzer to find and review the audited sessions and audit trail events in which you are interested. If you are the Master Auditor or been assigned an audit role, you can use Audit Analyzer to create and store queries that retrieve information from one or more audit stores. When you locate sessions or events of interest, you can review a summary of activity, play back all or part of the session, mark the session for follow-up, or change the status of the session.

The following topics are covered:

Delinea

Accessing Audited Sessions

Your access to audited sessions is controlled either through the audit roles you have been assigned, or through designation as a reviewer if you do not have an auditing role assigned to you. For more information on designating audit session reviewers, see Adding session reviewers without designating auditing roles.

If you have been assigned at least one audit role, or have been designated as a reviewer without an audit role, you can use Audit Analyzer to search for and replay the audited session activity collected from audited computers. Depending on the permissions defined for your audit role, you might also be able to annotate, update the status of, or delete the audited sessions to which you have access. If you have been designated as a reviewer of an audit session, you can only review and updated the status of the sessions to which you have access.

The first time you start Audit Analyzer, you are prompted to select an installation. If you have an audit role in that installation and the connection is successful, Audit Analyzer opens and displays the default categories for predefined queries:

- Audit Sessions
- Audit Events
- Reports

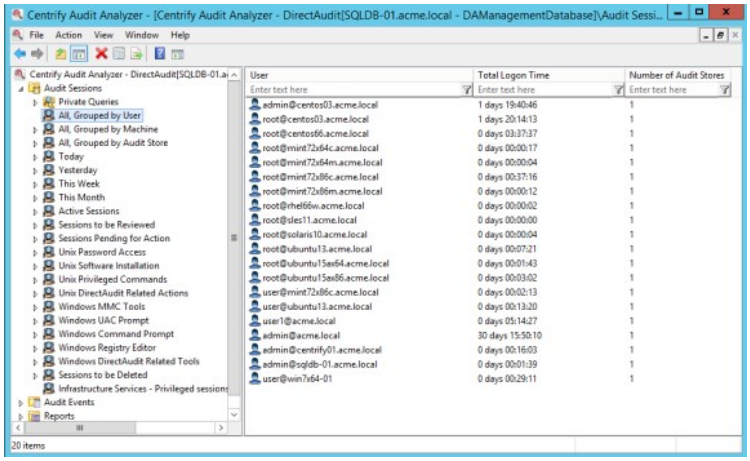
Predefined Queries for Audit Events

Audit Analyzer includes predefined queries that you can use to find the sessions that recorded audit trail events. To access the predefined queries for locating audit trail events, expand Audit Events. You can then select a predefined query to display a list of the audit trail events that meet the conditions of that query. You navigate to indexed lists of commands and events and replay sessions of interest for audit event queries in exactly the same way as audit session queries and you have the same options for viewing the activity captured. However, the details displayed for audit event queries are different from audit session queries.

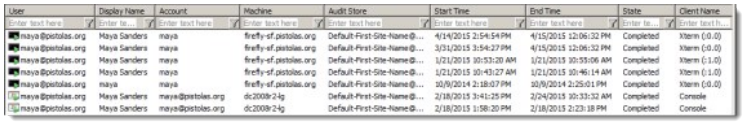
For each event, Audit Analyzer lists the name of the user, the name of the audited computer, the time of the event, the event name and description, and whether access was successful.

Predefined Queries for Audit Sessions

Audit Analyzer includes many predefined queries that you can use to find the sessions in which you are interested. To access the predefined queries, expand Audit Sessions. You can then select a predefined query to display a list of the audited sessions that meet the conditions of that query. For example, if you want to search for sessions by user, you can use the All, Grouped by User, then select the specific user whose sessions are of interest to see a list of all the sessions captured for that user. For example, in the right pane, you would select a user from the list:



After you select the user, Audit Analyzer displays detailed information about each of that user's sessions. For each session, Audit Analyzer lists the user name who started the session, the user display name, the account name used during the session, the name of the audited computer, the audit store where the session is stored, the start and end time for the session, current state, whether the audited session is a console or terminal client session, the review status of the session, any comments that have been added to the session, and the session size. For example:



Note that only completed sessions display the session size in Audit Analyzer.

Depending on the permissions associated with your audit role, you can right-click any session to view an indexed list of the activity captured, export the session activity to a comma-separated values file, update the review status for the session, or delete the session. If you have video capture auditing enabled for the installation, you can also select a session, right-click, then select **Replay** to review the session in the session player.

To view a description and definition for any predefined query, select the query, right-click, then select **Properties**. You can also export the query definition or the results from a query and perform other tasks on predefined queries. To perform any of these additional tasks, select the predefined query, right-click, then select the action you want to take.

Predefined Queries for Reports

Audit Analyzer includes predefined queries for generating reports. By default, the reports include information for all audited users, computers, and sessions. Select the type of report you are interested in generating, then specify additional criteria for filtering the report output. You can then save the modified report query or show the report.

If you click Show Report, the report is generated and displayed in a new window. You can then save the report as an HTML, PDF, CSV, or XML document.

User Activity Report

The default User Activity Report provides a detailed record of user actions for all audited users. The report includes the user name, the computer where the activity occurred, the time at which the activity occurred, and the event recorded. For example, if a user opened a Windows application or ran a UNIX command, the event would be recorded and included in the report you generate.

You should note that the User Activity Report does not include all desktop changes, such as navigation through directories using Windows Explorer. Instead, the report provides information about specific events. For example, the report will include information about when an application is opened, operations are performed, and when the application is closed. For more detailed information about user activity, you can enable video capture auditing for the installation and for specific desktops, applications, or commands using roles in Access Manager.

For information about enabling video capture auditing, see Enabling or disabling video capture auditing.

You can customize and filter the information included in a User Activity Report by specifying the query criteria and saving the report definition.

Privileged Activity Report

The default Privileged Activity Report provides a record of all actions taken with elevated privileges for all audited users and computers. The report includes the user name, the computer where the activity occurred, the time at which the activity occurred, and the event recorded. For example, if a user selected a role with administrative privileges, the event would be recorded and included in the report you generate.

You can customize and filter the information included in a Privileged Activity Report by specifying the query criteria and saving the report definition.

Centrify Zone Administration Activity Report

The default Centrify Zone Administration Activity Report provides a record of all zonerelated administrative actions taken for all audited users and computers. The report includes the user name, the computer where the activity occurred, the time at which the activity occurred, the client name, and the event recorded. For example, if an administrator created a new zone or delegated a management task to another user or group, the event would be recorded and included in the report you generate.

You can customize and filter the information included in a Centrify Zone Administration Activity Report by specifying the query criteria and saving the report definition.

Login by User Report

The default Login By User Report provides a record of both successful and failed login attempts for all audited users, computers, and sessions. The report includes the user name, the computer where the user attempted to log on, the time of the login attempt, and whether access was granted.

You can customize and filter the information included in a Login By User Report by specifying the query criteria and saving the report definition.

Login by Computer Report

The default Login By Computer Report provides a record of both successful and failed login attempts for all audited users, computers, and sessions. The report includes the user name, the computer where the user attempted to log on, the time of the login attempt, and whether access was granted.

You can customize and filter the information included in a Login By Computer Report by specifying the query criteria and saving the report definition.

Authorization Failure Report

The default Authorization Failure Report provides a record of authorization failure events for all audited users, computers, and sessions. The report includes the user name, the computer where the user attempted to log on or use a role, the time of the attempt, and the reason the user was denied access.

You can customize and filter the information included in a Authorization Failure Report by specifying the query criteria and saving the report definition.

Monitored Execution Report

If you have configured your auditing installation for advanced monitoring, then this Monitored Execution report shows the monitored commands being executed on the audited computers. This report includes information on commands that are run individually or as part of scripts. This report shows who ran one of the monitored commands even if that person is not an audited user.

The Monitored Execution report includes the user name, the computer where the commands were run, the time the command was run, the name of the command and the command arguments used, the process and parent process IDs, the "run as" user, the directory in which the command run, and whether the command was successful.

> **Note**: In the report, the Access Status column lists out whether the command was started successfully or not. This field does not describe whether the command completed successfully or not.
>
> **Note**: Advanced monitoring does not generate an audit trail event for commands for which you've enabled per-command auditing.

You can customize and filter the information included in a Monitored Execution report by specifying the query criteria and saving the report definition.

Detailed Execution Report

If you have configured your auditing installation to perform advanced monitoring, then this Detailed Execution report shows all of the commands being executed on the audited machines—including commands that are run as part of scripts or other commands.

The Detailed Execution report includes the user name, the computer where the activity occurred, the time at which the activity occurred, the command that was entered, the process and parent process IDs, the current directory, the actual command that was executed, the command arguments, the "run as" user, whether the command started or not (access status), and any additional access status details (such as "permission denied" if the access status is "failed").

> **Note**: In the report, the Access Status column lists out whether the command was started successfully or not. This field does not describe whether the command completed successfully or not.
>
> **Note**: Advanced monitoring does not generate an audit trail event for commands for which you've enabled per-command auditing.

You can customize and filter the information included in a Detailed Execution report by specifying the query criteria and saving the report definition.

File Monitor Report

If you have configured your auditing installation to perform advanced monitoring, the File Monitor report shows the sensitive files being modified by users on the audited machines. The File Monitor report includes any activity by any user (except root, -1) in the following protected areas on audited machines:

- /etc/
- /var/centrify/
- /var/centrifydc/
- /var/centrifyda/

> **Note**: The report includes the user name, the computer where the activity occurred, the time at which the activity occurred, the filename, the current directory, the kind of file access was attempted, if the file access was successful or not, the command that was used, the process and parent process IDs, and the "run as" user.
>
> If a monitored file is renamed, the report displays both the original and new filename. The order of filenames may differ slightly on each operating system.

MFA Failure Report

The default MFA Failure Report provides a record of multi-factor authentication (MFA) failure events for all audited users, computers, and sessions. The report includes the user's name, the computer where the user attempted to log on or use a role, the time of the attempt, and the reason that MFA authentication failed.

You can filter the information included in a MFA Failure Report by specifying the query criteria and saving the report definition.

Creating New Session Queries

You can create your own queries from existing queries or based on the criteria you define. Depending on the type of information you want to define as search criteria and whether you want to make the queries private or public, there are different type of queries you can define.

To search for audited sessions, you can create:

- Quick queries
- Private queries
- Shared queries

If you create a quick, private, or shared query, a new node is added to the Audit Analyzer console for that type of query under the Audit Sessions node. If you want to search for audit trail events, you can also create queries for audit events, which are added to Audit Analyzer under the Audit Events node.

Creating a new quick query

A quick query is a full-text search of the audit store database for a simple string or keyword. With a quick query, you can start typing the search string and see a list of potential matches from which you can select an item to look for sessions that contain the item. You should use quick queries when you want to find sessions based on a simple text string, such as a captured input or output, or based on a particular attributes, such as a user name or application, rather than using complex expressions.

To create a new quick query:

1. Open Audit Analyzer, select Audit Sessions, right-click, then select **New Quick Query**.
2. Type a search string into the search field.

   As you type, the Quick Query displays a list of possible matches that start with the text you are typing. For example, if you start typing the string "da" as the search term, the Quick Query list displays captured commands such as dacontrol, dad, and dadebug as potential matches:

The quick query uses SQL Server full text search.

The list of potential matches can include captured input and output, application names, user names, computer names, time stamps, and any other information stored in the audit store database.

   If a text string in the list is what you are looking for, select it. By default, the query will search for sessions that contain all of the text specified. If you want to search for any portion of the text specified, select **Find sessions containing ANY instead of ALL of the search terms**.

3. Click **Find** to display the matching logon sessions in the right pane.

Searching for a specific string

If you want to search for a specific string, you can enclose the command line string with quotation marks. For example, you can type "dacontrol i" to only return sessions that captured dacontrol with the -i option. If you type the same search string without quotation marks and select **Find sessions containing ANY instead of ALL of the search terms**, the quick query will return sessions that include dacontrol with and without the -i option.

Modifying a quick query

You can edit a quick query by selecting the query in the left pane, right-clicking, then selecting **Properties**. You can change the name and add a description on the **General** tab. Click the **Definition** tab to change the query text.

Creating a new private query

A private query is a set of search criteria that you define for your own use. Private queries are only visible to the auditor who creates them. You create private queries by selecting options in Audit Analyzer dialog boxes. Your selections are translated into complex expressions in the SQL Server query language. You can also save any predefined or shared query as a private query if you want to modify an existing query for private use.

To create a new private query:

1. Open Audit Analyzer, select **Audit Sessions**, right-click, then select **New Private Query**.
2. Type a name and description for the query.

   After you save the query, this information is available for viewing and editing on the General tab when you display the query's properties.
3. Select the type of sessions that you want the query to find.

   You can search for UNIX sessions, Windows sessions, and Linux Desktop sessions. By default, new queries search for all types of sessions.
4. Select an attribute for grouping query results, if applicable.

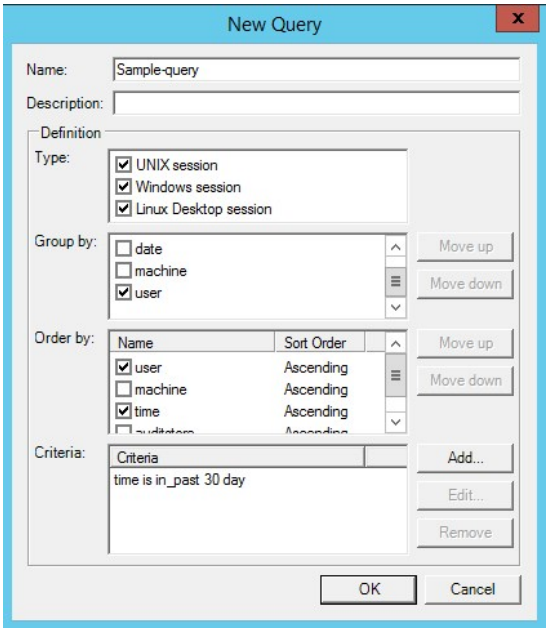
   You can select one or more attributes for grouping query results. If you specify more than one attribute, results are displayed as nested groups according to the order in which you specified the attributes. For example, if you select audit store, then user, then date, the query results are grouped by audit store, then by user for each audit store, then by date for each user.
5. Select an attribute for ordering query results within each group, if applicable.

   You can select ascending or descending sort order for each attribute. For example, you might group query results by user name and set the sort order for user to ascending, but the sort order for time to descending.
6. Click **Add** to add search criteria to filter the results of the query.
7. Select an appropriate attribute from the Attribute list based on the sessions you want to find.

   For example, you can search for sessions based on the period of time in which they were active or based on a specific state. You can also search for sessions based on the activity that took place during the session. For example, you can find sessions where specific UNIX commands or Windows applications were used.
8. Select the appropriate criteria for the attribute you have selected, then click **OK**.

   The specific selections you can make depend on the attribute selected. For example, if the attribute is **Review Status**, you can choose between "Equals" and "Not equals" and the specific review status you want to find., such as "To be Reviewed." If you select the attribute **Comment**, you can specify "Contains any of" and type the text string that you want to find any part of.

   When creating queries for user names or computers, you might want to use the "Starts with" option. If you use the default to match "Is (exactly)", you must include the fully qualified domain name of the user or computer.
9. Click **Add** to add another filter to the criteria for the query, or click **OK** to save the query and find the sessions that match the criteria you have specified.



Adding multiple filters to the query criteria

If you have more than one filter, different criteria attributes, such as Time and State, are separated by an implicit AND operation. Only sessions that match both criteria are returned. If you have repeated criteria attributes, for example, if you have two Time filters (time is not in past 10 days; time is in last month), the attributes are separated by an implicit OR operation. Sessions that match either criteria are returned.

Editing and removing filters from the query criteria

You can edit and remove any of the filters you specify. For example, if you are not finding the appropriate sessions, you might need to change or remove the criteria you have defined. After you have saved a query, you can right-click the query name, then select Properties to modify the query definition.

Specifying command or application filters in the query criteria

When you specify criteria for commands, applications, or outputs, the entry field displays a list of possible matches from audited sessions based on the text you are typing. For example, if you select "Windows Applications" as the attribute and "Contains any of" and start typing "word" as the text string, the entry field displays a list of possible matches that contain "word" in the application name. You can select a potential match or continue typing to specify the application by its display name or the executable file name. For example, you can specify winword.exe, Microsoft Word, or both.

Creating a New Shared Query

A shared query is a set of search criteria that you define for other auditors to use. Shared queries are visible to the auditors you specify. Only the auditor who creates a query can grant permission to other auditors to use the query. You create shared queries by selecting options in Audit Analyzer dialog boxes in exactly the same way as you create private queries. Your selections are then translated into complex expressions in the SQL Server query language. You can also convert a private or quick query to a shared query.

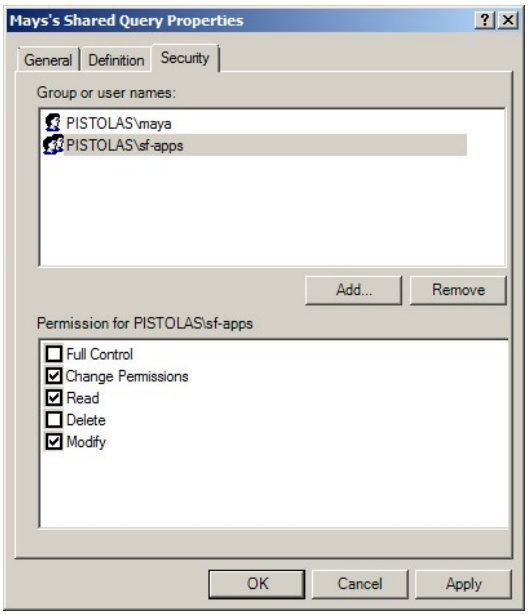
To create a new shared query:

1. Open Audit Analyzer, select Audit Sessions, right-click, then select **New Shared Query**.
2. Type the query name and select the session type, grouping, ordering, and other criteria for the query.

   If you need more information about specifying information for any field in the new query, press F1 to display context-sensitive help.
3. Click **Add** to add another filter to the criteria for the query, or click **OK** to save the query and find the sessions that match the criteria you have specified.
4. Expand **Shared Queries**, select the query name you specified in Step 2, right-click, then select **Properties**.

5. Click the **Security** tab.
6. Click **Add**.
7. Type the user or group name to identify the auditors who should have permission to use this query, then click **OK**.

   You can add multiple users or groups from the Select Users or Groups dialog box. You can also type part of the name, then click **Check Names** to look up user and group names.
8. Select each user or group, then select the appropriate permissions.



Searching for shared queries

After you publish queries and give other users permission to access them, other auditors can search for and select the shared queries they want to use. The shared queries are not automatically visible to users who have permission to use them.

To find shared queries you have permission to use:

1. Open Audit Analyzer, select Audit Sessions, right-click, then select **Open Shared Queries**.
2. Type the query name or click **Show existing queries**, then click **Find Now**.
3. Select one or more queries from the results returned, then click **OK** to add the query to your list of Shared Queries.

Creating queries for audit events

In addition to the predefined queries for audit events, you can create your own queries based on the criteria you define. Audit events are recorded for many activities, including both successful and failed operations. For example, you can search for events that are recorded when users attempt to log on and authentication fails or when users run commands or use applications with a role that grants elevated privileges. Audit trail events are also recorded when there are changes to the auditing infrastructure, and when there are changes to Centrify zones.

To specify the search criteria for a new audit event query:

1. Open Audit Analyzer, select Audit Events, right-click, then select **Query Audit Events**.
2. Type the query name and, optionally a description for the query.
3. Type a user name if you want to filter the event query by user name.

   You can specify one or more user names in userPrincipalName format (user@domain). Use semi-colons (;) to separate multiple user names. For example, to limit the search for audit events to events recorded for actions taken by the users ben, maya, and fred, you could type the following:

   ```
   ben;maya;fred
   ```
4. Type a computer name if you want to filter the event query by computer.

   You can specify multiple computer names separated by semi-colons.
5. Select the Event time option if you want to specify a time frame to filter the query based on when the event occurred.

   If you select this option, you can search for events that occurred:

   - before, not before, after, not after, between, or not between specific dates and times.
   - in or not in the last specified number of days, hours, or minutes.
   - during the specified period of time.
6. Select the Type option to search for events based on the type of activity performed.

   If you select this option, you must click **>** to view and select the event categories in which you are interested. For details about the type of events recorded in each category, select the category and review the Description displayed for that category.
7. Select the Result option to search for events based on the result of the activity performed.

   For example, you can use this option in combination with other options to search for only successful or failed operations.
8. Select the Role option, then a role name and zone if you want to filter the event query by role.
9. Select the Parameter option if you want to filter the query based on a specific parameter.

   If you select this option, you must click **>** to view and select the event parameters that are currently available and in which you are interested.
10. Click **OK** to save and run the new query.

After you create a new query, you can export the query definition or its results, email it to others, or modify its properties.

How Access Manager Roles Affect Audit Trail Events

If you only enable auditing without access control and privilege management features, audit trail events are recorded for all successful and failed operations on audited computers. The events are stored in the audit store database and can be returned in response to queries. These events are not associated with roles, so you should not use the Role filter in your query definition.

If you enable auditing with access control and privilege management, however, user activity is only recorded when a role with “auditing required” or “audit if possible” setting is used to perform one or more tasks. In most cases, roles that allow users to perform tasks using elevated privileges or in a restricted shell environment are configured with one of these audit settings. By default, the Windows Login and UNIX Login roles are also configured to “audit if possible” to capture all audit trail events on the computers where the auditing service is running. If a role is configured with audit not requested or required, only audit trail events are recorded.

If the auditing service is running on the computer where the user logs on or where the administrative tasks are performed, the audit trail event is collected and

transferred to the audit store database. Only the audit trail events that are captured and stored in the audit store database can be returned in response to audit event queries. Therefore, from Audit Analyzer, you can only query and report on audit trail events that are stored in the audit store database while a user performs tasks in an audited role on an audited computer.

Querying by Audit Event Type or by Role

In many cases, querying for audit trail events by event type produces more predictable results than querying for events by role. For example, to query for successful and failed login attempts, select Type, then select the Login Event category. In this particular case, the Windows Login and UNIX Login roles do not—as a user's effective role—capture successful and failed login attempts, so they should not be used as filters for querying successful and failed login events.

If you query using the Role filter, Audit Analyzer only returns the audit trail events associated with the selected role. In some cases, this might be the information you are looking for—for example, to review the execution of commands using a role with elevated privileges. On UNIX computers, however, many audit trail events are not linked directly to the actions taken with a specific role. For example, on a Linux or UNIX computer with the auditing service running, many command-line activities record audit trail events. These events are stored in the audit store database and can be queried, but are not associated with any role and not reported if you select a role filter.

Populating and Deleting the Roles Available

The list of roles available for querying is based on the roles you have defined using Access Manager. If you add a role definition, the new role displays in the list of roles when an audit trail about the role is generated.

If you delete a role from all zones, however, it will remain in the list until the last session that has events associated with that role is deleted or the audit store database is detached.

Organizing queries in custom folders

By default, queries are organized into folders by type. You can choose to organize your queries in other ways. For example, you can create a custom hierarchy of folders and move your queries into those folders. The folder information is stored locally and does not affect other auditors, so each auditor can have a private folder structure for favorite queries.

To create a custom folder hierarchy:

1. Open Audit Analyzer, select Audit Sessions, right-click, then select **New Folder**.
2. Select the new folder, right-click, then select **Rename** and type a new folder name.
3. Right-click the new top-level folder, then select **New Folder** to create sub-folders.

Exporting and Importing Query Definitions

You can export and import query definitions from one Audit Analyzer console to another to make queries available to different groups of auditors. You can also export query definitions for individual queries or for queries stored a custom folder hierarchy. For example, if you have a custom "Queries Required at All Sites" folder, you can select that folder and only export those query definitions.

To export query definitions:

1. Open Audit Analyzer, select the Audit Analyzer root node, right-click, then select **Export Query Definitions**.
2. Select a location and type a file name, then click **Save**.

   All of the query definitions are saved to an xml file.

To import query definitions:

1. Open Audit Analyzer, select the Audit Analyzer root node, right-click, then select **Import Query Definitions**.
2. Navigate to the location that contains the .xml file you want to import, then click **Open**.

   The imported queries are created as private queries. If you have an audit role with Manage Shared Query privileges, you can publish the imported queries as shared queries.

Displaying Session Information

After you select a query to see a list of sessions, such as the **Today** query to see a list of today's sessions or an individual user to see a list of sessions for that user, you can view an indexed list of the activity that took place during any of the individual UNIX or Windows sessions captured.

For example, you can select a Windows session, right-click, then select **Indexed Event List** to review a list of the applications that were opened during the session, in the order in which they were opened, the title of the active window, the type of activity, the desktop role used to access the application, and whether audit data was captured for the role being used. If you have video capture auditing enabled for the installation, you can replay the session entirely or from any point in the indexed list.

Similarly, for UNIX sessions, you can select a specific session, right-click, then select **Indexed Command List** to display a list of commands executed and the order they occurred. If you have video capture auditing enabled for the installation, you can replay the session entirely or from any point in the indexed list.

Adding Session Reviewers without Designating Auditing Roles

If you have been assigned an auditing role that allows you to replay, delete, and update the status of an auditing session, you can also designate users or groups the permission to replay and update the status of that session, even if they do not have an assigned auditing role.

> **Note**: Users and groups assigned as session reviewers cannot delete auditing sessions, and therefore cannot change the reviewer list for the sessions available to them.

To designate users or groups as reviewers of one or more auditing sessions:

1. In Audit Analyzer, select the session or sessions you want to be reviewed. You can do this by selecting the predefined groupings or by defining specific criteria using a query.
2. Right-click the selected sessions and select **Set Reviewers**.
3. Type all or part of the name of the user or group that you want to add to the list of reviewers and click **Check Names**.

   If you would like to add multiple reviewers, separate the full or partial names by semicolons.
4. Click **OK**.

To remove reviewers from a session, right-click the session and select **Clear Reviewers**.

Changing the Review Status for Audited Sessions

You can use the review status to keep track of audited sessions. For example, if you have a formal review process, you can change the state of sessions to indicate whether they are in the queue to be reviewed, have been reviewed, are awaiting some type of action, or should be deleted. For each change of state, you can add comments to more fully document what's been done or if any follow-up by another auditor is required.

By default, all audited sessions start with a review status of **None**.

To update the review status for a session:

1. Open Audit Analyzer and navigate to the session.
2. Select the session in the right pane, right-click, then select **Update Review Status**.
3. Select the appropriate new status.

   For example, select **To be Reviewed** if the session requires a review or **To be Deleted** if the session has no activity requiring further review or data that must be retained.
4. Type any notes for yourself or other auditors in the Comments dialog box, then click **OK**.

Viewing status history

The changes you and other auditors make to the review status for a session are recorded and cumulative, so that you can view the complete status change history for any session.

To view the status change history for a session:

1. Open Audit Analyzer and navigate to the session.
2. Select the session in the right pane, right-click, then select **Properties**.
3. Click the **Review Status** tab.

   Changes to the review status are listed with the most recent change at the top of the list and proceeding back in historical order. You can select any review status change in the list to see who made the change and any comments recorded when the change was made.

Adding comments to a session

The comments associated with a session are cumulative. For example, if you select **To Be Reviewed** and type a comment, then later change the state to **Reviewed** with another comment, both comments are displayed on the **Comments** tab if you view the session's Properties.

You can also add comments to a session without changing its review status. To add comments to a session without changing the review status, right-click the session, select **Properties**, then click the **Comments** tab. You can use this tab to record detailed information about sessions of interest. You can also use the Review Status attribute to find sessions by review status, and the Comment attribute to find sessions by comment text.

Reviewing and deleting your own sessions

By default, you can update the review status, add comments, and delete your own sessions if you have an audit role with the appropriate permissions. However, there are installation wide options to prevent any users from updating the review status or deleting their own sessions. These installation-wide options take precedence over your audit role permissions. Depending on how these options are set, you might be prevented from updating the review status and adding comments to your own sessions, prevented from deleting any of your own sessions, or prevented from both. If either installation-wide option is set, you might be blocked when you attempt to add a comment or delete a session.

Playing Back a Session

If you select the **Enable video capture auditing option** for an installation, you can replay session activity captured on audited Windows or UNIX computers.

For Windows computers, the video record captures desktop activity when users select roles with auditing enabled.

For UNIX sessions, the video record captures complete input and output typed in a UNIX shell during a session.

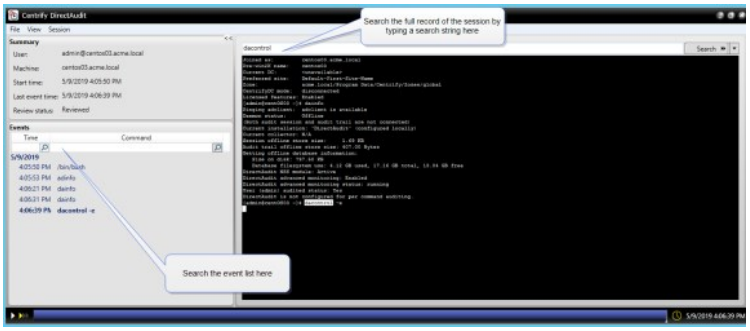
If the Replay option is available for a session on the rightclick menu, you can view a summary of the commands executed or applications opened in the session player. You can also search for commands, parameters, or events, control the playback speed and magnification from the session player, and update the session review status.

To play back a session when video capture auditing is enabled:

1. Open Audit Analyzer and navigate to the session.
2. Select the session in the right pane, right-click, then select **Replay** to open the session player.

   The left pane of the session player displays a summary of activity similar to the indexed list. For example, if the session is a Windows session:

   You can search on any column to find events of interest. If the session is a UNIX session, you can search the full session for any text string. For example, if you are playing a UNIX session, the right pane displays the shell session and a search field.



3. Click the **Play/Pause** icon ( ) at the bottom of the session player to start or stop the session you are viewing.

   You can also fast forward session playback by clicking the **Speed control** icon to play back at 2x or 3x the normal speed. The dark blue playback line across the bottom of the window represents the total time of the session. You can drag the **Timepoint needle** to go directly to a specific point in the session.

   The **Real-time** icon toggles to allow you to play back a session as it was recorded in real time or move swiftly from one user action to the next. The **Session point** in the lower right corner identifies the date and time of the current point in the session playback.

4. To update the session review status:

   1. Select **Session** › **Update Review Status**, and then select the desired review status.
   2. Add your review comments and click **OK**.

      The updated session review status displays in the session player.

5. Close the session player.

Starting the Session Player Separately

In most cases, you start the session player from Audit Analyzer. However, you can also start the session player from a Windows command prompt using standard Windows command line options or by specifying a Uniform Resource Identifier (URI).

Using Window command line options

If you use the Windows command line to start the session play, the installation name and session ID are required. The other arguments are optional.

daplayer /installation=*installation_name* /id=*session_guid*
[/conn=*auditserver_connection_string*]
[/store=*auditstore_ID*]
[/time=*timestamp*]

For example:

daplayer.exe /installation=MyInstallation
/id=""
/store=1
