Install and Upgrade

- Planning and Deployment Guide
- Licensing Guide
- Upgrade Guide

Most large-scale deployments rely on a project team to design and articulate a project plan, and team members take on specific roles and responsibilities. Depending on your role and responsibilities, you may want to read portions of this guide selectively.

> **Note**: Most of the information in this guide applies to all platforms. However, there are some deployment scenarios and tasks that are unique to Mac OS X computers. If you manage Mac OS X computers and users, refer to the Unexpected Link Text for additional information.

The guide provides the following information:

- Planning Deployment for an Enterprise provides an overview of key concepts and the deployment lifecycle, including suggestions for who should participate in the planning process and factors to consider that will affect your deployment strategy.
- Architecture and Basic Operations describes the key components of the Server Suite software architecture and how the components work together to provide authentication and authorization services.
- Deployment Process Overview provides an overview of the steps involved in a deployment project and a preview of the tasks you can expect to complete.
- Planning organizational units and security groups discusses the Active Directory objects and organizational model that is recommended to ensure a separation of duties for UNIX administrators.
- Installing Authentication & Privilege Services provides step-by-step instructions for installing and configuring Server Suite software components on Windows computers.
- Installing Agents on Computers to be Managed describes the installation options available and provides instructions for installing Server Suite software components on UNIX and Linux computers.
- Planning to use Server Suite zones describes the importance of zones and how you can use classic and hierarchical zone for identity management, access control, and delegated administration.
- Preparing To Migrate Existing Users And Groups describes the steps to take to prepare for migrating existing users and groups, including collecting and analyzing existing profile information and creating the first zone.
- Migrating Existing Users To Hierarchical Zones describes how to import and migrate an existing user population into hierarchical zones and enable authentication using Active Directory and Server Suite software.
- Joining Computers to a Domain and Zone describes how to complete the initial migration by joining the Active Directory domain and a Server Suite zone.
- Provisioning New User and Group Profiles After Migration describes how to use the Zone Provisioning Agent and Active Directory groups to automate provisioning of new users and groups.
- Validating Operations After Deploying provides suggestions for formal testing and validation activities you can perform to move from a pilot deployment to a production environment.
- Defining Role-Based Access for Users and Computers describes the most common roles that organizations create to complete the initial deployment and how to configure the appropriate rights and assign the roles to appropriate groups.
- Migrating And Managing Service Accounts describes the strategies you can use if you want to migrate local service accounts to Active Directory to improve security for those accounts.
- Planning to Deploy in a Demilitarized Zone (DMZ) describes how to deploy Server Suite components to allow communication between a perimeter (DMZ) zone and an internal zone.
- Managing and Evolving Operations After Deployment describes management activity for operations staff and additional services you may want to implement after deployment as you evolve the Server Suite software solution.
- Templates and Sample Forms provides examples of common documents and notification messages that you can customize and use throughout the deployment process.
- Permissions Required for Administrative Tasks provides information about the specific Active Directory permissions required to perform administrative tasks on objects specific to Server Suite.

Planning Deployment for an Enterprise

This section provides a brief review of the information you should have to begin planning a successful enterprise deployment of Server Suite. It includes an overview of the deployment life cycle, roles and responsibilities to consider in assembling a deployment team, and the factors you should consider during the planning phase that will affect how you deploy Centrify software.

For an overview of Centrify software and an introduction to basic tasks, see the *Evaluation Guide for Linux and UNIX*. For a general introduction to identity, access, and configuration management or more detailed information about performing administrative tasks, see the *Administrator's Guide for Linux and UNIX*.

What You Should Know Before Planning a Deployment

Before you begin planning a full scale deployment of Centrify software, you should be familiar with key concepts, terminology, and components for Server Suite and Active Directory. You should also have information about your existing environment.

Before you continue planning the deployment, verify you have information about:

- How Active Directory is used to store user, group, and computer information in your organization and the Active Directory schema you currently have deployed.
- How you currently manage services and provision users for both Windows and nonWindows computers.
- How the Centrify Agent installed on a UNIX, Linux, or Mac OS X computer makes that computer part of an Active Directory domain.
- How zones enable you to manage user profiles, control access to computer and application resources, and delegate administrative tasks.

If you are not familiar with Centrify architecture and the components that make up the Server Suite, see Architecture and basic operations to be sure you understand the concepts, core components, and operations that enable Active Directory users to log on to UNIX, Linux, and Mac OS X computers. This guide assumes you also have access to the *Administrator's Guide for Linux and UNIX* and can refer to it, as needed, for additional details.

Why Planning a Deployment is Important

Because Centrify software becomes a critical part of your IT infrastructure once deployed, it is important that you plan and test your deployment strategy and validate the results you expect before placing Centrify components into a production environment.

After you deploy Centrify software in a production environment, the rights and roles you define will control whether users can log on and what they can do on specific computers if they are allowed to log on. Because preventing users from accessing critical resources or services can affect business operations, you should analyze the requirements of your environment as thoroughly as possible before moving from a pilot deployment into production.

The deployment process described in this guide is intended to help you to migrate existing users and groups to Active Directory with minimal disruption to end-user activity and ongoing business services. The recommendations presented are designed to give you flexibility and provide you with a framework for deploying that minimizes the effect of the deployment on the existing user population.

> **Note**: Planning is important regardless of whether you are deploying on Windows, UNIX, Linux, or Mac computers. However, some deployment steps can be skipped if you are only deploying on Windows computers or if you aren't migrating any local users or groups. For more information about deploying only on Windows computers, see the *Administrator's Guide for Windows*. For information that is specifically about deploying on Mac computers, see the *Administrator's Guide for Mac*.

What to Expect During Deployment

In most organizations, a deployment takes place in the following stages:

Evaluation

A primary senior analyst or small group installs the software in an isolated test environment. The main goal of this stage is to learn basic concepts, terminology, and operations and validate any specific functionality that is critical to the organization adopting the software. The lab environment also allows you to test the planned changes to system and user management processes without affecting user access. This proof-of-concept stage often takes place before the decision to purchase the software or with the decision to purchase a small number of licenses for extended testing.

Analysis and Design

During this stage, a planning team does deeper analysis into the goals and requirements of the organization, the current state of the environment, and the deployment and management options that best suit the organization. The main goal of this stage is to design how you will use zones, import user account

information, and assign rights and roles through a combination of Active Directory groups and zone definitions. Most of the information in this guide is intended to help you make those decisions and validate them in a pilot deployment.

Pilot Deployment

The pilot deployment is intended to be more robust than the evaluation stage. The pilot deployment is typically 10 to 20 computers, often with a common administrative owner or administrative group. The main goal of this stage is to verify your analysis accurately described your environment and to uncover any gaps that might have been missed or special circumstances that require adjustment to the design planned for zones, user account information, or rights and roles. You can include more than 20 computers in the pilot deployment, but limiting the number makes the initial migration of the user population more manageable while you become familiar with the process.

Testing and Validation

After deploying the software, most organizations perform at least some formal testing of specific scenarios to ensure the authentication and authorization rules they have defined operate as expected and users are not locked out of computers they need access to but are prevented from logging on where they don't have access rights. The main goal of this stage is to execute a test plan that exercises software operations in a number of different use cases.

Roll-Out Deployment

After sufficient testing and verification of the pilot deployment, the deployment team can use a software delivery method to install Centrify Agent packages on remote computers and join an Active Directory domain. Typically, the roll-out is done in phases, so that Centrify software is deployed on a set of computers in one subnet, IP range, or administrative domain, then later deployed on another set of computers on a different subnet, with a different IP range, or in a different administrative domain. The goal of this stage is to deploy in a controlled manner, so that any issues can be resolved before they affect additional users or computers.

Ongoing Management and Evolution

As your environment changes and evolves, it is likely that you will want to refine, customize, and extend your deployment and your authentication, authorization, computer, and user management policies. You may also develop or enhance scripts that automate provisioning and decommissioning of accounts, or update business processes to take advantage of additional functionality, such as integration with other tools to capture Centrify data or configuring database applications to use PAM-based authentication. The goal of this stage is continuous improvement to streamline business processes and operational efficiency.

Preparing a Deployment Team

In large organizations, the network architecture and Active Directory infrastructure is often highly complex and sophisticated. Adding UNIX, Linux, and Mac OS X computers and users to this infrastructure requires careful planning and is handled best with a clearly documented deployment plan. This guide is intended to help you develop such a plan and to suggest the issues you should consider in designing a deployment that suits your organization. For an example of what a deployment plan might look like, see Simplified environment analysis and zone design template.

Depending on the size of your organization, you might want to assemble a cross-functional deployment team to plan and implement a deployment strategy, set up and test a pilot deployment program, and refine, document, and roll-out operations across the organization. In addition, a deployment team might include project leads and IT staff members who will be responsible for maintaining and managing Server Suite and Active Directory on an ongoing basis after deployment or developers who will extend or integrate applications to work with Server Suite and Active Directory.

A typical deployment team might consist of members in the following roles:

Active Directory Enterprise or Domain Administrators

Know the structure and trust relationships of one or more Active Directory forests, including the topology of the Active Directory site and the roles of the domain controllers. These administrators may also be responsible for provisioning and decommissioning accounts or maintaining the tools for these business processes.

UNIX Administrators or Administrators with Specific Expertise

Manage access for all or specific groups of UNIX, Linux, or Mac OS X computers. These administrators may be responsible for specific resources, such as the servers that host mission-critical applications or a web farm, or have specific knowledge, such Oracle database administration or AIX administrative tools.

Security Administrators

Establish security policies and audit trails and define the procedures for securing computer resources and user account information. These administrators may also define the provisioning rules for the organization or have detailed knowledge of the existing provisioning process.

IT or Network Architects

Understand the overall layout of the organization's network, including internal connectivity and access to the Internet, firewalls, port usage, bandwidth and latency issues.

Application Developers

Write programs that require authentication and authorization services. Application developers might also include UNIX programmers who will be responsible for writing scripts to automate administrative tasks, such as creating zones or adding new users to a zone.

Functional Testers

Develop test cases for the user scenarios the deployment team wants to validate.

Centrify Administrative Operators

Use Access Manager and other consoles on Windows, UNIX command line programs, ADEdit library, or PowerShell scripts to manage users, groups, computers, or zones. These operators might be delegated administrators for specific zones after deployment or existing Active Directory administrators who add and remove users from groups or manage Active Directory containers.

Database Administrators

Install and manage database instances and control access to database records. If you are planning a deployment that includes auditing user activity, the deployment team should include at least one database administrator to plan for and create the databases that will store captured sessions and audit meta-data. A database administrator can also provide procedures and guidance for backing up, archiving, and removing historical data as appropriate for your organization's record retention policies.

Internal or External Auditors

Understand regulatory compliance requirements for the organization and industry. Auditors typically know the type of information they need and can define the reports that will satisfy their needs.

Assembling a cross-functional team with members who have expertise in working with Active Directory and Windows architecture and members who have expertise in managing UNIX, Linux, or Mac OS X servers and workstations is often a key component of a successful deployment.

Preparing Deployment Documentation

In addition to deploying the software, the deployment team should prepare materials that document the solutions they are deploying and the processes and procedures to assist others in migrating. The deployment documentation might include training materials for new users and test plans to verify a successful deployment that can be reused when updating the software after the initial deployment.

In general, members of the deployment team should focus on the following activities to prepare for a roll-out of Server Suite to a production environment:

- Document the configuration settings you plan to use and update the documentation as needed based on the pilot experience. For example, during the planning phase you might have drafted a plan for user and group filtering or access controls that in practice you find must be adjusted. The pilot deployment gives you the opportunity to implement your planned solution but change it, if needed.
- Document and prototype any deployment scripts that you intend to use and any processes or policy decisions that impact using those scripts. For example, you might want to automate the join process or how new users are added to a zone or modify existing scripts that provision users.
- Document issues that require troubleshooting during the pilot deployment and the resolution for each issue. You can collect this information as an organization-specific operations manual for IT staff.
- Prepare training materials for testers, operations personnel, and end-users based on the experience gained in the pilot deployment and tailored to your organization's specific needs and internal policies.
- Prepare test plans that sufficiently cover the types of scenarios that are specific to your organization's needs and internal policies. For example, if you plan to use group policies, your test plans should include scenarios for testing the group policies you plan to implement.
- Update planning documents, such as the zone structure or role definitions that you developed during the planning phase in response to the practical experience gained in the pilot deployment.

- Create checklists or instructions that are specific to your organization's deployment. For example, you may want to create a "site preparation checklist" that covers specific steps administrators should take before deploying, a "deployment checklist" that includes site-specific naming conventions and migration instructions, and a "handoff to operations checklist" to ensure a smooth hand-over to data center staff after deployment is complete.

Defining Goals for the Deployment

One of the first tasks of the deployment team should be to define the goals you want to achieve and the criteria you will use to measure whether you have met those goals. As part of this process, you should define:

- **The primary reason for deploying Centrify in your organization.** For example, if providing centralized directory service or a single point of account administration is your most important goal, you may make different deployment decisions than if auditing and restricting user access to specific computers is your primary goal. That is, you want to be sure the deployment addresses your most pressing concerns first.
- **Priorities for any additional goals you want to set for the deployment.** For example, you may want to transition to a rationalized namespace over time, but this may be a lower priority for your organization than moving from decentralized computer administration to delegated administration of the tasks users can perform on specific computers.
- **Any specific auditing requirements or security requirements that are unique to your organization or industry.** For example, the way you organize computers into groups may be determined by specific reports you need to produce.
- **Internal policies for how you update and distribute software.** For example, you should define how frequently you apply operating system patches and whether you automate software distribution.
- **Internal policies for how you assign UNIX attributes and Active Directory account information.** For example, you should identify how you have assigned UIDs, GIDs, and other UNIX-specific attributes and whether there are existing naming conventions for Active Directory users and groups.
- **Plans for who will manage UNIX profiles after deployment.** For example, you should identify the group or groups that will manage which UNIX users and computers and whether there will be separate UNIX and Active Directory administrators with shared responsibilities or a clearly defined division of responsibilities. In most cases, Centrify recommends a separation of duties model that enables UNIX administrators to manage zones and Active Directory administrators to manage user objects and group membership.

Architecture and Basic Operations

This section provides an overview of the Server Suite architecture and the components for Windows and non-Windows computers. It also describes the basic flow of operation when users log in or access applications, and what happens when an Active Directory domain controller goes down.

The information in this section is not required for planning a deployment. It is intended as background information that can help you understand the authentication and authorization process in some detail. If you want to proceed directly to planning the deployment, you can skip this section.

Server Suite Platform-Specific Components

Server Suite provide an integration layer between Active Directory in a Windows environment and computers running other operating systems or application environments. Because of this, Server Suite includes components for managing Active Directory-based objects in the Windows environment and agents that run on each server or workstation to be integrated into Active Directory.

Server Suite Components for Windows

On Windows, Server Suite includes management consoles and services to simplify the management and integration of Linux and UNIX computers and users into Active Directory.

The key components for Windows that you use in deployment are:

- Access Manager console
- Zone Provisioning Agent configuration panel and Windows service

There are several additional Windows components available for you to use, depending on the version of Server Suite software you install and the requirements of your environment. For example, Server Suite offers extensions for working with NIS maps and Active Directory group policies, as well as components to support a multi-tier architecture for auditing activity in user sessions and the Network Information Service to support agentless authentication service.

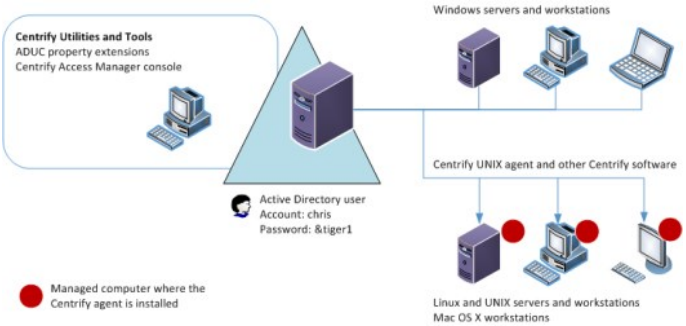
Components Installed on Managed Computers

On non-Windows computers, Server Suite software consists of the core Server Suite Agent (adclient), related libraries, and optional tools. The Server Suite Agent enables the local host computer—most commonly a Linux or UNIX computer—to join an Active Directory domain.

After the agent is deployed on a server or workstation, that computer is considered a **managed computer** and it can join any Active Directory domain you choose.

When a Server Suite-managed computer joins an Active Directory domain, it essentially becomes an Active Directory client and relies on Active Directory to provide authentication, authorization, policy management, and directory services. The interaction between the agent on the local computer and Active Directory is similar to the interaction between a Windows workstation and its Active Directory domain controller, including failover to a backup domain controller if the managed computer is unable to connect to its primary domain controller.

The following figure provides a simplified view of the integration between Windows and non-Windows computers through Server Suite software.



To use Microsoft Active Directory to centrally manage access across different platforms, you need to do the following:

- Prepare the Active Directory environment by installing the Access Manager console on at least one Windows computer and using the Setup Wizard to update the Active Directory forest.

- Ensure each UNIX, Linux, or Mac OS X computer can communicate with an appropriate Active Directory domain controller through DNS.
- Install the agent (adclient) on the UNIX, Linux, or Mac OS X computers that will be joining an Active Directory domain.
- Run the join command and specify the Active Directory domain on each UNIX, Linux, or Mac OS X computers that needs to join an Active Directory domain.
- Use Active Directory Users and Computers or Access Manager to authorize access to the UNIX, Linux, and Mac OS X computers for specific users and groups.

The next sections provide a more detailed discussion of the Server Suite architecture and a summary of what happens when a user logs on to a UNIX computer that has joined the Active Directory domain.

Storing Server Suite Properties in Active Directory

The Active Directory schema defines the object classes that can be stored in Active Directory, and the attributes that each object class must have, plus any additional attributes the object can have, and the object class that can be its parent. Schema definitions are also stored as objects in Active Directory. To store UNIX-specific attributes within the Active Directory schema, the schema must be able to include the properties that are associated with a UNIX user or group. For example, for a UNIX user, the schema needs to accommodate the following information fields:

- UNIX user name
- Password hash (optional)
- Numeric user identifier (UID)
- Primary group identifier (GID)
- General information (GECOS)
- Home directory
- Default shell

Some of these information fields are similar to standard user class attributes in Active Directory. For example, the Active Directory Display Name (displayName) attribute typically stores a user's full name—the same information typically stored in the GECOS field in an /etc/passwd file on a UNIX computer, so the displayName is used to define the contents of the GECOS field in a user's UNIX profile. Depending on the Active Directory schema you have installed, some of the information fields required for logging on to UNIX computers might not have an equivalent Active Directory attribute.

If you are using the default Active Directory schema, Server Suite stores UNIX-specific attributes in an Active Directory class under its own parent container for zones. Server Suite then organizes the information about individual UNIX computers, users, and groups by zone.

If your organization has already deployed a Microsoft-supported set of UNIX schema extensions, such as those defined in the Windows **Services for UNIX** (SFU) schema extension, you can store UNIX attributes in the fields defined by that schema as an alternative to using the zones container.

If you have deployed the **RFC 2307-compliant** Active Directory schema, you can store UNIX attributes in the fields defined by that schema and organized into RFC 2307-compliant zones.

After you have installed Server Suite components on a Windows computer, the first time you open the Access Manager administrative console, a Setup Wizard updates the Active Directory forest to include the Server Suite properties for UNIX attributes. You can then use Access Manager, the Active Directory Users and Computers MMC snap-in, ADEdit commands, or PowerShell scripts to view and modify the UNIX properties for any user, group, or computer.

> **Note**: For RFC 2307-compliant zones, the group name and UNIX name are stored in the same CN attribute. Therefore, if you change a group's name with its Active Directory Users and Computers' property page, the UNIX name is changed in Access Manager as well.

Using Access Manager

Access Manager is the primary user interface for managing all of the Server Suite-specific information stored in Active Directory. With Access Manager, you can:

- Manage access to all of your UNIX, Linux, and Mac OS X computers.
- Set and modify user and group properties for all of your UNIX, Linux, and Mac OS X users and groups.
- Create and manage zones and zone properties to simplify the process of giving users access to specific computers and migrating UNIX user accounts to Active Directory.
- Add Active Directory users and groups to zones.
- Import user and group information from local password and groups files or from NIS and NIS+ servers and domains.
- Import and maintain network information from NIS maps such as netgroup, auto.master, and automount or create custom NIS maps.
- Define and assign rights and roles that authorize or restrict access to specific computers and operations on managed computers.

You can also add other snap-ins to Access Manager or add Access Manager to another Microsoft management console snap-in. For example, you can add the

Active Directory Sites and Services and Active Directory Domains and Trusts snap-ins to Access Manager to consolidate management activity.

Allowing and Blocking Domains for Access Manager

You can configure Access Manager so that it can connect to trusted domains by setting the following registry key with a list of trusted domains and/or forests. The type of key is REG_MULTI_SZ:

HKLM\SOFTWARE\Centrify\CIMS\AllowedTrusts

Configuring a list of domains this way can be particularly useful and faster when you have a large amount of domains. Enter each domain as a separate line in the Registry Editor window.

For example, to specify a single domain:

acme.com

For example, to specify multiple domains:

acme.com
foo.com

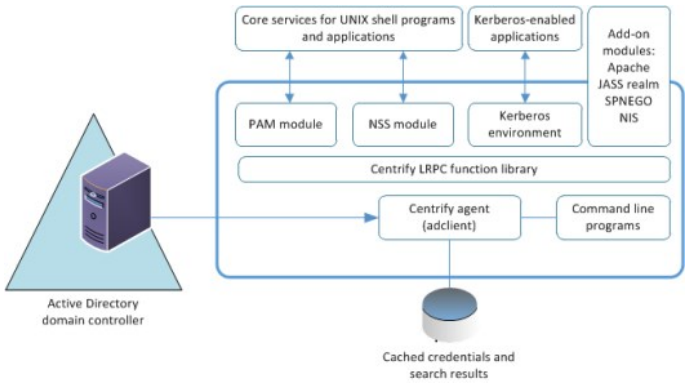
To block access to domains, you use the IgnoreTrusts key: HKLM\SOFTWARE\Centrify\CIMS\AllowedTrusts.

Core Agent Components and Services

The Server Suite Agent makes a UNIX, Linux, or Mac OS X computer look and behave like a Windows computer to Active Directory. Once installed, the agent performs the following key tasks:

- Joins UNIX, Linux, or Mac OS X computers to an Active Directory domain.
- Communicates with Active Directory to authenticate users logging on to the UNIX, Linux, or Mac OS X computer, and caches credentials for offline access.
- Enforces Active Directory authentication and password policies.
- Extends Active Directory group policies to manage the configuration of UNIX users and computers.
- Provides a Kerberos environment so that existing Kerberos applications work transparently with Active Directory.

Individual agents are platform-specific, but provide an integrated a set of services to extend Active Directory authentication, authorization, and directory service to managed computers. The following figure provides a closer look at the services provided through the Server Suite Agent:



As this figure suggests, the agent typically includes the following core components:

- The core component of the agent is the adclient process that handles all of the direct communication with Active Directory. The agent contacts Active Directory when there are requests for authentication, authorization, directory assistance, or policy updates, and then passes valid credentials or other requested information along to the programs or applications that need this information.
- The core component of the agent is the adclient process that handles all of the direct communication with Active Directory. The agent contacts Active Directory when there are requests for authentication, authorization, directory assistance, or policy updates, and then passes valid credentials or other requested information along to the programs or applications that need this information.
- The **Centrify Pluggable Authentication Module**, pam_centrifydc, enables any PAM-enabled program, such as ftpd, telnetd, login, and sshd, to

authenticate using Active Directory.

Note: For AIX and Mac OS X, the implementation is slightly different. For example, the agent for AIX can use PAM interfaces if you have configured the computer to use PAM modules or the interfaces in the Loadable Authentication Module (LAM) to handle behavior that on other platforms is done through PAM or NSS. Similarly, the agent for Mac OS X uses native interfaces where appropriate to provide services from Active Directory to the local computer.

- The **Centrify NSS** module is added to nsswitch.conf so that system look-up requests use the agent to look up and validate information using Active Directory through LDAP.
- The **ADEdit Tcl application and procedure library** and **individual UNIX command line programs** enable you to perform common administrative tasks, such as join and leave the Active Directory domain or change user passwords for Active Directory accounts interactively or within scripts to automate tasks.
- The **Server Suite-managed Kerberos environment** generates a Kerberos configuration file (etc/krb5.conf) and a default key table (krb5.keytab) file to enable your Kerberos-enabled applications to authenticate through Active Directory. These files are maintained by the agent and are updated to reflect any changes in the Active Directory forest configuration.
- The **Server Suite local cache** stores user credentials and other information for offline access and network efficiency.

In addition to these core components, the agent can also be extended with the additional software packages, including modified versions of programs such as Kerberos command line tools, OpenSSH, OpenLDAP, and PuTTY utilities. Server Suite-enabled versions of these programs allow you to use Active Directory accounts and Kerberos credentials for authentication, authorization, and policy enforcement services. Server Suite also provides authentication modules that enable you to configure single sign-on for web and database applications, and specialized extensions such as the adnisd Network Information Service, which enables you to publish information stored in Active Directory to NIS clients.

Key Operations Handled by the Adclient Process

The most important element in the agent is the adclient process. The adclient process runs as a single trusted service. This process is automatically added as a boot service and is started whenever you reboot a managed computer. The adclient process handles all of the direct communication with Active Directory and manages all of the operations provided through the other services.

The adclient process performs the following key tasks on managed computers:

- Locates the appropriate domain controllers for the local computer based on the Active Directory forest and site topology published by the Windows DNS server. If a domain controller becomes unavailable, the adclient process automatically locates the next available domain controller to ensure uninterrupted service.
- Provides Active Directory with credentials for the local computer account to verify the computer is a valid member of the domain.
- Delivers and stores user credentials so that users can be authenticated by Active Directory and, once authenticated successfully, can sign on even if the computer is disconnected from the network for mobile access or if Active Directory is unavailable.
- Caches query responses and other information, including positive and negative search results, to reduce network traffic and the number of connections to Active Directory and to ensure users can work uninterrupted and start new application sessions using their existing login credentials. All communication with Active Directory is encrypted to ensure security, and you can manage the cache through configuration parameters or group policy.
- Creates and maintains the Kerberos configuration and service ticket files to allow existing Kerberos-enabled applications to work with Active Directory without any manual configuration.
- Synchronizes the local computer's time with the clock maintained by Active Directory to ensure the timestamp on Kerberos tickets issued by the KDC are within a valid range.
- Resets the password for the local computer account in Active Directory at a regular interval to maintain security for the account's credentials.
- Provides all the authentication, authorization, and directory look-up services retrieved from Active Directory to the other Server Suite Agent services, such as the PAM service or the Apache authentication module.

How PAM Applications Work with Server Suite

Pluggable Authentication Modules (PAM) are a common mechanism for configuring authentication and authorization used by many UNIX programs and applications. If a program or application uses PAM for authentication and authorization, the rules for authenticating the user are configured in either the PAM configuration file, /etc/pam.conf or in application-specific files in the /etc/pam.d directory.

The Server Suite Agent for *NIX includes its own Pluggable Authentication Module (pam_centrifydc) that enables any application that uses PAM, such as ftpd, telnetd, login, and Apache, to authenticate users through Active Directory. When you join a domain, the pam_centrifydc module is automatically placed first in the PAM stack in systemauth, so that it takes precedence over other authentication modules.

The pam_centrifydc module is configured to work with adclient to provide a number of services, such as checking for password expiration, filtering for users and groups, and creating the local home directory and default user profile files for new users. The services provided through the pam_centrifydc module can

be customized locally on a computer, modified through Active Directory group policy, or configured through a combination of local and Active Directory settings.

Working in conjunction with the adclient process, the pam_centrifydc module provides the following services for PAM-enabled programs and applications:

- Requests the PAM-enabled application to prompt for a password when appropriate and verifies whether the application-provided user name and password are valid in Active Directory.
- Checks whether the user's password has expired in Active Directory. If the password has expired, the pam_centrifydc module prompts the user to change the password, and forwards the new password to the adclient process, which communicates the change to Active Directory.
- Queries the adclient process to determine whether any access control policies are applied. For example, the pam_centrifydc module uses the information in the centrifydc.conf file to determine whether a local user attempting to log on is mapped to an Active Directory account, whether specific users or groups have been granted or denied permission to log on to the local computer, or whether Active Directory authentication should be ignored for a specific user or group.
- Creates the local home directory and default user profile files for new users. The pam_centrifydc module uses skeleton files to set up the user environment when new Active Directory users log on to a managed computer for the first time.

Most of these tasks are performed during a user login session as a series of requests and replies from the pam_centrifydc module to Active Directory through the adclient process for those programs and applications that are configured to use PAM. Because PAM is the most common authentication service used by UNIX programs and applications, the pam_centrifydc module is the most commonly used for a typical log-on session. For a more detailed description of a typical log-on process, see What happens during the typical log-on process.

> **Note**: The order in which identity stores are listed in the nsswitch.conf file does not influence authentication. Authentication and authorization services are provided by Active Directory through the Server Suite Agent for *NIX and its PAM component, and by default, Active Directory is always tried before any other sources. The order in which sources are checked is controlled through the PAM configuration settings, for example, the lines defined in the pam.conf file. In general, you should not modify the PAM configuration because making changes to these settings can compromise security or produce unexpected and undesirable results.

How NSS Configuration Works with Server Suite

The Name Service Switch (NSS) provides a mechanism for identifying sources of network information a computer should use, such as local password and group files, NIS maps, NIS+ tables, LDAP, and DNS, and the order in which these sources should be consulted when looking up users, groups, host names, and other information.

When you join a domain, the NSS configuration file, nsswitch.conf, is automatically updated to use the Server Suite Agent's NSS module first. Using the adclient process and the service library, the Server Suite NSS module accesses network information that's stored in Active Directory through LDAP.

When a UNIX program or application needs to look up information, it checks the nsswitch.conf file and is directed to use the nss_centrifydc module. The nss_centrifydc module directs the request to Active Directory through the adclient process. The adclient process provides the information retrieved from Active Directory, then caches the information locally to ensure faster performance, reduce network traffic, and allow for disconnected operation.

> **Note**: The order in which identity stores are listed in the nsswitch.conf file does not influence authentication. Authentication and authorization services are provided by Active Directory through the Server Suite Agent and its PAM service, so Active Directory is always tried before any other sources, regardless of what you have specified in the nsswitch.conf file. Instead, the nsswitch.conf file determines the sources to use in responding to NSS queries such as getpwnam. In general, you should not modify this file because modifying the file can compromise security and complicate auditing activity. In addition, you should not specify ldap as a source in any nsswitch.conf file where you have installed the Server Suite Agent. Specifying ldap in the nsswitch.conf file can cause the system to crash.

How the Server Suite Agent Manages Kerberos Files

Kerberos is a network authentication protocol for client/server applications that uses encrypted tickets passed through a central Key Distribution Center to verify the identity of a user or service requesting access. Because Kerberos is an industry standard and a secure network authentication mechanism, you may already have UNIX programs and services that are configured to use it. To allow those existing Kerberized applications to work with Active Directory without manual configuration, the adclient process automatically creates and maintains the Kerberos configuration file, krb5.conf, and the krb5.keytab service ticket file to point Kerberos-enabled services and applications to the Key Distribution Center (KDC) in Active Directory when you join a domain.

The configuration file is initially created using information collected by probing DNS and Active Directory with the default domain set to the domain that the computer has joined. Whenever a logon or ticket validation is performed with a domain that is not in the configuration file, the configuration file is updated so that it includes the new domain. Although the adclient process can automatically update the file as needed, it does not destroy existing configuration entries that you may have added by hand. Because of this, Server Suite Agents work seamlessly with existing Kerberos-enabled applications.

> **Note**: The Authentication Service supports users defined in a Kerberos realm as long as the Kerberos domains or realms are resolvable by DNS.

Kerberos realm names are case sensitive, so be careful to check that the realm spelling and capitalization is correct. (Ref: CS-21846a)

What Happens During the Typical Log-on Process

The core Server Suite Agent for *NIX components work together to identify and authenticate the user any time a user logs on to a computer using any UNIX command that requires the user to enter credentials. The following steps summarize the interaction to help you understand the process for a typical log on request. The process is similar, though not identical, for UNIX commands that need to get information about the current user or group.

> **Note**: The following steps focus on the operation of the agent rather than the interaction between the agent and Active Directory. In addition, these steps are intended to provide a general understanding of the operations performed through the agent and do not provide a detailed analysis of a typical log on session.

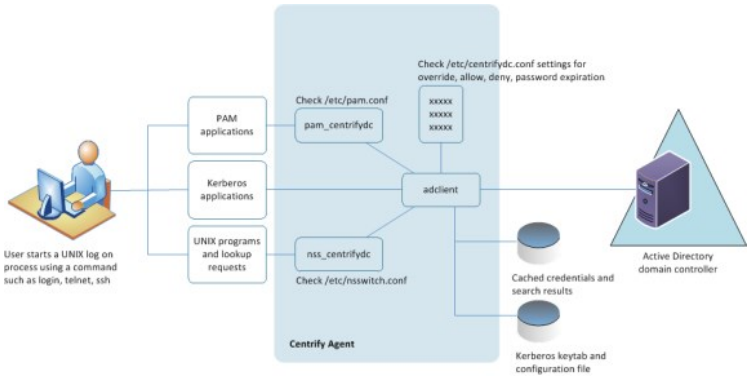
When a user starts the UNIX computer, the following takes place:

1. A login process starts and prompts the user to supply a user name.
2. The user responds by entering a valid local or Active Directory user name.
3. The login process, which is a PAM-enabled program, then reads the PAM configuration file, /etc/pam.conf, and determines that it should use the Server Suite PAM service, pam_centrifydc, for identification.
4. The login process passes the login request and the user name to the Server Suite PAM service for processing.
5. The pam_centrifydc service checks the pam.allow.override parameter in the agent configuration file to see if the user name entered is an account that should be authenticated locally.
    - If the user should be authenticated locally, the pam_centrifydc service passes the login request to the next PAM module specified in the PAM configuration file, for example, to the local configuration file /etc/passwd.
    - If the user is not listed as an override account, the pam_centrifydc service continues with the login request and checks to see if the adclient process is running, then passes the login request and user name to adclient.
6. The adclient process connects to Active Directory and queries the Active Directory domain controller to determine whether the user name included in the request is a user who has access to computers in the current computer's zone.
    - If the adclient process is unable to connect to Active Directory, it queries the local cache to determine whether the user name has been successfully authenticated before.
    - If the user account does not have access to computers in the current zone or can't be found in Active Directory or the local cache, the adclient process checks the Server Suite Agent configuration file to see if the user name is mapped to a different Active Directory user account with the adclient.mapuser.username parameter.
    - If the user name is mapped to another Active Directory account in the configuration file, the adclient process queries the Active Directory domain controller or local cache to determine whether the mapped user name has access to computers in the current computer's zone.
7. If the user has a UNIX profile for the current zone, the adclient process receives the zone-specific information for the user, such as the user's UID, the user's local UNIX name, the user's global Active Directory user name, the groups of which the user is a member, the user's home directory, and the user's default shell.
8. The adclient process checks for NSS override settings (nss.group.override and nss.user.override) to determine whether there are any changes to the user profile or additional restrictions that should override the profile retrieved or prevent the user from logging on.
9. The adclient process queries through the nss_centrifydc service to determine whether there's another user currently logged in with same UID.
    - If there is a potential conflict between local user account and the UNIX profile for an Active Directory account, the adclient process notifies the pam_centrifydc service of the potential conflict.
    - The pam_centrifydc service checks the Server Suite Agent configuration file to determine to issue a warning, ignore the conflict, or prevent the user from logging on.
    - If the login continues, the pam_centrifydc service asks the login process for a password.
10. The login process prompts the user to provide a password and returns the password entered to the pam_centrifydc service.
11. The pam_centrifydc service checks the pam.allow.users and pam.deny.users parameters in the agent configuration file to see if any user filtering has been specified to allow or deny access to specific user accounts. If any user filtering has been specified, the current user is either allowed to continue with the login process or denied access.
12. The pam_centrifydc service checks the pam.allow.groups and pam.deny.groups parameters in the agent configuration file to see if any group filtering has been specified to allow or deny access to members of specific groups. If any group filtering has been specified, the current user is either allowed to continue with the login process or denied access based on group membership.
13. If the current user account is not prevented from logging on by user or group filtering, the pam_centrifydc service queries the adclient process to see if the user is authorized to log on.
14. The adclient process queries the Active Directory domain controller through Kerberos to determine whether the user is authorized to log on to the current computer at the current time.
15. The adclient process receives the results of its authorization request from Active Directory and passes the reply to the pam_centrifydc service.
16. The pam_centrifydc service does one of the following depending on the content of the authorization reply:
    - If the user is not authorized to use the current computer or to log in at the current time, the pam_centrifydc service denies the user's request to

log on through the UNIX login process.

- If the user's password has expired, the pam_centrifydc service sends a request through the UNIX login process asking the user to change the password. After the user supplies the password, the login process completes successfully.
- If the user's password is about to expire, the pam_centrifydc service notifies the user of impending expiration through the login process.
- If the user is authorized to log on and has a current password, the login process completes successfully. If this is the first time the user has logged on to the computer through the agent, the pam_centrifydc service creates a new home directory on the computer in the location specified in the agent configuration file by the parameter pam.homeskel.dir.

The following figure provides a simplified view of a typical log-on process when using the Server Suite Agent for *NIX.



How Failover and Disconnected Access Work

The Server Suite Agent caches data from Active Directory so that users can log on and perform tasks even if the network or Active Directory server is unavailable, whether because of unexpected connectivity problems, scheduled maintenance, or offline operation of a portable computer. There are several configuration parameters that manage how the agent determines its connectivity to Active Directory, the domain controllers it should attempt to connect to, and the operation of the agent if it is unable to connect to any domain controller.

In most cases, you can set the values for the configuration parameters that control failover and disconnected operation by enabling Server Suite group policies for a site, domain, or organizational unit. Alternatively, you can set these parameters by editing the /etc/centrifydc/centrifydc.conf configuration file on individual computers.

For an overview of how the agent determines the connection status and locates a domain controller to use, see the following topics:

- Establishing a connection to DNS
- Connecting to the closest domain controller
- Restricting the domain controllers contacted
- Switching to disconnected mode
- Responding to DNS configuration changes
- Connecting to trusted forests and domains

Establishing a Connection to DNS

With each request to Active Directory, the Server Suite Agent first determines its connection status based on upon the availability of a Domain Name Service domain controller. If a DNS request for a host name takes longer than the number of seconds specified by the adclient.dns.response.maxtime parameter, the agent assumes DNS is down and switches to disconnected mode.

While running in the disconnected mode, the agent does not attempt any more synchronous network communications. Instead, it runs a background thread every 30 seconds to determine when DNS becomes available. The default value for the adclient.dns.response.maxtime is 10 seconds, but this value can be changed by group policy or by editing the /etc/centrifydc/centrifydc.conf file.

> **Note**: If the network is disconnected for a short period of time, but during that time no data is needed from Active Directory, the agent does not switch into disconnected mode. The status only changes if a connection attempt to DNS or to Active Directory through LDAP fails.

Connecting to the Closest Domain Controller

If the initial DNS request for a host name is successful, the Server Suite Agent attempts to connect to the appropriate domain controller and global catalog

for its joined domain using the **site information** found in DNS.

Site information is configured using Active Directory Sites and Services and is defined by subnet. Using the site information, the agent queries DNS for a list of the domain controllers in its site and attempts to connect to the nearest domain controller. It will continue trying to connect to each of the domain controllers in its site based on proximity until it finds a server available. If the agent is unable to connect to any of the domain controllers in its site or if no site information is available, the agent tries to connect to any remaining domain controllers listed in DNS.

Because connection status is determined by an attempt to bind to the Active Directory domain controller using an LDAP call, the adclient.ldap.socket.timeout parameter determines the maximum number of seconds the Server Suite Agent will wait for a socket connection timeout while binding to the LDAP server. The default value is 5 seconds.

Restricting the Domain Controllers Contacted

If you have a large Active Directory infrastructure or some unreliable subnets, you might want to restrict the domain controllers the agent should attempt to connect to if its primary domain controller becomes unavailable. You can limit the list of domain controllers the agent should attempt to connect to by setting the following property in the centrifydc.conf file:

dns.dc.domain_name: hostname [hostname] ...

where the domain_name is the Active Directory domain name and the hostname is a fully-qualified host name that can be resolved using DNS or the /etc/hosts file.

You can also limit the list of global catalog domain controllers the agent should attempt to connect to by setting the following property in the centrifydc.conf file:

dns.dc.forest_name: hostname [hostname] ...

where the forest_name is the forest root domain and the hostname is a fully-qualified host name that can be resolved using DNS or the /etc/hosts file.

Alternatively, you can use the adclient.server.try.max parameter or Maximum Server Connection Attempts group policy to limit the number of domain controllers the agent will attempt to connect to before switching to disconnected mode, eliminating the need to explicitly list the domain controllers using the dns.dc.domain_name and dns.gc.forest_name parameters. For example, to have the agent try a maximum of three domain controllers, you can set the following property in the centrifydc.conf file:

adclient.server.try.max: 3

Because global catalog and domain controller connections are handled independently, Server Suite Agent for *NIX can still provide authentication services if the global catalog domain controller is disconnected, as long as another domain controller is available.

Switching to Disconnected Mode

After a connection to a domain controller is established, each subsequent request for information from Active Directory checks the connection status. If a request is made to Active Directory and a response is not received within the number of seconds specified by the adclient.ldap.timeout parameter, that request is retried once. For the second request, the agent will wait up to twice as long for a response. If the second request is not answered within that amount of time, the connection to that specific domain controller is considered disconnected. Once a connection to a specific domain controller is in disconnected mode, a background thread will attempt to reconnect to that domain approximately every 30 seconds. By default, the agent waits 7 seconds for a response to the first request. If the request isn't answered, it retries the request and waits up to another 14 seconds for a response before switching to disconnected mode.

The adclient.ldap.timeout parameter specifies the maximum number of seconds to wait for Active Directory fetch, update, and delete requests to improve the response time when an initial connection attempt fails. A separate parameter, adclient.ldap.timeout.search, specifies the maximum time to wait for search requests. If the search timeout value is not specified, the default is double the adclient.ldap.timeout value. By default, therefore, the agent waits a maximum of 14 seconds for search requests.

The values for these parameters can be adjusted for high load or latency networks by configuring group policies or by editing the /etc/centrifydc/centrifydc.conf file.

Responding to DNS Configuration Changes

The DNS information collected when the agent starts and connects to a domain controller is not cached, and idle connections to Active Directory are dropped after 5 minutes by default. If you make changes in the DNS configuration, those changes are detected the next time the agent needs to reconnect, either

because an idle connection has been dropped, or the currently connected domain controller suddenly becoming unavailable.

Connecting to Trusted Forests and Domains

If the Server Suite Agent establishes a successful connection to the joined domain, it also generates or updates the /etc/krb5.conf file using the domain trust information from the global catalog, and attempts to connect to the trusted domains or to external forests to find all of the domains that are trusted.

Depending on the trust relationships you have defined, network topology, or firewall requirements, querying external trusted forests can have a significant, negative impact on network performance. You can control whether trusted domains and external forests are queried to establish transitive trusts and cross-forest authentication with the adclient.ldap.trust.enabled parameter. Setting the adclient.ldap.trust.enabled parameter to true indicates that you want the Server Suite Agent to query trusted domains and forests. Setting this parameter to false disables this feature so that the agent does not connect to any external forests or trusted domains.

If you set the adclient.ldap.trust.enabled parameter to true, you can control the maximum number of seconds to wait when searching for trust information in external forests and other trusted domains with the adclient.ldap.trust.timeout parameter. By default, the agent waits 10 seconds. The search operation is not retried if the request times out, but the request is regenerated approximately once an hour.

If your trusted domains and forests are widely distributed, have slow or unreliable network connections, or are protected by firewalls, you might want to increase the value for this parameter to allow time for the Server Suite Agent to collect information from external domains and forests.

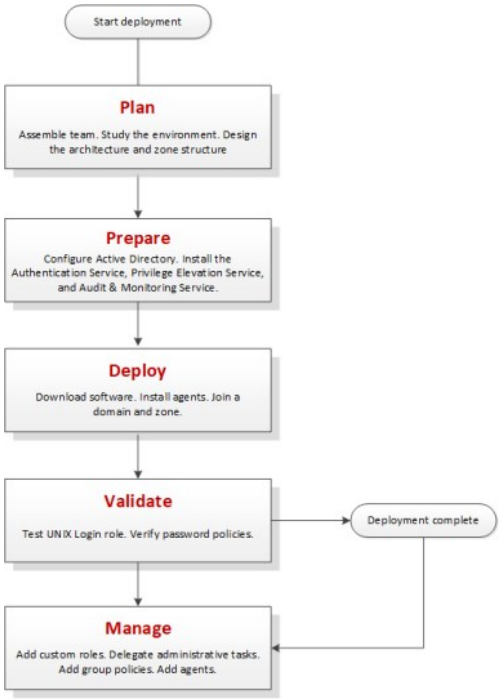
Deployment Process Overview

This chapter summarizes what's involved in deploying Centrify software. It includes simplified diagrams that highlight the steps involved and describes the tasks that are done only once, the tasks that are repeated to complete a deployment, and the tasks that may be part of the deployment project or ongoing administration after deployment.

The individual diagrams provide additional details about what's involved in each phase or the decisions you will need to make, such as who should be part of the deployment team, where to install the software, and who has permission to do what.

What's Involved in a Typical Deployment Project

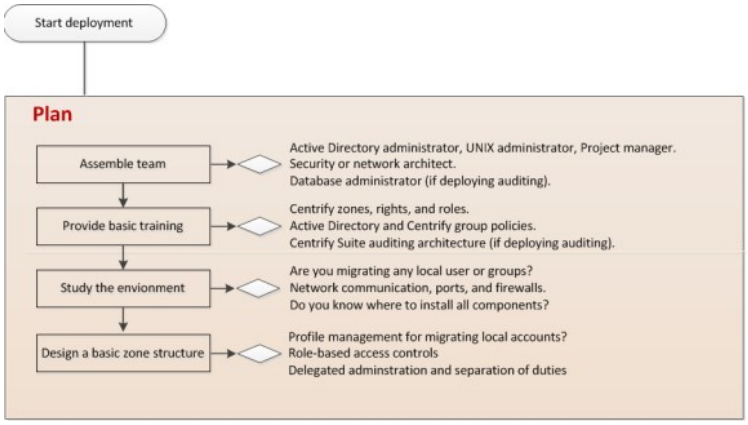
The following illustration provides a visual summary of the overall deployment process and highlights a few keys to a successful deployment.



The next sections provide additional details about each of these phases.

Plan

During the first phase of the deployment, you should collect and analyze details about your organization's requirements and goals. You can then make preliminary decisions about sizing, network communication, and what your zone structure should look like.



Here are the key steps involved:

- Assemble a deployment team with Active Directory and UNIX expertise.

  The team might also include specialists, such as database administrators, network architects, or application owners. For more information about assembling a deployment team, see Preparing a deployment team.

- Provide basic training so that members of the deployment team are familiar with Centrify concepts and terminology and know where to go for more information.

- Analyze the existing environment to determine your goals and requirements and identify target computers on which you plan to install Centrify components.

  This step is essential for designing the zone structure if you are migrating any local accounts or legacy profiles. It is also critical if you are deploying the auditing infrastructure. For more information about the questions to answer and factors that affect deployment, see Defining goals for the deployment.

- Design a basic zone structure that suits your organization.

  The zone structure depends primarily on how you want to use zones. For more information about deciding how to use zones, see Why use zones?.

- Identify a target set of computers for deployment and check that required ports are open.

Default Ports for Network Traffic and Communication

To help you plan for network traffic, the following ports are used in the initial set of network transactions when a user logs on and the agent connects to Active Directory:

- Directory Service - Global Catalog lookup request on port 3268.
- Authentication Services - LDAP sealed request on port 389.
- Kerberos – Ticket Granting Ticket (TGT) request on port 88.
- Network Time Protocol (NTP) Server – Time synchronized for Kerberos on port 123.
- Domain Name Service (DNS) – Host (A), Pointer (PTR), Service Location (SRV) records on port 53.

Depending on the specific components you deploy and operations performed, you might need to open additional ports. The following table summarizes the ports used for different editions of Centrify software.

389	Encrypted TCP/UDP communication	Centrify authentication service and privilege elevation service for Active Directory authentication and client LDAP service.
3268	Encrypted TCP communication	Centrify authentication service and privilege elevation service for Active Directory authentication and LDAP global catalog updates.

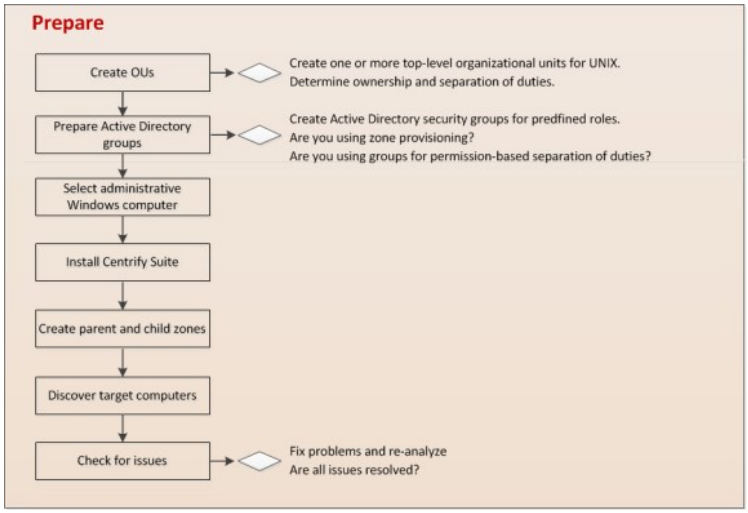
88	Encrypted UDP communication	Centrify authentication service and privilege elevation service for Kerberos ticket validation and authentication for agents and Centrify PuTTY.
464	Encrypted TCP/UDP communication for Kerberos password changes	Centrify authentication service and privilege elevation service for Kerberos ticket validation and authentication for agents, Centrify PuTTY, adpasswd, and passwd.
53	TCP/UDP communication	Centrify authentication service and privilege elevation service for clients using the Active Directory DNS server role for DNS lookup requests.
445	Encrypted TCP/UDP communication for delivery of group policies	Centrify authentication service and privilege elevation service for adclient and adgpupdate using Samba (SMB) and Windows file sharing to download and update group policies, if applicable.
123	UDP communication for simple network time protocol (NTP)	Centrify authentication service and privilege elevation service to keep time synchronized between clients and Active Directory for Kerberos ticketing.
22	Encrypted TCP communication for OpenSSH connections	Centrify authentication service and privilege elevation service to support secure shell connections on remote clients.
23	TCP communication for Telnet connections	Centrify authentication service and privilege elevation service to support telnet connections on remote clients if you cannot use secure shell (ssh). By default, telnet connections are not allowed because passwords are transferred over the network as plain text.
none	ICMP (ping) connections	Centrify authentication service and privilege elevation service to determine whether if a remote computer is reachable.
1433	Encrypted TCP communication for the collector connection to Microsoft SQL Server	Centrify authentication service, privilege elevation service, and audit and monitoring service to enable the collector service to send audited activity to the database.
5063	Encrypted TCP/RPC communication for the agent connection to collectors	Centrify authentication service, privilege elevation service, and audit and monitoring service to enable the auditing service to record user activity on an audited computer.
443	Cloud proxy server to Centrify cloud service	Centrify for mobile device management.

Network Connections and Database Management for Auditing

If you are planning a deployment with audit and monitoring service installed together with identity and privilege management, you must plan for reliable, high-speed network connections between components that collect and transfer audit data and how network traffic will be affected. You must also plan how you will create and manage the databases that store and retrieve audit data, your data archiving and retention policies, auditor permissions, and other details. For more information about planning and sizing for audit and monitoring service, see the *Auditing Administrator's Guide*.

Prepare

After you have analyzed the environment, you should prepare the Active Directory organizational units and groups to use. You can then install administrative consoles and prepare initial zones.



Here are the key steps involved:

- Create organizational units or containers to define a scope of authority.

  For example, if you want to organize all of the UNIX-related information together for your organization, you can create one top-level container for the enterprise, such as Centrify UNIX. If you want to define the scope of authority at a regional or business unit level, you might have separate top-level containers for the different regions or business units, for example, UNIX NA-SA, UNIX EMEA, UNIX PACIFIC or UNIX-Federal, UNIX-Consumer, UNIX-Industrial.

  The deployment project team should consult with the Active Directory enterprise administrator to determine the appropriate top-level containers or organizational units and who should be responsible for managing and delegating administrative tasks for the objects in those top-level containers. For more information about creating organizational units or containers in Active Directory, see Designing organizational units for Centrify.

- Create the appropriate Active Directory security groups for your organization.

  Groups can simplify permission management and the separation of duties security model. For more information about using groups, see Security groups to manage Centrify information.

- Select at least one administrative Windows computer and install Centrify components Access Manager.

  This step is not strictly required if you only use existing processes or scripts to perform administrative tasks, but Centrify recommends you have at least one computer where you can use the graphical user interface to perform common tasks. If you are deploying the audit and monitoring service infrastructure, you should also install Audit Manager and Audit Analyzer. For more information about installing Centrify software on Windows, see Installing Authentication & Privilege Services.

- Start the Centrify Access Manager console to run the Setup Wizard for the Active Directory domain.

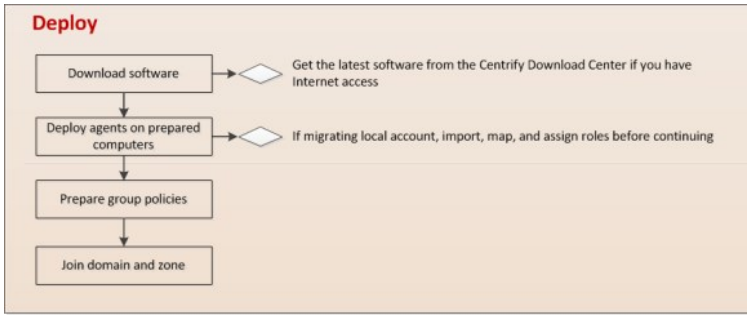
- Create a parent zone and the appropriate child zones as identified in your basic zone design.

  The hierarchical zone structure you use depends primarily on how you want to use inheritance and overrides. For more information about creating parent and child zones, see Creating the first zone.

- Determine the target set of computers and make sure that they have the appropriate connectivity.

Deploy

After you have prepared Active Directory, installed administrative consoles on at least one computer, and created at least one zone, you are ready to deploy on the computers to be managed.



Here are the key steps involved:

- Download agent software from the Centrify Download Center or a network location.
- Deploy the agent software on discovered computers that are ready for installation.
- Determine whether there are any local accounts to migrate.

  Right-click discovered computers, then click **Export Users and Groups** to generate a text file containing information about local accounts. Review the text file to determine whether there are any local accounts to migrate to Active Directory.

  If there are local accounts that must be able to log on to the discovered computer, import the groups, then users and assign them the default UNIX Login role. For more information about migrating local accounts, see Migrating existing users to hierarchical zones.
- Join the domain using the adjoin command.
- Prepare basic group policies.

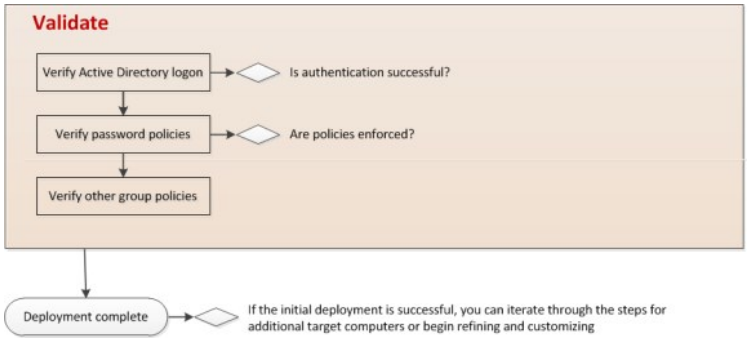
  The most common Windows computer configuration policies to deploy are:

  - Interactive Logon: Message text for users attempting to log on:—Enable and type a message that instructs the user to log on with an Active Directory user name and password.
  - Global Configuration Settings - MaxPollInterval:—Enable and set an interval if you are using Active Directory and the Centrify network time provider. Disable if you are using a native UNIX NTP daemon.
  - Enable Windows NTP Client—Enable if you are using Active Directory and the Centrify network time provider. Disable if you are using a native UNIX NTP daemon.

    The most common Centrify computer configuration policies to deploy are:
  - Set login password prompt—Enable and type a message that instructs the user to log on with an Active Directory user name and password.
  - Copy files—Enable to copy configuration files such as those required by autofs or sshd from the SYSVOL folder to managed computers.
  - Generate forwardable tickets—Disable to prevent logon tickets from being sent from one computer to another.

Validate

After you have deployed agents on target computers, you should test and verify operations before deploying on the additional computers.

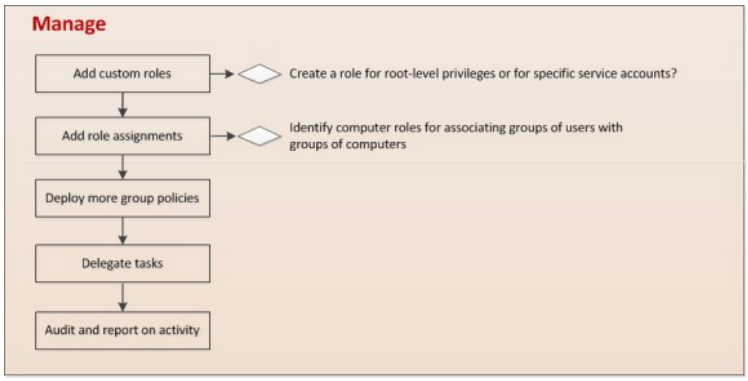


Here are the key steps involved:

- Log on to a target computer using an Active Directory user account and password to verify Active Directory authentication.
- Test password policy enforcement by attempting to change to a password that violates password complexity rules.
- Test account lockout and reset.

Manage

After you have verified the successful deployment on target computers, there are many ways you can refine, manage, and enhance on-going operations.



Here are a few of the key ways you can add value after deployment:

- Add custom roles and role assignments for users, groups, and computers.
- Import custom permissions from sudoers configuration files.
- Deploy group policies on the appropriate organizational units.
- Add the auditing infrastructure and add auditing to custom roles.
- Integrate Centrify software and Active Directory authentication and authorization services with database or web applications.

Deployment Tasks and Administrative Activity

For most deployments, there are tasks that you only perform once for an entire organization, tasks that are repeated until the deployment in complete, and tasks that are essential to deployment, but are also administrative tasks that you perform infrequently or periodically after deployment.

Steps You Only Take Once

In most organizations, you only perform the following tasks once in preparation for the deployment:

- Assemble a deployment team with Active Directory, UNIX, and other expertise.
- Provide basic training covering Centrify architecture, concepts, and terminology.
- Analyze the existing environment:
    - Find a target set of computers that share a common attribute, such as the same operating system or a similar user population.

  - Plan for permissions and the appropriate separation of duties for your organization.
  - Review network connections, ports, firewall configuration.
  - Identify computers for administration.

    Basic deployment—Access Manager

    Auditing—Audit Manager and Audit Analyzer consoles, collectors, audit databases and servers, and the installation management server

    Provisioning service—Zone Provisioning Agent and configuration tool

- Design a basic zone structure that suits your organization.
  - Single or multiple top-level parents.
  - Initial child zones, for example separate zones for Red Hat Linux and Mac OS X or different functional departments.
- Create organizational units or containers to define a scope of authority within Active Directory.
- Create Active Directory security groups for the UNIX Login role and the listed role.
- Create an Active Directory distribution group for provisioning groups and an Active Directory distribution group for provisioning users if using the provisioning service.
- Install Access Manager on at least one administrative Windows computer.
- Open Access Manager for the first time to run the Setup Wizard for the Active Directory domain.
- Create a parent zone and the appropriate child zones as identified in your basic zone design.

  Creating additional zones is an infrequent administrative task that is performed when the need arises. The basic zone design should be sufficient for the scope of your initial deployment.
- Prepare group policies to be applied.

Steps You Take More than Once During Deployment

During deployment, you perform the following tasks multiple times until you have rolled out the agent to all of the target computers that are in scope for the deployment:

- Download agent software from the Centrify Download Center or a network location.
- Deploy the agent software on computers that are ready for installation.
- If there are local accounts to migrate that must be able to log on to the discovered computer:
  - Import the groups, then users.
  - Map groups, then users to the appropriate Active Directory groups and users.
  - Assign migrated accounts the default UNIX Login role.
- Join the domain using the adjoin command.
- Verify Active Directory authentication and validate other operations.

After deployment, deploying new or updated agents is an ongoing administrative task that should be performed on a regular basis unless you have change control issues that either prevent software updates, do not allow Internet connections from the computer where Access Manager is installed, or do not want to deploy the agent on computers added to your network.

Steps You Take After Deployment to Begin Managing Zones Effectively

After you have migrated existing user populations, deployed the agent, and joined a domain, there are additional tasks you perform to complete the deployment and transition into effective zone administration.

The following tasks are optional but illustrate common administrative tasks that are often part of the deployment process to prepare for ongoing administration and improvements to operational security and efficiency:

- Create custom roles for accounts that have permission to run privileged commands.
- Create computer roles to link groups of computers with specific user role assignments.

- Map service accounts to Active Directory accounts.
- Deploy the basic set of group policies for computers and users.

What Happens After Deployment?

After deployment, ongoing management of UNIX computers, users, and groups is often handed off to Active Directory or Windows administrators or an internal service desk provisioning team to align with previously established processes and procedures for Windows servers and workstations. This is entirely a matter of organizational policy. However, in many cases UNIX administrators must continue to work with their Windows counterparts to ensure the appropriate rights and roles are assigned and the appropriate group policies are deployed.

Sample Workflow for Deployment Decisions

Centrify software solutions are extremely flexible so that they can be adapted to a wide variety of organizational requirements. All of this flexibility, however, can make deployment decisions difficult, especially in large scale or complex environments. To help you sort out the questions to ask, use the following work flow and responsibilities diagram as a guide.

This sample workflow diagram is only intended as a visual guide to the key design decisions you need to make. Many of these topics are covered in more detail in other chapters in this guide. For many organizations, however, the best guidance comes from an on-site Centrify Professional Services consultant or a Centrify partner with experience designing deployment solutions tailored to your organization's business requirements. For customized help and advice, contact your Centrify sales representative.

Planning Organizational Units and Security Groups

One of the important steps in planning a successful deployment of Server Suite is to consider how the software fits into your Active Directory infrastructure. This section describes the issues you should consider in the planning phase that affect how Active Directory and Centrify-specific objects are organized and suggests an organizational model you can use to successfully deploy Centrify within an existing Active Directory infrastructure.

If you are planning a deployment for managing and monitoring access to Windows computers, only Licenses and Zones parent containers is applicable and you can skip the other topics in this section. If you are planning a deployment that includes a mix of different platforms, however, you should review the recommendations for using organizational units (OUs) and groups.

If you plan to audit activity on any platform, Centrify recommends creating separate Active Directory security groups for auditors, administrators, and the computers that make up the audit and monitoring service infrastructure. Planning a deployment that includes the audit and monitoring service infrastructure requires additional resources and expertise. For more information about deploying auditing components, see the *Auditing Administrator's Guide*.

Identifying Stakeholders and Business Processes

Deploying Server Suite requires you to add objects to the Active Directory forest and, in most cases, update business processes for provisioning and removing users. It is important to identify who will be affected, which processes will be updated, how planned changes affect different parts of the business, and when you plan to deploy as early as possible in the planning stage.

It is also important to contact one or more Active Directory administrators to establish who will be creating the necessary objects in Active Directory and communicate the permissions required to create and manage those objects. If internal policies only allow Active Directory administrators to create organizational units (OUs) or security groups, you may need to negotiate when those activities take place and who will own the objects after they are created.

Identifying the appropriate people and processes early in the project helps eliminate unnecessary delays to the deployment and adoption of Centrify software. Communicating how the deployment affects the user and administrative communities helps ensure you can deploy rapidly and complete the project on-time.

> **Note**: The single biggest obstacle to storing UNIX data in Active Directory is overcoming internal process issues, such as change control restrictions, naming convention requirements, or proper authorization to perform administrative tasks. If you identify and resolve these challenges at the start of the project, deploying Centrify software across the enterprise becomes a fairly straightforward and painless task.

If you are a UNIX administrator, keep in mind that changes to Active Directory often require a formal change request and approval process, which can take time and delay the project. The earlier you begin planning the changes to Active Directory and the appropriate separation of duties for managing UNIX objects before, during, and after migration, the more successful the deployment will be.

Designing Organizational Units for Centrify

You can store Centrify-specific objects anywhere in the Active Directory structure if you choose. However, Centrify recommends that you create a single, high-level organizational unit (OU) specifically for Centrify objects at or near the top-level of an Active Directory forest root domain. Using one high-level organizational unit simplifies the management of Centrify containers and UNIX data.

Consolidating all UNIX data under a single organizational unit also enables you to establish an appropriate separation of duties without affecting any other previously-established OUs or permissions in Active Directory and reduces the need for additional process documentation or training. The disadvantage is that there may be strict authorization policies against setting up new organizational units.

Selecting a Location for the Top-Level OU

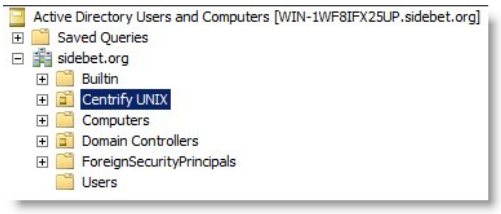
If you plan to follow the Centrify recommendation to create a top-level organizational unit for Centrify-related objects, such as Linux and UNIX computers, this high-level OU should be named so that it is easy to identify. For example, name the OU Centrify or Centrify UNIX. In deciding where this top-level OU should be placed, you should review your current Active Directory infrastructure.

There are several common scenarios:

- Single forest with a single domain
- Single forest with an empty root domain
- Single forest with account and resource domains
- Multiple forests with trust relationships
- Forests separated by a firewall (DMZ)

Single Forest with a Single Domain

If you have a single forest with a single Default-First-Site domain, you can create the top-level OU fat the same level as the default containers for Computers, Users, and other top-level objects. This is the simplest implementation of an Active Directory infrastructure. In this scenario, the top-level Centrify OU might look similar to this:



Single Forest with an Empty Root Domain

In this scenario, the forest root domain is used for the DNS namespace with one or more child domains that store information about computers, users, and groups. This is the most common Active Directory implementation. There are two important considerations if this is your Active Directory infrastructure:

- It is likely you will have a disjointed DNS namespace that you will need to resolve when you join computers to the domain.
- You might want to use multiple top-level Centrify OUs for the site. For example, assume the empty forest root domain, sidebet.org, contains three child domains:

  us.sidebet.org

  europe.sidebet.org

  asia.sidebet.org

  In this scenario, you might have a top-level Centrify OU in each child domain that includes UNIX computers to allow for more efficient data management and delegation of administrative tasks. However, if the child domains are centrally managed, you might want to create a single OU for Centrify in the forest root or one of the child domains. In general, you should base your decision on who will be responsible for managing the Centrify objects. If there are separate administrative groups for each child domain, create a top-level Centrify OU in each child domain.

Single Forest with Account and Resource Domains

In this scenario, the forest root domain has at least two child domains. One child domain stores computer principals and related information. This domain is the **resource** domain. Another child domain stores the user and group principals. This domain is the **account** domain. This scenario requires a trust relationship that allows the computers in the resource domain to trust the users and groups in the account domain. If this is your Active Directory infrastructure, you should store the Centrify data in the resource domain. For example, if the root domain, sidebet.org, contains the child domains accounts.sidebet.org and resources.sidebet.org, you would define the top-level Centrify OU in the resources.sidebet.org (OU=Acme,DC=resources,DC=sidebet,DC=org).

Multiple forests with Trust Relationships

In this scenario, you have more than one forest needing access to Centrify data. If you have multiple forests in your organizations, you should create the top-level OU for Centrify in the forests that have UNIX computers. The forests must also be configured with either a one-way or two-way trust relationship. Cross-forest authentication requires a forest functional level of Windows Server 2003 or later. Trust relationships that involve Windows NT 4.0 domains or Kerberos V5 realms are not supported.

Cross-forest Authentication for Two-way Trust Relationships

For forests that have a two-way trust relationship, users from either forest can be authenticated to log on to the other forest. For example, if you have configured a two-way trust relationship between the forest root domain sidebet.org and youbet.org, and there are both UNIX computers and UNIX users in both forests, you would create one top-level Centrify OU in each forest and users from either forest can be authenticated to the computers in either forest.

Cross-forest Authentication for One-way Trust Relationships

To allow for cross-forest authentication with a one-way trust, Centrify authenticates users in the trusted “accounts” forest to allow those users to log on to computers in the “resources” forest. Users in the trusting “resources” forest cannot log on to computers in the “accounts” forest.

For cross-forest authentication with a one-way trust, when you add the user from the "account" forest to the Centrify zone, the user's samAccountName attribute is stored in the zone object. Therefore, once the user is added to the zone, their samAccountName cannot change without causing authentication to fail.

Analyzing Trust Relationship to Prevent Authentication Failures

If your Active Directory environment does not permit one- or two-way trusts between forests, however, or uses a complex combination of one-way and two-way trust relationships between forests, users who attempt to log on from a remote forest may be denied access if the forest they are logging on to or the forest they are logging in from do not share a trust relationship.

As part of your deployment planning you should review your entire Active Directory infrastructure and determine whether you will be authenticating users from multiple forests and how trust relationships are defined for the forests users need access to. You may want to change the trust relationships you have defined.

For information about configuring trust relationships, see your Active Directory documentation.

Forests separated by a firewall (DMZ)

If you have a firewall between a forest outside of the firewall (the perimeter or DMZ forest) and a protected forest inside the firewall (the internal or corporate forest), the best security practice is to make the DMZ a separate forest with no trust relationship.

In this scenario, the top-level Centrify OU is created in the corporate forest protected by the firewall. This configuration ensures that the domain controllers in the perimeter forest cannot compromise the corporate domain controllers or get access to the corporate global catalog (GC), which stores information about all domains in the forest. Although defining no trust relationship between the perimeter forest and the corporate forest is considered the best practice for security reasons, this configuration prevents authentication through the firewall.

If you want to enable authentication for users in the corporate forest and allow them to access resources in the perimeter forest, Centrify recommends that you create a separate Active Directory forest for the computers to be placed in the network segment you are going to use as the demilitarized zone. You should then establish a one-way outgoing trust from the internal forest to the DMZ forest. For more information about deploying Centrify in a DMZ, see Planning to deploy in a demilitarized zone (DMZ).

Creating Recommended Organizational Units

In addition to the top-level Centrify OU, Centrify recommends you create several additional organizational units for managing UNIX groups, users, and computer accounts and rights and roles. These additional organizational units are intended to help you establish an appropriate separation of duties before, during, and after migration.

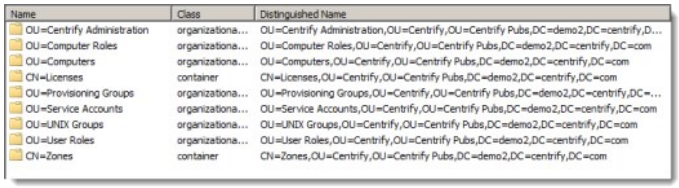
Centrify recommends the following organizational units as a starting point:

- Centrify Administration
- Computer Roles
- Computers
- Provisioning Groups
- Service Accounts
- UNIX Groups
- User Roles

Creating Organizational Units in Access Manager

If you want to create the recommended organizational unit structure for Centrify objects during your initial deployment, you can do so automatically using the Access Manager Setup Wizard. The first time you start Access Manager, it opens the Setup Wizard by default. From the Setup Wizard, you can create all of the containers for the recommended deployment structure automatically without any manual configuration. Alternatively, you can create a completely custom deployment structure by first creating a PowerShell script that creates the containers you want to use then running the custom script from within the Setup Wizard.

If you use the default script, the wizard adds the recommended organizational units and groups under the top-level **Centrify** OU and ensures all of the permissions are properly set on the objects within it. You can then select an existing organizational unit or create a new organizational unit for the components of the deployment structure. If you use the default deployment script without modification, it creates a structure like this:



Name	Class	Distinguished Name
OU=Centrify Administration	organizationa...	OU=Centrify Administration,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,D...
OU=Computer Roles	organizationa...	OU=Computer Roles,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=com
OU=Computers	organizationa...	OU=Computers,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=com
CN=Licenses	container	CN=Licenses,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=com
OU=Provisioning Groups	organizationa...	OU=Provisioning Groups,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=...
OU=Service Accounts	organizationa...	OU=Service Accounts,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=com
OU=UNIX Groups	organizationa...	OU=UNIX Groups,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=com
OU=User Roles	organizationa...	OU=User Roles,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=com
CN=Zones	container	CN=Zones,OU=Centrify,OU=Centrify Pubs,DC=demo2,DC=centrify,DC=com

If you want to customize the script, you can use the wizard to export it. After exporting the script, you can modify it in a text editor, then restart the wizard to use the modified script. The Setup Wizard will also create the parent container for Licenses and the parent container for Zones in the Active Directory location you select.

As you roll-out the deployment, you might find additional OUs are useful. For example, you might create additional OUs because specific permissions must be granted to create, modify, delete, and manage the objects within them. By creating this organizational structure, you can control who has permission to manage the Centrify objects contained in each OU.

By using the recommended deployment structure and associated permissions, you will have a solid foundation for deploying Centrify software across the enterprise without affecting any of your existing Active Directory structure. The recommended deployment structure will also enable you to easily apply group policies and manage user, group, and computer accounts.

For more information about the purpose of the additional organizational units, see the appropriate section.

Centrify Administration Organizational Unit

The Centrify Administration OU is intended to store Active Directory security groups that ensure the separation of duties and the segregation of Centrify-related administrative operations in Active Directory.

In most cases, you will want to allow your existing Active Directory account fulfillment or provisioning team to edit UNIX groups and, potentially, the user role groups that allow for elevated permissions in UNIX. If users you have identified as Centrify Administrators are stored in the same organizational unit as the rest of the UNIX groups, then members of the fulfillment or provisioning team could grant themselves permissions to create, modify, and delete zones. With these permissions, a disgruntled provisioning staff member could delete one or more zones and prevent access to production computers. To prevent this security risk, Centrify recommends you create a separate Centrify Administration organizational unit and protect access to it.

Computer Roles Organizational Unit

The Computer Roles OU is intended to store the computer group accounts that are associated with a specific computer role. For example, if you plan to have a computer role for computers that host Oracle databases and the set of users assigned the database administrator role, you might create an Active Directory security group called Oracle_Production_Computers in this OU for the computers that host Oracle databases. If you were to add a new Oracle database instance, you would add the computer account for that database server to the Oracle_Production_Computers in this OU.

In most cases, the computer groups in this organizational unit are associated with the user role groups you add to the User Roles OU. For example, if you have a computer role for computers that host Oracle databases, you might have user role groups for database administrators and another user role group for database users. If you were to change who should be allowed to use the database or perform database administration activities, you would modify the membership of these two user role groups.

Computers Organizational Unit

The Servers OU is intended to store new computer principals in Active Directory. This organizational unit enables you to efficiently deliver computer-based group policies from Active Directory. For example, you can use a group policy to turn off SNTP updates from Active Directory for Centrify-managed computers to prevent those computers from having two registered time sources. Having a separate OU also enables you control who has the permissions and authority to create, update, and delete computer objects in the domain.

Provisioning Groups Organizational Unit

The Provisioning Groups OU is intended to store Active Directory distribution groups that are used by the Zone Provisioning Agent. The Zone Provisioning Agent is a Windows service that processes the business rules for creating or deleting UNIX profiles in zones. For example, if a new Active Directory user principal is in one of these group principals, and the group is associated with a zone, the user is automatically provisioned with a UID and a GID in that zone.

> **Note**: The profile does not allow the user to log on to computers in the zone. Identity management is separate from access management. The user's role assignments control access.

During the migration process, users you have identified as Centrify Administrators should have the appropriate permissions and authority to create, delete, and manage the membership of these Active Directory distribution groups. After migration, the team that owns the process for the provisioning UNIX accounts will need the same permissions and authority. For details about the permissions required to perform these tasks, see Setting permissions for zone groups.

Service Accounts Organizational Unit

The Service Accounts OU is intended to store the Windows service account for the Zone Provisioning Agent and any UNIX-specific service accounts that do not correlate to existing Active Directory user accounts. For example, you can use this OU for application service accounts, such as Oracle or MySQL, to enable centralized password management and auditing. By migrating service accounts from UNIX, you can centrally manage the account information, passwords, and privileges for those service accounts and their associated UNIX groups.

Unix Groups Organizational Unit

In this deployment model, the UNIX Groups OU is intended to store Active Directory security groups that are migrated from /etc/group files or NIS group maps that you want to preserve.

As part of the initial migration, you should identify one or more users as **Centrify Administrators** who should be granted the appropriate permissions and the authority to create new Active Directory group principals, and to add Active Directory user principals to the new groups.

After the migration is complete, another team might be responsible for managing the UNIX groups migrated into Active Directory. The team that owns the process for adding UNIX users to a UNIX group, removing UNIX users from a UNIX group, or creating new UNIX groups will need the permissions and the authority in Active Directory to create and delete group principals and manage the membership of those group principals in this OU (for example, ou=unix groups,ou=Centrify). For details about the permissions required to perform these tasks, see Setting permissions for zone groups.

User Roles Organizational Unit

The User Roles OU is intended to store Active Directory security groups that are associated with user role definitions that grant privileges or restrict access. For example, a user role definition might grant permission to execute commands as root or using a service account such as oracle. By associating an Active Directory group with a role definition, you can grant or deny privileges by managing Active Directory group membership.

During the migration process, users you have identified as Centrify Administrators should have the permissions and the authority to add users to the appropriate user role groups and to create new Active Directory group objects in the OU (for example, ou=user roles,ou=Centrify). After migration, your organization should decide who should be responsible for creating new user role groups and associating them with zones and who should be able to add and remove users from the User Roles organizational unit.

Licenses And Zones Parent Containers

Regardless of whether you choose to create the organizational units for the recommended deployment structure or a custom deployment structure, Centrify requires the following parent containers:

- Licenses parent container object for license keys. You must have at least one parent container for license keys in the forest. You can create more than one of these container objects to give you more granular control over who has access to which licenses.
- Zones parent container object for individual zone (ZoneName) objects. You must have at least one parent container for zones. You can create more than one parent Zones container to give you more granularity for delegating administrative tasks.

You can select the parent containers for Licenses and Zones when you run the Setup Wizard, when creating a new zone, or when managing licenses in Access Manager.

Some organizations prefer to create and manage Active Directory objects manually to ensure tight control over the objects and their attributes. For example, you might want to manually create separate parent containers for different business departments or locations if you want to manually set permissions and refine who has access to them. However, managing permissions manually can be complex and error-prone. In most cases, Centrify recommends that you establish appropriate permissions on the deployment structure and use the Zone Delegation Wizard to manage administrative permissions on individual zones and the objects contained in zones.

Security Groups To Manage Centrify Information

If you use the default recommended deployment script, the script automatically creates the following Active Directory security groups for managing Centrify-related objects:

- CentrifyAdministrators
- AuthorizationManagers
- ComputerManagers
- UnixDataManagers

Each security groups is granted the appropriate permissions to perform specific administrative tasks. For example, users who are members of the Centrify Administrators group should be able to create, modify, and delete zones.

If you are not using the recommended deployment script, you should create similar security groups for managing Centrify-related objects.

Delegating Control For Centrify Administrators

The CentrifyAdministrators security group is intended for members of the administrative or security team who are responsible for managing all Centrify-related information stored in Active Directory. You should add members to the group to grant specific users the rights required to manage Centrify licenses, zones, user roles, computer roles, provisioning groups, and the user, group, and computer profiles in each zone.

Members of the Centrify Administrators security group are responsible for identifying an organization's zone requirements and creating the zone hierarchy. Centrify Administrators also decide when to create new zones, delete obsolete zones, or consolidate existing zones. In most cases, Centrify Administrators define the basic access rights for zones and delegate administrative tasks to other users and groups on a zone-by-zone basis.

Permissions for the Centrify Administrators group are applied at the top-level of the deployment structure—for example, ou=Centrify—and grant privileges on the organizational units, containers, and object within the deployment structure. If you don't create this group or a similar security group, only members of the Domain Admins group can create new zones.

If you are managing security and individual permissions manually for Active Directory objects, see Permissions required for administrative tasks for information about the permissions required for individual tasks.

Delegating Control For Authorization Managers

The AuthorizationManagers security group is intended for members of the security team who are responsible for managing role-based access rights. You should add members to the group to grant specific users the rights required to manage user roles, computer roles, access privileges, and role assignments.

You can delegate tasks to the AuthorizationManagers group on the User Roles and Computer Roles organizational units using Active Directory Users and Computers. You can delegate zone administration tasks to the group in Access Manager.

Delegating Tasks For User Role Groups

In Active Directory Users and Computers, select the User Roles organizational unit, right-click, then select Delegate Control to start the Delegation of Control Wizard. Select the security group you are using for authorization managers and delegate the following tasks:

- Create, delete and manage groups
- Modify the membership of a group

Delegating Tasks For Computer Role Groups

In Active Directory Users and Computers, select the User Roles organizational unit, right-click, then select Delegate Control to start the Delegation of Control Wizard. Select the security group you are using for authorization managers and delegate the following tasks:

- Create, delete and manage groups
- Modify the membership of a group

Delegating Zone-specific Tasks

As a member of the CentrifyAdministrators security group, you can grant zone-specific permissions to the members of the AuthorizationManagers group. After you have created the appropriate zones, you can delegate the following zone administration tasks to authorization managers:

- Manage roles and rights
- Manage role assignments
- Modify computer roles
- Add computer roles

Delegating Control For Computer Managers

The ComputerManagers security group is intended for members of the UNIX administration team who are responsible for managing computer accounts. You should add members to this security group to grant specific users the rights required to manage computer objects in the Servers organizational unit in Active Directory.

As a member of the CentrifyAdministrators security group, you can also grant zone-specific permissions to the members of the ComputerManagers group. After you have created the appropriate zones, you can delegate the following zone administration tasks to computer managers:

- Join computers to the zone
- Remove computers from the zone

If you are managing security and individual permissions manually for Active Directory objects, see Permissions required for administrative tasks for information about the permissions required for individual tasks.

Delegating Control For Unix Data Managers

The UnixDataManagers security group is intended for members of the UNIX administration team who are responsible for managing computer accounts. You should add members to this security group to grant specific users the rights required to manage UNIX users and groups objects in the UNIX groups and Service Accounts organizational units in Active Directory.

You can delegate tasks to the UnixDataManagers group on the UNIX Groups and Service Accounts organizational units using Active Directory Users and Computers. You can delegate zone administration tasks to the group in Access Manager.

Delegating Tasks For Unix Groups

In Active Directory Users and Computers, select the UNIX Groups organizational unit, right-click, then select Delegate Control to start the Delegation of Control Wizard. Select the security group you are using for UNIX data managers and delegate the following tasks:

- Create, delete, and manage groups
- Modify the membership of a group

Delegating Tasks For Service Accounts

In Active Directory Users and Computers, select the Service Accounts organizational unit, right-click, then select Delegate Control to start the Delegation of Control Wizard. Select the security group you are using for UNIX data managers and delegate the following tasks:

- Create, delete, and manage user accounts
- Reset user passwords and force password change at next logon

Delegating Zone-Specific Tasks

As a member of the CentrifyAdministrators security group, you can also grant zone-specific permissions to the members of the UnixDataManagers group. After you have created the appropriate zones, you can delegate the following zone administration tasks to UNIX data managers:

- Add users
- Add groups
- Remove users
- Remove groups
- Modify user profiles
- Modify group profiles

Planning for Data Storage in Active Directory

Centrify stores all of the UNIX attributes required for users, groups, and computers in Active Directory, so that this information can be centrally managed. It stores these attributes without requiring you to make any modifications to the Active Directory schema you choose to use.

Changing The Zone Type

If you create a new zone using the default zone options, the new zone is created as a hierarchical zone that uses the Active Directory RFC2307-compatible schema attributes for user and group profiles. If you deselect the Use the default zone type option, you can choose to create either a hierarchical zone or a

classic zone and how you want zone information stored in the Active Directory schema.

If you are not using the default zone type and storage model, you have the following options:

- A **Standard zone** stores user and group attributes in the keywords attribute of the serviceConnectionPoint object for the user or group rather than in the user or group object.
- An **RFC2307-compatible zone** stores user and group attributes in the attributes that are defined in the RFC2307-compatible schema for user and group objects.
- An **SFU zone** stores user and group attributes in the Services for UNIX (SFU) schema attributes for the user or group object.

It is worth noting that in the default zone storage model—which uses the default Active Directory RFC2307-compatible schema—some schema attributes are not indexed. For example, in the default Active Directory RFC2307-compatible schema, the uid attribute is not an indexed attribute. Because of this limitation, queries that use this attribute might take longer than expected.

Modifying Indexed Attributes For Zones

Depending on the requirements of your organization, you might see improved performance either by creating standard Centrify zones rather than RFC2307-compatible zones or by indexing the uid attribute in default zones. Before selecting a strategy for all or selected zones, however, you should consider that indexing the uid attribute requires you to modify the Active Directory schema.

Modifying the Active Directory schema is an advanced operation that should only be performed by experienced administrators. In addition, you must be a member of the Domain Admins group or the Enterprise Admins group in Active Directory or been delegated similar authority to perform this operation. If you choose to modify the schema to improve performance, you can use "Run as ..." to select an account with appropriate permissions before performing the following steps.

To index an attribute:

1. Open a Command Prompt window, then type the following command to register the schema management assembly on your computer:

   regsvr32 schmmgmt.dll

2. Click Start, click Run, type mmc /a, then click **OK**.
3. In the console root, select the File menu, then click **Add/Remove Snap-in**.
4. Under Available Standalone Snap-ins, double-click Active Directory Schema, click **Add**, then click **OK**.
5. On the File menu, click **Save**, navigate to the %systemroot%/Sytem32 directory, type a file name for the console, then click **Save**.
6. Click **Start > All Programs** to select the Administrative Tools folder, right-click, then select **Open**.
   - If necessary, select **Organize > Layout > Menu bar** to display menus.
   - On the File menu, select **New**, then click **Shortcut**.
   - In the Create Shortcut Wizard, click in **Type the location of the item**, type the name you used for the file in Step 5, then click **Next**.
   - Select the file name in Type a name for this shortcut field, type **Active Directory Schema**, then click **Finish**.
7. Click **Start > All Programs > Administrative Tools** to select Active Directory Schema, right-click, then select **Open**.
8. Expand Attributes to select a specific attribute, such as uid, right-click, then select **Properties**.
9. Select **Index this attribute**, then click **OK**.

Viewing and Manipulating Data in Active Directory

You can view, access, and manage any information stored in Active Directory—including Centrify profiles, rights, roles, and role assignments—using ADSI Edit or using any tools that can perform standard LDAP operations such as ldifde and OpenLDAP commands such ldapsearch, ldapadd, ldapdelete and ldapmodify. For example, depending on the type of operating system and tools you prefer to use, you might view and manage Centrify profiles and zones using any combination of the following tools:

- Access Manager
- Access Module for Windows PowerShell
- Audit Module for Windows PowerShell
- Active Directory Users and Computers

- The Server Suite Windows API
- The ADEdit Tcl application and procedure library
- Centrify command-line programs

By using these tools, you can manipulate Centrify information manually or create scripts to automate key tasks such as the provisioning of new accounts. For example, you can write scripts that access the Centrify Windows API or ADEdit procedures to automatically create computer, user, or group accounts, create new zones, or assign users to roles. As part of your planning process, you should determine whether there are tasks you want to automate through the use of scripts, so that members of the development team can create or modify the appropriate tools and test them thoroughly before deploying across the organization.

Installing Authentication & Privilege Services

This section provides instructions for installing all identity and privilege management components on Windows computers in your network. There are several Windows-based components that enable you to manage the deployment and ongoing operations of Server Suite software. You should install all of the identity and privilege management components on at least one Windows computer. Depending on the division of responsibilities in your organization, you may want to install different components on more than one Windows computer.

When you install identity and privilege management components, the following features are installed:

- The Privileged Access Service, which enables MFA login, MDM, and other platform services.
- The Privilege Elevation Service and Authentication Service, which together enable computers where Server Suite software is installed to use the Active Directory infrastructure located on the domain controller, and enable users and zone-joined computers to have elevated privileges. The services include ADUC extensions, GPOE extensions, PowerShell extensions, Server Suite utilities, and Access Manager.

Access Manager is the administrative console that enables you to create zones and configure rights and roles for Active Directory users running applications on Windows computers.

You should always install the Windows components first before you install the Server Suite Agent on the non-Windows computers you intend to manage.

Preparing for Installation on Windows

Before installing Server Suite management components on Windows, you should verify that the computers where you are planning to install meet all of the system requirements and prerequisites and that you have all of the information you need to install and configure the software packages.

At a minimum, you should install the following Server Suite components on one or more Windows computers during the first stage of deployment:

- Access Manager console
- Zone Provisioning Agent

You can install these components together or independently using the setup program. Alternatively, you can install these components independently without running the setup program by using individual setup programs for each component.

Installing Server Suite

Access Manager, which is installed when you install Server Suite, is the primary management console for performing access control and privilege management operations. You typically install Access Manager directly on the computers used by one or more administrators. Alternatively, you can install it on a physical or virtual server accessed remotely by one or more administrators. The most important requirement is that the computer where you install Access Manager must be able to connect to the Active Directory domain and forest.

The Access Manager console can be installed from the setup program or from a standalone executable separate from the setup program. Before you install, you should verify your environment meets the system requirements to ensure a successful deployment.

Preparing Active Directory and DNS

All of the Server Suite software components rely on critical pieces of Active Directory infrastructure. Before you install:

- Verify Active Directory is installed and you have access to at least one Windows computer acting as a domain controller for the Active Directory forest to which you want to add UNIX computers.
- Check the configuration of DNS and whether you are using a Windows computer as the primary DNS server.
- Verify the DNS server allows secure dynamic updates and your domain controllers are configured to publish updated service locator (SRV) records.
- Verify DNS resolution and network communication between the UNIX computers and the Active Directory domain controller. You can use the ping command to test communication between the domain controller and the UNIX computer.

Identifying the Windows Computer and Log On Credentials

Depending on how you plan to manage Server Suite properties, you should identify an appropriate Windows computer and the user account credentials you should use. For example:

- Check whether the Windows computer has Active Directory Users and Computers installed.

  If you want to manage Server Suite properties using Active Directory Users and Computers, the Active Directory Users and Computers MMC snap-in

must be available on the local computer.

- Check whether the Windows computer is a domain computer, such as a Windows XP workstation, or a domain controller.

  If you install on a domain controller, you must use your own logon credential to connect to Active Directory. In most cases, you can install on any computer that has access to a domain controller.

- Verify that the Windows computer can connect to Active Directory.

- Verify that you have a Windows user account and password with sufficient rights to install software on the local computer and permission to update the Active Directory forest.

  After installation, you must be able to create new container objects in the Active Directory forest. Alternatively, an Active Directory administrator can manually configure the environment or temporarily modify your account permissions to enable you to perform setup tasks. For information about the specific rights required to perform tasks in the Setup Wizard, see Permissions required to use the Setup Wizard.

Checking Operating System and Software Requirements

Before installing on Windows, check that you have a supported version of one of the Windows operating system product families. For example, you can use Windows 7 for any console components. Alternatively, you can install components on computers in the Windows Server product family—such as Windows Server 2008 or Windows Server 2012—so that your administrative computer can be configured with additional server roles.

For more detailed information about supported platforms for specific components, see the release notes.

You should also verify that you have the .NET Framework, version 4.5 or later, installed. If the .NET Framework is not installed, the setup program can install it for you. Alternatively, you can download the .NET Framework from the Microsoft Download Center, if needed.

Checking Disk and Memory Requirements

You should also check that the computer where you are installing the Access Manager console meets the following requirements:

CPU speed	Minimum 550 MHZ
RAM	25MB
Disk space	100MB

Running the Setup Program on a Windows Computer

You can install Server Suite software using the setup program on the CD or included in the download package. The setup program copies the necessary files to the local Windows computer. There are no special permissions required to run the setup program other than permission to install files on the local computer. From the setup program, you can choose which components of you want to install.

> **Note**: If you intend to install the Zone Provisioning Agent using the setup program, you should review the requirements and other information in Installing Zone Provisioning Agent before you proceed, but you can skip the standalone installation instructions in those sections. Use the individual setup programs for components if you want to install a specific component on a specific computer. For example, use the Centrify_Zpa*version*win64.exe program to selectively install Zone Provisioning Agent components on a computer where Access Manager is not installed.

To install Authentication & Privilege on Windows:

1. Log on to the Windows computer and insert the CD or navigate to the directory where you downloaded Server Suite files.

   If the Getting Started page is not automatically displayed, double-click the autorun.exe program to start the installation of the Server Suite software.

2. On the Getting Started page, click **Authentication & Privilege** to start the setup program for identity and privilege management components.

   If any programs must be updated before installing, the setup program displays the updates required and allows you to install them. For example, you might be prompted to install or update the Microsoft .NET Framework or Microsoft SQL Server Compact edition.

3. At the Welcome page, click **Next**.
4. Review the terms of the license agreement, click **I agree to these terms**, then click **Next**.
5. Type your name and organization, then click **Next**.
6. Expand and select the Delinea Administration and Delinea Utilities components you want to install, then click **Next**.

   If you are managing access to Linux, UNIX, and Mac OS X computers, you should select the following Server Suite Administration components for deployment:

   - **ADUC property page extensions** if you want to include Server Suite profiles when displaying properties in Active Directory Users and Computers.
   - **Access Manager** if you want to use an administrative console to manage Server Suite zones and roles.
   - **Group Policy Management Editor extension** if you want to deploy Server Suite group policies.

     You should also select the following Server Suite Utilities components for deployment:

   - **Zone Provisioning Agent** if you want to automatically provision user and group profiles into zones.

     If you want to skip the installation of any component on the local computer, click to deselect the item that you want to skip, then click **Next**. For example, if you want to skip installation of the Server Suite Reporting Service and its Microsoft SQL Server database, deselect the Server Suite Reporting Service option, then click **Next**.
7. Accept the default location for installing components, or click **Browse** to select a different location, then click **Next**.
8. Review the components you have selected, then click **Next**.

   The setup program begins installing the selected components.
9. When setup is complete for the selected packages, click **Finish** to close the setup program.

   Depending on the components you selected, you might see options to configure reporting service, the Zone Provisioning Agent, or both. You can deselect these options if you want to skip configuration or plan to install the components in a different computer. For details about configuring the Server Suite reporting service, see the *Report Administrator's Guide*. For details about configuring the Zone Provisioning Agent after installing it with the Server Suite setup program, see Configuring the Zone Provisioning Agent.

Installing Zone Provisioning Agent

The Zone Provisioning Agent enables automated provisioning of user and group accounts into Server Suite zones. You configure the Zone Provisioning Agent to monitor specific Active Directory groups that are linked to a zone. When you add or remove users or groups from the monitored groups, the Zone Provisioning Agent adds or removes corresponding users or groups in the zone.

You can install the Zone Provisioning Agent with the Server Suite setup program or as a standalone service separate from the installation of other Server Suite components. In most cases, it is installed on its own apart from the installation of other Server Suite components. After the Zone Provisioning Agent is installed, you can configure the business rules for adding and removing groups and how the attributes associated with user or group profiles are automatically generated.

About Zone Provisioning Agent and its Requirements

The Zone Provisioning Agent is intended to run on an ongoing basis on a computer that is always available. It requires a Windows user account with the right to Log on as a service. If you have a single forest, you can install the Zone Provisioning Agent on one or two computers. If you install the Zone Provisioning Agent on two computers, you should only run one instance at a time. The Zone Provisioning Agent on the second computer is intended for standby operation. You should only start the Zone Provisioning Agent on the second computer if the first instance fails.

> **Note**: The business rules that control provisioning are stored in Active Directory. If only one computer has the Zone Provisioning Agent and that computer stops running, the automated provisioning of UNIX users and group is interrupted until the computer and the Zone Provisioning Agent are restarted. Users with existing access to UNIX computers are not affected.

The Zone Provisioning Agent has the following components:

- **Zone Property Page Extension** must be installed on the same computer as the Access Manager console. This extension adds a tab to the Zone Properties for configuring provisioning rules.
- **Provisioning Agent** can be installed separately from the property page as a standalone service or on the same computer as Access Manager. The computer where you install the service should be available at all times. In most cases, this Windows service is not installed on the same computer as Access Manager.
- **Command Line Utility** can be installed separately or on the same computer as Access Manager. The command line utility allows you to write scripts for provisioning tasks or update zones on demand.

If you have more than one forest, you should install a Zone Provisioning Agent in each forest. If you have geographical domains within a single forest, you may want to install a Zone Provisioning Agent in each geographical domain. If you install a second instance of the Provisioning Agent for failover, be sure that only one instance of the Provisioning Agent runs in each forest.

Zone Provisioning Agent account permissions

Cfy_SVC_ZPA	Active Directory account	**Log on as a service**	The Zone Provisioning Agent requires permission to create UNIX profiles-- that is, the service connection points in each zone where it needs to perform provisioning operations. The service account that runs the Zone Provisioning Agent requires the **Log on as a service** right set as a local computer security policy, or in the default domain policy.

Create a service account for the Zone Provisioning Agent

The Zone Provisioning Agent must run using a valid Windows user account with the right to Log on as a service. In most cases, you should create a dedicated user account, called the **service account**, for the service to run as rather than use an existing user account.

To create a new service account for the Zone Provisioning Agent:

1. Open Active Directory Users and Computers.
2. Select the **UNIX Service Account** organizational unit.
3. Right-click, then select **New > User**.
4. Type a display name and logon name for the service account, then click **Next**.
5. Type and retype a password for the service account and modify the account options as follows, then click **Next**:
   - Uncheck **User must change password at next logon**
   - Check **User cannot change password**
   - Check **Password never expires**
6. Click **Finish** to add the service account.

Configure the local or domain group policy to allow the account to log on as a service

After you have created the service account, you must edit either a local security policy or the default domain group policy to grant the service account the **Log on as a service** right.

If you edit the default domain policy, the Zone Provisioning Agent can run on any Windows computer. If you need to move the service from one computer to another, no additional configuration is required.

Alternatively, you can edit the local security policy specifically on the computers that run the Zone Provisioning Agent. If you use the local policy, however, you may need to investigate whether other group policies are applied to the computer running the Zone Provisioning Agent to see if inheritance disables your local policy setting.

To edit the default domain group policy:

1. Open the Group Policy Object Editor and navigate to **Computer Configuration > Windows Settings > Security Settings > Local Policies > User Rights Assignment > Log on as a service**.
2. Right-click **Log on as a service**, then select **Properties**.
3. Select **Define these policy settings**, then click **Add User or Group**.
4. Click **Browse** to search for the service account you created.
5. Select the service account, then click **OK** to add the account and **OK** again to apply the policy.

Installing the Zone Provisioning Agent on the Access Manager computer

You can install both the Zone Provisioning Agent service and the Zone Property Page Extension on the computer where Access Manager is installed. At a minimum, you should install the Zone Property Page Extension on the same computer as the Access Manager console. The Zone Property Page Extension enables you to configure the Active Directory groups to monitor and the business rules for how to derive each user and group attribute.

> **Note**: If you select the Zone Provisioning Agent when you install components using the Server Suite setup program, all Zone Provisioning Agent components are installed. If you want to selectively install Zone Provisioning Agent components on a computer, you can install by running the Centrify_Zpaversionwin64.exe program.

To install the Zone Provisioning Agent on the Access Manager computer:

1. Log on to the Windows computer where Access Manager is installed.
2. Double-click the Centrify_Zpaversionwin64.exe file to start the Zone Provisioning Agent setup program.
3. If a User Account Control message is displayed, click **Yes**.

   If necessary, the setup program prompts you to install the Delinea Common Components.
4. On the **Welcome** screen, click **Next**.
5. Accept the licensing agreement, then click **Next**.
6. Select the features to install, then click **Next**.

   The Zone Property Page Extension is only applicable on the computer where the Access Manager console is installed. Selecting this option adds the Provisioning tab to the Zone Properties for individual zones. You can install or uncheck the other features on the computer where the Access Manager console is installed.
7. Click **Next** to accept the default location for the Zone Provisioning Agent files, or click **Browse** to select a different location, then click **Next**.
8. Click **Install** to begin installation.
9. Click **Finish** to complete the installation.

Installing the Zone Provisioning Agent on its own

You can install the Provisioning Agent as a standalone service on a computer with a relatively light load. The computer where you install the Provisioning Agent should be one that is online at all times. If the computer is shut down or suspended, the Provisioning Agent service will be suspended and no provisioning can occur. You can install a second instance of the Zone Provisioning Agent on another computer, and use your existing method of determining if a service has failed to monitor the availability of the first instance. For example, configure monitoring of the Windows Event log to notify you if the Zone Provisioning Agent service stops.

If you install the Provisioning Agent service as a standalone service, you should also install the Command Line Utility on the same computer.

To install the Zone Provisioning Agent as a standalone service:

1. Log on to the Windows computer that has a light load and is rarely shut down or offline.
2. Double-click the Centrify_Zpaversionwin64.exe file to start the Zone Provisioning Agent setup program.
3. If a User Account Control message is displayed, click **Yes**.

   If necessary, the setup program prompts you to install the Delinea Common Components.
4. On the **Welcome** screen, click **Next**.
5. Accept the licensing agreement, then click **Next**.
6. Select the Provisioning Agent and Command Line Utility features, then click **Next**.
7. Click **Next** to accept the default location for the Zone Provisioning Agent files, or click **Browse** to select a different location, then click **Next**.

8. Click **Install** to begin installation.
9. (Optional) Uncheck the **Configure and start Zone Provisioning Agent** option, then click **Finish**.

   If you leave **Configure and start Zone Provisioning Agent** selected, you are prompted to provide the service account name and password, then click **Start** to start the agent service. It is recommended that you configure the monitored containers, polling interval, and logging options, in addition to the service account name and password before starting the service. Therefore, you should open Access Manager to set up the Server Suite organization structure in Active Directory. For more information about the initial configuration, see Running Access Manager for the first time.

Configuring the Zone Provisioning Agent

By default, the Zone Provisioning Agent monitors all domains in the entire forest. If you use the recommended Server Suite organizational structure described in Creating recommended organizational units, it is recommended setting the Zone Provisioning Agent to only monitor the top-level Server Suite organizational unit or the Zones container. These objects are created in the Setup Wizard the first time you open Access Manager. After the initial configuration, you can perform the steps in this section to configure the Zone Provisioning Agent. For more information about the initial configuration, see Running Access Manager for the first time.

The most common reason for monitoring more than one organizational unit is if you have a regional or team-based OU structure in Active Directory, where each region or team is responsible for managing its own UNIX data. In this scenario, a provisioning staff member in Sidney, Australia, wouldn't be responsible for account fulfillment of a UNIX user in Chicago. To ensure the appropriate separation of duties between the different regions or teams, you would have more than one Server Suite organizational unit, and you would configure the Zone Provisioning Agent to search each of the regional organizational units.

To configure the Zone Provisioning Agent

1. Open the Zone Provisioning Agent Configuration Panel by clicking **Start > All Programs > Server Suite 2021.1 > Zone Provisioning Agent Configuration Panel**.
2. In the Monitored containers section, click **Add**.
3. Navigate to select the Server Suite organizational unit or the Zones container, then click **OK**.
4. Select **Entire Forest** *forest_name* from the list of Monitored containers, then click **Remove**.
5. Set the provisioning polling interval in minutes.

   The polling interval controls how often the Zone Provisioning Agent checks monitored containers for changes and processes the business rules for provisioning users and groups into zones. The appropriate interval often depends on the expectations of the user population or on service level agreements that define the provisioning team's commitments. In general, you should avoid polling more frequently than necessary to reduce the affect the Zone Provisioning Agent has on the performance of your domain controllers.
6. If desired, you can specify which domain controller that the Zone Provisioning Agent uses.
   1. To specify the domain controllers, click **Advanced**.

      The Advanced Domain Controller Settings dialog box displays.
   2. Click **Add** to open a separate dialog box in which you can add a domain and pick from a list of domain controllers. Click **OK** to save your chances.
   3. Click **Change** if you want to change the specified domain controller, or click **Remove** if you need to remove the specified domain controller.
7. Type the service account name or click **Browse** to locate the service account name, then type the password for the account.
8. Click **Apply**.
9. Click **Start** to start the Zone Provisioning Agent.

Whitelisting Domains for the Zone Provisioning Agent

You can configure the Zone Provisioning Agent so that it can connect to trusted domains (whitelisting) by setting the following registry key with a list of trusted domains and/or forests:

HKLM\SOFTWARE\Centrify ZPA\AllowedDomains

Configuring a list of domains this way can be particularly useful and faster when you have a large amount of domains.

For example, to specify a single domain:

HKLM\SOFTWARE\Centrify ZPA\AllowedDomains: "acme.com"

For example, to specify multiple domains:

HKLM\SOFTWARE\Centrify ZPA\AllowedDomains: "acme.com", "foo.com"

Running Access Manager for the First Time

The first time you start the Access Manager console, a Setup Wizard guides you through the initial configuration of the Active Directory forest. This initial setup creates the recommended or a custom deployment structure including the parent containers for Licenses and Zones and sets the permissions for modifying the objects within the containers. These steps are only performed once and can be done manually, if you choose.

Because the Setup Wizard creates container objects, you might need to use a domain administrator account. This requirement depends on the specific permissions your organization has configured for different classes of users. For example, if your organization only permits Domain Admins to create parent and child objects in Active Directory, you need to use an account with those permissions to run the Setup Wizard. For more information about the permissions required to perform specific configuration steps, see Permissions required to use the Setup Wizard.

Access Manager Account Permissions

n/a	Domain administrator (when running Access Manager for the first time)	domain admin (in most cases)	Because the Setup Wizard creates container objects, you might need to use a domain administrator account. This requirement depends on the specific permissions your organization has configured for different classes of users. For example, if your organization only permits Domain Admins to create parent and child objects in Active Directory, you need to use an account with those permissions to run the Setup Wizard.

To start the Setup Wizard and update the Active Directory forest

1. Open Access Manager from the desktop shortcut or Start menu.
2. Verify the name of the domain controller displayed is a member of the Active Directory forest you want to update or type the name of a different domain controller if you want to connect to a different forest, then click **OK**.
    - If you want to connect to a different forest, type the name of a domain controller in that forest.
    - If you want to connect to the forest with different credentials, select **Connect as another user**, then type a user name and password to connect as.
3. At the Welcome page, click **Next**.
4. Select **Use currently connected user credentials** to use your current log on account or select **Specify alternate user credentials** and type a user name and password, then click **Next**.
5. Select **Generate the recommended deployment structure** if you want to create all of the containers for the recommended deployment structure automatically.

    If you select this option, select whether you want to generate the default deployment structure or generate a custom structure, then click **Next**.

    - If you are generating the default structure, clicking Next enables you to select or create the location for the deployment structure in Active Directory. For example, if you want to create the top of the default deployment structure at the domain level, click **Next**, then click **Browse** to select the domain name. After you have selected a location, click **OK**. then click **Next** to create the deployment structure.
    - If you are generating a custom structure, clicking Next enables you to export the script that creates the default structure or run a script you have previously written.

      If you are generating a default or custom deployment structure, verify the successful execution of the script that creates the structure, then click **Next** to continue.

6. Verify the parent container for licenses is in the top-level Server Suite container if you are using the default deployment structure or the container of your choice, then click **Next**.

   You can add other Licenses containers in other locations later using the Manage Licenses dialog box.

   If you are not using the recommended deployment structure, the default container for license keys is domain_name/Program Data/Centrify/Licenses. To create the parent container in a different location, you can click **Browse**.

7. Review the permission requirements for the container, then click **Yes** to continue.

   If you don't want to allow the permissions for the selected container, click **No** and select a different container to continue.

8. Type or copy and paste the license key you received, then click **Add**.

   If you received multiple license keys, add each key to the list of installed licenses, then click **Next**. If you received license keys in a text file, click **Import** to import the keys directly from the file instead of adding the keys individually, then click **Next**.

   You can also add and remove license containers and keys after the initial configuration.

   For details about licensing, including how to request new license keys after deployment, check license usage and compliance, and how license counts are determined, see the *License Management Administrator's Guide*.

9. Verify that the **Create default zone container** option is selected and the parent container for zones is in the top-level Server Suite container or the container of your choice, then click **Next**.

   If you are not using the recommended deployment structure, the default container for zones is domain_name/Program Data/Centrify/Zones. To create the parent container in a different location, you can click **Browse**.

   You can skip creating the parent container in the forest or have more than one Zones parent container. For example, if you have a regional OU structure in Active Directory—where each region is responsible for its own set of zones—each region should have its own top-level organizational unit. For example, if you have separate OU structures for Tucson, AZ, and Newark, NJ, you would have separate deployment structures—SS-AZ and SS-NJ, for example—with separate parent containers for zones under each deployment structures. Users in each region can select the appropriate parent container when they create new zones.

   > **Note**: Users must have permission to read and create container objects on the parent Zones container and all child objects. You should verify the appropriate users have the permissions required to create new zones.

10. If you are using the recommended deployment structure, click **Next** to continue.

    This option allows "self-service" join operations for computers in the Computers container. It is only applicable if you are not using the recommended deployment structure. If you want to support "self-service" join operations and are not using the recommended deployment structure, select **Grant computer accounts in the Computers container permission to update their own account information**, then click **Next**.

11. If you plan to use Access Manager to manage information stored in Active Directory and maintain data integrity, click **Next** to continue.

    You should select **Register administrative notification handler for Microsoft Active Directory Users and Computers snap-in** if you want to automatically maintain the integrity of the information in Server Suite profiles.

    This option prevents Server Suite profile information from being left "orphaned" when changes are made to Active Directory objects such as users and groups. This option is not selected by default because it requires you to have Enterprise Admin or Domain Admin rights for the forest root domain.

12. Select **Activate Centrify profile property pages** if you want to be able to display Server Suite profiles in any Active Directory context, then click **Next**.

    Setting this option ensures that displaying the properties for a user, group, or computer always displays the Centrify Profile tab regardless of how you navigate to the Properties dialog box.

13. Review and confirm your configuration settings, click **Next**, then click **Finish**.

Installing Agents on Computers to be Managed

This chapter describes the recommended steps for deploying Server Suite software on the nonWindows computers that you want to add to Active Directory. The chapter also describes the alternatives you can use to install agent packages on non-Windows computers, including using native Linux installers to install Server Suite packages manually and automatically.

About the Deployment Process

The steps in this section, and in Preparing to migrate existing users and groups and Migrating existing users to hierarchical zones, are iterative in nature. In most cases, you will select a subset of computers for deployment, and repeat the steps for each target group until you have migrated all of the computers and users in the enterprise into Active Directory.

There is no technical requirement that you only work with a subset of computers at a time, but in practice the process of checking computers for potential problems and resolving open issues is more manageable when applied to a subset of computers. It is also more practical to migrate user populations in stages rather than all at once. After you step through the process a few times, you'll be able to anticipate and resolve potential issues more quickly and move into a more rapid deployment model.

Select a Target Set of Computers

As a first step in preparing to install Server Suite software, you should select a target set of computers on which to deploy. The target set can be based on any criteria you choose. In many organizations, new software must always be installed in the development environment first, then in the pre-production environment, before it can be deployed in the production environment. If your organization has this type of requirement, the first target set of computers would be the computers in the development environment.

Other possible candidates for the target set might be computers that:

- Have been identified for changes by an audit finding
- Are in the same physical location, such as a particular data center
- Share common attributes, such as all Red Hat Linux computers or all of the servers in a Web farm
- Are used by a particular department, project, or line of business
- Have a common set of users who need access to the computer resources

After you have identified a target set of computers, you are ready to begin the deployment. You should notify the user community that you are planning to install software on the target set of computers. For example, you may want to notify users by sending out an email message similar to the sample provided in Preliminary software delivery notification email template.

After you have identified a target set of computers to work with, you can use adcheck to check whether those computers have any issues that need to be resolved before you install new software on them. Checking the environment before you install helps to reduce change control issues.

Options for deploying Server Suite Agent Packages

You can:

- Run the agent installation script locally on any computer and respond to the prompts displayed.
- Create a configuration file and run the installation script remotely on any computer in silent mode.
- Use the install or update operations in the native package installer for your operating environment.
- Use a commercial or custom software distribution tool.

If you want to use one of these installation options and need more information, see the appropriate section.

Install Interactively on a Computer

The Server Suite Agent installation script, install.sh, automatically checks the operating system, disk space, DNS resolution, network connectivity, and other requirements on a target computer before installing. You can run this script interactively on any supported UNIX, Linux, or Mac OS X computer and respond to the prompts displayed.

To install Server Suite software packages on a computer interactively

1. Log on or switch to the root user if you are installing on a Linux or UNIX.

   If you are installing on Mac OS X, you can log on with any valid user account.

Note: On Mac OS X computers, you can install interactively using the graphical package installer or the install.sh script. For information about installing and joining an Active Directory domain using the Mac OS X package installer, see the Mac-specific instructions in the *Administrator's Guide for Mac*.

2. Mount the cdrom device using the appropriate command for the local computer's operating environment, if necessary. On most platforms, the CD drive is automatically mounted.

   Note: If you have downloaded the package from an FTP server or website, verify the location and go on to the next step.

   The instructions for mounting the CD drive are platform-specific. For example on Linux, you can use a command similar to the following:

   ```
   `mount /mnt/cdrom`
   ```

   To manually mount the CD drive on AIX, run a command similar to the following:

   ```
   `mount -v cdrfs -o ro /dev/cd0 /cdrom`
   ```

   To mount the CD drive on HP-UX, run a command similar to the following to display the long file names:

   ```
   mount -F cdfs -o rr /dev/dsk/c0t0d0 /mnt/cdrom
   ```

3. Change to the appropriate directory that contains the Server Suite Agent package you want to install.

   For example, to install an agent on a Linux computer from a downloaded Server Suite ISO or ZIP file, change to the Agent_Linux directory:

   ```
   cd Agent_Linux
   ```

   Similarly, if you are installing on a Solaris, HP-UX, AIX or other UNIX computer, change to the Agent_Unix directory. If installing on a Mac OS X computer, change to the Agent_Mac directory.

   If you downloaded individual agent packages from the Delinea Download Center, unzip and extract the contents. For example:

   ```
   gunzip -d centrify-infrastructure-services-VERSION-platform-arch.tgz
   ```

   ```
   tar -xf centrify-infrastructure-services-VERSION-platform-arch.tar
   ```

4. Run the install.sh script to start the installation of the agent on the local computer's operating environment. For example:

   ```
   ./install.sh
   ```

5. Follow the prompts displayed to select the services you want to install and the tasks you want to perform. For example, you can choose whether you want to:

   - Perform a default installation.
   - Perform a custom installation by selecting the specific packages to install.
   - Join a domain automatically at the conclusion of the installation.

     Depending on your selections, you may need to provide additional information, such as the user name and password for joining the domain.

Run the Bundle Installation from a Mounted Network Volume

You can install agents from a mounted network volume using the install-bundle.sh script. This script is available on the agent CD or ISO file that contains all of the supported agent platforms in compressed format. The bundle installation script automatically determines the platform required and extracts the contents of the appropriate TGZ file, then starts the normal installation process.

To use the install-bundle.sh script

1. Copy the install-bundle.sh script onto a network file system share and mount the shared directory.
2. Verify that the file is executable and that you have appropriate privileges to run it. For example:

   ```
   chmod +x install-bundle.sh
   ```

   ```
   chmod 755 install-bundle.sh
   ```

3. Run the script without command line options to start the installation or add command line options to install the agent silently.

For example, to start an interactive installation, type a command similar to this:

```
sudo ./install-bundle.sh
```

To install the agent silently, type a command similar to this:

```
./install-bundle.sh --std-suite --adjoin_opt="sidebet.org --password pa\$swd sudo ./install-bundle.sh

zone global --container sidebet.org/UNIX/Servers --server demo.sidebet.org"
```

To see complete usage information for the install-bundle.sh script, type:

```
./install-bundle.sh --help
```

Install Silently Using a Configuration File

Installing without user interaction enables you to automate software delivery and the management of remote computers. If you want to install files without any user interaction, you can run the install.sh script silently invoking the script with the appropriate command-line arguments. You can also customize the packages installed and other options by creating a custom configuration file for the installer to use.

- To see the install.sh silent mode and other command line options, enter `install.sh h`
- To install Authentication & Privilege default packages and configuration options silently, run:

  ```
  install.sh --std-suite
  ```

- To install Authentication & Privilege and Audit & Monitoring default packages and configuration options, run:

  ```
  install.sh --ent-suite
  ```

- To install a customized set of packages that all have the same version number, run:

  ```
  install.sh -n
  ```

About the Sample Configuration Files Available

You can customize the install.sh execution script. There are two sample configuration files for installing software packages silently. These sample configuration files are located in the same directory as the install.sh script:

```
centrifydc-suite.cfg

centrify-install.cfg
```

If you want to customize the packages installed or other configuration options, you can modify the sample `centrifydc-suite.cfg` or `centrifydc-install.cfg` file.

The `centrifydc-suite.cfg` file is used when you run install.sh with the `--stdsuite` or `--ent-suite` options. If you run `install.sh --std-suite` or `install.sh --ent-suite` with a customized version of the `centrifydc-suite.cfg` file, you can selectively install compatible add-on packages that do not have the same version number as the core Server Suite Agent.

Alternatively, you can run `install.sh -n` with a customized version of the `centrifydc-install.cfg` file to install the agent and add-on packages if they all have the same version number.

If you run the install.sh script silently and it cannot locate the `centrifydc-suite.cfg` or `centrifydc-install.cfg` file to use, default values defined directly in the script itself are used.

Setting the Parameters in a Custom Configuration File for the Installation Script

If you want to specify values for the install.sh script to use, you should edit the sample `centrifydc-suite.cfg` or `centrifydc-install.cfg` file in its default location before invoking the install.sh script in silent mode.

> **Note**: The parameters in the `centrifydc-install.cfg` or `centrifydc-suite.cfg` file are the same, except that the `centrifydc-suite.cfg` file is used when installing a set of services to allow packages with different version numbers to be installed together. Because you should not modify the compatibility defined in the `centrifydc-suite.cfg` file, those parameters are not included in the table.

To customize the installation using the `centrifydc-install.cfg` or `centrifydc-suite.cfg` file, you can set the following parameters:

Parameter	Description
ADCHECK	Indicate whether you want to run the `adcheck` program to check the configuration of a local computer and

its connectivity to Active Directory. Note that the install.sh script calls adcheck twice. After the first call, adcheck performs several required pre-installation steps to make sure you can install the Centrify Agent on the host computer. These steps are mandatory and cannot be skipped. However, the second call to adcheck is used to perform post-installation steps to make sure the agent has been installed successfully. The second set of checks is optional and can skipped. Set this parameter to Y if you want to run adcheck after installing. For non-interactive installations, the default is N. | | ADLICENSE | Indicate whether you want to install licensed features. Set this parameter to Y if you have purchased and installed license keys. If you downloaded and want to install unlicensed Centrify Express agents, set this parameter to N. | | GLOBAL_ZONE_ONLY | Specify whether you want to install the agent in a Solaris 10 global zone and no other zones. Set this parameter to Y only if you are running the install.sh script on a Solaris 10 computer and want to install the agent in the Solaris 10 global zone and none of your non-global zones. In most cases, you only set this parameter to Y if you use sparse root zones. The default setting for this parameter is N so that the agent is installed in all Solaris zones. If the script is not running on a Solaris 10 computer, this parameter is ignored. | | ADJOIN | Indicate whether you want to attempt to join an Active Directory domain in non-interactive mode. Set this parameter to Y to attempt to join the domain automatically. Set this parameter to N to manually join the domain after installation. | | ADJ_FORCE | Overwrite the information stored in Active Directory for an existing computer account. Set this parameter to Y to replace the information for a computer previously joined to the domain. If there is already a computer account with the same name stored in Active Directory, you must use this option if you want to replace the stored information. You should only use this option when you know it is safe to force information from the local computer to overwrite existing information. | | ADJ_TRUST | Set the **Trust for delegation** option in Active Directory for the computer account. Trusting an account for delegation allows the account to perform operations on behalf of other accounts on the network. | | DOMAIN | Specify the domain to join, if you set the ADJOIN parameter to Y. Set this parameter to the name of a valid Active Directory domain. | | USERID | Specify the Active Directory user name to use when connecting to Active Directory to join the domain. Set this parameter to a valid Active Directory user name. | | PASSWD | Specify the password for the Active Directory user name you are using to connect to Active Directory. Set this parameter to the password for the Active Directory user name specified for the USERID parameter. | | COMPUTER | Specify the computer name to use for the local host in Active Directory. Set this parameter to the computer name you want to use in Active Directory if you don't want to use the default host name for the computer. | | CONTAINER | Specify the distinguished name (DN) of the container or Organizational Unit in which you want to place this computer account. The DN you specify does not need to include the domain suffix. The domain suffix is appended programmatically to provide the complete distinguished name for the object. If you do not specify a container, the computer account is created in the domain's default Computers container. Note that the container you specify must already exist in Active Directory, and you must have permission to add entries to the specified container. | | ZONE | Specify the zone to which you want to add this computer. | | SERVER | Specify the name of the domain controller to which you prefer to connect. You can use this option to override the automatic selection of a domain controller based on the Active Directory site information. | | DA_ENABLE | Indicate whether you want to automatically enable the auditing service on the local computer. The valid settings are: Y if you want to enable auditing with the default auditing configuration. N if you don't want to enable auditing. K if you are upgrading and want to keep your current auditing configuration unchanged. | | DA_X_ENABLE | Indicate whether you want to automatically enable the Linux desktop auditing service on the local computer. The valid settings are: Y if you want to desktop enable auditing with the default auditing configuration. N if you don't want to enable desktop auditing. K if you are upgrading and want to keep your current auditing configuration unchanged | | DA_INST_NAME | Specify the name of an auditing installation if you set the DA_ENABLE parameter to Y. | | REBOOT | Indicate whether you want to automatically restart the local computer after a successful installation. Set this parameter to Y if you want to automatically restart the local computer or to N if you don't want the computer restarted automatically. | | INSTALL | Specify the operation to perform. The valid settings are: Y to install the Server Suite Agent for *NIX and any other Server Suite software packages if they are not already installed on the local computer. U to update older versions of the Server Suite Agent for *NIX and any other Server Suite packages you have installed. The update option only updates software from one major release version to another. It does not update the software if the major release version is same between packages. R to reinstall or repair the Server Suite Agent for *NIX and any other Server Suite packages you have installed. You can reinstall packages that have the same major release version but different build number or repair packages by installing an older version of the package. E to remove the software currently installed. K to keep current software unchanged. Set this parameter to Y to install or to U to update the Server Suite Agent for *NIX and other packages. If you want to install or update other packages, select the operation to perform for each package. For example to update the Server Suite Kerberos package and keep the current Server Suite LDAP proxy service, you might specify the following: CentrifyDC_krb5="U" CentrifyDC_ldapproxy="K" Note that these additional packages may have dependencies or require a specific version of the Server Suite Agent for *NIX to be installed. Before installing or updating additional packages silently, you should review the information in the *Upgrade and Compatibility Guide*. | | UNINSTALL | Specify whether you want to forcibly uninstall all installed packages. | For example, you can edit the centrifydc-install.cfg or centrifydc-suite.cfg file to silently install the Server Suite Agent for *NIX, join the domain, and automatically reboot the computer at the completion of the installation process with a file similar to this:

```
ADCHECK="N"
 ADLICENSE="Y"
 \# Solaris 10 -G option, installation in global zone only
 GLOBAL_ZONE_ONLY="N"
 ADJOIN="Y"
 ADJ_FORCE="N"
 ADJ_TRUST="N"
 DOMAIN="sample.company.com"
 USERID=administrator
 PASSWD="securepassword123"
 \#COMPUTER=my_host_name
 \#CONTAINER="my_computers"
 ZONE="global_zone"
 \#SERVER=server_name
 DA_ENABLE="N"
 DA_INST_NAME=""
 REBOOT="Y"
 \# Install the core agent package
```

```
INSTALL="Y"

\# Skip installation for other packages
CentrifyDC_nis=
CentrifyDC_krb5=
CentrifyDC_ldapproxy=
CentrifyDC_openssh=
CentrifyDC_web=
CentrifyDC_apache=
CentrifyDC_idmap=
CentrifyDA=
```

This sample configuration file does not install any of the Server Suite add-on packages. You can also use the configuration file to silently install or update selected packages. For example, to update the LDAP proxy service and OpenSSH on a computer, you would modify the configuration file to indicate that you want to update those packages:

```
CentrifyDC_ldapproxy="U"
CentrifyDC_openssh="U"
```

Customizing the Return Codes for the Installation Script

Normally, when you run the install.sh script silently, the script returns an exit code of 0 if the operation is successful. If you want the script to return exit codes that indicate whether the operation performed was a successful new installation, a successful upgrade, a successful uninstall, or there were errors preventing installation, you can also use the custom_rc option. For example:

```
install.sh -n --custom_rc
```

When you specify this option, the following return codes that are defined in the install.sh script are used to provide more detailed information about the result:

CODE_SIN=0	Successful installation
CODE_SUP=0	Successful upgrade
CODE_SUN=0	Successful uninstallation
CODE_NIN=24	Did nothing during installation
CODE_NUN=25	Did nothing during uninstallation
CODE_EIN=26	Error during installation
CODE_EUP=27	Error during upgrade
CODE_EUN=28	Error during uninstallation
CODE_ESU=29	Error encountered during setup, for example, the UID is not the root user UID, the operating environment is not supported or not recognized, or the script is executed with invalid arguments

Use Other Automated Software Distribution Utilities

You can also install Server Suite software using virtually any automated software distribution framework. For example, you can use software delivery offerings from HP OpsWare or IBM Tivoli, or features such as Apple Remote Desktop, or software distribution in the Casper Suite to deliver Server Suite software to remote computers. You can also use any custom software delivery tools you have developed specifically for your organization. If you use a commercial or custom software distribution mechanism, review the release notes text file included with agent package for platform-specific installation details.

Using a Native Package Installer

If you want to manually install a software package using a native installation program instead of the Server Suite installation script, you can follow the instructions in the *Upgrade and Compatibility Guide* for the most common native package installers, such as the Red Hat or Debian package manager. You should note that these native packages are signed with a GNU Privacy Guard (GPG) key. You need to import the key to verify the package authenticity before installing the package. You can download the RPM-GPG-KEY-centrify file from the Delinea Download Center.

Alternatively, you can use any other installation program you have available for the local operating environment. For example, if you use another program such as SMIT, YAST, APT, SUSE, or YUM to install and manage software packages, you can use that program to install Server Suite software packages.

Perform the following steps to install the Server Suite Agent using a native installation program that does not require a connection to a package repository. To use a native installation program that requires a repository connection (such as yum, SUSE or APT), see Enabling package repositories.

To install the agent using a native installation program

1. Log on as or switch to the root user.
2. If you are installing from a CD and the CD drive is not mounted automatically, use the appropriate command for the local computer's operating environment to mount the cdrom device.
3. Copy the appropriate package for the local computer's operating environment to a local directory.

   For example, if installing from the CD and the operating environment is Solaris 10 SPARC:

   ```
   cp /cdrom/cdrom0/Unix/centrifydc-release-sol10-sparc-local.tgz .
   ```

4. If the software package is a compressed file, unzip and extract the contents. For example, on Solaris:

   ```
   gunzip -d centrifydc-release-sol10-local.tgz  tar -xf centrifydc-release-sol10-sparc-local.tar
   ```

5. Run the appropriate command for installing the package based on the local computer's operating environment. For example, on Solaris:

   ```
   pkgadd -d CentrifyDC-a admin
   ```

   If you are not sure which command to use for the local operating environment, see the documentation associated with the package installer you are using.

Enabling Package Repositories

You can also download and install agents using Linux package management software for your operating system. To do this, you set up a repository for your operating system and then use the software's command line tools to manage automatic agent updates.

- **RedHat, CentOS, or Amazon systems**: Use the "Yellowdog Updater, Modified (yum)" tool to update the rpm-redhat repository. For details, see To set up and configure a RedHat, CentOS, or Amazon repository.
- **SuSE systems**: Use the Zypper tool to update the rpm-suse repository. For details, see To set up and configure a SUSE repository.
- **Debian or Ubuntu systems**: Use the Advanced Package Tool (APT), apt-get, or Aptitude tools to update the deb repository. For details, see To set up and configure a Debian or Ubuntu repository.
- **Atomic systems**: Use curl or wget to update the wget repository. For details, see To access a raw package (WGET) repository.
- **Alpine Linux systems**: For details, see To set up and configure an Alpine Linux repository.

You must perform one of the above procedures to enable the repository.

> **Note**: The procedures in this section require that you log in to the Delinea Support Portal and go to the Delinea Repo site. On that page, click the link to generate the repo key. You will then specify the repo key in a yum (RHEL, SUSE, and so forth) or APT (Debian, Ubuntu, and so forth) configuration file. There are some examples on the Delinea repo site about how to add the key to your configuration file.
>
> **Note**: For additional details about configuring and using SUSE or yum repositories, see the documentation for the distribution of Linux you are using. For additional details about configuring and using APT repositories, see the documentation for the distribution of Debian Linux or Ubuntu you are using.

WARNING: If you specify your repository on the command line, be sure to clean out your command history afterwards. Because the URL for your repository includes the credentials to access it, leaving this information around in command history is not a secure practice.

Delinea

Redhat

To Set Up and Configure a Redhat, Centos, or Amazon Repository

1. Create a /etc/yum.repos.d/centrify-rpm-redhat.repo configuration file to use the official Delinea package repository, and download a RPM-GPG-KEY-centrify key from the Delinea Support Portal.

   You can manually create the configuration file or you can use a setup script to generate the file automatically.

   Note: For the baseurl parameter, enter your Delinea repo URL token in place of **<URLtoken>**.

   - **To create the repository configuration file manually**

     Create a file with the following:

     ```
     # Source: CENTRIFY
     # Repository: CENTRIFY / rpm-redhat
     # Description: YUM repository for RedHat packages (RPMs)

     [centrify-rpm-redhat]
     name=centrify-rpm-redhat
     baseurl=https://cloudrepo.centrify.com/URLTOKEN/rpm-redhat/rpm/any-distro/any-version/$basearch
     repo_gpgcheck=1
     enabled=1
     gpgkey=https://downloads.centrify.com/products/RPM-GPG-KEY-centrify
     gpgcheck=1
     sslverify=1
     sslcacert=/etc/pki/tls/certs/ca-bundle.crt
     metadata_expire=300
     pkg_gpgcheck=1
     autorefresh=1
     type=rpm-md
     ```

- **To create the repository configuration file automatically from a script**

  ```
  curl -1sLf ' https://cloudrepo.centrify.com/URLTOKEN/rpm-redhat/cfg/setup/bash.rpm.sh' | sudo -E bash
  ```

  You should see output that lists out your repository details, such as the following example:

  ```
  # Source: CENTRIFY
  # Repository: CENTRIFY / rpm-redhat
  # Description: YUM repository for RedHat packages (RPMs)

  [centrify-rpm-redhat]
  name=centrify-rpm-redhat
  baseurl=https://cloudrepo.centrify.com/URLTOKEN/rpm-redhat/rpm/el/6/$basearch
  repo_gpgcheck=1
  enabled=1
  gpgkey=https://cloudrepo.centrify.com/URLTOKEN/rpm-redhat/cfg/gpg/gpg.BDD3FD95B65ECA48.key
  gpgcheck=1
  sslverify=1
  sslcacert=/etc/pki/tls/certs/ca-bundle.crt
  metadata_expire=300
  pkg_gpgcheck=1
  autorefresh=1
  type=rpm-md
  ```

  Note: The gpgkey listed in the output is a public key.

2. Execute the yum info command to verify the repository connection. You should see output similar to the following.

   ```
   #yum info CentrifyDC
   Loaded plugins: langpacks, product-id, search-disabled-repos, subscription-manager
   2020-11-24 10:20:22,669 [INFO] yum:17896:MainThread @connection.py:905 - Connection built: host=subscription.rhsm.redhat.com port=443 handler=/subscription auth=identity_cert
   ca_dir=/etc/rhsm/ca/ insecure=False
   2020-11-24 10:20:22,671 [INFO] yum:17896:MainThread @repolib.py:464 - repos updated: Repo updates

   Total repo updates: 0
   Updated
    <NONE>
   Added (new)
    <NONE>
   Deleted
    <NONE>
   This system is not registered with an entitlement server. You can use subscription-manager to register.
   Available Packages
   Name        : CentrifyDC
   ```

```
Arch        : x86_64
Version     : 5.7.0
Release     : 207
Size        : 23 M
Repo        : centrify-rpm-redhat/x86_64
Summary     : Centrify DirectControl Agent
URL         : http://www.centrify.com/
License     : BSD with portions copyright (c) Centrify Corporation 2006-2020 and licensed under Centrify End User License Agreement
Description : RPM to install Centrify DirectControl on Linux platforms.
```

3. Install the Server Suite Agent for *NIX rpm package.

```
# yum install CentrifyDC
```

> **Note**: To uninstall the Server Suite Agent rpm file, you can use the erase command. For example:

```
# yum erase CentrifyDC
```

Delinea

SuSE

To Set Up and Configure a Suse Repository

1. If you have used a Delinea repository before, it's recommended that you first delete the old repositories in the /etc/zypp/repos.d/*centrify* directory.
2. Create a new SUSE repository.

   You can manually create the repository or you can use a setup script to create the repository automatically.

   > **Note**: For the baseurl parameter, enter your Delinea repository URL token in place of URLTOKEN.

   - **To create the SUSE repository configuration file manually**

     Create a file with the following:

     ```
     /etc/zypp/repos.d # cat /etc/zypp/repos.d/centrify-rpm-suse.repo
     [centrify-rpm-suse]
     name=centrify-rpm-suse
     enabled=1
     autorefresh=1
     baseurl=https://cloudrepo.centrify.com/URLTOKEN/rpm-suse/rpm/any-distro/any-version/$basearch
     type=rpm-md
     repo_gpcheck=1
     gpgcheck=1
     gpgkey=https://downloads.centrify.com/products/RPM-GPG-KEY-centrify
     ```

- **To create the SUSE repository configuration file automatically from a script**

  ```
  curl -1sLf 'https://cloudrepo.centrify.com/URLTOKEN/rpm-suse/cfg/setup/bash.rpm.sh' | sudo -E bash
  ```

3. Refresh the cache.

   ```
   /etc/zypp/repos.d # zypper refresh
   ```

4. Verify the connection to the repository.

   ```
   /etc/zypp/repos.d # zypper packages |grep centrify
   ```

   You should see output similar to the following:

   ```
   mysusemachine:/etc/zypp/repos.d # zypper refresh
   Retrieving repository 'centrify-rpm-suse' metadata ----------[\]

   Retrieving repository 'centrify-rpm-suse' metadata .............[done]
   Building repository 'centrify-rpm-suse' cache .....................[done]
   All repositories have been refreshed.
   utsles15ppcle:/etc/zypp/repos.d # zypper packages | grep Centrify
   | centrify-rpm-suse  | CentrifyDA            | 3.7.0-172        | ppc64le
   | centrify-rpm-suse  | CentrifyDA            | 3.6.1-324        | ppc64le
   | centrify-rpm-suse  | CentrifyDC            | 5.7.0-207        | ppc64le
   | centrify-rpm-suse  | CentrifyDC            | 5.6.1-330        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-cifsidmap  | 5.7.0-207        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-cifsidmap  | 5.6.1-330        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-curl       | 5.7.0-207        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-curl       | 5.6.1-330        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-ldapproxy  | 5.7.0-207        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-ldapproxy  | 5.6.1-330        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-nis        | 5.7.0-207        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-nis        | 5.6.1-330        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-openldap   | 5.7.0-207        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-openldap   | 5.6.1-330        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-openssh    | 8.2p1-5.7.0.207  | ppc64le
   | centrify-rpm-suse  | CentrifyDC-openssh    | 7.9p1-5.6.1.329  | ppc64le
   | centrify-rpm-suse  | CentrifyDC-openssl    | 5.7.0-207        | ppc64le
   | centrify-rpm-suse  | CentrifyDC-openssl    | 5.6.1-330        | ppc64le
   ```

5. Install the Server Suite Agent rpm package.

   ```
   # zypper install CentrifyDC
   ```

   > **Note**: To uninstall the Server Suite Agent rpm file, you can use the remove command. For example:

   ```
   # zypper remove CentrifyDC
   ```

Delinea

Debian Ubuntu

To set up and configure a Debian or Ubuntu repository

1. Create the repository:

   You can manually create the repository or you can use a setup script to create the repository automatically.

   - **_To create the Debian or Ubuntu repository configuration file manually**

     1. Update the /etc/apt/sources.list file to include the official Delinea package repository.

        ```
        deb https://cloudrepo.centrify.com/URLTOKEN/deb/deb/debian any-version main /etc/apt/sources.list.d/centrify-deb.list
        ```

2. Import your GPG key and update the repository.

   ```
   # bash -c 'wget -O - https://support.delinea.com/s/product-downloads/products/RPM-GPG-KEY-centrify | apt-key add -'
   ```

3. Comment out the no-debsig line in /etc/dpkg/dpkg.cfg to enable GPG signature validation.

   ```
   # grep no-debsig /etc/dpkg/dpkg.cfg
   # no-debsig
   ```

4. Clean and update the local archives.

   ```
   # apt-get clean
   # apt-get update
   ```

- **To create the Debian or Ubuntu repository configuration file automatically from a script**

  ```
  curl -1sLf 'https://cloudrepo.centrify.com/URLTOKEN/deb/cfg/setup/bash.deb.sh' | sudo -E bash
  ```

  Note: Enter your Delinea repository URL token in place of URLTOKEN.

If you manually created your APT repository, the configuration details are in the /etc/apt/sources.list file. If you used the setup script to create the APT repository, the configuration details are in a separate file such as centrify-deb.list in the /etc/apt/sources.list.d directory.

2. Execute the apt list command to verify the repository connection. You should see output similar to the following.

   ```
   # apt list --all-versions | grep centrify
   centrifyda/buster 3.7.0-172 amd64
   centrifyda/buster 3.6.1-324 amd64
   centrifydc-adbindproxy/buster 5.7.0-217 amd64
   centrifydc-adbindproxy/buster 5.6.1-334 amd64
   centrifydc-cifsidmap/buster 5.7.0-207 amd64
   centrifydc-cifsidmap/buster 5.6.1-330 amd64
   centrifydc-curl/buster 5.7.0-207 amd64
   centrifydc-curl/buster 5.6.1-330 amd64
   centrifydc-ldapproxy/buster 5.7.0-207 amd64
   centrifydc-ldapproxy/buster 5.6.1-330 amd64
   centrifydc-nis/buster 5.7.0-207 amd64
   centrifydc-nis/buster 5.6.1-330 amd64
   centrifydc-openldap/buster 5.7.0-207 amd64
   centrifydc-openldap/buster 5.6.1-330 amd64
   centrifydc-openssh/buster 8.2p1-5.7.0.207 amd64
   centrifydc-openssh/buster 7.9p1-5.6.1.329 amd64
   centrifydc-openssl/buster 5.7.0-207 amd64
   centrifydc-openssl/buster 5.6.1-330 amd64
   centrifydc/buster 5.7.0-207 amd64
   centrifydc/buster 5.6.1-330 amd64
   ```

3. Execute the apt install or apt-get install commands to install Delinea packages. For example:

   ```
   # apt install centrifydc centrifydc-nis
   # apt-get install centrifydc-5.7.0-207
   ```

   Note: To uninstall the Server Suite Agent for *NIX rpm, you can use the remove command to delete the Server Suite Agent for *NIX package or the purge command to also delete any configuration files. For example:

```
# apt remove centrifydc=5.7.0-207
```

To Access a Raw Package (wget) Repository for Atomic

Use the WGET repository for Atomic packages or any raw or plain files such as *.zip, *.tar, *.tgz, and so forth .

1. Browse the package index to determine which file you want to download. You can view the package index in HTML or JSON:
    - HTML version is at https://cloudrepo.centrify.com/URLTOKEN/wget/raw/
    - JSON version is at https://cloudrepo.centrify.com/URLTOKEN/wget/raw/index.json

        Note: Enter your Centrify repository URL token in place of URLTOKEN.
2. Download the desired file using either curl or wget. For example:

    curl -1 -O 'https://cloudrepo.centrify.com/URLTOKEN/wget/raw/versions/Latest/CentrifyDC-atomic.x86_64.tgz'

    or

    wget 'https://cloudrepo.centrify.com/URLTOKEN/wget/raw/versions/Latest/CentrifyDC-atomic.x86_64.tgz'

To Set Up and Configure an Alpine Linux Repository

1. To configure the repository automatically, run the following commands:

```
sudo apk add --no-cache bash
curl -1sLf \ 'https://cloudrepo.centrify.com/URLTOKEN/apk/setup.alpine.sh' \ I sudo -E bash
```

   Note: Enter your Delinea repository URL token in place of URLTOKEN.

2. Or, if you want to manually configure the repository, run the following commands:

```
curl -1sLf 'https://cloudrepo.centrify.com/URLTOKEN/apk/rsa.5DD8742729E6E4B2.key' > /etc/apk/keys/apk@centrify-5DD8742729E6E4B2.rsa.pub
curl -1sLf 'https://cloudrepo.centrify.com/URLTOKEN/apk/config.alpine.txt?distro=alpine&codename=v3.13' >> /etc/apk/repositories
apk update
```

When configuring the repository manually, you reference the Delinea public RSA key: apk@centrify-5DD8742729E6E4B2.rsa.pub.

1. Execute the apk add command to install the Server Suite packages. For example:

```
# apk add centrifydc centrifydc-nis
```

   To uninstall the Server Suite Agent for *NIX rpm, you can use the del command to delete the Server Suite Agent for *NIX package. For example:

```
# apk del centrifydc=5.8.0-xxx
```

About the Files And Directories Installed on the Agent

When you complete the installation, the local computer will be updated with the following directories and files for the core Server Suite Agent for *NIX:

/etc/centrifydc	The agent configuration file and the Kerberos configuration file.
/usr/share/centrifydc	Kerberos-related files and service library files used by the Centrify Agent to enable group policy and authentication and authorization services.
/usr/sbin /usr/bin	Command line programs to perform Active Directory tasks, such as join the domain and change a user password.
/var/centrify	Directories for temporary and common files that can be used by the agent.
/var/centrifydc	Before joining the domain, the directory contains basic information about the environment, such as the IP address of the DNS server and whether you installed licensed or express agent features. After you join the domain, several files are added to this directory to record information about the Active Directory domain the computer is joined to, the Active Directory site the computer is part of, and other details.

Depending on the components you select during installation, additional files and directories might be installed or updated. For example, if you install Enterprise Edition, the computer is updated with additional files and directories for auditing.

Joining an Active Directory Domain at a Later Time

At this point, you have delivered the software to target computers, but not changed their configuration. Users still have exactly the same access as they did before installing Server Suite software. The computer's configuration changes only happen when the computer joins an Active Directory domain, that is, joining the domain is what "activates" Server Suite software.

You have the option to automatically join an Active Directory domain when you install Server Suite Agents the install.sh script. In most cases, however, you should not do so unless you have already planned your user migration and created your initial zones. Typically, it is best to analyze the user population and prepare for migration before joining the domain to ensure minimal disruption of user activity and ease the transition to new software. Over time, as you become more familiar with the migration process and refine your zone design, you can adapt the steps to suit your organization.

If you want to join the domain at the same time you deploy the Server Suite software, you should do the following before you install files on the UNIX computers:

1. Download the Server Suite software for all platforms or the subset of platforms you intend to support.
2. Analyze existing user and group accounts.
3. Identify your zone requirements and create the initial zone design.
4. Migrate users and groups into the appropriate zones and role assignments.
5. Use the install.sh script or a custom script to install Server Suite Agents and join the domain.

The additional steps are described in the next sections. You can also manually join a domain at any time after installation by using the `adjoin` command.

Installing the Agent on Solaris Systems

This section covers information about installing the Server Suite Agent for *NIX on Solaris systems. The procedures differ depending on whether you're installing svr4 or IPS packages. If you're installing IPS packages onto a system with Solaris 11 child zones, there's a separate procedure for that deployment.

For which packaged file to use for installation, refer to the table below.

Solaris 10	svr4	x86	centrify-server-suite-2021.1-sol10-x86.tgz
Solaris 10	svr4	Sparc	centrify-server-suite-2021.1-sol10-sparc.tgz
Solaris 11	svr4	x86	centrify-server-suite-2021.1-sol10-x86.tgz
Solaris 11	svr4	Sparc	centrify-server-suite-2021.1-sol10-sparc.tgz
Solaris 11	IPS	x86	centrify-server-suite-2021.1-sol11-i386.tgz
Solaris 11	IPS	Sparc	centrify-server-suite-2021.1-sol11-sparc.tgz

Installing the Solaris Svr4 Agent Packages

Download the solaris package appropriate for your Solaris system and run the install.sh script as mentioned in the "Install interactively on a computer" section. You can follow the same procedure if you're installing on a system with or without child zones.

You can run the following command to verify the Solaris agent package svr4 installation status:

```
pkginfo | grep -i centrify
```

Note that there is no space between "pkg" and "info"; if you search for "pkg info" you'll be searching for IPS packages.

Installing the Solaris IPS Agent Packages

This procedure is for systems where you are doing a fresh install of Server Suite software onto a Solaris 11 system with IPS support.

This procedure is the same as for the regular install script, except that you run the `install-ips.sh` script, not the install.sh script -- see the "Install interactively on a computer" section.

You'll need the centrify-infrastructure-services-VERSION-sol11-i386.tgz file or the `centrify-infrastructure-services-VERSION-sol11-sparc.tgz` file for this procedure, depending on the type of system you have.

To install the Solaris IPS packages

1. Download the Server Suite package for your version of Solaris.
2. Extract the Server Suite packages onto the system.
3. Run the `install-ips.sh` script. For example:

   ```
   ./install-ips.sh
   ```

4. Follow the prompts displayed to select the services you want to install and the tasks you want to perform. For example, you can choose whether you want to:
   - Perform a default installation.
   - Perform a custom installation by selecting the specific packages to install.
   - Join a domain automatically at the conclusion of the installation.

     Depending on your selections, you may need to provide additional information, such as the user name and password for joining the domain.

5. You can run the following command to verify the Solaris agent package IPS installation status:

   ```
   pkg info l grep -i centrify
   ```

   Note the space between "pkg" and "info"; if you search for "pkginfo" you'll be searching for svr4 packages.

Installing the Solaris IPS Agent Packages With Child Zones

When you install the agent onto a Solaris 11 computer enabled with IPS that also has one or more child zones configured, you need to import the agent packages into a new repository and then install directly from the repository.

You do this install in the global zone and the repository will automatically install the files into the child zones.

You'll need the centrify-infrastructure-services-VERSION-sol11-i386.tgz file or the centrify-infrastructure-services-VERSION-sol11-sparc.tgz file for this procedure, depending on the type of system you have.

To install the Solaris IPS agent packages onto a system with one or more child zones

1. Create a directory and extract the IPS tgz file into that directory.

   For example, create directory called "install-ips" and extract the contents of the tgz file into that directory.

   1. Create a repository:

      For example, run the following command to create a repository called "my-repo":

      Tip: You can run the zfs list command to list all of the zone file systems.

      ```
      zfs create rpool/export/my-repo

      zfs set atime=off rpool/export/my-repo

      pkgrepo create /export/my-repo

      pkgrepo set -s /export/my-repo publisher/prefix=centrify

      pkgrepo -s /export/my-repo refresh

      pkgrepo -s /export/my-repo info

      pkg set-publisher -G '*' -M '*' -g /export/my-repo centrify

      pkg publisher
      ```

      You should see the repository listed.

      ```
      PUBLISHER TYPE STATUS P LOCATION
      centrify origin online F file:///export/my-repo
      ```

2. Import the packages into the repository. You need to import the packages that end with .p5p and you need to import them one at a time.

   1. In the directory where you extracted the Server Suite Agent packages, list out the files in that directory (use the ls command).

      The full package list of files that you need to import into the repository looks something like this:

      ```
      centrifyda-3.7.0-sol11-i386.p5p

      centrifydc-5.7.0-sol11-i386.p55

      centrifydc-curl-5.7.0-sol11-i386.p5p

      centrifydc-ldapproxy-5.7.0-sol11-i386.p5p

      centrifydc-nis-5.7.0-sol11-i386.p5p

      centrifydc-openldap-5.7.0-sol11-i386.p5p

      centrifydc-openssh-5.7.0-sol11-i386.p5p

      centrifydc-openssl-5.7.0-sol11-i386.p5p
      ```

   2. Import each package into the repository.

      For example, if you're installing all 8 packages, you'll run the following 8 commands:

```
pkgrecv -s centrifyda-3.7.0-sol11-i386.p5p -d /export/my-repo '*'
pkgrecv -s centrifydc-5.7.0-sol11-i386.p55 -d /export/my-repo '*'
pkgrecv -s centrifydc-curl-5.7.0-sol11-i386.p5p -d /export/my-repo '*'
pkgrecv -s centrifydc-ldapproxy-5.7.0-sol11-i386.p5p -d /export/my-repo '*'
pkgrecv -s centrifydc-nis-5.7.0-sol11-i386.p5p -d /export/my-repo '*'
pkgrecv -s centrifydc-openldap-5.7.0-sol11-i386.p5p -d /export/my-repo '*'
pkgrecv -s centrifydc-openssh-5.7.0-sol11-i386.p5p -d /export/my-repo '*'
pkgrecv -s centrifydc-openssl-5.7.0-sol11-i386.p5p -d /export/my-repo '*'
```

3. You can verify that the packages imported correctly by listing out the repository packages.

   For example, run the following command:

   ```
   pkgrepo list -s /export/my-repo
   ```

   You'll see a list of packages where each package has a long version. For example:

   ```
   centrify security/centrifydc 5.7.0.207:20200726T052946Z
   ```

3. Install the packages from the repository into the parent and child zones.

   Be sure to reference the package's entire version. When you install the centrifydc package, the other packages for cURL, OpenLDAP, and OpenSSL are also installed.

   For example, to install centrifydc, you'd run the following command, :

   ```
   pkg install -r security/centrifydc@5.7.0.207:20200726T052946Z
   ```

   For example, to install all the packages with one command, you'd run something like this:

   ```
   pkg install -r security/centrifydc@5.7.0.207:20200726T052946Z security/centrifydc-ldapproxy@5.7.0.207:20200726T053320Z security/centrifydc-nis@5.7.0.207:20200726T053352Z
   security/centrifydc-openssh@5.7.0.207:20200727T065442Z security/centrifyda@3.7.0.171:20200725T014652Z
   ```

4. You can run the following command to verify the Solaris agent package IPS installation status:

   ```
   pkg info | grep -i centrify
   ```

   Note the space between "pkg" and "info"; if you search for "pkginfo" you'll be searching for svr4 packages.

Uninstalling the Agent on Solaris Systems

To uninstall the Solaris svr4 packages

1. In the directory where you have downloaded and extracted the Centrify Agent packages, run the following command:

   ```
   ./install.sh -e -n
   ```

2. You can run the following command to verify the Solaris agent package svr4 installation status:

   ```
   pkginfo | grep -i centrify
   ```

   Note that there is no space between "pkg" and "info"; if you search for "pkg info" you'll be searching for IPS packages.

To uninstall the Solaris IPS packages

1. In the directory where you have downloaded and extracted the Server Suite Agent packages, run the following command:

   ```
   ./install-ips.sh -e -n
   ```

2. You can run the following command to verify the Solaris agent package IPS installation status:

   ```
   pkg info | grep -i centrify
   ```

   Note the space between "pkg" and "info"; if you search for "pkginfo" you'll be searching for svr4 packages.

To uninstall the Solaris IPS packages on systems with one or more child zones

1. To uninstall a single package from both parent and child zones, run the following command:

   pkg uninstall -r *packagename*

   For example, to uninstall only the CentrifyDA package, run the following command:

   pkg uninstall -r security/centrifyda

   To uninstall more than one package or all installed packages, enter the package names separated by a space. For example:

   pkg uninstall -r security/centrifyda security/centrifydc-curl security/centrifydc-ldapproxy

2. You can run the following command to verify the Solaris agent package IPS installation status:

   pkg info l grep -i centrify

   Note the space between "pkg" and "info"; if you search for "pkginfo" you'll be searching for svr4 packages.

Sun Solaris Installation Notes

This section describes the unique characteristics or known limitations that are specific to using authentication service on a computer with the Solaris operating environment.

Changing the Local User Password on Solaris

On Solaris, the passwd command is designed to update the databases listed in the nsswitch.conf file or the specific repositories you indicate with the -r option. Therefore, by default, you can use passwd command without any command line options to update your password wherever necessary.

Once you install authentication service and join the domain, however, Active Directory becomes the primary repository for user account information and changing the password for any local user account you need to maintain outside of Active Directory requires you to explicitly specify the repository to update with the -r option.

For example, if you want to change the password for a local user account in /etc/passwd, you must specify the files repository when you run the passwd command:

passwd -r files user

If you want to update the password for an Active Directory user account, you can use the passwd command without the repository option on Solaris 10. For example:

passwd adusername

If you are using an earlier version of the Solaris operating environment, however, you must use the adpasswd command that is installed with authentication service to update the password for Active Directory user accounts. For information about using adpasswd, see the adpasswd man page or the Administrator's Guide for Linux and UNIX.

Installing Authentication Service Packages into Solaris 10 Zones

All zones should be up and running during an upgrade from a previous release of Server Suite Authentication Service and its add-on packages (for example sudo or Server Suite for Web Applications) should not be installed directly into a sparse zone, they should be installed from the global zone only.

Installing Authentication Service Packages into Solaris 11 Child Zones

You need to install SVR4 packaging tools in the child zone before authentication service can be installed.

To check if the SVR4 package has been installed, run

$ pkg info svr4

If it is not installed yet, run the following to install it:

$ pkg install pkg:/package/svr4

Note that the command above may need internet connection (depends on how the IPS repository is configured in the zone).

Creating a Home Directory for New Users on Solaris

In most operating environments, when new users log on successfully, the authentication service will automatically create the user's home directory. On Solaris, however, the home directory is typically auto-mounted over NFS, so the option to automatically create a new home directory for new users is off by default. You can turn on this feature, if suitable to your environment, by adding the following to /etc/centrifydc/centrifydc.conf:

```
pam.create.homedir: true
```

With this flag, the first time a user logs in the home directory will be created. The user will see the message "Failed to create home directory", but this can be ignored.

In Express mode use auto.schema.homedir to specify the home directory for users. Use % as a placeholder for a user's name.

For example:

```
auto.schema.homedir: /export/home/${user}
```

Planning to Use Server Suite Zones

One of the most important aspects of managing computers with Server Suite software is the ability to organize computers, users, and groups into **zones**. This section discusses the primary reasons for using zones and provides an overview of how to analyze and migrate an existing user population into zones, including an introduction to assigning roles that enable users to access computer resources. These topics will then be described in greater detail in the next sections to help you create an initial zone structure and migrate users and groups for a target set of computers.

Why Use Zones?

A zone is similar to an Active Directory organizational unit (OU) or NIS domain. Zones allow you to organize the computers in your organization in meaningful ways to simplify the transition to Active Directory and the migration of user and group information from existing identity stores. The primary benefits to using zones are:

- Identity management through user and group profile definitions
- Access and authorization control through rights and role definitions
- Delegated computer management for zone-based administrative tasks

Zones also enable you to centrally manage configuration policies for computers and users through group policies, but for most organizations the key considerations for designing a zone structure involve:

- Identity management because zones enable you to migrate from a complex UID space, where a user can have multiple UIDs or different profile attributes on different computers or a single UID might identify different people depending on the computer being used. With zones, you can associate multiple UNIX profiles with a user and identify the correct profile attributes for any user on any given computer.
- Access and authorization management because zones enable you to grant specific rights to users in specific roles on specific computers. By assigning roles, you can control who has access to which computers.
- Delegated computer management because zones enable you to assign specific administrative tasks to specific users or groups on a zone-by-zone basis, allowing you to establish an appropriate separation of duties. With zones, administrators can be given the authority to manage a given set of computers and users without granting them permission to perform actions on computers in other zones or access to other Active Directory objects.

In most organizations, the first goal in designing the zone structure is to migrate users and computers from an existing identity store, such as NIS, NIS+, local files, or LDAP, to Active Directory and to do so with the least possible disruption to user activity, business services, and the existing infrastructure. Over time, you can also use zones to organize computers along departmental, geographical, or functional lines using whatever strategy works best for your organization.

Although Server Suite supports a **workstation mode** that does not require you to create and manage zones—a single Auto Zone is defined instead—most organizations find using zones to be an essential part of their migration to Active Directory. The next sections provide more information about why zones are an important part of the planning process. For more information about using Auto Zone, see Deploying to a single Auto Zone.

Identity Management Using Zones

For most organizations, it is impractical to attempt to rationalize user accounts across the enterprise to achieve a single global UID for each user. For example, most organizations have multiple identity stores already in use on their current UNIX platforms. These identity stores may include LDAP directories, NIS or NIS+ domains, and local /etc/passwd and /etc/group configuration files. With these multiple identity stores, it is common for a single user to have a different user name, UID, group memberships, or other attributes defined for different computers.

Zones allow you to import the information from these legacy identity stores without consolidating the multiple profiles that each user may have. For example, a single user might have an account in a UNIX LDAP directory, another defined in a NIS domain, and one or more local /etc/passwd files. Zones enable the profiles from these different identity stores to map to a single Active Directory user account without changing the user profile defined in each of the legacy directories. By keeping the profiles intact, the user's file ownership and log in permissions are not affected by the migration to Active Directory, making the transition from a legacy system to Active Directory more transparent to end users and less of a management burden for the deployment team.

Role-based Access Control and Zones

As a practical matter, you may choose to use Server Suite zones to ease migration to Active Directory by creating a separate zone for each legacy identity store. However, you can also use zones to group computers by department, by function, or by any other criteria you choose. Using zones in this way gives you a great deal of flexibility in controlling who has access to the UNIX, Linux, and Mac OS X computers in your environment and makes it easier to set up account information for new users based on job function or other criteria.

Through role assignments, zones provide a scope of resources particular users can access, allowing you to define who can do what on which computers. For example, all of the computers in the finance department could be grouped into a single zone called "finance" and the members of that zone could be

restricted to finance employees and senior managers, each with specific rights, such as log on to a database, update certain files, or generate reports. This gives you better control over access to systems based on well-defined roles. You can also limit access to certain types of applications, such as database management utilities or web services. For example, you can define specific actions specific users are allowed to perform by assigning them different roles in different zones.

Using Zones to Delegate Administrative Duties

Zones can also be useful for grouping computers that form a natural administrative set or that should be managed by different administrative teams. For example, you may want to group computers that are managed by a local support organization in one zone and computers that are managed by a corporate IT group in another zone.

Using zones, you can then control what different groups of users can do within the zones they have permission to access. For example, you can set up regional zones to provide a separation of duties, authorizing users in San Francisco to manage computers and user profiles in their local office while a team in Barcelona has authority to join computers and manage group profiles for offices located in Spain.

Zones provide a convenient way for you to assign individual administrative responsibilities to specific users or groups based on a set criteria, such as department, geographic location, or functional role.

Deploying to a Single Auto Zone

In most cases, if you are deploying on Linux or UNIX computers and have an existing user population to migrate to Active Directory, you would create a hierarchical zone structure of multiple zones. However, multiple zones are not required for all situations. You can greatly reduce the time required and complexity of your deployment if a single zone suits your organization's needs. For example, if you are deploying on Mac OS X or Windows computers or if you have a mix of computer platforms but do not have an existing user population to migrate, you might benefit from deploying agents using the Auto Zone option.

With Auto Zone, you have a single zone for an entire forest. All of the users and groups you have defined in Active Directory for the forest automatically become valid users and groups on the computers that join the Auto Zone. If the forest has a two-way trust relationship with another forest, all Active Directory users defined in that trusted forest are also automatically valid on computers that join the Auto Zone.

If you simply want to use the Active Directory users and groups you have already defined on the nonWindows computers you manage, you can skip the planning and creation of zones and simply add computers to the Auto Zone when you join the domain. The UNIX profile attributes that are required to access computers in the Auto Zone are then automatically derived from user attributes in Active Directory or from settings defined in group policies or configuration parameters.

> **Note**: You cannot use Auto Zone to give automatic access to users and groups in a forest or domain with a one-way trust relationship with another forest or domain.

You can use Auto Zone without enabling any group policies or changing any of the default configuration settings. You can also join a domain through the Auto Zone without installing Access Manager. However, you can use group policies or configuration parameters to specify a subset of Active Directory users or groups as valid Auto Zone users. The settings are then enforced on computers in the Auto Zone.

Using Auto Zone can make sense in small or larger organizations if you are not migrating existing users and groups or maintaining legacy UNIX profile attributes. However, if you use Auto Zone, you cannot use zone-specific features. For computers in the Auto Zone, you cannot configure rights and roles, assign roles to users and groups, or provide different profile attributes on different computers.

For information about joining a domain using Auto Zone, see the man page for adjoin or the *Administrator's Guide for Linux and UNIX*. For information about using group policies or configuration parameters, see the *Group Policy Guide* or *Configuration and Tuning Reference Guide*.

Classic and Hierarchical Zones

If you plan to deploy using zones—which is the most common deployment model—you have to option to create **classic** or **hierarchical** zones. Classic zones provide a simple model for organizing computers and backwards compatibility for organizations with older versions of the Server Suite Agent. Hierarchical zones enable you to establish parent-child zone relationships, allowing profile attributes, rights, and roles to be inherited down the zone hierarchy. Classic zones are peers to each other and do not inherit profile attributes, rights, or roles from each other.

One of the first decisions you need to make in planning your zone structure is whether you will use classic zones, hierarchical zones, or some combination of both.

Should You Use Classic Zones?

Classic zones provide a simple structure for delineating users and groups based on a criteria you choose, such as by region or department. They are most

appropriate if you have a well-defined and well-managed UNIX namespace with very few users who require special handling because of multiple profiles or conflicting profile attributes.

Classic zones are simple to manage as long as you only need a few. For example, imagine you have three regional zones with no users in common that are managed independently by their own zone administrators with only one enterprise system administrator who must have a profile in each zone. In that scenario, classic zones provide a simple solution because only one user account, the enterprise system administrator, must have a profile in each zone.

However, classic zones are very limited in complex environments where users need profiles in multiple zones or where there are multiple independently-managed UNIX namespaces to migrate to Active Directory. That is because classic zones do not share data across zone boundaries. The data must be created and managed in each zone independently. By contrast, hierarchical zones support inheritance, enabling you to create parent and child zones that share information as needed. Because classic zones do not support inheritance, you cannot use variables to define profile attributes or any other hierarchical zone features.

For most organizations, classic zones are primarily used to enable a new zone that works with pre-5.0 versions of the Server Suite Agent. If you have an older version of Server Suite software installed and already have some zones deployed in your environment, you can continue to use those zones as-is. After upgrading, you then have the option to create any new zones as classic zones to operate within the legacy zone environment or as hierarchical zones.

> **Note**: If you already have zones deployed, you can convert them to hierarchical zones after you deploy the new version of Server Suite software, if you choose to do so. However, there's no requirement for you to convert existing zones to hierarchical zones.

When Should You Use Hierarchical Zones?

For most organizations, Server Suite recommends that you use hierarchical zones for all new zones that you create. Hierarchical zones provide greater flexibility to inherit profile information, rights and role definitions, and user and group role assignments.

Because hierarchical zones allow you to share or override information at any point in the hierarchy, they also allow you to design a simpler zone structure than classic zones and support an easier deployment model. Typically, a simpler zone structure is easier to manage, but hierarchical zones also allow you to implement a very sophisticated zone structure to address complex access control rules, if you so choose.

How Many Zones Do You Need?

The goal in planning to use zones is to have a fairly small number of zones that organize the computers and users in your organization most effectively. As an example, consider an organization where some UNIX computers are used to host financial applications. Those computers are centrally managed by the IT organization, which follows well-established conventions for issuing user login names, user IDs, and home directories. The same organization has a software development group that includes numerous UNIX workstations that are not centrally managed by the IT organization and computers and accounts are added when needed and managed independently.

Because enterprise-wide conventions are not enforced for the UNIX computers in the software development group, it's possible that the local login names and user IDs may conflict with the names and IDs used on the computers running the financial applications. In addition, users in the software development group may use a different convention for their home directories or prefer different login shells.

Without zones, the IT organization would need to eliminate any duplicate user IDs and verify each login name was unique across all of the computers. By placing the computers running the financial applications in one zone and the computers in the development lab in another zone, the IT organization can avoid the overhead of checking and changing existing account information and can set default zone settings, such as different default home directories or login shells, that are most appropriate to the users in each zone.

There are many different approaches you can take to defining the scope of a zone, including organizing by platform, department, manager, application, geographical location, or how a computer is used. The factors that are most likely to affect your initial zone design, however, will involve migrating user and group profiles, identifying the appropriate access control policies and role assignments, and delegating administrative tasks to the appropriate users and groups. For many organizations, the most important issue during the initial deployment is a successful migration of existing users. Using hierarchical zones with the ability to override attributes simplifies this task, helping to reduce the total number of zones you need to deploy.

A Closer Look at Using Zones in a Hierarchical Model

In older versions of Server Suite software, zones were always parallel with each other and did not share or inherit data except through manual processes. Starting with Infrastructure Services 2012, however, you have the option to use hierarchical zones that support the inheritance of user and group data and provide a great deal of flexibility for defining the rights and roles for who can access which computers and what those users can do on the computers to which they have access.

How Inheritance Provides Additional Benefits

As discussed in Why use zones?, the primary benefits to using zones are:

- Identity management through user and group profile definitions
- Access and authorization control through rights and role definitions
- Delegated computer management for zone-based administrative tasks

Hierarchical zones provide additional flexibility for each of these benefits. For example, because hierarchical zones allow inheritance, hierarchical zones enable you define partial profiles and use variables that can be substituted at run-time when a user accesses a specific computer in a particular zone. Hierarchical zones also enable you to define access control rules and delegate administrative tasks at any point in the zone hierarchy.

This flexibility makes planning for hierarchical zones a key component of a successful deployment.

How Many Levels Should You Use in the Zone Hierarchy?

There are no predefined limits to the number of zones that can be used in a zone hierarchy or the number of levels deep zones can be nested in the hierarchy you define. For practical purposes, however, it is recommended using a hierarchy similar to the following:

- One or more top-level **parent** zones that include basic profile information for all users and groups that access the UNIX, Linux, and Mac OS X computers.
- One to three levels of intermediate **child** zones based on natural access control or administrative boundaries.

At each level in the hierarchy, profile information and access controls are inherited from the zone above and either applied or overridden by the child zone settings. At the lowest level of the hierarchy, you can override profile attributes or role assignments on any individual computers using **machine override** settings, if needed.

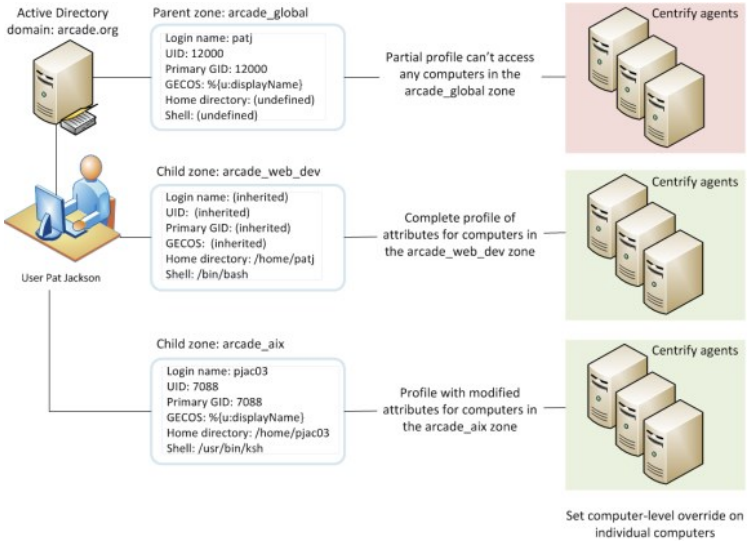
In addition, hierarchical zones support computer-based access rules, called **computer roles**, that enable you to selectively map a set of users with a particular role assignment access to a particular set of computers.

Identity Management and Inherited Profile Information

User and group profiles specify attributes such as the UID, primary group, home directory, and shell that are required for logging on to UNIX computers. You can specify all or part of the profile anywhere in the zone hierarchy, but users must have a complete profile to access computers they have permission to access. If the user or group profile is incomplete, it is invalid and ignored.

Working with Partial Profiles in the Zone Hierarchy

The profile information in the zone hierarchy is resolved from top to bottom for each user. For example, assume the user Pat Jackson has the login name patj and UID 12000 defined in the parent zone arcade_global and those profile settings are inherited without change, along with a default shell, home directory and other properties that are defined in the child zone arcade_web_dev. In a second child zone, arcade_aix, the UID for patj is set to 7088 to override the inherited UID. Changes to the profile properties can be made in any zone and inherited down the tree down to overrides set for specific individual computers, if needed.



Working with Variables in the Zone Hierarchy

Partial profiles enable you define a subset of profile attributes for users and groups that can be completed by lower level zones in the zone hierarchy. You can also define variables for resolving profile attributes. The variables are then substituted at run-time by adclient. For example, adclient can resolve the variable %/% to a platform-specific home directory for each user without having the attribute manually defined. You can set the variables at any level in the zone hierarchy, and they are inherited and resolved, or can be overridden, at a lower level in the tree.

You should note that variables can only be used to define profile attributes in hierarchical zones. You cannot import them or use them in classic zones.

Complete Profiles Do Not Grant Access

Creating user profiles in a zone does not give users access to any computers in the zone. The zone hierarchy simply creates a set of profiles with the potential to be granted access to computers. In previous versions of Server Suite software, enabling a UNIX profile for a user in a zone granted that user access to the computers in that zone by default. With hierarchical zones, the profile information only establishes the required properties for the user's identity, but does not grant access to any computers in any zones.

Access to computers is controlled through the definition of rights and roles.

Access Controls and the Assignment of Rights and Roles

A user must have a complete UNIX profile to log on to any computer in a zone. However, a complete profile alone does not allow a user to access any computers. The user must also have at least one role assignment that grants access somewhere in the zone hierarchy before any type of access is granted. Role assignments can be made anywhere in the zone hierarchy and inherited at a lower level in the tree.

Understanding Roles and Rights

Rights represent specific operations users are allowed to perform. A **role** is a collection of rights that can be defined in a parent or child zone and inherited. For example, a role defined in a parent zone can be used in a child zone, in a computer role, or at the computer level.

There are only a few predefined rights, called system rights. The system rights for Linux, UNIX, and Mac OS X are:

- **Password login and non password (SSO) login are allowed**: Specifies that a user is allowed to log on interactively using a password or without a password using a single sign-on token.
- **Non password (SSO) login is allowed**: Specifies that a user is allowed to log on using a single sign-on token.
- **Account disabled in AD can be used by sudo, cron, etc.**: Specifies that an account that is disabled is allowed to access the computer. This right enables service accounts that run without a password to perform operations.
- **Login with non-Restricted Shell**: Controls whether a user gets a full shell or is forced into a restricted shell. Users must be assigned at least one role with this right to have access to a standard shell environment. A restricted shell only allows a user to execute explicitly defined commands.

The system rights for Windows computers are:

- **Console login is allowed**: Specifies that users are allowed to log on locally using their Active Directory account credentials.
- **Remote login is allowed**: Specifies that users are allowed to log on remotely using their Active Directory account credentials.

In addition to the platform-specific system rights, there is a common system right that allows users to bypass auditing or role restrictions to log on when there are problems on a computer. The **Rescue rights** option allows you to specify the users who can log on if problems with the authorization cache or the auditing service on a computer are preventing all other users from logging on.

You grant users permission to access computers by assigning them to a role that includes one or more access rights. By default, zones only contain the following predefined roles to grant basic access rights:

- **UNIX Login** role allows users assigned this role to log on and access UNIX computers in the zone.
- **Windows Login** role allows users assigned this role to log on and access Windows computers in the zone.

There are additional predefined roles that grant specific rights, such as the right to log on if auditing is required but not available. The predefined roles exist in each zone, but their role names are qualified by the zone name so that the same role name in a parent zone and a child zone are considered different roles. For deployment, the predefined roles enable you to migrate existing users without developing custom role definitions. After deployment, you can define additional rights, roles, and role assignments to refine how users and groups access computers in different zones.

Working with a Candidate Set of Profiles

Ultimately, the purpose of the zone structure is to determine who has access, and what kind of access, to a computer. The candidate set of profiles that have the potential to access a computer is resolved by traversing the zone hierarchy from top to bottom. Because profile data is defined separately from the role assignments that control access, you can define an inclusive set of user profiles in a parent zone to create a candidate set that can then be applied to multiple child zones. In each child zone or at the individual computer level, you can use role assignment to control access for specific users from the inclusive candidate set.

Delegation in Hierarchical Zones

Hierarchical zones enable you to create a separation of duties for zone administration without recreating user and group profiles in multiple child zones. You can create full or partial profiles in the parent zone and inherit them into the child zone. Within each child zone, zone administrators can modify the profiles, as needed, and assign roles to control access to the computers they manage.

Designing a Zone Structure for Your Environment

Because the flexibility of hierarchical zones is a key element in designing the zone structure for your deployment, the next sections describe how to set up and use parent and child zones through sample deployment scenarios. The scenarios illustrate a basic deployment model, which will then be used to discuss how to migrate existing users and groups to Active Directory.

Your own zone structure and deployment model can be more complex than the one described in this guide. However, the deployment model described in the next sections is intended to ensure that you have a successful initial deployment. Over time, it is likely that you will change and adapt the zone structure to requirements that are specific to your organization. There are also multiple ways to accomplish the tasks described in the next sections of this guide. You can use other strategies and techniques for deployment if appropriate for your organization.

Preparing To Migrate Existing Users And Groups

This section describes how to prepare your environment for migration and computer access, including how to create and configure the initial zones. This chapter also describes how to import existing account information into Active Directory, set up provisioning for new users and groups, and configure role-based access controls.

Collecting And Analyzing Users and Groups

Before you create any zones, you should collect and analyze information about existing users and groups in the target set of computers. After you have investigated user and group attributes and identified invalid accounts and conflicting attributes, you can draft a basic zone design that addresses the needs of that user population. The goal of the initial zone design is to provide access to those users who currently have access, so they can transition to Active Directory with no disruption to their work. Later, you can refine access to computers through role assignments, filtering, and other options, if needed.

Collecting Information from Other Departments in Your Organization

Before you look at the content of identity stores you want to migrate, you should consider other sources of information that will help you identify a definitive set of legitimate users. For example, it can be useful to contact people in other departments who have reliable knowledge about the current organization or historical knowledge about how the organization has evolved. Individuals with information about a segment of the user population can help you identify accounts that are obsolete or were created for testing, or belong to users who have left the company or moved to another department.

As a starting point for collecting information about existing users and groups, consider doing the following:

- Contact HR to get an up-to-date list of current active-duty employees, contractors, and consultants. You can use this information to compare personnel records to the UNIX accounts to be migrated. After you identify which accounts correspond to people in the organization, you can create a spreadsheet to record the UNIX user names, UIDs, and other useful fields for those accounts.
- Contact enterprise security administrators or department-level UNIX administrators to determine whether all of the accounts defined for a computer still need access to that computer. For example, you should determine if any users validated as current employees have changed departments or job functions. If a user no longer needs access to some computers, you may not need to add a profile for that user.
- Identify any conventions used in defining the namespace. For example, is there a standard format for the contents of the GECOS field? How do the conventions used for UNIX, Linux, or Mac OS X accounts compare to the conventions used in Active Directory? For example, is the convention used for the UNIX login name the same as the convention used for the user's sAMAcountName in Active Directory? Does the GECOS field follow the same conventions as the user's displayName in Active Directory?
- Identify which user attribute fields that can be used as primary keys for identifying a unique user. Depending on the conventions you use for creating new accounts, the user name, user identifier (UID), or the GECOS field may be a reliable field for identifying real users and mapping them to Active Directory accounts. If you use a standard provisioning convention across platforms for an attribute such as the GECOS field or user name, the convention makes it much easier to identify unique users and map user profiles to Active Directory accounts.

Using a Script to Retrieve User and Group Profiles for Each Computer

Alternatively, you can write a script to retrieve all of the /etc/passwd and /etc/group files in the target set of computers. For example, to create a hostname.passwd and hostname.group file for each computer in a target set of computers, you might use code similar to the following:

```
for name in `cat hostname.txt`; \
do scp $name:/etc/passwd $name.passwd; \
scp $name:/etc/group $name.group; \
done
```

This sample script includes the computer host name in the file name, so that you can determine which user and group definitions came from which computer. If you use a script to collect user and group information, copy all of the files generated by the script to a common location for analysis.

Collecting Data from NIS Domains

If you're migrating users and groups from a NIS domain, you can use ypcat or niscat to generate a copy of the NIS passwd and group maps once for each NIS domain. For example, run commands similar to the following:

```
ypcat passwd > `domainname`.passwd
ypcat group > `domainname`.group
```

If you are collecting user and group information from NIS maps, copy all of the files generated by these commands to a common location for analysis.

Identifying Accounts that Should Not Be Migrated

After you have collected information about the existing users and groups in the target set of computers, examine each of the passwd and group files and NIS domain maps to create a list of users and groups that you do not plan to migrate into Active Directory. For example, in most cases, there's no compelling business reason to migrate default system accounts, such as nfsnobdy or games, that will not map to Active Directory users. You should also eliminate accounts for people who have left your organization, and accounts that are locked or obviously invalid.

Eliminate Default System Accounts

In most cases, you can ignore all UNIX users with a UID less than 99 because those are the default operating system accounts. You may also want to skip migration for some or all UNIX service accounts unless you explicitly want to manage those service accounts, and any privileged commands they run, through Active Directory and zones.

You can manage the passwords for UNIX service accounts using Access Manager without having those accounts defined in zones or in Active Directory. Therefore, you may want to leave most or all of the service accounts as locally defined accounts.

In general, the only reasons to migrate default system or service accounts to Active Directory are:

- If you want to use Active Directory password policies for the account.
- If the service account itself owns one or more privileged commands that you want to manage through Centrify role definitions rather than locally in the sudoers file.

Typically, only service accounts that own special permissions, such the oracle user account, are migrated to Active Directory.

Remove Other Invalid Accounts

You should also skip migration for users who have left the organization and profiles that contain invalid data. Scan the data set for user accounts and groups that are locked or indicate they were created for testing. You should also check for profiles that contain obvious errors or legacy information no longer used.

In some cases, you may need to contact workstation or application owners directly to determine whether a profile should be skipped for migration. For example, assume the /etc/group file contains an entry for clowns with krusty, bozo, and tadams as members and there are valid user profiles for those three users. You may suspect the clowns group was created for some local testing, and therefore, not a candidate for migration. However, there's no definitive indication that the clowns group should be skipped without more information.

Create a List of the Users and Groups to Ignore

Add all of the accounts that should not be migrated to a text file. For example, create a text file named user.ignore and include all of the user accounts you don't want to migrate into Active Directory. For default system and service accounts that have known UIDs, you can create the text file programmatically using code similar to the following:

```
cat *.passwd | \egrep "x?:[0-9]:[0-9].|x?:[0-9][0-9]:[0-9].|x?:60[0-9][0-9][0-9]:[0-9]|x?:65[0-9][0-9][0-9]:[0-9]" | \
cut -d ":" -f1 | \
sort | \
uniq | \
sed 's/^/\^/' > user.ignore
```

Other accounts you have identified as invalid can be added manually or using code if they share some common attribute, such as LOCKED in the password field.

Analyze User Profiles for Conflicting Attributes

After the initial analysis to remove profiles that should not be migrated, you have a candidate data set of users and groups to import. The next step is to analyze the attributes in user profiles to identify any potential problems that you will need to address when you move the profiles into zones. Delinea Professional Services offers scripts that assist in this process. If you are analyzing the files manually or writing your own scripts, here are the common issues you need to check for:

- Determine whether any user name has more than one UID in the target set of computers. The UID is the primary way of determining file ownership and file permissions. On a single UNIX system, a user can only have one UID. However, across all of the computers in the target set, the same user name might have more than one UID.
- Determine whether any UIDs are associated with more than one user name.
- Determine whether any users have other profile conflicts, such as more than one primary GID, home directory, or shell on the computers in the target

set.

In doing your preliminary analysis, keep in mind that you need to know which user profiles are associated with which people in your organization. For example, do the user names ldavis and davle refer to the same person (Len Davis) or to different people (Len Davis and Leslie Davidson).

This analysis of existing user profiles will help you identify the requirements of your initial zone design. The zone design allows you to use conflicting attributes as-is, without modifying any of the legacy data. You need to be aware of where there are conflicts so you can address them, but you do not need to change values for any attributes.

Analyze Group Profiles for Conflicting Attributes

You need to perform a similar analysis across the groups in the target set of computers. Delinea Professional Services offers scripts that assist in this process. If you are analyzing the files manually or writing your own scripts, here are the common issues you need to check for:

- Determine whether any group name has more than one GID in the target set of computers. Like the UID, the GID affects file ownership and file permissions. On a single UNIX computer, a group name can only have one GID. However, across all of the computers in the target set, the same group name might have more than one GID.
- Determine whether any GIDs are associated with more than one group name.
- Determine whether any group has a different set of members on any computers in the target set. Group membership is particularly important for zone design. The members of a group must be consistent across all of the computers in a zone.

As with the user analysis, this analysis of existing group profiles will help you identify the requirements of your initial zone design. The zone design allows you to use conflicting attributes as-is, without modifying any of the legacy data. You need to be aware of where there are conflicts so you can address them, but you do not need to change values for any attributes.

Create a Working Set of User and Group Profiles

After you have identified profiles that should not be migrated and noted any conflicting attributes you need to address, you have a known set of user and group profiles that you plan to migrate into Active Directory. The next step is to remove the users who should be ignored from list of users to import, and to remove the groups that should be ignored from the list of groups to import. You can do this manually or write a script that removes the profiles defined in the user.ignore and group.ignore files and outputs the results to a new file. For example, you might use code similar to the following to remove ignored users and generate a working set of user profiles:

```
mkdir output; \
for name in `cat hostname.txt`; \
do egrep -v -f user.ignore $name.passwd > \output/$name.passwd; \
done
```

How Migration Affects the Zone Design

As discussed in Why use zones?, identity management is one of the primary benefits of using zones. Identity management is important because most organizations have an existing user population where users can have multiple UIDs or other attributes, such as different default shells, on different computers and groups with the same name can have different members. Each user has one Active Directory user object but may have multiple UNIX profiles, some with attributes in common and some with different settings. Zones allow you to migrate the profile information as it is defined, setting overrides where necessary, so that you can manage and report on the accounts without rationalizing the user namespace.

For all of the computers in a zone, a user or group has one profile definition, but the user or group could have different profile attributes on the computers in a different zone. Hierarchical zones make the zone design even more flexible. Hierarchical zones allow you to define one or more profile attributes in a parent zone and use those profile attributes in all child zones. In practice, this enables you to define a dominant set of attributes in a parent zone, and inherit the common attributes in one or more child zones. You can also override any attribute at any point in the zone hierarchy down to an individual computer.

For example, if a UNIX administrator has a consistent profile across all of the UNIX computers, but a customized home directory on two Mac OS X computers, you could define the default profile for the user in a parent zone, then create a child zone for the Mac OS X computers and inherit all of the profile attributes except the home directory setting.

In planning the migration, you identify the attributes that are the same across the target set of computers and where there are differences. If you use hierarchical zones, the primary task is identify one or more potential parent zones. For example, if you are migrating two NIS domains, you might create two parent zones because the UID space is unique in each domain but there would be conflicting attributes if the domains were combined into a single parent zone. The computers in each of the parent zones would inherit the UID and other profile attributes from each distinct NIS domain.

After you have identified one or more parent zones, you can plan how you will use child zones and overrides to manage profile attributes, implement access

controls, and delegate administrative duties.

Creating the First Zone

It is recommended that you plan to use hierarchical zones and create at least one top-level parent zone. A single top-level zone for your organization is also useful for long-term management of UNIX profiles. You can have more than one top-level parent zone. For example, if your organization has subsidiaries that are run independently or distinct geographical locations managed by different teams, you may want to create separate parent zones for those lines of business or locations.

Having a single top-level parent zone enables you to create an administrative group of super-users who can log on to every UNIX computer in your organization. It also allows to define some common rights and roles that can be inherited by child zones and the computers in those zones. Having a global or master zone for the entire organization also simplifies setting up provisioning for new accounts. However, there's no restriction on the number of parent or child zones you create. If you have a distributed environment and delegate administrative authority to separate teams, you can create as many parent zones as you find useful.

This guide describes how to set up the migration environment using one top-level parent zone. If you create more than one parent zone, you may need to repeat steps or extrapolate additional steps from the information presented here.

Create a Top-level Parent Zone

Before you migrate users and groups or add computers to the domain, you must have at least one zone. It is recommended that you create one top-level parent for your organization, which is similar to having a single forest root domain.

To create the top-level parent zone

1. Log on to the Windows computer where Authentication & Privilege is installed and open Access Manager.

   If you are not currently connected to the appropriate forest, specify the domain controller to which you want to connect.

2. In the console tree, select **Zones** and right-click, then click **Create New Zone**.

3. Type the zone name and, optionally, a longer description of the zone.

   In most cases, you should use the default parent container and container type that you created when you configured the Active Directory forest, and the default zone type, which creates the new zone as a hierarchical zone, then click **Next**.

   The only reasons for changing the default settings would be if you want to:

   - Create a zone in a new location to separate administrative activity for different groups of administrators.
   - Create zones as organizational units because you want to assign group policy objects to zones.
   - Create a classic zone for backwards compatibility or are using the Microsoft Services for UNIX (SFU) schema.

     For additional details about any of the zone fields, press F1 to view context-sensitive help.

4. Review the information about the zone you are creating, then click **Finish**.

Add Provisioning Groups to the Parent Zone

The next step in configuring the top-level parent zone is to create two Active Directory groups that will enable automated provisioning and de-provisioning of users and groups in the toplevel parent zone. By creating these provisioning groups in the parent zone, you can integrate the provisioning of UNIX users and groups with your existing processes for provisioning Active Directory users.

The provisioning groups are not required for migration, but a recommended configuration for the top-level parent zone you are creating as the first zone in the environment.

It is recommended you follow the naming conventions suggested for these groups. If you use a different naming convention, you should be sure it is well documented in your internal process documentation.

To add the provisioning groups for user and group profiles to the parent zone

1. Start Active Directory Users and Computers.
2. Expand the forest domain and the top-level UNIX organizational unit you created in Selecting a location for the top-level OU.
3. Select Provisioning Groups, right-click, then select **New > Group**.
4. Type the group name using the format ZoneName_Zone_Groups. For example, if the zone name is arcadeGlobal, type arcadeGlobal_Zone_Groups, then click **OK**.

   The Zone Provisioning Agent will use this group when processing the business rules for adding or removing group profiles in the parent zone.
5. Select Provisioning Groups, right-click, then select **New > Group**.
6. Type the group name using the format ZoneName_Zone_Users. For example, if the zone name is arcadeGlobal, type arcadeGlobal_Zone_Users, then click **OK**.

   The Zone Provisioning Agent will use this group when processing the business rules for adding or removing user profiles in the parent zone.

To prevent problems in UIDs and GIDs for existing users and groups, you should import existing user and group profiles before defining the business rules for automated provisioning of new accounts. After you complete the migration of the existing user population, you will define the business rules for the ZoneName_Zone_Groups and ZoneName_Zone_Users groups you just created.

Create Groups for the Default Roles in fhe Parent Zone

The next step in configuring the top-level parent zone is to create two Active Directory groups for the default listed and UNIX Login roles that are predefined in hierarchical zones.

- If you have a single top-level parent zone, users with a listed role can be recognized as having a valid profile on every UNIX computer in the organization. However, users in the listed role are not allowed to log on to any of those computers.
- If you have a single top-level parent zone, users with a UNIX Login role can log on to every UNIX computer in the organization.

For the toplevel parent zone, the UNIX Login role is intended for enterprise-level systems administrators who need to be able to log on to any UNIX computer in the organization. Because these are powerful roles in the parent zone, only a limited number of users would ever be assigned to these roles. However, the listed and UNIX Login roles are key components of migration when you create one or more child zones. If no users in the organization will be assigned these roles in the parent zone, you can skip the creation of the Active Directory groups for roles in the parent zone.

To create the groups for listed and UNIX Login roles in the parent zone

1. Start Active Directory Users and Computers.
2. Expand the forest domain and the top-level UNIX organizational unit you created in Selecting a location for the top-level OU.
3. Select the User Roles organizational unit, right-click, then select **New > Group**.
4. Type the group name using the format ZoneName_Role_RoleName. For example, if the zone name is arcadeGlobal, type arcadeGlobal_Role_Listed, then click **OK**.
5. Select the User Roles organizational unit, right-click, then select **New > Group**.
6. Type the group name using the format ZoneName_Role_RoleName. For example, if the zone name is arcadeGlobal, type arcadeGlobal_Role_Login, then click **OK**.

Delegate Administrative Tasks on the Parent Zone

The next step in configuring the top-level parent zone is to delegate administrative authority to the Zone Administrators group and to delegate specific permissions to the service account for the Zone Provisioning Agent to enable automated provisioning of user and group profiles in the parent zone.

To delegate administrative tasks on the top-level parent zone

1. Start Access Manager.
2. In the console tree, expand the **Zones** node.
3. Select the top-level parent zone, right-click, then click **Delegate Zone Control**.
4. Click **Add**.

5. Change the Find list from User to **Group**, type z, then click **Find Now**.
6. Select Zone Administrators in the results, then click **OK**.
7. Click **Next**.
8. Select **All** to enable members of the Zone Administrators group to perform all administrative tasks on the top-level parent zone, then click **Next**.
9. If you are delegating the task of joining computers to a zone, you can specify the scope of computers you can join to the zone; you pick a container in Active Directory to grant access to.

   If you leave the scope blank, the scope is the domain root. Be aware that the postalAddress field is used for information about joining computers to a zone; if you lookup the permissions for people you've delegated the task of joining computers to a zone, they'll have permissions to the postalAddress field for the affected computers.
10. Review your selections, then click **Finish**.
11. Right-click, then click **Delegate Zone Control**.
12. Click **Add**.
13. Type all or part of the service account name for the Zone Provisioning Agent that you created in About Zone Provisioning Agent and its requirements, click **Find Now**, then select the service account in the results and click **OK**.
14. Click **Next**.
15. Select the following delegation rights for the Zone Provisioning Agent service account, then click **Next**:
    - Change zone properties
    - Add users
    - Add groups
    - Remove users
    - Remove groups
16. Review your selections, then click **Finish** to save the changes and close the dialog.

Link a Role Group to a Role Assignment in the Parent Zone

The next step in configuring the top-level parent zone is to link the Active Directory role groups created in Create groups for the default roles in the parent zone with the listed and UNIX Login role definitions that are predefined in the parent zone. You create this link between an Active Directory group name and the combination of rights associated with a role name by assigning the Active Directory group to the role.

1. Start Access Manager.
2. In the console tree, expand **Zones**, the top-level parent zone, and Authorization nodes.
3. Select Role Assignments, right-click, then click **Assign Role**.
4. Find the ZoneName_Role_Listed Active Directory group, then click **OK**.
5. Click **Browse**.
6. Select the listed role from the list of available roles, then click **OK**.
7. Check that the Start immediately and Never expire options are selected and appropriate or deselect those options and set start and end times, then click **OK**.
8. Repeat Step 3 through Step 7for the ZoneName_Role_Login Active Directory group and the UNIX Login role.

Create One or More Child Zones

After you have created a parent zone and prepared it with provisioning and role groups, you can create one or more child zones. You can create the child zones based on any logical model you choose. This is where the analysis of common and conflicting attributes and some creativity come into play.

Logical Models for Defining Zones

Because the zone design uses hierarchical zones, you can override attributes at any zone or computer level to deal with conflicts in legacy profile data. With this flexibility, you can experiment with different possible designs, for example, based on delegated administrative authority or physical location. Some common models for grouping a set of computers, users, groups, roles, and rights in the same zone include:

- **By shared identity store** For example, existing identity stores, such as NIS domains or a centralized user and group database, often provide a natural boundary for zones. This strategy is especially effective if each identity store has a consistent namespace, without profile conflicts. It is less effective if the computers that share a common administrative group use local /etc/passwd and /etc/group file to store account information.
- **By application or function** For example, you might want to groups all of your database servers or web farm servers into their own zones. As part of this design, you might need to evaluate whether you are combining development computers with production servers and what role assignments you'll need to control what users can do on each type of computer.
- **By geographical region or line of business** For example, all of the UNIX computers that support a business unit could be logically grouped together. As part of this design, you might evaluate whether different business units should be responsible for provisioning users or assigning roles within their own business unit.
- **By host name** If you already have a meaningful host name convention that identifies machine owners or primary function, you may want to create zones based on that naming convention.
- **By platform and operating system** You can use this strategy, for example, to create separate zones for Red Hat Linux workstations and Sun Solaris UNIX workstations.
- **By department or user community** You can use this strategy, for example, to create separate zones for the computers that host financial applications and computers used by software developers.

You are not required to create child zones. You could control access to the parent zone through role assignments. For most organizations, however, one or more child zones makes it easier to assign roles and manage group membership.

Depending on your target set of computers, you may decide to start with one or two child zones or skip the creation of a child zone.

Create a Child Zone under the Parent Zone

Creating a child zone is similar to creating a parent zone. You select the parent in the left pane, then create and configure the child zone to prepare an environment into which you will migrate existing users and groups.

To create a child zone under the parent zone

1. Start Access Manager.
2. In the console tree, expand the **Zones** node.
3. Select the top-level parent zone, right-click, then click **Create Child Zone**.
4. Type a name and description for the child zone, then click **Next**.

   For example, if you are organizing by functional group, this zone might be finance or engineering. If you are organizing by data center location, the child zone might be sanfrancisco or seattle.
5. Click **Finish** to complete the zone creation.

The new zone is listed under the Child Zones node in the left pane.

Create Role Groups for Child Zones

The next step in configuring the child zone is to create two Active Directory groups for the default listed and UNIX Login roles that apply to this zone.

- In the child zone, users with a listed role can be recognized as having a valid profile but only on computers that are joined to the child zone. Users in the listed role for the child zone cannot log on to any of the computers joined to the child zone.
- In the child zone, users with a UNIX Login role are allowed to log on to every UNIX computer joined to the child zone if they have a UNIX profile for the zone.

For the child zone, the UNIX Login role is intended zone-level administrators and users who were previously able to log on to the UNIX computers joined to the child zone. The listed and UNIX Login roles are key components of migration when you create one or more child zones.

To create the role groups for listed and UNIX Login roles in the parent zone

1. Start Active Directory Users and Computers.
2. Expand the forest domain and the top-level UNIX organizational unit you created in Selecting a location for the top-level OU.
3. Select User Roles, right-click, then select **New > Group**.
4. Type the group name using the format ChildZoneName_Role_RoleName. For example, if the child zone name is sanfrancisco, type

sanfrancisco_Role_Listed, then click **OK**.
5. Select User Roles, right-click, then select **New > Group**.
6. Type the group name using the format ChildZoneName_Role_RoleName. For example, if the zone name is sanfrancisco, type sanfrancisco_Role_Login, then click **OK**.

Delegate Administrative Tasks on the Child Zone

The next step in configuring the child zone is to delegate administrative authority to the Zone Administrators group. The steps are the same for the child zone as the parent zone, except that you expand the Child Zones node and select the name of the child zone before selecting the Delegate Zone Control command. You should still assign the Zone Administrators group All permissions.

You also have the option of assigning the permissions to join or leave to the Join Operators Active Directory group. If you pre-create computer accounts and allow the computer to join itself to the Active Directory domain, you can skip this step.

If you don't want to pre-create the computer account and allow the self-service join, you must give members of the Join Operators group the following administrative tasks:

- Join Computers to the Zone
- Remove Computers from the Zone
- Modify Computer Profiles

Link Role Groups to Role Assignments in the Child Zone

The next step in configuring the child zone is to link the Active Directory role groups created in Create role groups for child zones with the listed and UNIX Login role definitions that are predefined in the child zone. You create this link between an Active Directory group name and the combination of rights associated with a role name by assigning the Active Directory group to the role. The steps are the same for the child zone as the parent zone, except that you expand the **Child Zones** node and select the name of the child zone before selecting the **Authorization** node.

When you search for the Active Directory group to assign, you will select the ChildZoneName_Role_Listed, for example sanfrancisco_Role_Listed, for the listed role, and ChildZoneName_Role_Login, for example sanfrancisco_Role_Login, for the UNIX Login role.

Users who are added to the ChildZoneName_Role_Login group will be able to log on to computers that are joined to the child zone or any of its own children, but will not be able to log on to computers in other child zones.

Create Computer Objects For The Target Set Of Computers

When you manage UNIX computers with Centrify software, you add computer objects to Active Directory for those computers. These computer objects can be created automatically when a computer joins the domain, or created in Active Directory before the computer joins the domain. In most cases, Centrify recommends that you create the computer account objects before joining, if possible.

For deployment and migration, creating the computer objects before joining provides the following key advantages:

- You can define computer-level overrides before computers are added to the zone. This allows you to resolve issues with divergent UNIX profiles without having to change file permissions at the file system level.
- You can check who will have access to which UNIX computers before those computers join the Active Directory domain.

Pre-creating the computer objects enables you to check that you have user profiles and role assignments correctly defined before you join the UNIX computers to zones. Verifying this information before the join operation helps to ensure a smooth migration without disrupting users' access to files or applications.

Prepare A Computer Object Before Joining

In most cases, you should pre-create the computer object for every UNIX computer in every zone. For individual computers, you can use the Prepare Computer wizard to guide you through the process. However, you will probably want to create a Windows or UNIX script for performing the operation repeatedly. For example, you can use adedit or the Windows API to create a script.

To prepare a computer account in Active Directory using Prepare Computer

1. Start Access Manager.
2. In the console tree, expand the **Child Zones** node, then expand the child zone for this computer to join.

3. Select the Computers node, right-click, then click **Prepare Computer**.
4. Accept the default preparation options, then click **Next**.
5. Accept the default to **Create a new computer object**, then click **Next**.
6. Type the name of the computer object to create and modify the DNS host name of the computer object, if necessary.

   The computer name is the name of the computer principal in Active Directory. The DNS name is how the UNIX computer is currently registered in DNS. If you have a disjointed DNS namespace, you should be sure the DNS name is the name used in the computer's DNS entry.
7. Click **Change** and navigate to the organizational unit for storing computer principals. For example, if you created the organizational unit structure described in Creating recommended organizational units, select UNIX Servers and Workstations and click **OK**, then click **Next**.
8. Select an option for joining the computer to the domain, then click **Next**.
   - If you want to require users to interactively join the computer to Active Directory, click **Browse** to select the Join Operators group.
   - If you want to allow the computer to join itself to the zone, select **Allow the computer to join itself to the zone**. This option automatically associates the computer with the correct zone, so there's less chance of a human error.
9. Click **Browse** to select the Zone Administrators group, then click **Next**.

   With this setting, users in the Zone Administrators can override any inherited attributes of a UNIX user or a UNIX group profile on the computer.
10. Review your selections, then click **Next** to create the computer account.
11. Click **Finish** to complete the process.

You have now finished preparing the environment for migration and are ready to begin importing groups and users and assigning them appropriate roles.

Migrating Existing Users To Hierarchical Zones

Now that you understand how zones are used and have prepared an environment for an initial migration, you are ready to import the existing users and groups that you have identified as candidates for being migrated to Active Directory.

This section uses a sample data set to illustrate how to migrate an existing user population into hierarchical zones and how to assign the appropriate roles to convert from a legacy authentication model to Active Directory and Server Suite.

Importing Group Profiles

After you have created one or more zones and separated the users and groups to ignore from the users and groups that you think should be migrated to Active Directory, you must decide which groups apply to which zones. For example, if you have some groups with the same group profile and group membership in all zones, you would import those groups into the top-level parent zone so that they also exist, with the same definition, in all child zones. If a group is only applicable for computers in a child zone, you can import the group profiles directly into that zone. You can also override group profile attributes on specific computers, if needed.

After you have made these decisions, importing the groups is a simple process using either the **Import from UNIX** wizard or ADedit scripts with two important considerations:

- Group names must be unique in Active Directory. If you create a group with a common name, such as admins, you cannot create another group with the same name.
- Having the same UNIX group name on computers in different zones can create group collisions and inadvertent privilege escalation or file ownership conflicts.

To prevent group name collisions, Centrify recommends that you include the zone name in the Active Directory group name. You may also want to add a suffix that identifies the group as an UNIX security group. In most cases, you create the Active Directory group object for the UNIX group in the UNIX Groups organizational unit if you created the organizational unit structure described in Creating recommended organizational units.

You should import group profiles and create the corresponding Active Directory groups for those groups before you import users. If you import group profiles first, you can resolve secondary group membership for users immediately after you import user profiles.

Import Unix Groups that Apply to All Computers into the Parent Zone

If your organization has a default UNIX administrators group or security group that you want to be available on all UNIX computers, that group is a good candidate for importing into the parent zone. Other groups that might be candidates for the parent zone are special purpose UNIX groups that own sudoers permissions that apply to all UNIX computers or an auditing group that requires access to all computers.

If you have identified any common groups, use the Import from UNIX wizard or a script to import the UNIX groups that should be available for all computers into the top-level parent zone.

To Import Unix Groups Using the Import from Unix Wizard

1. Start Access Manager.
2. In the console tree, expand **Zones** and the top-level parent zone.
3. Select UNIX Data, right-click, then click **Import from UNIX**.
4. Click **UNIX configuration files**, then click **Browse** to locate and select the group file to import, then click **Next**.
5. Select the option to automatically shorten the UNIX name, if desired, then click **Next**.
6. Leave **Store in Active Directory** selected and click **Next**.
7. Select **Check data conflicts while importing**, then click **Finish**.

   This step places the profiles under Groups as Pending Import.
8. Select one or more group names that are Pending Import, right-click, then select **Create new AD groups**.
9. Click **Browse**, navigate to the UNIX Groups organizational unit and click **OK**, then click **Next**.

10. Click **Add a prefix to group name**, type the parent zone name and an underscore (*), select the group scope as Global, then click **Next**. For example, if the parent zone name is arcadeGlobal, use the prefix arcadeGlobal.*

    Optionally, click **Add a suffix to group name** and type a suffix that identifies the group as a UNIX security group, for example, _unix.

11. Review the information displayed, then click **Finish**.

For more information about importing groups, see the *Administrator's Guide for Linux and UNIX*.

Import Unix Groups that Apply Only to a Specific Zone into a Child Zone

From your initial analysis and zone design, you should also have a reasonable plan for groups that apply to specific child zones. Groups imported into a child zone are visible to all the UNIX computers in that zone, but not in other zones. For example, assume you have identified an application-specific group, ora_app01, that allows users to use a database, and the database application exists three computers. In your zone design, you decide those three computers should be a single child zone. In that case, you import the ora_app01 group profile into the child zone group because the database application group is only relevant to the UNIX computers in the child zone.

The steps for importing into a child zone are the same as for the parent zone, except that you select the UNIX Data under the child zone name in the console tree and specify the child zone name as the prefix for the Active Directory group name.

Import a Group Profile or Override Attributes on Specific Computers

In some cases, you may have a UNIX group that only exists on one computer in a zone or exists on more than one computer but has different attributes on different computers. You can use computer-level overrides to handle these cases. Computer-level overrides enable Zone Administrators to create and manage group profile attributes manually for individual computers.

To create a group profile for a specific computer

1. Use Active Directory Users and Computers to create an Active Directory group in the UNIX Groups organizational unit. If the group only applies to a specific computer, you may want to use the computer name as the prefix.
2. Start Access Manager.
3. Expand the console tree to display the individual computer object under the zone the computer will join.
4. Expand UNIX Data, select Groups and right-click, then click **Create UNIX Group**.
5. Click the attributes to define, type the appropriate values, then click **OK**.
    - Click **GID** to manually specify a GID for the group profile on the selected computer.
    - Click **UNIX group name** to manually specify a group name for the profile on the selected computer.

Avoiding Group Collisions When Using Computer-level Overrides

If you create group profile overrides on individual computers, you should make sure that the UNIX group name and GID are not being used by any other groups in the parent or child zone. If the group profile defined for the computer is the same as a group profile defined for a group in the parent or child zone, users who should only be able to access files on the local computer may be able to access files owned by the group defined for the parent or child zone. This can be a difficult problem to identify. For example, assume you have an Active Directory group named contract_admins, but you have used the UNIX group name admins and the same GID as a group in the parent zone. Any user who is a member of the contract_admins group in Active Directory is going to have the same GID as the parent zone's admins group. If that happens, members of the contract_admins group will have access to the same files as the admins group in the parent zone.

The only way to identify when this problem occurs is by running the following command for a user in the contract_admins group:

id -a

Importing User Profiles

You can import user profiles into the parent zone or into child zones. If you import user profiles into the parent zone, all existing users will be included in the candidate set of users who have the potential to log on to all of the UNIX computers in the organization. However, they are not granted any access by default. Instead, the management of identity information, such as the user name, UID, and primary group, is separate from privilege management. Users cannot access any UNIX computers until they are assigned a valid role with the specific permissions they need to be recognized, allowed to log on, or run specific commands.

Although you can import users into the parent zone without granting them access rights, you may prefer to import them into one or more child zones. By

importing users into specific child zones, you can limit the scope of their potential access. In general, this option is applicable for the majority of your end-users and can apply to other users, such as database administrators, project managers, and contractors who won't ever need access to all the UNIX computers in the organization.

At this stage you should decide whether to give users the potential to access all computers in the organization, or only the computers in one or more specific child zones. After you import the user profiles, you will use the default listed and UNIX Login roles or custom roles to control access to the UNIX computers.

The steps for importing user profiles into a parent or child zone are essentially the same as importing groups. You can use the **Import from UNIX** wizard or ADedit scripts to import the profiles into one or more zones. The profile information for any user can be different in each zone. If the profile information is divergent on any computer within a zone, you can set computer-specific overrides for any or all attributes.

Tip: If you are importing users from a file, you can write a script that modifies the GECOS field to use the same format used in the Active Directory displayName attribute before importing so that users are automatically mapped to their corresponding Active Directory accounts. For example, if your convention for the GECOS field is first_name last_name (Jae Wilson) but the convention used in Active Directory is last_name, first_name (Wilson, Jae), you must manually map the UNIX user account to the Active Directory account. If you modify the format of the GECOS field before importing, the Import from UNIX wizard can automatically suggest a candidate for mapping the UNIX user to an Active Directory user, if an account exists.

After you import users, their profiles are placed under Users as Pending Import. If the user has an existing Active Directory account, you can select the user name, right-click, then select **Extend existing AD user**. If an Active Directory account does not exist, you can select the user name, right-click, then select **Create new AD users**. You can then use **Check Status** to resolve group membership for Pending Groups. This command adds the imported users to the appropriate Active Directory groups that have UNIX profiles in the zone to complete the first phase of the migration to Active Directory.

For more information about importing users and resolving group membership, see the *Administrator's Guide for Linux and UNIX*.

How Group Membership Works Within Zones

When a UNIX group profile is imported into a zone, its group name and GID are recognized by all computers joined to that zone. However, the group membership might vary by computer. For a user to be a member of the UNIX group, the user must:

- Be a member of the Active Directory group.
- Have a complete UNIX user profile defined somewhere in the zone hierarchy (in the parent zone, a child zone, or with computer-level overrides).
- Be assigned the listed role or the UNIX Login role somewhere in the zone hierarchy (in the parent zone, a child zone, or with computer-level overrides).

For example, assume the users Alison and Clyde are assigned the UNIX Login role for the Engineering zone. As discussed in Create role groups for child zones, that means they are also listed as members of the Engineering_Role_Login role group in Active Directory. Clyde is also a member of the denali project group in the Engineering zone and has a profile defined in the parent zone. Alison's profile is defined in the Engineering zone. If the denali project group (Engineering_Denali in Active Directory) is added to the Engineering zone, both Alison and Clyde can log on to computers in the Engineering zone, but only Clyde will be a member of the denali UNIX group in the Engineering zone.

Assigning Roles to Existing Users and Groups

You have now imported the existing user and group profiles for a target set of computers into Active Directory. This is one critical component of migration because users must have a valid UNIX profile, that is, a unique user name, UID, primary GID, home directory and shell, in a zone for them to be recognized as valid users. However, Server Suite separates UNIX profile management from UNIX privilege management. Users cannot log on to UNIX computers until they are assigned a role that allows them to log on to those computers.

As discussed in Access controls and the assignment of rights and roles, a role is a collection of rights and there are two default roles: the listed role and the UNIX Login role. As part of deploying Server Suite software with the least disruption to your environment, your existing users must be able to log on to the UNIX computers they currently use. That is the primary purpose of the UNIX Login role: to allow you to quickly give log on access to a set of users in one or more zones. The UNIX Login role in the parent zone is intended for enterprise administrators who need log on access to all computers. The UNIX Login role in the finance zone would be for those users who currently have interactive access to the limited number of computers in that zone and would expect to have that access after migration.

The listed role is intended for users who need a valid profile defined but do not need interactive log on access to the computers in a zone. For example, you assign the listed role to remote NFS users so that they have access to their files without the ability to log on and open a shell. You can also use the listed role to give users access to applications, such as ClearCase or Samba, that require a UNIX profile without the ability to log on locally or remotely. The listed role in the software-dev zone would be for those ClearCase users who need to be recognized on all computers in the zone so they can check files in and out.

The next step in the migration is to identify which users should be assigned to each role in each zone you have created.

Using Active Directory Groups for Roles

For most organizations, the most efficient way to manage role assignment is by adding users to Active Directory groups, then managing those groups. Therefore, for management purposes, a Centrify access role should always be linked to an Active Directory security group. The Active Directory groups that identify the users in specific Centrify user roles are stored in the User Roles organizational unit. All of the users in a specific role group will share a common set of rights under UNIX. You can then use machine-level overrides for handling edge cases for individual computers.

Adding Users to Role Groups

There are many different ways you can add UNIX user profiles to an Active Directory group. For example, you can manually select a UNIX profile in a zone, right-click, then select **Add to a group** or select groups under the Role Assignments node for the zone, and modify the group membership. In most organizations, however, you can leverage your existing provisioning process. If your current provisioning process involves managing a group in Active Directory, whether it is through automated scripts or human processes, you can use the same process for provisioning UNIX users.

Migrating Existing Users into The Unix Login Role in The Parent Zone

In Create groups for the default roles in the parent zone, you created Active Directory security groups for UNIX Login and listed roles in the parent zone. If you want to give all users the potential to log in to all UNIX systems, you can make them members of the parentZone_Role_Login group.

Users who are members of this group and have a complete UNIX profile in the parent zone can log on to all UNIX computers that are joined to the parent zone and all UNIX computers joined to the child zones of the parent zone. However, if you add users to the parentZone_Role_Login group in Active Directory, but do not define a UNIX user profile in the parent zone, those users will only be able to log on to the UNIX computers in the child zones where they have a UNIX user profile defined or the individual computers where you define machine-level overrides to give them a UNIX profile.

The default UNIX Login role associated with the parentZone_Role_Login group does not grant any additional privileges. It simply allows users to log on to UNIX computers. Therefore, one strategy for migrating users is to add them all to parent zone's Login role group. You can then control access based on where the user's UNIX profile is defined and control what the user can do using additional role assignments. For example, you may create custom roles to grant expanded UNIX privileges.

Migrating Existing Users into the Unix Login Role in Child Zones

If you define user profiles for most of your users in the parent zone, you should not make them members the parentZone_Role_Login group. Instead, you can add users to the appropriate childZone_Role_Login groups. All of your existing UNIX users who can currently log on interactively to existing UNIX systems should be added to one or more childZone_Role_Login groups. For example, users who currently have access to all of the computers in the Engineering zone should be added to the Engineering_Role_Login Active Directory group. If those users also have a UNIX profile in the parent zone or the Engineering zone, they will be able to log on to all of the computers in the Engineering zone. If a user only needs access to a specific computer in the zone, you can use a machine-level override to give the user access to that specific computer.

You can use the Access Manager console, Active Directory Users and Computers, ADEdit or custom scripts to add UNIX user profiles to the appropriate childZone_Role_Login groups. If possible, you should integrate this part of the migration with your existing provisioning process to ensure that future requests for UNIX role assignments use the processes that line of business personnel already understand.

Migrating Existing Users into the Listed Role in Child Zones

After you have assigned users who must be able to log on to the UNIX Login role, you should identify users who should be assigned the listed role to limit the number of users allowed to log on. The listed role is intended for existing UNIX users who have a UNIX user profile in one or more zones that you want to allow to be listed in getent output without the ability to log on to UNIX computers in those zones.

The listed role is most commonly used for users who access UNIX applications, such as ClearCase, or Samba, or an NFS-mounted file system, that require a UNIX profile. In practical terms, however, this role also allows you to migrate users you aren't sure have been authorized for access. With this role, the user profile is recognized but the user cannot log on locally or remotely.

You can use the Access Manager console, Active Directory Users and Computers, ADEdit or custom scripts to add the UNIX user profiles to the appropriate childZone_Role_Listed groups. If possible, you should integrate this part of the migration with your existing provisioning process to ensure that future requests for UNIX role assignments use the processes that line of business personnel already understand.

Keep in mind that the childZone_Role_Listed group affects all the UNIX computers joined to the specified child zone. Before you move a user to the childZone_Role_Listed group, you should check whether there are any computers in the zone that the user must be able to access to prevent accidentally locking the user out. You can use a machine-level override to grant the UNIX Login role on a specific computer, if needed.

Using a Computer-level Override for the Unix Login Role

You can also create computer-level overrides for the UNIX Login or listed role, if needed. This is not typically part of the migration process. However, if your initial analysis identified a zone where overrides would be useful, you can include overrides in your migration plan. For example, assume you have a zone where most of the user profiles are common across a set of computers. If you import the UNIX profiles for that user population, you see that two users would have access to a UNIX computer where they previously did not have access. To preserve the existing access while migrating from the legacy environment, you can define the UNIX profile in the zone but control access for those two users with a computer-level override.

Managing Role Assignment Without Role Groups

You are not required to use Active Directory security groups to manage role assignments. You can manually add users and groups to roles within any zone. Manually adding a user or group to a role without using Active Directory groups makes integration with provisioning systems more difficult, however. Most identity management and provisioning systems are designed to work with Active Directory groups inherently. Therefore, associating Active Directory groups with Server Suite roles typically provides easier integration with existing provisioning processes.

If you decide to manually manage role assignments, you can use the Server Suite Access Module for Windows PowerShell, Server Suite Access SDK, or ADedit to create scripts that manipulate the objects in Active Directory. Role assignments are stored in Active Directory using Microsoft Authorization Manager containers. If you want to add and remove user and group assignments, you will need to develop custom code to accomplish those tasks.

Verifying Effective Users On Each Zone

Now that you have imported profiles and assigned existing users to the appropriate roles, you can verify who has access to the computers in each zone before you proceed with joining a domain. Checking the Effective Users in each zone enables you to verify the users who have been assigned the UNIX Login and listed roles before any users are affected by the changes.

You should have a checklist of the users who require interactive access on the computers in the target set and which user profiles you suspect only need to be recognized without the ability to log on. You can then using the Effective Users option to see the role assignments for the pre-created computer objects in the target set of computers. By comparing the list of users to the role assignments, you should be confident that you are ready to complete the migration by joining UNIX computers to the Active Directory domain.

Performing this step before joining the domain helps to ensure the transition to Active Directory does not interfere with end-users daily work or the delivery of business services. Therefore, verifying UNIX Login and listed access before joining computers to the domain is a key part of a successful migration.

To access the Effective Users for a zone

1. Start Access Manager.
2. In the console tree, expand **Zones** and the top-level parent zone.
3. Select a zone, right-click, then click **Show Effective UNIX User Rights**.
4. Review the list of UNIX user profiles for the zone in the UNIX users section.
5. Select a user name to display additional information about each user:
    - **Zone Profile** displays details about inherited profile attributes. For existing users being migrated, the profile attributes are typically explicitly defined. If a profile is defined higher up in the zone hierarchy, the Inheritance tab indicates where the profile attributes are defined.
    - **Role Assignments** lists the role assignments for the selected user in the zone. For the initial migration, users must be assigned the UNIX Login or listed role.
    - **PAM Access** lists the specific PAM application access rights associated with the roles a user is assigned. For example, the default UNIX Login role has the login-all PAM access right, which enables PAM authentication for all computers in the zone.
    - **Commands** lists the specific UNIX command rights associated with the roles a user is assigned. For example, you can define a role that allows users to run specific privileged commands as root. You can click the Commands tab to see the specific privileged commands defined for the role.
    - **SSH Rights** lists the specific secure shell (ssh) command rights associated with the roles a user is assigned.
6. Click **Close** when you have finished checking role assignments for the users in target computer of computers.

You can also select **Show Effective UNIX User Rights** for individual UNIX computers and generate Hierarchical Zone reports that describe the effective rights for computers and users.

Adding Existing Users and Groups to Provisioning Groups

After you have added the existing users and groups to the appropriate Login and Listed role groups, the next step for completing the migration to Active Directory is to add the existing user and group profiles to the Provisioning Groups you created for the parent zone. This step is not directly related to data migration, but enables you to prepare the environment for automated user and group fulfillment using on the Zone Provisioning Agent.

Add Existing Users To The Provisioning Group For The Parent Zone

At this point, you have imported legacy data into one or more child zones and accepted divergent profile attributes using computer-level overrides. You should now add all of your imported UNIX users to the provisioning group in the top-level parent zone. Adding users as members of the provisioning group will enable the Zone Provisioning Agent to define a new "universal" UNIX profile for legacy users based on business rules you establish for the parent zone. The new profile will not affect the existing file ownership, but will make it easier to provision and deprovision users moving forward.

As discussed in Installing Zone Provisioning Agent, the Zone Provisioning Agent enables you to define business rules for creating new UNIX profiles for new UNIX users. After you complete the migration and enable the Zone Provisioning Agent, it runs at a regularly scheduled interval to determine whether there are new users or users who should be removed. At each interval, the Zone Provisioning Agent compares the members of the parent zone's Users provisioning group with the user profiles currently defined for the zone.

If there are UNIX profiles for users who aren't members of the provisioning group, the Zone Provisioning Agent removes those user profiles. To prevent the Zone Provisioning Agent from removing the imported data, you must add the Active Directory users associated with the imported user profiles to the parent zone's Users provisioning group.

To add existing UNIX users to the provisioning group for the parent zone

1. Start Active Directory Users and Computers.
2. Expand the forest domain and the top-level UNIX organizational unit you created in Selecting a location for the top-level OU.
3. Expand the Provisioning Groups organizational unit, then select the parentZoneName_Zone_Users group. For example, if the parent zone is arcadeGlobal, select arcadeGlobal_Zone_Users, right-click, then select **Properties**.
4. Click the **Members** tab, then click **Add**.
5. Search for and select the imported user accounts that you have mapped to Active Directory users, then click **OK**.
6. Click **OK** to save the provisioning group and close the Properties.

Add Existing Groups to the Provisioning Group for the Parent Zone

As with imported users, you should also add all of your imported UNIX groups to the provisioning group in the top-level parent zone. Adding the group profiles as members of the top-level provisioning group will enable the Zone Provisioning Agent to define a new "universal" UNIX profile for each group based on business rules you establish for the parent zone. The new profile will not affect the existing file ownership, but will make it easier to provision and deprovision users moving forward. Adding the UNIX group profiles to the top-level parent zone ensures that the Zone Provisioning Agent does not remove the imported groups from the zone.

To add existing UNIX groups to the provisioning group for the parent zone

1. Start Active Directory Users and Computers.
2. Expand the forest domain and the top-level UNIX organizational unit you created in Selecting a location for the top-level OU.
3. Expand the Provisioning Groups organizational unit, then select the parentZoneName_Zone_Groups group. For example, if the parent zone is arcadeGlobal, select arcadeGlobal_Zone_Groups, right-click, then select **Properties**.
4. Click the **Members** tab, then click **Add**.
5. Search for and select the imported user accounts that you have mapped to Active Directory users, then click **OK**.
6. Click **OK** to save the provisioning group and close the **Properties**.

Joining Computers to a Domain and Zone

You have completed the preparation of the environment and added existing users and groups to Active Directory. The steps up to this point have not affected the day-to-day activities of any UNIX users or groups, and have not changed the configuration of any UNIX computers. The final step in the migration requires you to join UNIX computers to the Active Directory domain. This step does have the potential to affect end-users.

This section describes how to complete the migration by joining the target set of computers to an Active Directory domain and a Server Suite zone.

Using Adjoin on New Computers

You can run the adjoin command interactively or in a script to join UNIX computers to Active Directory. One advantage to using the adjoin command is that it enables you to add the join operation to the steps for building a new UNIX computer. For example, if you have a process for provisioning a new UNIX computer, you can add an adjoin step that allows the new UNIX computer to join itself to Active Directory. Provisioning new computers to join the domain when they are built ensures that there are no new local users being defined on those UNIX computers.

Running Adjoin Requires Unix and Active Directory Privileges

On UNIX, running adjoin requires you to log on as root, be a member of the wheel group, or have root equivalent privileges in the sudoers file. On Mac OS X computers, adjoin requires the administrator account and password.

Specifying the Required Options

The basic syntax for the adjoin command is:

adjoin [*options*] domain_name [--zone zone_name | --workstation]

The domain_name should be a fully-qualified domain name; for example, sales.acme.com. If you are using adjoin to provision new computers, there are several options you should specify on the command line or in the script.

- Use the --container or -c option to specify the location for the computer account. Typically, you should use the organizational unit that you created for UNIX Servers and Workstation under the top-level UNIX organizational unit. It must be the location you used when you pre-created the computer object. For example:

  -c "ou=UNIX Server and Workstations,ou=UNIX"

- Use the --selfserve or -S option to specify that you want the computer to join itself to the Active Directory domain.
- Use the --zone or -*z* option to specify the name of the zone to join. You must specify a zone name unless you are joining Auto Zone using the --workstation option.
- If you have a disjointed DNS environment where the Active Directory domain for the computer account does not match the name of the DNS domain, you must also specify the -name and
  --alias options. The --name option specifies the name of the Active Directory computer object and the --alias will be the fully-qualified DNS name of the computer.

For example, update your provisioning process for a new computer to include a command similar to the following:

adjoin -c "ou=UNIX Server and Workstations,ou=UNIX" -S -z production arcade.net

For complete information about adjoin options, see the adjoin man page.

Pre-staging Before Using Adjoin on a New Machine

When joining a large AD environment, the join procedure can take a very long time - up to dozens of minutes. This becomes a concern in some use cases, such as starting an Amazon EC2 instance that needs to join the domain to provide service.

To speed up the adjoin process, the adjoin --prestage option uses existing cache files instead of populating cache from scratch.

Some preparation is required to take advantage of the --prestage option:

- Prepare a pre-staged cache directory on a joined machine
- Copy the cache directory to the new machine

Security Requirements

To use the --prestage option, ensure the following:

- Joined and new machine requirements:
  - The --prestage option can only be used between machines that have the same platform, architecture, and Authentication Service (Centrify DirectControl) release version installed.
  - Adclient cache data encryption feature cannot be enabled on the joined machine. See the adclient.cache.encrypt parameter.
- Pre-staged cache directory on joined machine requirements:
  - On a joined machine, create or designate a directory for the pre-staging cache files.
    - The directory must be in a safe path. That means all levels of parent directories are owned by system accounts.
    - The directory cannot be either group or world writable.
- Content for the pre-staged cache directory on the joined machine:
  - Place the cache files (dz.cache, dc.cache, gc.cache,.idx and kset. files) in the specified directory.
  - Ensure the cache files are owned by system accounts.
  - Files cannot be either group or world writable.
  - Symlink is not allowed for the cache files.
- Zone hierarchy changes are not allowed between the staging directory and the new machine. This includes:
  - zone name change
  - zone GUID change
  - zone schema change

Preparing to Use the --prestage Option

1. Create a directory on a joined machine. For example, /pre.
2. Stop adclient on that machine.
3. Copy the /var/centrifydc/ directory to the pre-staged directory on the joined machine.

   For example:

   Copying the /var/centrifydc/ directory to the pre-staged directory, /pre, places a copy of the required files in /pre/centrifydc/.
4. Verify the pre-staged directory on the joined machine contains all the .idx, .cache, and kset. files.
5. Copy the pre-staged directory to the new machine.

   Use a method of your choice, such as scp or sftp.

   This is done so the pre-staged files are available locally on the new machine.
6. Add the option to the adjoin command when adding the new machine. The syntax is:

   -E | --prestage <directory>

   where directory is the path to the pre-staged directory on the new machine.

   For example, if the pre-staged files are in directory, /pre/centrifydc/, use the following adjoin command.

   adjoin -z <zone> -E /pre/centrifydc<domain>

Verify Authentication After Joining the Domain By Logging On

As the final step in the initial migration, you should verify that authentication for an Active Directory user is successful. You can do this by logging on to the UNIX console using either the UNIX user name or the Active Directory User Principal Name for a user assigned to the UNIX Login role. When prompted, type the Active Directory password for the account. If you are able to log on using the Active Directory password, you know that authentication is being handled by Active Directory and the user account has been successfully migrated.

You should also verify that you can log on remotely using a secure shell (ssh) connection and that you can use other services such as ftp.

If users have trouble logging on after a UNIX computer has joined the domain, it is typically because they're not assigned the UNIX Login role or don't have a

valid UNIX profile in the zone. You can use the Show Effective UNIX User Rights command to check which users have profiles and what roles have been assigned to users who have access to the selected computer.

Provisioning New User and Group Profiles After Migration

After you have completed the basic migration for a set of existing users and groups, you can continue with the Centrify deployment by configuring the environment for automated provisioning of new users and groups. At this stage, you have already built the foundation for the automated addition and removal of users and groups. The next steps involve defining the business rules for creating new user and group profiles. The goal of this section is to help you identify and integrate a provisioning process for new UNIX users and groups.

Integrating with Existing Provisioning Processes

The Zone Provisioning Agent and the provisioning groups you created in Add provisioning groups to the parent zone are intended to integrate the provisioning of UNIX users and groups with your existing account fulfillment process. Those groups enable you to leverage existing processes because most organizations have well-defined and standardized procedures for provisioning new Active Directory users based on Active Directory group membership.

If possible, you would like to use the same or a similar process for provisioning UNIX users and groups. If you can integrate the provisioning of UNIX users and groups with your existing process, the people in your organization can use tools they are familiar with and won't have to learn an entirely new process.

However, defining the business rules for adding new user and group profiles to zones requires some planning. In particular, you need to make decisions about Active Directory group membership, primary group definitions for users in zones, and how profile attributes are defined.

Defining the Business Rules for New Groups in the Parent Zone

You have already started the process of integrating the provisioning for UNIX users and groups when you added imported accounts to the Active Directory provisioning groups in Adding existing users and groups to Provisioning Groups. The next step is to define the business rules for creating new UNIX group profiles in the top-level parent zone.

> **Note**: The business rules you define only affect new UNIX user and group profiles. The imported legacy data remains unchanged, and the Zone Provisioning Agent will not modify any attributes on the existing user and group profiles.

Configure the Business Rules for Automated Provisioning of Group Profiles

You configure the business rules for automated provisioning of group profiles on a zone-by-zone basis. When you use hierarchical zones, you typically want to configure the business rules for the parent zone so that the profile can be inherited in all child zones. Remember that the profile, by itself, does not provide any access to the computers in the child zones, and that you can override any inherited attributes in any zone or on individual computers.

To Configure the Business Rules For Groups in the Parent Zone

1. Start Access Manager.
2. In the console tree, expand the **Zones** node.
3. Select the top-level parent zone, right-click, then click **Properties**.
4. Click the **Provisioning** tab.

   If you are defining business rules for a parent hierarchical zone and want to establish a "source zone" for profile attributes, click **Advanced**. You can then select the Source zone for any or all user and group profile attributes. If you select Source zone for any attribute on the Advanced Provisioning page, you can click **Browse** to search for and select the zone to use as the source zone. In most cases, selecting a source zone is not necessary if you using hierarchical zones, but this option can be useful if you are migrating from classic to hierarchical zones.
5. Click **Enable auto-provisioning for group profiles**.
6. Click the Find icon to search for and select the "groups" zone provisioning group as the Source Group.

   If you followed the recommended naming convention, search for and select parentZoneName_Zone_Groups. For example, if the zone name is arcadeGlobal, select arcadeGlobal_Zone_Groups.
7. Select a method for assigning a new GID to new UNIX group profiles:
   - **Generate from group SID** generates new GIDs that are guaranteed to be unique in the forest based on the Active Directory security identifier (SID) of the group. Selecting this option ensures groups defined in the parent zone have a unique GID across all zones in the Active Directory forest.
   - **RFC 2307 attribute** uses the gidNumber attribute from the RFC 2307 schema to define GID values for the Active Directory groups that you add

to the parent zone. This option requires you to add the RFC 2307 attribute to Active Directory group principals.
- **Use auto-incremented GID** selects the next available GID in the parent zone. In most cases, you should avoid using this option because it does not guarantee unique GIDs.
- **Generate using Apple scheme** generates group GIDs based on the Apple algorithm for generating numeric identifiers from the Active Directory group's objectGuid. This option is only supported for hierarchical zones.

8. Select a method for assigning a new group name to new UNIX group profiles:
   - **SamAccountName attribute** generates the group name for UNIX group profile based on the sAMAccountName value.
   - **CN attribute** uses the common name attribute to define group names for the Active Directory groups you add to the zone. You should only select this option if you verify the common name does not contain spaces or special characters. Otherwise, you should not use this option.
   - **RFC 2307 attribute** uses the cn attribute from the RFC 2307 schema to define group names for the Active Directory groups you add to the zone.
   - **Zone default value** uses the Group name setting from the Group Defaults tab to define group names for the Active Directory groups you add to the zone. In most cases, the default is a variable that uses the sAMAccountName attribute.

     By default, all UNIX group names are lowercase and invalid characters are replaced with underscores.
9. Click **OK** to save your changes.

Add Security Groups to the Parent Zone

The most common way to provision UNIX users is to use a private group identifier as the primary group. With this approach, every user has a unique primary GID that is the same as the UID.

Although not required, another common approach to provisioning UNIX users involves adding a small number of key security groups to the parent zone. For example, if you have a commonly-used group such as All US Employees to which you normally add valid Active Directory users as members, you could add that security group to the parent zone to assign all UNIX users the same primary GID in the parent zone. This approach makes provisioning UNIX users easier because you have already defined Active Directory users as members of that group. If you want to use an Active Directory group to set the primary GID for provisioned users, keep in mind that the size of the group membership can affect the performance of the Zone Provisioning Agent and how long it take to complete provisioning.

If you choose to have the user's primary group defined by Active Directory group membership, the Active Directory group must be in the same Active Directory forest as the users being provisioned. If the Active Directory group is located in another forest, provisioning fails.

If you want to use this approach:

1. Add the security group to the provisioning group for the parent zone (for example, parentZoneName_Zone_Groups).
2. Open the Properties for the parent zone, click the **Provisioning** tab, and define the business rules for the UNIX group profile provisioning associated with the security group.

   At the next update interval, the Zone Provisioning Agent adds a profile for the group to the zone. You can also run the zoneupdate command to add the profile without waiting until the next update interval. For example:

   zoneupdate *zoneName*
3. Click the **User Defaults** tab for the parent zone, select the ellipsis **<...>** option for the Primary Group and select the GID for the group profile that the Zone Provisioning Agent added to the zone.

Defining The Business Rules For New Users In The Parent Zone

In addition to the business rules for group profiles, you configure similar rules for new UNIX user profiles. When you use hierarchical zones, you typically want to configure these business rules for the parent zone so that the profile can be inherited in all child zones. Remember that the profile, by itself, does not provide any access to the computers in the child zones, and that you can override any inherited attributes in any zone or on individual computers.

> **Note**: The business rules you define only affect new UNIX user and group profiles. The imported legacy data remains unchanged, and the Zone Provisioning Agent will not modify any attributes on the existing user and group profiles.

To Configure The Business Rules For User Profiles In The Parent Zone

1. Start Access Manager.
2. In the console tree, expand the **Zones** node.
3. Select the top-level parent zone, right-click, then click **Properties**.
4. Click the **Provisioning** tab.

   If you are defining business rules for a parent hierarchical zone and want to establish a "source zone" for profile attributes, click **Advanced**. You can then select the Source zone for any or all user and group profile attributes. If you select Source zone for any attribute on the Advanced Provisioning page, you can click **Browse** to search for and select the zone to use as the source zone. In most cases, selecting a source zone is not necessary if you using hierarchical zones, but this option can be useful if you are migrating from classic to hierarchical zones.
5. Click **Enable auto-provisioning for user profiles**.
6. Click the Find icon to search for and select the "users" zone provisioning group as the Source Group.

   If you followed the recommended naming convention, search for and select parentZoneName_Zone_Users. For example, if the parent zone name is arcadeGlobal, select arcadeGlobal_Zone_Users.

   This is the same group to which you added the Active Directory users associated with imported user profiles as described in Add existing users to the provisioning group for the parent zone.
7. Select a method for assigning a new UID to new UNIX user profiles:
   - **Generate from user SID** generates new UIDs that are guaranteed to be unique in the forest based on the Active Directory security identifier (SID) of the user. Selecting this option ensures users defined in the parent zone have a unique UID across all zones in the Active Directory forest.
   - **RFC 2307 attribute** uses the uidNumber attribute from the RFC 2307 schema to define UID values for the Active Directory users that you add to the zone. This option requires you to add the RFC 2307 attribute to Active Directory user principals. Otherwise, you should not use this option.
   - **Use auto-incremented UID** uses the next available UID in the parent zone. In most cases, you should avoid using this option because it can create UID conflicts with users in other zones.
   - **Use custom ID** enables you to use the employeeId, employeeNumber, or uidNumber attribute as the UID for new users. You should only select the employeeId or employeeNumber attribute if your organization already populates the employeeId or employeeNumber attribute with a unique value for each user account.
   - **Generate using Apple scheme** generates user UIDs based on the Apple algorithm for generating numeric identifiers from the Active Directory user's objectGuid. This option is only supported for hierarchical zones.
8. Select a method for assigning a new UNIX user login name to new UNIX user profiles:
   - **SamAccountName attribute** generates the user login name for new UNIX users based on the sAMAccountName attribute.
   - **CN attribute** uses common name attribute for user names. You should only select this option if you verify the common name does not contain spaces or special characters. Otherwise, you should not use this option.
   - **RFC 2307 attribute** uses the uid attribute from the RFC 2307 schema to define user names for the Active Directory users that you add to the zone. This option requires you to add the RFC 2307 attribute to Active Directory user principals. Otherwise, you should not use this option.
   - **Zone default value** uses the setting from the User Defaults tab for the zone. In most cases, the default is a variable that uses the sAMAccountName attribute.
9. Select a method for assigning a new shell and home directory to new UNIX user profiles.
   - **RFC 2307 attribute** uses the loginShell attribute for the shell and the unixHomeDirectory attribute for home directory from RFC 2307 schema for the default shell and home directory
   - **Zone default value** uses the values you define on the User Defaults tab, which can include runtime variables for the shell and home directory.

     Runtime variables are populated with platform-specific values when a user tries to log on to a UNIX computer. For example, if a user logs on to a Linux computer with a profile that uses the runtime variable for the home directory, the home directory is /home/username. If the user logs on to a Solaris computer, the runtime variable becomes /export/home/username.
10. Select a method for assigning a primary group to new UNIX user profiles.
    - **RFC 2307 attribute** uses the gidNumber attribute from the RFC 2307 schema for primary group values. This option requires you to add the RFC 2307 attribute to Active Directory user principals. Otherwise, you should not use this option.

- **Zone default value** uses the values you define on the User Defaults tab. This setting enables you to use a specific group profile as the primary group for all UNIX users. If you don't change the default value for the primary group on the User Defaults tab, the default primary group is a private group.
- **Private group** uses the user's UID as the primary GID.
- **Active Directory group membership** uses the Active Directory group with the highest priority as the primary UNIX group. With this option, the Zone Provisioning Agent checks which groups a user belongs to and a prioritized list of groups you have defined. If you select this option, click the Configure icon to search for and select the Active Directory groups to include in the prioritized list. This option allows different users to have different primary GIDs in the same zone.
- **Generate using Apple scheme** generates the user's primary group identifier (GID) based on the Apple algorithm for generating numeric identifiers from the Active Directory objectGuid for the user's primary group. Note that the user's primary group must configured for the zone. If the primary group is not configured for the zone, an error will be logged in the Windows Event Log when the user is provisioned. This option is only supported for hierarchical zones.
- **Generate from group SID** generates new primary GIDs based on the user's Active Directory primary group using the Centrify algorithm for generating GIDs.

  If you select the Active Directory group membership option and a user isn't a member of any of the groups in the list of prioritized groups, the Zone Provisioning Agent will not create a UNIX user profile for the user, because it won't be able to determine the primary group. As noted in Add security groups to the parent zone, the most common approach is to have all users assigned the same primary GID in a zone.

11. Click **OK** to save your changes.

    By default, the GECOS field in new UNIX user profiles is populated using the displayName attribute for the user.

How Hierarchical Zones Affect Provisioning

Because hierarchical zones enable profile attributes to be inherited, defining the business rules for new users and groups in the parent zone enables the Zone Provisioning Agent to generate consistent profiles for all child zones.

When you define a UNIX profile for a group or a user in a parent zone, the attributes are automatically inherited by all child zones. For groups, inheritance makes the group GID and group name available in all child zones. For users, inheritance gives every user defined in the parent zone the potential to log on to every UNIX computer. You then use role assignments to control which computers users can actually access, and, once you begin defining custom roles, what they can do on those computers.

By default, all of the attributes in each new profile are inherited from the parent zone. You can then override any of the attributes as needed in each of the child zones or on individual computers on a case-by-case basis. This flexibility enables you to establish a consistent UID and GID namespace across all zones based on unique SID and sAMAccountName values, while granting exceptions to the specific cases where you need them.

For individual computers, UNIX user and group profiles are inherited from the zone the computer has joined. Typically, this is a child zone or the child of a child zone. You can manually override any attribute or set of attributes for individual computers. Any attributes you do not override are inherited from the zone and the business rules you defined for the Zone Provisioning Agent.

Adding New Users to a Provisioning Group and a Role Group

For new Active Directory users to be effective users of a zone, they must be added to the parent zone's "users" provisioning group and to a role group. You can add users to these groups manually using Active Directory Users and Computers or you can update your existing provisioning process for modifying the membership of Active Directory groups to add users to the appropriate groups. The key points to understand are:

- Users are added to a **provisioning group** so that the Zone Provisioning Agent creates a UNIX profile for them. A user must have a complete UNIX profile to be a valid user on UNIX computers. Centrify recommends creating the profile in the parent zone, but you can create the profile in any zone or on individual computers.
- Users are added to a **role group** so that they have a valid role assignment that allows them to log on or perform specific tasks. Initially, you only have two possible role assignments, listed or UNIX Login, but you are likely to create more.

Add The User to a Provisioning Group

Using Active Directory Users and Computers, scripts, or internal procedures, the basic workflow for a new user would be similar to this:

1. A new Active Directory user requests access to UNIX computers.

2. You add the user principal name to an Active Directory group principal. If you are adding the user to the parent zone, you add the user to the "users" provisioning group parentZoneName_Zone_Users.

   If you wanted to create the profile in a child zone instead of the parent zone, you would add the Active Directory user to the childZoneName_Zone_Users. If you use some other naming convention for the provisioning group, you would search for and select that group.

3. The Zone Provisioning Agent monitors this group and at the next interval (or ondemand) creates a UNIX profile for the user in the zone, based on the business rules you defined.

   Note: If you remove a user from the Active Directory provisioning group, the Zone Provisioning Agent removes the UNIX user profile from the zone.

4. You notify the user that a new UNIX profile has been created with information about the login name and initial Active Directory password to use.

Add the User to a Role Group

Users must also have a role assignment for the zone where you want to grant access. A role assignment is required before the UNIX user profile is usable.

Using Active Directory Users and Computers, scripts, or internal procedures, the basic work flow for a new user would be similar to this:

1. A new Active Directory user requests access to UNIX computers.
2. You add the user principal name to the appropriate Active Directory group principal. If you want to allow the user to log on to computers in a child zone, you add the user to the Login role group childZoneName_Role_Login.

   If the user should be recognized but not allowed to log on, you would add the Active Directory user to the childZoneName_Role_Listed. After you have created custom roles, you would search for and select groups based on the specific rights a user needs.

3. Run the Zone Provisioning Agent update command in preview mode to verify your changes. For example:

   zoneupdate /p *zoneName*

4. Check the results of the zoneupdate preview, then run the command without the preview option to execute the business rules for provisioning. For example:

   zoneupdate *zoneName*

Adding a New Unix Group Profile to All Zones

If you want to make a new UNIX group available to all zones, you should first create a new Active Directory group. In most cases, groups are not shared across multiple zones because of the potential for privilege escalation based on group membership. However, the steps for creating a UNIX profile that spans all zones or only the computers in a specific zone are similar.

Using Active Directory Users and Computers, scripts, or your existing provisioning process, the basic workflow for a new group would be similar to this:

1. Create a new Active Directory group for access to UNIX computers in the UNIX Groups organizational unit (ou=UNIX Groups, ou=UNIX).

   For example, if you are creating a new Active Directory group for the denali project team in the parent zone arcadeGlobal, use Active Directory Users and Computers to create a new group named arcadeGlobal_denali.

2. (Optional) Add users to the group if you know who to add.

   For example, if you are creating the group for a new project and you have a list of authorized users for that project, you can click the Members tab to add those Active Directory users to the new group. If those Active Directory users have a valid UNIX profile and role assignment in the zone, their secondary group membership is updated with the new group.

3. Add the new Active Directory group to the appropriate zone provisioning group. If you are adding the group to the parent zone, you add the user to the "groups" provisioning group parentZoneName_Zone_Groups.

   If you wanted to create the profile in a child zone instead of the parent zone, you would add the Active Directory group to the childZoneName_Zone_Groups. If you use some other naming convention for the provisioning group, you would search for and select that group.

4. Run the Zone Provisioning Agent update command in preview mode to verify your changes. For example:

zoneupdate /p *zoneName*

5. Check the results of the zoneupdate preview, then run the command without the preview option to execute the business rules for provisioning. For example:

   zoneupdate *zoneName*

6. The Zone Provisioning Agent creates a UNIX profile for the group in the zone based on the business rules you defined.

   Note: If you remove an Active Directory group from the Active Directory provisioning group, the Zone Provisioning Agent removes the UNIX group profile from the zone.

Using the Zoneupdate Program for Controlled Automation

You can use the zoneupdate.exe program with command line options to provision profiles in controlled way, allowing you to verify that profiles and access rights are defined correctly for subsets of users or groups without affecting the production environment.

At a minimum, you must specify the zone name or canonical name for the zone to use the zoneupdate.exe program. The command line options are similar to the options available on the Provisioning tab when you display a zone's properties.

For example, to use the provisioning properties defined for a zone, you only need to specify the zone name at the command line:

zoneupdate default

If you use the canonical name for the zone, you specify the full path to the zone:

zoneupdate "centrify.com/program data/Centrify/zones/default"

You can override the default provisioning properties for a zone by specifying one or more of the following command line options.

Options are not case-sensitive. If you specify an option more than once, only the last value is used.

/z:ZoneName or /SourceZone:ZoneName	The name of a source zone. If you do not specify a zone name and there's not a source zone defined in the zone's provisioning properties, you cannot use the zoneupdate command to copy user or group attributes from one zone to another. A source zone is required for classic zones. It is optional for parent hierarchical zones, but can be useful if you are migrating from classic to hierarchical zones.
/d:DomainName or /Domain:DomainName	The name of the domain to process. If you do not specify a domain name, the zoneupdate program processes the Active Directory domain to which the computer is joined.
/dc:DCName or /DomainController:DCName	The name of the target domain controller to connect. No option - This will use the default domain controller of target domain.
/uu:Option or /UserUid:Option	The method to use to set the user's numeric identifier (UID) value. You can specify any one of the following values: Auto to generate UIDs based on the Active Directory domain name and the RID of a user object. This setting is equivalent to selecting Generate from user SID in the Provisioning tab. AppleScheme to generate UIDs based on the Apple algorithm for generating numeric identifiers from the Active Directory user object's objectGuid. This setting is equivalent to selecting Generate using Apple scheme in the Provisioning tab. RFC2307 to use the uidNumber attribute in the Active Directory RFC2307 schema for the user's UID value. ZoneDefault to use the UID defined on the User Defaults tab for the zone. If there's no default value, the Next UID value for the zone is used. SourceZone to copy the UID from the same user in a specified source zone. EmployeeId to copy the UID from the employeeId attribute of the user object. EmployeeNumber to copy the UID from the employeeNumber attribute of the user object. uidNumber to copy the UID from the uidNumber attribute of the user object. If you don't use one of these values, you can set the UID to not have any value. For example: /uu:empty If you use this setting, users will have an incomplete profile in the zone.
/un:Option or /UserName:Option	The method to use to set the user's name. You can specify any one of the following values: sAMAccountName to use the Active Directory user's sAMAccountName attribute as the UNIX user name. CN to use the user's common name (CN) attribute as the UNIX user name. RFC2307 to use the uid attribute in the Active Directory RFC2307 schema as the UNIX user name. ZoneDefault to use the user name defined on the User Defaults tab for the zone. If there's no default value zone, the

	sAMAccountName is used. SourceZone to copy the user name from the same user in a specified source zone. If you don't use one of these values, you can set the user name to an explicit value. For example: /un:hunter
/us:Option or /UserShell:Option	The method to use to specify the user's default login shell. You can specify any one of the following values: RFC2307 to use the loginShell attribute in the Active Directory RFC2307 schema as the default shell. ZoneDefault to use the shell specified on the User Defaults tab for the zone. SourceZone to copy the shell defined for the user in a specified source zone. If you don't use one of these values, you can set the login shell using an explicit value. For example: /us:/bin/bash
/uh:Option or /UserHomeDirectory:Option	The method to use to specify the user's default home directory. You can specify any one of the following values: RFC2307 to use the unixHomeDirectory attribute in the Active Directory RFC2307 schema for a user as the default home directory. ZoneDefault to use the home directory specified on the User Defaults tab for the zone. SourceZone to copy the home directory defined for the user in a specified source zone. If you don't use one of these values, you can set the home directory to an explicit value. For example: /uh:/home/hunter
/ug:Option or /UserPrimaryGroup:Option	The method to use to specify the user's primary group identifier. You can specify any one of the following values: AppleScheme to generate the user's primary group identifier (GID) based on the Apple algorithm for generating numeric identifiers from the Active Directory objectGuid for the user's primary group. Note that the user's primary group must configured for the zone. If the primary group is not configured for the zone, an error will be logged in the Windows Event Log when the user is provisioned. This setting is equivalent to selecting **Generate using Apple scheme** in the Provisioning tab. PrimaryGroupSID to generate the user's primary group identifier (GID) based on the Centrify algorithm for generating numeric identifiers from the Active Directory security identifier of the user's primary group. PrivateGroup to set the user's primary GID value to be the same as the user's UID value. RFC2307 to use the gidNumber attribute f in the Active Directory RFC2307 schema as the primary group identifier or a user. ZoneDefault to use the primary group specified on the User Defaults tab in the zone. If there's no default value, zoneupdate.exe will stop provisioning the user. SourceZone to copy the primary group defined for the user in a specified source zone. example: /ug:empty If you use this setting, users will have an incomplete profile in the zone. GroupMembership to set the user's primary GID based on the user's Active Directory group membership. If a user is a member of the Active Directory groups ops-mgrs and ops-labs and one of those groups has a UNIX profile in the zone but not the other, the group with the UNIX profile in the zone will be used as the primary GID for the user. If both group have a UNIX profile in the zone, the one with higher priority will be used. You can set the priority for selecting the primary group to use in the Access Manager console. If the priority is the same, zoneupdate.exe will stop provisioning the user. If you don't use one of these values, you can set the primary GID to not have any value.
/uc:Option or /UserGecos:Option	The method to use to specify the user's GECOS field. You can specify any one of the following values: RFC2307 to use the gecos attribute in the Active Directory RFC2307 schema for a user. ZoneDefault to use the value defined for the GECOS field on the User Defaults tab for the zone. If you don't use one of these values, you can set the primary GID value to an explicit value. For example: /uc:Thompson, Hunter S.
/gg:Option or /GroupGid:Option	The method to use to set the group numeric identifier (GID) value. You can specify any one of the following values: Auto to generate the GID based on the Active Directory domain name and the RID of a group object. This setting is equivalent to selecting Generate from group SID in the Provisioning tab. AppleScheme to generate GIDs based on the Apple algorithm for generating numeric identifiers from the Active Directory group object's objectGuid. This setting is equivalent to selecting Generate using Apple scheme in the Provisioning tab. RFC2307 to use the gidNumber attribute in the Active Directory RFC2307 schema for the group GID value. ZoneDefault to use the GID defined on the Group Defaults tab for the zone. If there's no default value, the Next GID value for the zone is used. SourceZone to use the GID defined for the group in a specified source zone. If you don't use one of these values, you can set the GID to not have any value. For example: /gg:empty If you use this setting, groups will have an incomplete profile in the zone.
/gn:Option or /GroupName:Option	The method to use to set the group name. You can specify any one of the following values: samAccountName to use the Active Directory group samAccountName attribute as the UNIX group name. CN to use the group's common name (CN) attribute as the UNIX group name. RFC2307 to use the cn attribute in the Active Directory RFC2307 schema as the UNIX group name. ZoneDefault to use the group name defined on the Group Defaults tab for the zone. If there's no default value, the sAMAccountName is used. SourceZone to copy the group name from the group in a specified source zone. If you don't use one of these values, you can set the group name to an explicit value. For example: /gn:apps-lab
	An Active Directory group to use to populate a Centrify zone with users. Use the sAMAccountName and, optionally, the domain name to identify the group. For example, to use the Active Directory engineers group in the currently connected

/u:ADGroupName or /UserSource:ADGroupName	domain to populate users in the default zone: zoneupdate /u:engineers default To use the Active Directory engineers group in a specific domain, you can use the /d:DomainName option or group_name@domain_name. For example to use the Active Directory engineers group in the testdomain.org domain to populate users in the default zone: zoneupdate /u:engineers@testdomain.org default
/g:ADGroupName or /GroupSource:ADGroupName	An Active Directory group to use to populate a Centrify zone with groups. Use the sAMAccountName and, optionally, the domain name to identify the group. For example, to use the Active Directory employees group in the currently connected domain to populate groups in the default zone: zoneupdate /g:employees default
/v or /Verbose	Display detailed information about the provisioning of users and groups. When you use this option, the output format is: Group: groupname:gid User: uid:username:shell:home:primarygid
/p or /Preview	Preview the users or groups to be provisioned or removed. In preview mode, the zoneupdate.exe program does not create or remove any UNIX profiles.
/el or /EventLog: Level	Enable logging to the Event log. You can use the Event Viewer to check the log results. For the log level, you can specify any one of the following values: None - don't write any provisioning activities to the Event log. This is the default setting. Normal - Write only the name of the provisioned users and groups to the Event log. Verbose - Write the UNIX profiles for the provisioned users and groups to the Vent log.
/l or /Log:Level	Enable logging and set the level of detail recorded in the log file. For the log level, you can specify any one of the following values: Error to log only error messages. Warning to log warnings and error messages. Information to log informational messages, warnings, and errors. Verbose to log all messages, including details about the user and group profiles created or removed. Logging is off by default. If you enable logging, the default file location for the log file is: C:\Users\user_name\AppData\Roaming\Centrify\Zone Provisioning Agent\Log You can change the default log file path by modifying the following registry key: HKEY_LOCAL_MACHINE\Software\Centrify ZPA\LogLevel

Using Any Active Directory Attribute in a Profile

In addition to the provisioning properties you can set for a zone using Access Manager, you can manually configure the Zone Provisioning Agent to use any attribute in Active Directory to define a value for any field in automatically-provisioned UNIX user or group profiles. For example, if your organization uses a custom attribute, such as org_global_id, for all users, you can manually configure the Zone Provisioning Agent to use that attribute for the numeric user identifier (UID) in automatically-generated user profiles.

To manually specify an Active Directory attribute to use in a UNIX profile:

1. Open Microsoft ADSI Edit.
2. Select a target zone, right-click, then click **Properties**.
3. Select the **description** attribute, then click **Edit**.
4. Type a profile provisioning attribute and specify the Active Directory attribute to use for the profile.

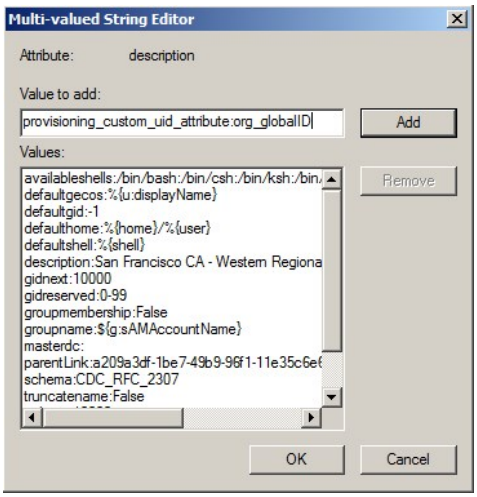
   The valid provisioning attributes are:

   provisioning_custom_uid_attribute
   provisioning_custom_gid_attribute
   provisioning_custom_primary_group_attribute
   provisioning_custom_user_unixname_attribute
   provisioning_custom_group_unixname_attribute
   provisioning_custom_home_directory_attribute
   provisioning_custom_shell_attribute

   The format for the entry is:

   provisioning_custom_uid_attribute:attribute_name

Replace *attribute_name* with the Active Directory attribute you want to use. For example:



5. Click **Add**, then click **OK**.
6. Run the Zone Provisioning Agent update command in preview mode to verify your settings. For example:

   zoneupdate /p *zoneName*

7. Check the results of the zoneupdate preview, then run the command without the preview option to execute the business rules for provisioning. For example:

   zoneupdate *zoneName*

If the Active Directory attribute type is different from the target profile value, the Zone Provisioning Agent attempts to convert the data type. If the data conversion fails, the Zone Provisioning Agent reports an error and stops the provisioning process.

Provisioning Users When Across Trusted Domains

The Zone Provisioning Agent includes two utilities in its Tools folder to assist you in provisioning users when there are trust relationships between domains. These two utilities are CopyGroup and CopyGroupNested. These utilities enable you to mirror group membership or a group hierarchy from a trusted domain and forest in a target domain and forest.

To use these command line utilities, you must have an account that can log on to the trusted source domain and the target domain. The account should also have read permission on the source domain and permission to update the target domain.

For example, assume you have configured the AJAX domain to have a one-way trust with the ACME domain and you have your Active Directory users and groups defined in the ACME domain. If you want to allow the users and groups in the ACME domain to log on to computers that are joined to the AJAX domain, you can log on to the AJAX domain controller with an account that has administrative privileges in both the AJAX and ACME domains, then run the CopyGroup utility to mirror the group membership from a group in the ACME source domain as zone users in the AJAX target domain.

For more information about the command line arguments and options for these utilities, see the usage message displayed for each utility.

Monitoring Provisioning Events

The Zone Provisioning Agent writes events to the Windows event log. You can use tools that monitor the event log to notify you of specific provisioning events. The following table lists the event identifiers and messages the Zone Provisioning Agent records.

1	Information	Summarizes the result after a provisioning run. Centrify zones updated. Domain controller: domain_controller_name Container: container_name Start time: start_time End time: end_time Successful: successful_message Failure: failure_message
2	Error	Indicates that provisioning failed for a specific domain because the domain was not found. Domain domain_name not found.

3	Error	Indicates that provisioning failed because the domain controller was not accessible. Domain server domain_controller_name is down.
4	Error	Indicates that provisioning failed because the domain was not operational. Domain domain_name is not operational.
5	Error	Indicates that provisioning failed without a specific cause. Failed to update zones in domain domain_name on domain controller domain_controller_name.
6	Error	Indicates that provisioning failed because there was a problem with the agent connecting to the Active Directory. Failed to update zones in domain domain_name on domain controller domain_controller_name. Error on Active Directory service.
7	Error	Indicates that provisioning failed because there was an unexpected error when updating the zones in a specific domain. Unexpected error when updating the zones in domain domain_name on domain controller domain_controller. Details: detail_message.
8	Information	Provides verbose user provisioning information, including details about the provisioned user profile. User provisioned to a Centrify zone. User: user Zone: zone UID: uid Name: name Shell: shell Home directory: home_directory Primary group: primary_group Gecos: gecos
9	Information	Provides basic user provisioning information. User provisioned to a Centrify zone. User: user Zone: zone
10	Information	Provides verbose user de-provisioning information, including details about the user profile removed. User removed from a Centrify zone. User: user Zone: zone UID: uid Name: name Shell: shell Home directory: home_directory Primary group: primary_group Gecos: gecos
11	Information	Provides basic user de-provisioning information. User removed from a Centrify zone. User: user Zone: zone
12	Information	Provides verbose group provisioning information, including details about the provisioned group profile. Group provisioned to a Centrify zone. Group: group Zone: zone GID: gid Name: name
13	Information	Provides basic group provisioning information. Group provisioned to a Centrify zone. Group: group Zone: zone
14	Information	Provides verbose group de-provisioning information, including details about the group profile removed. Group removed from a Centrify zone. Group: group Zone: zone GID: gid Name: name
15	Information	Provides basic group de-provisioning information. Group removed from a Centrify zone. Group: group Zone: zone
16	Warning	Indicates that the Zone Provisioning Agent received a warning message during the provisioning process. Warning occurred when provisioning a Centrify zone. Zone: zone Details: detail_message
17	Error	Indicates that provisioning failed because there was a problem with the permissions on the account used to run the Zone Provisioning Agent. Insufficient permission to setup the log file. Please contact your local administrator. Details: detail_message
18	Error	Indicates that provisioning failed because there was a problem with creating the log file in the log file location. Failed to create the log file. Please contact your local administrator. Details: detail_message
19	Information	Indicates that provisioning is paused to allow another provisioning cycle to complete. Zone Provisioning Agent failed to start another provisioning cycle at current_time because the previous provisioning cycle is not yet complete. The provisioning request is pending until Zone Provisioning Agent finishes the previous provisioning cycle.
20	Error	Indicates that provisioning failed because the computer was not found in the domain being provisioned. This computer is not joined to a domain or the domain is not available.
21	Error	Indicates that provisioning failed because there was a problem loading domain information. Failed to load domain information. No zone will be provisioned. Error: error_message

22	Error	Indicates that provisioning failed because there was a problem with the functional operation of the domain. Functional error occurred with domain domain_name.
23	Error	Indicates that provisioning failed because authentication failed for the account used to run the Zone Provisioning Agent. Domain domain_name authentication failed.
24	Error	Indicates that provisioning failed because the authentication system failed. Domain domain_name authentication (system) failed.
25	Error	Indicates that provisioning failed because there was an unexpected error when loading a specific domain. Unexpected error occurred when loading domain domain_name.
26	Error	Indicates that provisioning failed because the Active Directory forest was not found. Forest forest_name not found.
27	Error	Indicates that provisioning failed because the root domain controller was not accessible. Forest server server_name is down.
28	Error	Indicates that provisioning failed because the forest was not operational. Forest forest_name is not operational.
29	Error	Indicates that provisioning failed because there was a problem with the functional operation of the forest. Functional error occurred with forest forest_name.
30	Error	Indicates that provisioning failed because authentication failed at the forest level for the account used to run the Zone Provisioning Agent. Forest forest_name authentication failed.
31	Error	Indicates that provisioning failed because the authentication system failed at the forest level. Forest forest_name authentication (system) failed.
32	Error	Indicates that provisioning failed because there was an unexpected error at the forest level. Unexpected error occurred when loading forest forest_name.
33	Error	Indicates that provisioning failed because there was an error during the provisioning process. Error occurred when provisioning a Centrify zone. Zone: zone Details: detail_message
34	Warning	Indicates that provisioning might be incomplete because the account used to run the Zone Provisioning Agent does not have permission update zone in a specified domain. Insufficient permission to update the zones in domain domain.

Adding New Profiles Manually

Provisioning groups enable automated provisioning of UNIX profiles for users and groups with the Zone Provisioning Agent. Server Suite does not require you to use provisioning groups and business rules to create new users and groups. You can also manually create UNIX users and groups in any zone using the Access Manager console, ADedit, or custom scripts. Adding profiles manually to a zone provides you with control over the definition of individual UNIX profiles on a zone-by-zone basis.

Validating Operations After Deploying

This section provides sample activities for creating test cases and performing a formal validation of the Server Suite deployment. Although not required, executing a set of test cases that exercise Server Suite functionality will help you validate operations before extending the deployment to additional computers in the enterprise.

The specific use case scenarios and test cases you execute will depend on your organization's goals and requirements.

Understanding Testing as Part of Deployment

Most organizations initially deploy in a lab environment that simulates the production environment. The lab environment allows you to test the planned changes to system and user management processes. For example, if you plan to automate migration using scripts, you should build and test the operation of your tools to verify they work as you intend. After testing in a lab, most organizations move to a pilot deployment with a limited number of computers and users to continue verifying that authentication, authorization, and directory services are all handled properly in a real-world environment before moving to a full-scale migration across the enterprise.

In many cases, the pilot deployment also requires more formal testing of specific use cases to validate the deployment before rolling out software to additional computers. This phase of the deployment may also include activities designed to help users transition to Active Directory.

To validate the deployment:

- Execute test cases that verify authentication.
- Execute test cases the verify authorization rules for login access and restricted access.
- Execute test cases that verify the provisioning process.
- Execute test cases that address issues unique to your organization or your user community.

Other activities you may want to perform as part of the validation process include:

- Test configuration changes and customize configuration parameters.
- Document test results.
- Troubleshoot any authentication or authorization issues, if any are found.
- Train staff on new procedures.
- Communicate process changes to the users who are migrating to Active Directory.

  For example, if you plan to eliminate local account access, implement stricter password policies, or apply new access controls, you should prepare the user community for these changes.

Validating Basic Authentication and Password Policy Operations

Before you begin testing organization-specific scenarios, such as the integration of migration scripts or customized access control policies, you should verify basic operations are handled as expected. At a minimum, you should perform some of the following tests to verify basic operations:

- Verify a UNIX profile exists for the Active Directory users and groups to be used in testing.
- Verify the UNIX computer has successfully joined an Active Directory domain and the computer account has been created correctly.
- Verify an Active Directory user assigned the UNIX Login role is authenticated and can access computers in the zone used for testing.
- Verify migrated users assigned the UNIX Login role can log on using their UNIX or Active Directory user name and Active Directory password.
- Verify an Active Directory user assigned the Listed role has a valid UNIX profile, but cannot log on to computers in the zone used for testing.
- Verify that workstation authorization or account lockout policies defined in Active Directory are enforced.
- Verify that password management policies defined in Active Directory are properly enforced.
- Verify that a previously authenticated user is authenticated successfully when the UNIX lab computer is offline.
- Verify that common lookup commands and commands that require user and group information work as expected.

You can verify authentication, authorization, and password policy operations by setting options in Active Directory and attempting to log on and log off the computers in the pilot deployment.

Running Commands on the Unix Computer to Verify Operations

To confirm that a UNIX computer is a member of the Active Directory domain, you can run commands that retrieve information from Active Directory on the

UNIX lab computer itself or by viewing the UNIX computer's account information in Active Directory Users and Computers or the Access Manager console.

Verify the Computer Is Joined to Active Directory

To verify a computer is joined to the Active Directory domain and is retrieving information from Active Directory by running commands on the UNIX computer:

1. Log on to the UNIX computer.
2. Type the following command to retrieve information about the computer's connection to Active Directory:

   adinfo

   This command returns basic information such as the host name for the computer, whether the computer is joined to the domain, and whether the computer is currently connected to Active Directory. For example:

   Local host name: magnolia
   Joined to domain: ajax.org
   Joined as: magnolia.ajax.org
   Current DC: ginger.ajax.org
   Preferred site: Default-First-Site-Name
   Zone: ajax.org/Centrify/Zones/default <!--TODO: company name in file> Last password set: 2017-12-21 11:37:22 PST
   CentrifyDC mode: connected

   For more detailed information about the environment, you can use --diag or other options with the command. For information about the options available and the information displayed for each option, see the adinfo man page.
3. Type the following command to verify that the adclient process is running:

   ps -aeflgrep adclient

   The command should return output similar to the following:

   root 1585 1 0 14:50 ? 00:00:29 adclient
4. Type the following command to confirm that lookup requests use the information in Active Directory:

   getent passwd

   The command should list all of the Active Directory user accounts that are members of the zone and all local user accounts in the /etc/passwd file format. For example:

   ben:x:601:100:Ben Waters:/home/ben:/bin/bash
   ashish:x:501:100:Ashish Menendez:/home/ashish:/bin/bash
   sunni:x:900:100:Sunni Ashton:/home/sunni:/bin/bash
   jolie:x:502:100:Jolie Ames:/home/jolie:/bin/bash
   pierre:x:1001:100:Pierre Leroy:/home/pierre:/bin/bash
5. Review the contents of the /var/log/messages file and look for messages that indicate authentication problems or failures.

Verify Authentication for an Authorized User

To verify that an authorized Active Directory user can log on to a UNIX computer:

1. Restart the computer to display a logon screen or prompt.
2. Log on with the Active Directory user account you created for testing and provide the Active Directory password for that account.
   - The user account must have a complete UNIX profile.
   - The user account must be assigned the UNIX Login role.
   - If the user account has been configured to set a new password at the next logon, you should be prompted to change the password. In this case, you must type and confirm the new password before continuing.
3. Log on using the UNIX login name for the user account and the Active Directory password.
4. Type commands to check the UID and GID assignments, home directory ownership, and other information for the logged on user.

Test Additional Administrative Tasks

You may want to try other typical administrative tasks that you expect to perform in the production environment. For example, you may want to test and verify the following tasks:

- Changing the password for an Active Directory user using the passwd or adpasswd command on a UNIX computer changes the user's Active Directory password for Windows computers.
- Logging on as a user from another trusted Active Directory domain or another trusted forest is successful when you specify the user's fully-qualified domain name (for example, milo.cutter@paris.arcade.com).
- Setting a user's effective group membership using the adsetgroups command.
- Logging on using previously cached credentials. Offline authentication enables users to log on when computers are disconnected from the network or have only periodic access to the Active Directory domain. For example, users who have laptop computers must be able to log on and be successfully authenticated when they are not connected to the network.

Resolving Issues in the Pilot Deployment

Executing a formal test plan is intended to help you uncover issues that need to be resolved, troubleshoot any unexpected behavior, and correct any potential problems before end-users are affected. The pilot deployment enables you to deploy Server Suite software packages on a subset of typical users in the production environment in a controlled way. You can then use the pilot deployment to evaluate server and network load and how adding new computers and users to the Active Directory affects your environment. The initial deployment also allows you to closely monitor the experience of the user community participating in the pilot program.

With the pilot deployment, you can also develop and refine your processes and operational expertise before you roll out Server Suite authentication and authorization services to the entire organization.

You can install Server Suite Agents at any time without affecting any user or computer operations. Installing the Server Suite Agent on UNIX computers has no effect until you join the computer to the domain. Setting up the initial zone or set of zones does not affect the operation of any existing Active Directory infrastructure or Windows environment. Therefore, you can install the software for the pilot whenever it is convenient to do so.

Before you join computers to the domain, you must define and assign appropriate roles to the user community. Users who don't have role assignments will not be allowed to log on to any computers. It is essential for you to test and validate role definitions and assignments to ensure users won't be locked out of the computers they need access to when computers join the domain.

Preparing Training and Documentation for Administrators and Users

The deployment team should develop and deliver training for end-users, technical support personnel, help desk operators, and account fulfillment personnel. This role-based internal training will help new team members come up to speed and also help with the resolution of technical issues.

You should also train staff members to understand that there will be two fulfillment processes in place during migration: the legacy account fulfillment process for computers that have not joined the domain and a new account fulfillment process for computers that have joined an Active Directory domain. Both fulfillment processes should be clearly documented and staff should be trained on how to determine which process to use. For example, training material should indicate how the UNIX provisioning team can determine whether a computer is in a zone, so that members know whether to use the legacy process or the new process.

After a computer is migrated to Active Directory, you should not allow any local account provisioning on that computer. You should also be sure that this is clearly documented in training materials, especially if you don't have centralized management of account creation policies. If you don't prevent local account provisioning, orphaned and noncompliant UNIX accounts can continue to exist, may create conflicts in the UID and GID namespace, and create audit compliance issues because they are not included in required reports.

As you migrate each set of computers to an appropriate zone, you should also notify all affected users before you complete the migration. This notification can take the form of an email, voicemail, meeting with project personnel or management, or any other logical combination. Notifying users in advance helps to reduce the number of account lockouts caused by UNIX users attempting to log on using their old UNIX password on migrated computers.

Deploying to the Production Environment

After the initial deployment is stable and you have migrated existing users and groups successfully, you can begin moving the rest of your UNIX computers, users, and groups to Active Directory. In most cases, this migration is done in stages by repeating the tasks described in this guide for additional target sets of computers, users, and groups. After each stage, you should allow a period of time for monitoring and resolving issues for the migrated user population. Your deployment plan should include a schedule for when different sets of users are to be migrated and an analysis of how those users should be placed into zones according to your migration plan.

In general, you should migrate an increasing number of computers into zones in each stage of the production deployment. For example, in the first round of

migration, you might migrate 15% of the computers into the first set of zones. You should then allow time in the schedule to troubleshoot and resolve issues to ensure that the migration was successful. In the next phase, you then might migrate another 25% of the computers. After you determine the second phase of the migration is successful, you might migrate the remaining computers into the remaining zones.

> **Note**: Whenever possible, you should also plan to migrate all of the computers that have been identified for a particular zone at the same time. Migrating all of the computers in a zone at the same time helps to reduce user confusion over which password to use when authenticating.

Training the Support Staff for a Production Deployment

You should provide the following information or training to the IT support staff who are responsible for a set of users to be migrated to Active Directory:

- **Review of the deployment project plan**. Have the support staff read the deployment plan and review any changes to policies or procedures that deployment will entail.
- **Schedule for deployment**. Make sure members of the support staff are aware of when the deployment is scheduled to take place and that they will be available at that time and for a reasonable period thereafter.
- **Location of documentation**. Make sure all internal, operating system, and Server Suite-specific documentation is available so that support staff can use those documents to help them resolve any end-user issues that arise during the production deployment.
- **Pilot deployment experience and feedback**. Explain the result of the pilot deployment, including any issues encountered during the pilot and the resolution for each issue.
- **Common Windows and Active Directory administrative tasks**. For support staff members who are familiar only with supporting UNIX-based computers, provide training about Windows and Active Directory concepts and administration, as appropriate. If administrators will be using Windows-based programs or scripts to manage UNIX users and computers, they may need training specific to those tools. For example, administrators may need training to use Active Directory Users and Computers, Visual Basic scripts, or Access Manager console to manage Active Directory data.
- **Common UNIX administrative tasks**. For support staff members who are familiar only with supporting Windows-based computers, provide training about UNIX concepts and administration, as appropriate. If administrators will be using UNIX-based programs or scripts to manage UNIX users and computers, they may need training specific to those tools. For example, administrators may need training to create and use ADedit or LDAP scripts to manage Active Directory data.
- **Common access control and privilege management tasks**. Make sure members of the support staff are familiar with the tasks described in the *Administrator's Guide for Linux and UNIX*, and provide hands-on training in performing the most common of those tasks.
- **Internal policies and procedures specific to your network and business environment**. Create an operations handbook with details about common scenarios the support staff may be required to address, such as adding new UNIX computers or users to Active Directory.
- **Reporting and tracking issues related to Server Suite software**. Make sure support staff members know how to report issues or problems with authentication, authorization, or directory services. If your organization uses a bug or problem-ticket system for tracking issues, set up a new subject area for Server Suite-related issues.

Preparing the User Community in a Production Deployment

As you prepare to migrate a set of users to Active Directory, you should provide training or informational materials to inform that user community about what to expect. For example, if your organization has decided to implement policies that prevent locally-defined user accounts from accessing some computers, be sure that the user community affected by this policy understands the change. Similarly, if your organization has decided to eliminate service accounts or restrict access to computers previously available, you should communicate these changes and notify users about any migration issues that may affect file access permissions and file ownership.

When you are ready to migrate a specific set of users, you should inform the user population about the upcoming deployment by providing the following information:

- **Schedule for deployment**. Make sure that department managers and end-users know when the switch to Active Directory is scheduled to occur.
- **Computers and applications affected**. Make sure that department managers and end-users know if their workstations or the servers they access for business applications are included in the deployment. If users need access to a computer that is being added to an Active Directory domain, they need to know whether their user account is in the same domain as the computer or a different domain. If there are applications hosted on a computer that is being added to an Active Directory domain, users need to know how this will affect access to the hosted application. For example, users may need to select a domain when logging on, or log on using the user_name@domain_name format.
- **Active Directory account information**. Make sure that end-users know their Active Directory account information and understand that they must use their Active Directory password to access their UNIX workstations after the deployment is complete. You should inform users about the valid logon names and formats they can use, the Active Directory password assigned to their account if it is a new account, whether they are required to change their password when they next log on, and any password complexity rules you have implemented. Active Directory may lock accounts if users attempt to log on using their UNIX password, which could result in a large number of Help Desk requests for password resets.
- **Changes to access policies**. Make sure that department managers and end-users are aware of any changes to access control policies. For example, if you are using group policies to deny access to some users or groups who could previously log on to a computer, you should inform those

users or groups of the change and that it will take effect after the migration to Active Directory.

Populating Zones in a Production Environment

In planning your deployment, you should have determined your basic zone requirements and how you will migrate existing user communities to Active Directory. Based on your analysis, you should have a zone design with one or more parent zones and the child zones for each parent to define a candidate set of users and groups with the potential to access a given set of computers.

Typically, you should focus on one zone at a time, importing and mapping the existing users to Active Directory accounts. You should also determine whether you need to create new Active Directory accounts for any of the existing users or groups you are importing. If possible, you should use Active Directory group membership and role assignments to manage access for UNIX users and groups, you import.

Joining a Domain in a Production Environment

In smaller organizations or organizations where individual users have permission to join their own workstation to the Active Directory domain, you can run the adjoin command interactively on individual computers. This option works well when computers are distributed across many different domains or when individual users are joining their own workstation to the domain.

In larger organizations, however, you may want to use a custom script to remotely join a group of UNIX computers to an Active Directory domain. If you develop a custom script for joining a domain, the script should restart services or reboot the computers where it runs.

After joining a domain, you should monitor computers closely for a few days before extending the deployment to additional computers.

If the join operation fails or users cannot log on, you can run the adleave command to restore the computer to its previous state.

Defining Role-Based Access for Users and Computers

By default, Server Suite includes two roles—the listed role and the UNIX Login role—that are required for migration. This section discusses additional role-based controls you can define for better management of privileged access and authorized activity.

> **Note**: If you have well-defined access rules and command privileges in sudoers configuration files, you can import those definitions and use them as the basis for creating custom roles in Access Manager. For information about importing sudoers files and converting the imported definitions into roles, see the *Administrator's Guide for Linux and UNIX*.

Addressing the Business Problem of Role-based Security

Privilege management and role-based access controls are approaches to the basic business problem of securing an enterprise's key computer systems and sensitive data. Restricting access based on a user's role or specific job requirements can require you to make some difficult decisions about who has access to what and why access is granted or denied. These decisions also have the potential to disrupt user activity or existing business processes. Therefore, you should do thorough planning to identify the roles to implement, who should have permission to execute privileged commands, and who should have restricted access.

Defining the appropriate rights for users in different roles often requires negotiation with different groups in the organization to achieve the right balance of security and functional capability. Before implementing a solution, you should have these conversations and set expectations about what will change in the user's environment.

Creating a Root-Equivalent Role Definition

One of the first roles you should plan to create is an administrative role that is equivalent to specifying ALL:ALL in a sudoers file or giving users access to the root password on their computers. The purpose of this role definition is to allow selected users to execute privileged commands on a regular basis. The role definition allows them to execute commands without being given the root password or having privileges hard-coded in individual sudoers files on multiple computers.

Because this role definition enables system administrators to execute privileged commands without the root password, you can improve security for the organization and reduce the chance of an audit finding for access to the root password.

You can create this role definition in a parent zone or a child zone to control its scope. In most cases, you should only assign the role in a child zone or on an individual computers.

Define the Right for Running All Commands

Rights and roles are defined at the zone level and inherited down the zone hierarchy. If you define a right in the top-level zone, it is available in all child zones. If you define a right in a child zone, it can be used in that zone and any of its child zones. Similarly, you can define roles in the top-level parent or any child zone, depending on where you want to make the role available. In this example, the right to run all commands as the root user is defined in a top-level parent zone.

The following instructions illustrate how to define a right for running all commands using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Server Suite Windows API are available in other guides, the *Server Suite Software Developer's Kit,* or in community forums on the Delinea website.

To define a right for running all commands as root:

1. Open Access Manager.
2. Expand Zones and select the top-level parent zone.
3. Expand **Authorization > UNIX Right Definitions**.
4. Select **Commands**, right-click, then click **New Command**.
5. On the General tab, type a name for this command right and, optionally, a description for this right, then define the right to run all commands like this:
    - Type an asterisk (*) in the Command field to indicate all commands are allowed.
    - Select **Specific path** and type an asterisk (*) in the field to indicate that any path is allowed.
6. Click the Restricted Shell tab and deselect the **Can be used in a restricted role** option if you want to prevent this command from being used in a role that uses a restricted shell environment.

7. Click the Run As tab to verify the command can be used by dzdo and is set to run as root by default.
8. Click **OK** to use the default environment variable settings and command attributes.

   Alternatively, you can click the Environment and Attributes tabs if you want to view or set additional properties for this right definition.

Create a Role Definition for Running All Commands

After you have defined the right to allow a user to run any command with root privileges, you can create a role definition for that right. You must create a role definition somewhere in the zone hierarchy before you can assign users to the role.

To create a role definition with the right to run all commands as root:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the role definition.
3. Expand Authorization.
4. Select **Role Definitions**, right-click, then click **Add Role**.
5. Type a name and description for the new role, then click **OK**.

   For example, type a name such as root_equivalent and descriptive text such as Users with this role can run any command with root privileges.

   Optionally, you can select **Allow local accounts to be assigned to this role** if you want to assign both Active Directory users and local users to the role. This option is only available when you first create a role definition. You can also click **Available Times** if you want to limit when the role is available for use. By default, roles are available at all times.

   If you are using the UNIX Login role to grant access to computers in the zone and want to use the default auditing level of **Audit if possible**, you can click **OK** then skip to Step 8.
6. If you are not assigning the UNIX Login role to grant access to computers, click the System Rights tab and select the following options:
   - Password login and non-password (SSO) login are allowed
   - Non-password (SSO) login is allowed
   - Login with non-Restricted Shell

     Note that you cannot set these system rights if you selected the option to allow local users to be assigned to this role.
7. If you don't want to use the default auditing level, click the Audit tab.
   - Select **Audit not requested/required** if you have the auditing service enabled but don't want to audit user activity when this role is used.
   - Select **Audit if possible** to audit user activity where you have the auditing service enabled.
   - Select **Audit required** to always audit user activity. If the auditing service is not installed or not available, users in this role are not allowed to log on.
8. Select the new role definition, right-click, then click **Add Right**.
9. Select the right you defined for running all commands as root, then click **OK**.

Assign an Active Directory Group to the Role

As discussed in previous chapters, you should associate Centrify role definitions with Active Directory security groups so that you can manage them using the processes and procedures you have for managing Active Directory group membership. If you are using the recommended deployment structure and naming conventions, you would create a new Active Directory group in the ou=User Roles, ou=Centrify organizational unit using the format ZoneName_Role_RoleName. For example, you would create an Active Directory group named sanfrancisco_role_rootequivalent. You can then assign the new role definition to that group.

To assign the role definition to an Active Directory group:

1. Open Access Manager.

2. Expand Zones and the individual parent or child zones required to select the zone name where you want to assign the role definition.
3. Expand Authorization.
4. Select **Role Assignments**, right-click, then click **Assign Role**.
5. Select the role definition you created for root-level access, such as root_equivalent, then click **OK**.
6. Click **Add AD Account** to search for and select the Active Directory security group you created for the role.
    - Select **Group** as the object to find.
    - Optionally, type all or part of the group name.
    - Click **Find Now**.

      Select the group you created for the role in the results, then click **OK**.
7. Click **OK** to complete the assignment.
8. Add members to the Active Directory security group for the role definition using Active Directory Users and Computers, an internal script, or another tool.
9. Test the role assignment by checking whether the user you added to the Active Directory group can execute privileged commands using dzdo in place of sudo.

   dzdo /usr/share/centrifydc/din/adflush

   Details about commands that are executed with dzdo are logged to the secure syslog facility on the computer where they were executed.

Creating a Restricted Role for a Shared Service Account

The root-equivalent role definition provides centralized management for a limited number of administrators who have permission to execute all commands on selected computers. Another common reason for defining a role is to execute privileged commands associated with a service account. In many organizations, service account passwords are known by multiple users, making them a security risk. For example, all of the database administrators in the organization might know the password for an oracle service account, an account with permission to perform privileged database operations. Because the password is shared information, it presents a security risk and a potential audit finding that might have costly consequences.

Setting up a role definition for a service account involves creating a command right for switching to the service account user and defining a PAM access right for role.

Define the Right for Switching to a Service Account

The steps for defining a right for switching to the service account user are similar to defining the rights for the root-equivalent user, but the definition is more restrictive.

To define a right for switching to a service account:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new command right.
3. Expand **Authorization > UNIX Right Definitions**.
4. Select **Commands**, right-click, then click **New Command**.
5. On the General tab, type a name for this command right and, optionally, a description for this right, then define the right to switch to the service account. For example, if the service account is oracle:
    - Type su - oracle in the Command field.
    - Verify the Standard user path is selected.
6. Click the Restricted Shell tab, under Can be used in a restricted role, select **Specific user or uid**, then type root.

7. Click the Run As tab, deselect **Can be used by dzdo**.

   These settings specify that this right can only be used in a restricted shell environment and users can only run the commands that are explicitly allowed in the restricted role they are assigned. If this is the only right defined for a role, the only command users assigned to the role can run is su - oracle. For a role definition with this right to be effective, you would add command rights for the specific database operations users should be allowed to perform after switching to the oracle service account. For example, if the oracle service account is used to run a backup-all-dbs script, you would add a right to allow the execution of that script.

8. Click **OK** to use the default environment variable settings and command attributes.

   Alternatively, you can click the Environment and Attributes tabs if you want to view or set additional properties for this right definition.

Define a PAM Access Right to Allow Logging On

The default UNIX Login role allows users to log on using a password or without a password in an unrestricted environment. If you are creating a role definition for a service account, you can use PAM access rights to control the specific PAM-enabled applications users can use to log on. To illustrate controlling how users log on, this example of a restricted role for the oracle service account only allows users to log on with ssh.

To define a PAM access right for a specific application:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new PAM right.
3. Expand **Authorization > UNIX Right Definitions**.
4. Select **PAM Access**, right-click, then click **Add PAM Access Right**.
5. Type a name and, optionally, a description of the PAM application for which you are adding an access right.

   For the Application field, type the platform-specific name for the PAM application as defined in the PAM configuration file or PAM directory. For example, type ssh or sshd. You can also use wildcards in this field to perform pattern matching for the application name.

6. Click **OK** to save the access right for this PAM-enabled application.

Create a Restricted Role Definition for the Service Account

After you have defined the rights that allow a user to log on using a PAM-enabled application and run the su - command for a service account, you can create a role definition for these rights. You must create a role definition somewhere in the zone hierarchy before you can assign users to the role.

To create a restricted role definition for switching to a shared service account:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new role definition.
3. Expand Authorization.
4. Select **Role Definitions**, right-click, then click **Add Role**.
5. Type a name and description for the new role, then click **OK**.

   For example, type a name such as oracle_service and descriptive text such as Users with this role can start a secure shell session and switch to oracle.

   By default, this role is available at all times. You can click **Available Times** if you want to specify days of the week or select times of the day for making the role available.

6. Click the System Rights tab and select at least one option that allow users assigned to this role definition to log on, then click **OK**.

   In this example, users open a secure shell to switch to the service account so you might select **Non-password (SSO) login is allowed**.

   If a service account instead of a user account is used to log on, it might be mapped to a disabled Active Directory account. In this case, you might select the **Account disabled in AD can be used by sudo, cron etc** system right to ignore the disabled state and allow the service account to log on.

7. Select the new role definition, right-click, then click **Add Right**.
8. Select the rights you defined for running the switch user (su -) command and logging on with the PAM application ssh, then click **OK**.

Assign an Active Directory Group to the Role

As discussed in previous chapters, you should associate Server Suite role definitions with Active Directory security groups so that you can manage them using the processes and procedures you have for managing Active Directory group membership.

If you are using the recommended deployment structure and naming conventions, you would create the Active Directory group in the ou=Service Accounts, ou=Centrify organizational unit using the format ZoneName_Service_RoleName. For example, create an Active Directory group named sanfrancisco_service_oracle. You can then assign the new role definition to that group.

To assign the role definition to an Active Directory group:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to assign the role definition.
3. Expand Authorization.
4. Select **Role Assignments**, right-click, then click **Assign Role**.
5. Select the role definition you created for using secure shell and switching to the service account access, such as oracle_service, then click **OK**.
6. Click **Add AD Account** to search for and select the Active Directory security group you created for the role definition.
    - Select Group as the object to find.
    - Optionally, type all or part of the group name.
    - Click Find Now.

      Select the group you created for the role in the results, then click **OK**.
7. Click **OK** to complete the assignment.

Working in a Restricted Shell Environment

When users who are assigned to this role want to open a secure shell session and switch to the oracle service account, they will be placed in a restricted shell environment. Within the restricted shell, they can only execute the commands you have added to the role definition until they exit the restricted shell session. In this example, the role definition only allows users to log on using ssh and execute one command, su - oracle. If those users are also assigned the UNIX Login role, they will have access to an unrestricted shell when they close the restricted shell session.

If you want users who access a shared service account to work exclusively within the restricted shell environment, you must remove the UNIX Login role assignment in the zone or on the computer where they should only have restricted shell access. Before removing the UNIX Login role assignment, however, you should consider the trade-off between improved operational security and audit compliance and reduced operational access. Depending on the rights you add to a role that runs in a restricted shell environment, the restricted shell can dramatically limit what users can do.

Testing Access in a Restricted Shell

If you create a role definition for a shared service account that runs in a restricted shell environment, you should test it before migrating any users to it. You can use the dzinfo command with the --test option from a UNIX command prompt. For example, type dzinfo, the user name to test, the --test option, then the full path to the command to test:

dzinfo raejames --test "/usr/bin/su - oracle

You can also run the dzinfo command with the --roles option to see information about the rights defined for the current user or a specified user. For example, run the following command to check the roles and rights defined for the user raejames:

dzinfo raejames --roles

For more information about using this command, see the dzinfo man page.

What Users See in a Restricted Shell Environment

For users assigned to a role that runs in a restricted shell, logging on opens a dzsh shell. Within that shell users can only execute the commands you have explicitly defined for them. In this example scenario for a shared service account, typing su - oracle is the only allowed command. If the user types any other command, the shell reports that the command is not allowed.

Creating a Role Definition for Temporary Root Access

Another common use case for role definitions occurs when you want to provide temporary access to privileged commands. For example, you might want to provide temporary rootlevel access to an application developer troubleshooting a problem on a production server or to a consultant you've hired for a specific period of time. These types of role definitions are often used as overrides on individual computers.

The steps for creating a role definition with temporary root access are similar to the steps for creating the other roles, except that you specify time constraints for the role. The time constraints might include specific hours of the day, days of the week, or a start and end time for a role assignment. The next sections summarize the steps for creating a role with temporary root-level access.

Define a Command that Allows Root Access

The steps for defining a right for switching to the root user are similar to defining the right to run commands for the root-equivalent user, but it is recommended that you create a separate right definition for this case.

To create the right to switch to the root user:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new command right.
3. Expand Authorization > UNIX Right Definitions.
4. Select **Commands**, right-click, then click **New Command**.
5. On the General tab, type a name, such as emergency_access, for this command right and, optionally, a description for this right, then define the right to switch to the root user:
    - Type the command for switching to the root user. For example, type su - root in the Command field.
    - Verify Standard user path is selected.
6. Click the Restricted Shell tab and verify **Can be used in a restricted role** and **User running the command are selected**.

    These options enable you to use this command right in combination with other rights in a role definition that requires a restricted shell environment.
7. Click the Run As tab and verify **Can be used by dzdo** and **Any user** are selected, then click **OK**.

    In most cases, you can leave the default settings for the other properties. If you want to make changes, click the Environment and Attributes tabs before saving the new command.

Create a Role Definition for Temporarily Running as Root

After you have defined the right to switch to the root user, you can create a role definition for that right.

To create a role definition with the right to run the emergency_access command:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new role definition.
3. Expand Authorization.
4. Select **Role Definitions**, right-click, then click **Add Role**.
5. Type a name and description for the new role.

    For example, type a name such as emergency_access and descriptive text such as Users with this role can temporarily run commands with root

privileges.

6. Click **Available Times** to specify days of the week or select times of the day for making the role definition available.

   For example, you might want to allow access only on Friday, Saturday, and Sunday and deny access the rest of the week. After you have set the days and times for the role definition to be available, click **OK**.

7. Click **OK** to save the role definition.
8. Select the new role definition, right-click, then click **Add Right**.
9. Select the emergency_access command you defined for switching to the root user, then click **OK**.

   To use this role, a user must be assigned to the UNIX Login role for the zone or a role definition that has, at a minimum, the following System Rights:

   - Password login and non-password (SSO) login are allowed
   - Login with non-Restricted Shell

Assign the Role as a Computer-level Override

In most cases, a role definition of this type is assigned to a specific computer rather than applied to all computers in a zone.

To make a role assignment on an individual computer:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that contains the computer for which you want to define a computer-level role assignment.
3. Expand Computers, then select the specific computer on which you want to make a role assignment.
4. Select **Role Assignments**, right-click, then click **Assign Role**.
5. Select the role definition you created for temporary root access, such as emergency_access, then click **OK**.
6. Click **Add AD Account** to search for and select the Active Directory user who should have temporary root access:

   - Leave User as the object to find.
   - Optionally, type all or part of the use name.
   - Click Find Now.

     Select the user in the results, then click **OK**.

7. Deselect **Start immediately** and set a specific Start time for the role assignment.
8. Deselect **Never expire** and set a specific End time for the role assignment.
9. Click **OK**.

Verify the Role Assignment on the Computer

You can run dzinfo --roles or dzinfo username --roles to see if the emergency_access role is available based on the start time for the role definition and the local time of the Linux or UNIX computer.

At the specified start time for the role assignment on the local computer, the user you assigned to the emergency_access role can type the following command:

dzdo su - root

The user is not prompted to provide the password and becomes the root user on the local computer until the specified role assignment end time. The one caveat to be aware of is that the user would continue to have root access after the specified end time if the shell session remains open continuously. If a user is still logged on after the time period has expired, you should check whether the user still requires root-level access. If the session has remained open but the user should no longer have root access, kill the session and log the user off.

Creating a Role Definition With Specific Privileges

The previous examples of role definitions granted broad privileges. You can also use role definitions to grant or deny very specific rights. For example, you might want to deny access to a specific set of commands for a specific group of administrators who otherwise have broad access rights or to strictly limit exactly what commands users can execute. Depending on the requirements of your organization, you might configure these types of role definitions to be used in a restricted or unrestricted shell.

The steps for creating a role definition with specific privileges are similar to the steps for creating the other roles. In this example, rights are defined to prevent the execution of specific commands and combined with a right to grant access to all commands not explicitly listed.

Define Command Rights to Prevent the Use of Commands

The steps for defining rights that deny access to specific commands are similar to the steps defining other rights, but require different syntax. In this example, you create a "blacklist" of commands users cannot execute.

To create the right to switch to the root user:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new command right.
3. Expand Authorization > UNIX Right Definitions.
4. Select **Commands**, right-click, then click **New Command**.
5. On the General tab, type a name, such as No password resets, for this command right and, optionally, a description for this right, then define the right:
    - Type !passwd * in the Command field.
    - Verify Standard user path is selected.

      An exclamation point (!) at the start of a command disallows matching commands. Command rights that start with the exclamation point take precedence over others that don't.
6. Click the Restricted Shell tab and verify **Can be used in a restricted role** and **User running the command are selected**.

   These options enable you to use this command right in combination with other rights in a role definition that requires a restricted shell environment.
7. Click the Run As tab and verify **Can be used by dzdo** and **Any user** are selected, then click **OK**.

   In most cases, you can leave the default settings for the other properties. If you want to make changes, click the Environment and Attributes tabs before saving the new command.
8. Repeat Step 4 to Step 7to create rights for the following specific commands:

   !groupadd *
   !useradd *
   !groupdel *
   !userdel *

Create a Restricted Shell Role Definition that Uses the Command Rights

After you have defined all of the command rights that disallow specific commands, you can create one or more role definitions to use those rights. For example, you might create one role definition to run in an unrestricted shell that requires users to invoke dzdo to execute privileged commands and another role definition that runs in a restricted shell but does not require users to execute privileged commands using dzdo. The second role might be useful if you have existing scripts that would have to be modified if invoking dzdo is required.

To create a role definition for specific command rights:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name where you want to create the new role definition.

3. Expand Authorization.
4. Select **Role Definitions**, right-click, then click **Add Role**.
5. Type a name and description for the new role.

   For example, type a name such as operators and descriptive text such as Users with this role can run privileged commands but not reset passwords, add or delete users and groups.
6. Click **System Rights** if you want this role definition to be used in a restricted shell environment as a replacement for the predefined UNIX Login role.

   To use this role, a user must be assigned to a role definition that has at least one UNIX system right, such as Password login and nonpassword (SSO) login are allowed or Nonpassword (SSO) login is allowed.
7. Click **OK** to save the role definition.
8. Select the new role definition, right-click, then click **Add Right**.
9. Select all of the command right that disallow specific operations, the command right that grants access to all remaining commands, and a PAM access right, then click **OK**.

   For example, you might add the following previously-defined command rights to this role definition:

   No password resets
   No user adds
   No group adds
   No user deletes
   No group deletes
   Root like access (* for all commands not explicitly disallowed)
   PAM ssh/login allowed

   This role definition allows members of the operators role to execute any command within a restricted shell environment except those explicitly disallowed, including privileged commands, without invoking dzdo first. You can assign the role definition to the appropriate Active Directory users or groups like the previous role definitions.

Create an Unrestricted Shell Role Definition that Uses the Command Rights

The command rights were configured to allow execution in either a restricted shell environment or an unrestricted shell environment. In an unrestricted shell environment—for example, the default shell environment when users are assigned the UNIX Login role—commands that require administrative privileges must be executed by first invoking the dzdo command, which is similar to invoking commands with sudo.

You can control whether users are required to enter a password when they execute privileged commands using dzdo by setting the **Authentication required** on the Attributes tab when you create a command right. By default, no password is required. If you were adding a new command right that requires authentication, you would click the Attributes tab, select **Authentication required** then select one of these options:

- **User's password** if users are required to enter their own password before executing the command.
- **Run as target's password** if users are required to enter the password for the target account that is executing the command.

In most cases, the default of no password is appropriate because the user has been previous authenticated before invoking dzdo to execute a privileged command and the **Run as target's password** option requires the user to know the privileged account password. For example, if the run-as user is root, the **Run as target's password** authentication option requires the user to know the password for the root account.

The steps for creating the role definition that includes the previously-defined command right are the same for the unrestricted shell as for the restricted shell except that at Step 6 of Create a restricted role definition for the service account in the System Rights tab, you would also select the **Login with non-Restricted Shell** option if you are not using the UNIX Login role. You could add all of the same command rights to the role definition and grant the same privileges and exceptions.

The primary difference between the two role definitions would be how users execute their privileged commands.

In the restricted shell environment, users running the adflush command requiring administrative privileges:

dzsh $ adflush

In the unrestricted shell environment, users running the adflush command requiring administrative privileges:

[tulo@ajax]$ dzdo adflush

Creating a Role Definition with Rescue Rights

The Rescue rights option allows you to control which users should be able to log on if problems with the authorization cache or auditing service are preventing all other users from logging on. For example, if you have a computer with sensitive information, such as credit card numbers or intellectual property, you might require auditing for all users in the role with access that computer. If the auditing service is stopped or removed on that computer, no one would be able to log on and use the computer until auditing is restored. If you create a role with the Rescue rights option selected, only the users assigned to that role are able to log on and continue working until the problem that caused the lockout is found and fixed.

Users who are in a role granted access because they have rescue rights can still be audited through the system logging facility. However, their activity is not recorded in the audit store database if the auditing service is not available.

Creating Additional Custom Roles and Role Assignments

The previous sections described common roles that organizations implement to begin the process of migrating and removing locally defined privileged accounts. For most organizations, locallydefined accounts with privileged access present a security risk and are often identified as a compliance issue by auditors.

By creating role definitions similar to those described in this chapter, you can eliminate the need to share root and service account passwords while still providing privileged access to computers where it's needed. These additional roles are not required, however. You can choose to create them or create a completely different set of role definitions to suit your organization. For example, you might decide to create custom roles specifically tailored to the needs of database administrators, backup operators, and web application developers. Similarly, you might decide to create separate role definitions that are customized with AIX command rights for AIX administrators that are different from the command rights defined for Solaris administrators.

As with the common role definitions, additional custom role definitions can be created in the top-level parent zone and available throughout the zone hierarchy or in any child zone. They can also span all the computers in a zone or be assigned specifically to individual computers.

If you plan to create your own custom role definitions and role assignments, keep the following key points in mind:

- Rights associated with roles are cumulative. Users receive all of the rights in all of the roles they are assigned.
- Users must be assigned at least one role that allows an interactive login or Kerberos authentication to have any access to any computers. For existing users, this is accomplished by assigning the default UNIX Login role during the migration to Active Directory.
- Users must be given the Login with non-Restricted Shell system right to have access to a full shell. If they assigned in a role without this right, they can only execute the commands explicitly defined for their role.

For users who have previously had full shell access, this limitation can be frustrating, unexpected, and unworkable. Before placing or moving users into a restricted role, be sure those users and managers throughout the organization are well-informed and wellprepared for the change and understand the business reasons for the change.

Working with Computer Roles

In addition to the role definitions that confer specific rights when assigned to users and groups, Server Suite provides a mechanism for linking a specific group of computers to a group of users with a specific role assignment. These computer-based access rules, called **computer roles**, identify computers that share a specific attribute that you define and a set of users with common access rights.

For example, you can define a computer role that identifies a set of computers as Oracle database servers linked to a set of users who have been assigned the oracle_dba role. You can then add and remove users from the Active Directory role group linked to the oracle_dba role to grant or remove the rights associated with the oracle_dba role. In this example, the computer role identifies computers that host Oracle databases and the set of users assigned the database administrator role.

The same set of computers might include computers with AIX and Solaris operating systems. You could then create separate computer roles that link the AIX computers to a group of AIX administrators and the Solaris computers to a group of Solaris administrators.

Planning to Use Computer Roles

Because computer roles provide you with a great deal of flexibility for defining access rights, you might want to do some planning before you create new computer roles. For example, before you create a computer role you must know the criteria you want to use to group computers into one or more Active Directory security groups. You must also identify the users who will have a common set of access rights based on the computer grouping.

At a high-level, defining a computer role requires the following:

- Identify computer roles you want to define.

  Decide on the attribute the computers in a particular group share. For example, you can use a computer role to identify computers in the web farm, that host specific applications, or serve a specific department.

- Identify the users for the computer role and create Active Directory groups for them.

  You might need multiple groups because different sets of users have different access requirements. For example, if you are creating a computer role for a set of Oracle servers, you might need separate Active Directory groups for database users, database administrators, and backup operators.

- Identify the role definitions each set of users should be assigned.

  You might need to create specific access rights and role definitions for different sets of users. For example, if you are creating access rights for database users, database administrators, and backup operators, the database users may be able to use the predefined UNIX Login role, while administrators need permission to run privileged commands, and backup operators might be assigned a limited set of commands in a restricted shell.

How Computer Roles Simplify the Management of Access Rights

Deciding how best to use computer roles requires some upfront planning and configuration that might not be part of your initial deployment plan. To make effective use of computer roles, you also need to plan for and prepare appropriate role definitions for different sets of users. However, computer roles provide a powerful and flexible option for managing access to Server Suite-managed computers using your existing processes and procedures for managing Active Directory group membership.

For example, if you create a computer role group for Oracle servers and you deploy a new Oracle server, you simply add the computer account for the new server to the computer role group in Active Directory. If new database administrators join your organization, you simply add them to the Active Directory security group for Oracle database administrators. The computer role links the computer role group to the user role assignment and no additional updates are needed to accommodate organizational changes. If you need to modify the access rights, you can change the role definition and have the changes apply to all members of the group.

Because creating and managing computer roles is typically an ongoing administrative task after initial deployment, it is covered in the *Administrator's Guide for Linux and UNIX*. <!--TODO: xref -->

Migrating And Managing Service Accounts

After you have migrated accounts for the users who log on to the UNIX computers in your organization, the next step in the deployment is to decide how you want to manage the service accounts for applications in your environment. This section describes the options available and why you should consider migrating local service accounts to Active Directory.

Why Migrate Service Accounts?

A service account is typically a local user and group account dedicated to a specific application or to performing specific operations. In many cases, the service account has escalated permissions that allow it to run privileged operations on behalf of the application it supports. In addition, service accounts often have no password or a password that is wellknown to multiple users. Service accounts without a password typically require a local sudoers policy to control access. Service accounts with a shared passwords present a security risk because users can avoid an audit trail and, if passwords are managed locally, they may not conform to the password policies that are enforced for normal user accounts.

Therefore, the primary reason for migrating service accounts to Active Directory is to provide better security for accounts that can execute privileged commands, start and stop processes, or run specialized jobs on computers in your network.

Note that not all organizations choose to migrate and manage service accounts in Active Directory. There is no technical requirement that you do so. However, Server Suite provides you with several options for improving the security for service accounts. You should consider the options available, then decide which, if any, are most applicable for your environment.

Identifying Service Accounts to Migrate Tto Active Directory

Every UNIX platform has its own set of standard service accounts that are installed by default. For example, most UNIX platforms include services accounts for common applications, such as gopher, mail, ftp, and uucp. For most of these standard service accounts, there's no business reason to map them to accounts in Active Directory, unless you are trying to eliminate all local accounts on your UNIX computers.

In most cases, you can skip migration for the standard service accounts included by default when you installed the operating system as described in Eliminate default system accounts.

However, service accounts that run or manage applications or own an application's files are typically good candidates for mapping to Active Directory users. For example, an Oracle database instance has an oracle service account that owns the database server and the related processes that run in the background. Although usually linked to an application, a service account can also be account created to run scheduled jobs and own the files related to those jobs.

Service accounts that are good candidates for mapping to Active Directory users are ones that perform business operations without a password, rely on a shared password known to multiple users, or use shared SSH keys.

Service Accounts Without a Password

Most UNIX service accounts do not use passwords because UNIX services don't require an interactive log on to own files or run jobs. The most common way for users to access the service account is through the configuration of the sudoers file. The sudoers file provides rules that allow a subset of users to run the su command and change to the service account user. Mapping this type of service account to an Active Directory user eliminates the need for managing access through local sudoers policies and enables you to enforce the same password complexity rules for service accounts as normal user accounts.

Service Accounts with a Shared Password

The second most common way for users to access service accounts is with a shared account password. In this scenario, multiple users know the password for the service account and may be able to log on directly as that account. With shared accounts, there is no authoritative way to identify who is logging in to use the account. If you have any service accounts that rely on a shared password, you should consider migrating those accounts to Active Directory to eliminate the shared password.

Service Accounts that Use SSH Keys

Another common attribute of service accounts is that they often have a set of SSH keys that are available on multiple computers. The SSH keys allow the service account to transfer information from one UNIX computer to another without a password. In this scenario, a specific or the default SSH key for the service account exists in the authorized keys file on each of the computers to which the service account must connect.

Mapping a Service Account to an Active Directory User

After you identify one or more service accounts as candidates for mapping to an Active Directory user principal, you should identify an appropriate Active

Directory user principal for the service account to map to. In most cases, there won't be an appropriate user already defined in Active Directory, so you will need to create one or more new users.

Create a New Active Directory User Account

You can use Active Directory Users and Computers or another tool to create a new user principal for each service account you are migrating to Active Directory.

> **Note**: In most cases, you submit a request for a new account to be created using the procedure defined for your organization. For example, you might submit a request by filling out a service desk ticket and have the request serviced by a member of the account fulfillment team. The steps in this section only apply if you have permission to create new Active Directory user accounts. If you are not responsible for creating new Active Directory user principals, you can skip the following procedure.

To create a new Active Directory user for a service account:

1. Start Active Directory Users and Computers.
2. Expand the forest domain and the top-level UNIX organizational unit you created in Selecting a location for the top-level OU.
3. Select Service Accounts, right-click, then select **New > User**.
4. Type a name and account login information for the service account, then click **Next**.
5. Type and confirm the password to use for the service account in Active Directory, select the **User cannot change password** and **Password never expires** options, then click **Next**.

   The password must conform to your existing password policies for Active Directory users.

   If you are creating a new user to replace a shared account, type the password currently in use if it is acceptable within your site's Active Directory rules for password complexity. If you use the shared password, you should change the password after migration. If the current password is not complex enough, you should type a new password that complies or contact the Active Directory Enterprise Administrator for alternatives.
6. Click **Finish** to complete the creation of the new user principal.

Map the Unix Service Account to the Active Directory User

After you create a new Active Directory user principal for the service account, the next step is to map the UNIX account to the Active Directory user.

In preparation for this step, you should notify the user community that the service account will be unavailable for a brief period of time, so that you can make the change and verify that everything works as expected. You should then stop the service and any jobs associated with the service account.

By notifying users and making the service account unavailable for a period of time, you can prevent the change from affecting people who depend on the service to do their jobs. You can then use Access Manager to select the service account and map it to an Active Directory user.

To map the service account to an Active Directory user with Access Manager:

1. Start Access Manager.
2. Navigate to the UNIX user account
3. Navigate to the service account under a specific computer's Users node or under the Local Account Users node.
4. Select the service account, right-click, then click **Map to AD User**.
5. Type all or part of the Active Directory user name, click **Find Now**, then select the account in the results and click **OK**.

   Clicking OK updates the configuration on the remote host. You could accomplish the same thing by manually editing the configuration file (centrifydc.conf) or with a group policy.
6. Verify the service starts and executes operations as expected by switching to the root user or the service account and attempting to start the service.
7. Check for messages in the log files that the service account writes to. The entries should be regular service startup messages. You should verify that there are no errors or authentication failure messages.

After you verify that the service starts as expected and that any jobs it owns start successfully, you can notify users that the service is available or do additional testing. Depending on your organization and the service account you have mapped to Active Directory, developers, database owners, application owners, and others may want to do full regression testing or execute specific test cases.

How the Mapped User Changes Your Environment

The Active Directory user you create for a service account must be enabled for authentication to work. However, enabling this new user account does present some potential risks to your environment. For example, on UNIX computers, creating the new user may have added a password for a service account that did not previously have one. If the new password is known to more than one person, the account may be considered a shared account and result in an audit finding.

Also, because the new account is a valid Active Directory user principal, anyone with the password can potentially log on to any Windows computer in the forest. By giving the service account a valid password and enabling the account, you have granted access to the Windows network for an account that previously had no access to Windows computers.

If you disable the account, you prevent that account from accessing all Windows and UNIX computers, running jobs, or executing required tasks. If you leave the account enabled and the password is compromised, both Windows and UNIX computers are vulnerable to attack. Even if the password is not compromised, failed password attempts could trigger an account lockout policy, rendering the service unusable.

Mapping service accounts to Active Directory users is a simple technique for managing access and password complexity for service accounts. If you have strong passwords and carefully control access to the account and its password, you can mitigate the risks. This strategy is also best suited to service accounts that already use a password. However, if granting the service account access to the Windows network presents too great of a risk, you should consider alternatives.

Creating a Service Account Role in a Zone

As discussed in How the mapped user changes your environment, mapping a service account to a Windows user makes the account vulnerable to attack. If the attack results in a guessed password, the attacker would be able to log on as the service account, and, potentially, impersonate the service account on multiple computers on the network using SSH keys. Because the mapped user is also a valid Windows account, a successful dictionary attack might also grant access to Windows computers on the network. If the attack did not result in a guessed password, the failed password attempts could lock out the service account, making it unusable.

For service accounts that do not have a password, this vulnerability to a password-guessing attack would be a new security risk that did not previously exist. Therefore, simple account mapping is typically not the best solution for service accounts that are secured using sudoers policies or SSH keys instead of an account password.

If simple account mapping is not the appropriate solution for the service accounts in your organization, you may want to consider creating one or more service account roles. Roles enable you to securely manage the privileges of UNIX service accounts through Active Directory.

Create an Active Directory User Account for the Service

Because roles are tightly integrated with Active Directory user and group definitions, linking a service account to a role requires that you have an Active Directory user object to work with. In most cases, you should use your existing procedures to request a new user account. If you are responsible for creating new Active Directory user principals, see Create a new Active Directory user account.

Define a New Role with System Rights

It is recommended that you create the role definition for a service account in the appropriate child zone. If you want to make the role definition available in all child zones, however, you can create it in the parent zone. The specific selections you make for the role depend on the requirements of the service account for which you are creating the role definition. The steps described here provide general guidelines. Other settings may apply for the role definition in your organization.

To create a new role for a service account:

1. Start Access Manager.
2. In the console tree, expand **Zones** and the top-level parent zone.
3. Select the specific zone for which you want to define a role, and expand **Authorization**.
4. Select **Role Definitions**, right-click, then click **Add Role**.

5. On the General tab, type a name and description for the new role, then click **OK**.
6. Click the **System Rights** tab and select the following options that allow the service account to access UNIX computers using SSH keys or Kerberos, then click **OK**:
    - Non-password (SSO) login is allowed
    - Account disabled in AD can be used
    - Login with non-restricted shell

    In most cases, you should select the Login with non-restricted shell option. This option enables the service account to execute all of its commands in a standard shell. To have the service account run in a restricted shell, you must be able to identify and define rights for all of the commands that the service runs. The service account must also be able to execute all of its commands within the restricted shell (dzsh) environment. For most organizations, this additional security requires significant research and testing before it can be implemented. However, forcing a service account to run in a restricted shell reduces the likelihood that a compromised service account could be used to attack computers on the network.
7. Select the new role, right-click, then click **Add Right**.
8. Select the login-all right for the zone, then click **OK**.

    This predefined right grants access rights for all PAM applications. If you determine that a specific service account should only use a specific PAM application, such as SSH or FTP, you can define a right that only allows that application to be used, then select that right in the role definition to specify that the service account must use the selected PAM application for access.

Create a Unix Profile for the Service Account and Assign the Role

After you define the role for the service account, you can create a UNIX profile for the service account. In most cases, you should define the UNIX profile for service accounts using machine-level overrides, rather than defining them for zones. Defining profiles for service accounts using machine-level overrides has the following advantages:

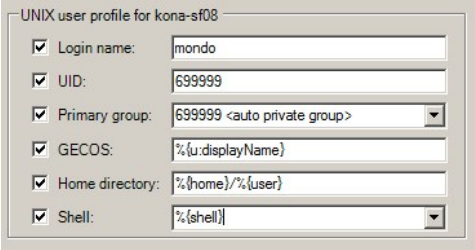
- Profile attributes are not affected the Zone Provisioning Agent. Most service accounts require specific UID and GID values. By specifying these values using a machine-level override, you don't have to worry about them changing when the Zone Provisioning Agent runs.
- You can explicitly identify which computers the service account can run on. If you define the UNIX profile for a service account in a zone, all of the computers in the zone are available to the same service account. If you define the UNIX profile using machinelevel overrides, the service account only runs on computers where it has a profile and the profile attributes for the service account can be different on different computers in the same zone.
- You can restrict the scope of the role assignments on a computer-by-computer basis. By defining the UNIX profile using machine-level overrides, you can configure different service account owners for development, testing, and production computers in the same zone.

If the profile attributes are consistent across most of the computers in a zone and the service account should run able to run on all of those computers, you can define all or part of the UNIX profile for the parent or child zone to reduce the management of profile attributes on individual computers. However, if the legacy accounts had different attributes on different computers, it is typically best to use machine-level overrides.

To create the UNIX profile and assign the service account role using machine-level overrides:

1. Start Access Manager.
2. In the console tree, expand **Zones** and the top-level parent zone.
3. Expand the Child Zones node, select a specific child zone and expand it to display the Computers node.
4. Select computer for which you want to define machine-level overrides, right-click, then click **Add User**.
5. Click **Browse** to search for and select the Active Directory user account for the service, then click **Next**.
6. Select **Define user UNIX profile** and **Assign roles**, then click **Next**.
7. Select and define the attributes in the UNIX profile for the service account, then click **Next**.

    You can use inherited default values for any of the attributes from the default values specified for the zone or selectively override the default values for any of the attributes. For example if you define user defaults using runtime variables in the zone, you can use the inherited values for the Login name, GECOS field, Home directory, and Shell and explicitly define the UID and primary GID for the service account profile.



8. Select the default UNIX Login role, click **Remove**, then click **Add**.
9. Click **Browse**, select the role you created for the service account, then click **OK**.
10. Click **OK** to accept the default start and end times for the role assignment, then click **Next**.
11. Review your selections, click **Next**, then click **Finish**.

Secure the Active Directory User Account

At this point, you have an enabled Active Directory user mapped to a UNIX profile for the service account. Having an enabled Active Directory user mapped to a service account, however, still presents a potential security risk as discussed in How the mapped user changes your environment. The next step is to decide how to secure the account to reduce the risk that it will be compromised and allow an attacker to gain access to the computers on your network. Depending on your organization's infrastructure and requirements, there are essentially two options available:

- Use SSH public key authentication
- Use Kerberos authentication

Each of these options has advantages and disadvantages and require different steps to configure.

Using Ssh Keys for Authentication

If you already use distributed SSH keys on hosts that run services, you can take advantage of that infrastructure and secure the service account by disabling the Active Directory user object in Active Directory. This is a common configuration that enables computertocomputer communication without a pass-phrase.

To use SSH public key authentication:

- Define the role for the service account with the **Account disabled in AD can be used by sudo, cron, etc** system right enabled. The role should not allow an interactive login.
- Ensure that the computers that communicate with each other have the SSH public key in the authorized_keys file.
- Select the Active Directory user principal you created for the service account and set the **Disable Account** option.

After you disable the account, it cannot be used for authentication on Windows or UNIX computers and it is not susceptible to a password-guessing attack. The account can continue to run UNIX services and use PAM-aware applications to communicate to other computers on the network using the SSH public key.

The primary advantage of using SSH authentication is that if you already have SSH public keys distributed to allow computer-to-computer communications, services should continue to work after the Active Directory user principal is disabled. There is very little configuration required to implement this solution.

There are, however, disadvantages to using SSH public keys. For example, you must manage key distribution. To allow a UNIX service account to communicate with other UNIX computers, you must generate the SSH key, and distribute that key to all of the hosts that the service account needs to communicate with. In addition, the most common configuration of SSH authentication allows keys to be used without a pass phrase. If the private key is compromised, an attacker could effectively impersonate the service account across multiple computers on the network and reacting to a compromised key can be timeconsuming because it requires you to remove the public key from every $HOME/.ssh/authorized_keys file distributed across the enterprise.

Using Kerberos Tickets for Authentication

If you are not already using distributed public-private SSH keys for authentication, you may want to consider using Kerberos authentication. Kerberos authentication is more secure than SSH keys and using Kerberos enables you to centrally manage access for service accounts, but it requires additional configuration.

To use Kerberos to secure UNIX service accounts:

- Install Kerberos-enabled software. You can use the Server Suite-provided version of OpenSSH or OpenSSH, version 3.9 or later, if it has been compiled with Kerberos support.
- Ensure the Active Directory user principal for the service account is enabled. Unlike SSH authentication, Kerberos requires the user account to be enabled to request ticket granting tickets or service tickets for other computers.
- Use the setspn.exe program to create at least one new Service Principal Name (SPN) for the UNIX service account.
- Run the adkeytab command on every UNIX computer where you want to re-use the Active Directory user principal that you created the new SPN for. This command creates a Kerberos keytab file that is only readable to the service account user. The keytab file allows the service account to request a ticket granting ticket so that it can communicate with other UNIX computers.
- Use the kinit command to request a ticket granting ticket from Active Directory for the UNIX service account. The ticket granting ticket (TGT) allows the service account to request additional host tickets for SSH communications to other UNIX computers.
- Use the klist command to list the tickets for the UNIX service account.

Testing And Migration

If you decide to use Kerberos for service accounts, you should test the computertocomputer communication. If you are migrating from authentication using SSH public-private keys, you can move ore rename the authorized_keys file for the service account on remote hosts to test authentication. After you test the Kerberos authentication of SSH communications and are certain that it works, you can delete the id_rsa, id_rsa.pub, and authorized_keys files for the service account that you have migrated.

Renewing Ticket Granting Tickets

Using Kerberos gives you consolidated control over UNIX service accounts. If an account is disabled in Active Directory, it cannot be used after any existing tickets expire.

If the service account runs scheduled jobs, you may want to create a crontab entry for the UNIX service account to run the kinit command at a regular interval so that the TGT doesn't expire. If the ticket expires and the kinit command isn't embedded in the job the service run, computer-to-computer communication will fail until the next time kinit is executed. For example, you may want to add logic to run klist to check whether there is a valid TGT, then run kinit is no valid TGT is found.

More Information

For information about using the setspn.exe program, see the Microsoft documentation for that program. For information about using Server Suite command line programs, see the corresponding man page.

Remove Local Service Accounts from Remote Computers

After you have migrated service accounts to roles in Active Directory, tested operations, and verified that commands and jobs run as expected, you can remove the local service accounts from remote computers to prevent them from being used.

For most organizations, removing local service accounts is a recommended security practice. However, you should leave the default operating system accounts as local accounts. In most cases, those accounts are not migrated to Active Directory. The default accounts for each platform are listed in the user.ignore file that is installed with the platform-specific Server Suite Agent.

Planning to Deploy in a Demilitarized Zone (DMZ)

Many organizations require both an internal network for corporate assets and a physical or logical subnet that exposes resources or services to a larger, external network, such as the Internet. For security, computers and resources in the external-facing perimeter network or demilitarized zone (DMZ) have limited access to the computers in the internal network. Because communication between the computers in the DMZ and the corporate network is restricted and protected through the use of a firewall, there are specific constraints on configuring authentication and authorization services.

This section describes how to deploy Server Suite components in specific DMZ scenarios.

Identifying the Computers to Protect

The computers that are most vulnerable to attack are computers that provide services such as e-mail, host external-facing web applications, and manage network routing through Domain Name Servers (DNS). Computers that provide these services are typically isolated from the internal network on their own subnet and allowed to communicate with the internal network through specifically designated channels. This configuration allows computers in the DMZ to provide services to both the internal and external network, but controls the traffic allowed to be routed between the computers in the DMZ and the internal network clients.

Creating a Forest and Trusts for a DMZ

It is recommended that you create a separate Active Directory forest for the computers to be placed in the network segment you are going to use as the demilitarized zone. You should then establish a **one-way outgoing trust** from the internal forest to the DMZ forest.

Defining a one-way trust allows existing internal forest users to access resources in the DMZ without separate credentials or being prompted for authentication. The one-way trust also prevents any accounts defined in the DMZ forest from having access to the internal network. Accounts defined in the DMZ forest can only access computers inside the DMZ domain. If a privileged account in the DMZ forest is compromised, that compromise is limited to the scope of the DMZ forest.

For Server Suite, the one-way trust enables you to:

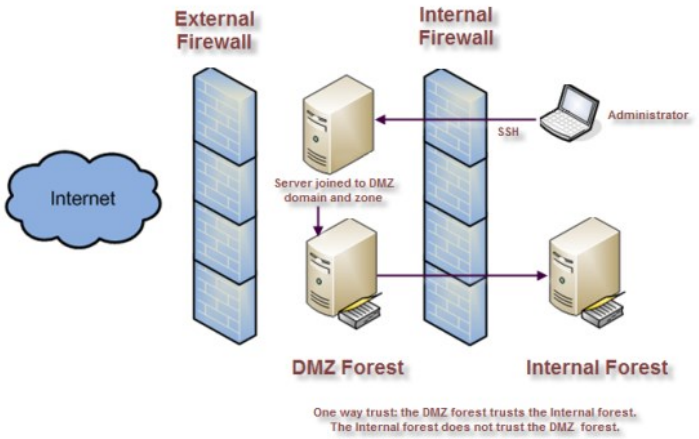
- Use the internal forest for authentication and authorization services for user accounts.
- Define computer accounts in the DMZ domain without permission to read data from the trusted domain of the internal forest.

In most cases, you should not use an existing Active Directory domain when deploying Server Suite Agents in a DMZ. Using an existing domain requires opening additional ports through the internal firewall to allow computers to connect directly to the domain controllers in the internal forest. Allowing computers in the DMZ to connect directly to the internal forest implicitly grants access to resources behind the internal firewall.

Defining Zones for Computers in the DMZ

You should create one or more zones in the DMZ forest and specify those DMZ zones when computers join the DMZ domain. You should also create and manage UNIX group profiles in the DMZ domain. However, you should define user accounts and UNIX profiles for in the internal forest and not the DMZ forest. Defining user accounts in the internal forest ensures that users can use a single password to authenticate across all network resources, including those in the DMZ.

The following figure provides an overview of the basic architecture for deploying Server Suite Agents when you have computers in a DMZ.



To enable authentication for resources in the DMZ, users must have:

- A valid Active Directory user principal.
- A complete UNIX profile in one or more zones in the DMZ.
- A UNIX Login, listed, or custom role assignment that allows access computers in the DMZ.

Creating a Firewall and Securing the Network

You should establish firewall rules that allow communication from the DMZ domain controllers to the internal domain controllers. Other computers in the DMZ, for example, the UNIX servers you want to isolate from the internal network, should have limited access to the corporate network. The most common exception is to allow communication from the corporate network to the DMZ network using port 22.

The client and server port requirements to enable communication through the firewall depend on the Windows operating system you have installed on the domain controllers and the functional level of the forest. For information about the specific ports to open and the services that use the ports, see Microsoft Active Directory documentation, such as *How to configure a firewall for domains and trusts*.

In addition to configuring a firewall that minimizes exposure to the corporate network, you should remove insecure network protocols, if possible, or replacing insecure authentication programs, such as POP3 and FTP, with Kerberos-enabled programs. These security steps reduce the potential for password exposure and the risk of an account in the corporate domain being compromised.

How to Join a Domain with a Read-Only Domain Controller (RODC)

With Windows Server 2008, you have the option of installing read-only domain controllers (RODC). Read-only domain controllers enable you to deploy a domain controller that hosts read-only partitions of the Active Directory database. Deploying a read-only domain controller enables you to make Active Directory data and reliable authentication services available in locations that cannot ensure physical security required for a writable domain controller.

You can also deploy read-only domain controllers to handle special administrative or application management requirements. For example, you may have line-of-business applications that are required to run on a domain controller, or application owners who must have access to the domain controller to configure and manage operations but not allowed to modify Active Directory objects as they could with a writable domain controller. You can grant a non-administrative domain user the right to log on to the read-only domain controller while minimizing the security risk to the Active Directory forest.

For more information about read-only domain controllers, see the *Read-Only Domain Controller (RODC) Planning and Deployment Guide*.

To join a domain that has a read-only domain controller:

1. Create a computer account for the computer in the DMZ that will connect to the readonly domain controller using a writable domain controller as described in Creating computer objects for the target set of computers.

   Note: You can create the computer account using the Access Manager console, an adedit script, or using the adjoin command with the --precreate command line option. However, be sure to create the computer account in a DMZ zone.

2. Use Active Directory Sites and Services or the repadmin program to replicate the computer account in the read-only domain controller. For example,
   - In the console tree, expand Sites, and then expand the site of the domain controller that you want to receive configuration updates.

- Expand the Servers container to display the list of servers that are currently configured for that site.
- Double-click the server object that requires the configuration updates that you want to replicate.
- Right-click **NTDS Settings** below the server object, and then click **Replicate configuration to the selected DC**.
- In the Replicate Now message box, click **OK**.

3. (Optional) Open a Command Prompt and use the repadmin /showrepl command to verify successful replication on the read-only domain controller.
4. Block the route from the UNIX computer to the writable domain controller, if necessary.
5. Run the adjoin command with the self-service option. For example:

   adjoin mydomain.local --password c%ntrify --name quad90 --selfserve

   Because you have already created the computer account in Active Directory, you don't need to specify the zone to join the domain.

Enabling NTLM Authentication through a Firewall

Having a domain controller in the perimeter forest trust the internal domain requires you to open up ports through the firewall. The specific port requirements depend on the Windows operating system version and functional level of the forest. As an alternative, you can use NT LAN Manager (NTLM) authentication to allow Active Directory users in the internal forest to log on to computers in the perimeter forest.

Using NT LAN Manager (NTLM) authentication enables you to have a more restrictive firewall with a one-way forest trust between the perimeter forest and the internal forest. For example, if the firewall prevents you from using the ports required for Kerberos authentication or if you have limited communications between the forests to a specific port, you can use NTLM authentication to pass authentication requests from the domain controllers in the perimeter domain to the internal domain controllers through the transitive trust chain.

> **Note**: This configuration still requires a one-way trust relationship between the internal forest and domain controllers outside of the firewall.

Configuring the Domain Controllers that Allow NTLM Authentication

You can use the pam.ntlm.auth.domains configuration parameter to specify the domain controllers in the DMZ forest that should use NTLM authentication. This parameter requires that you specify the domain controllers using their Active Directory domain names. In addition to setting this parameter, you must be able to map NTLM domain names to their corresponding Active Directory domain names to support looking up user and group information in the cache.

Configuring a Map that Converts NTLM Domains to Active Directory

For Server Suite to automatically construct this map, it must be a able to send LDAP search requests to the domain controllers in the corporate forest. If the firewall restrictions will block these search requests, you must manually define a topology map that converts NTLM domain names into Active Directory domain names. To manually configure how Active Directory domain names map to NTLM domain names, define entries in the /etc/centrifydc/domains.conf file using the following format:

ActiveDirectory_Domain_Name: NTLM_Domain_Name

For example:

arcade.com: ARCADE
ajax.org: AJAX

You can refresh the list of domain controllers in DMZ forest at any time by modifying the configuration parameters, then running the adreload command.

Managing and Evolving Operations After Deployment

In previous sections, you prepared for deployment, migrated existing users, configured automated provisioning for new users and groups, and added one or more custom roles for privilege management. Most of these activities are related to the initial deployment and extending deployment to additional sets of target computers and interactive users.

This section discusses management activity, evolving operational security, and adding services to extend authentication and authorization after deployment. Often, at this stage, the deployment project team begins to transition activity to an operations team or support staff.

Understanding How Server Suite Software Affects Operations

Through Active Directory, Server Suite software provides a consolidated solution to authentication, authorization, and policy management for Linux, UNIX, and Mac OS X computers. Because of this consolidation, however, you may need to make changes or additions to the IT tasks or operational procedures you currently have in place. Therefore, when you deploy Server Suite software in a production environment, you should consider how it impacts the management tasks typically performed by operations staff members.

The routine tasks that may be affected by adding Server Suite software to the environment fall into the following categories:

- Change management
- System administration
- Security administration
- Service desk operations
- Capacity management

Understanding Change Management Activities

Change management typically involves testing and installing updates to the operating system or installed applications. For example, most organizations follow a controlled process for reviewing and implementing changes to the operating system because of patches or new releases.

If you are preparing to update the operating system, the support staff should also plan to test that user log-ons and role assignments continue to function correctly after update. If a system patch or update affects the operation of Server Suite software, you should contact Customer Support to determine whether the patch is supported.

Staff members should also periodically review new and maintenance releases of Server Suite software to get the latest features, fixes to known issues, and enhancements requested by Server Suite customers. After downloading the software, you can review the release notes included in each package to determine what's changed and the suitability of the update for your organization.

Understanding System Administration Activities

Most system administration tasks involve managing users and groups. After deploying Server Suite software, this information is centralized in Active Directory for both Windows and non-Windows computers. Therefore, any administrative action for a user account affects that user on both Windows and UNIX computers. For example, if you disable a user account in Active Directory, the user will be unable to log on to any Windows or UNIXbased computer in the forest.

Typically, there is a period of time where staff members must use one set of steps for provisioning users and groups on the computers not yet joined to the domain and another set of steps for provisioning users and groups on computers that have successfully joined the domain. After you complete the migration to Active Directory, you can leverage the processes and tools you use for provisioning Windows users and groups for ongoing administration of UNIX users. For example, you can use Active Directory Users and Computers, in-house custom scripts, Access Manager, ADEdit, or another management tool to perform administrative tasks.

After deployment, you should prepare any site-specific or platform-specific instructions the operations staff should follow if you are making changes to the processes or tools they are familiar with.

Understanding Security Administration Activities

Security administration involves ensuring that operators are granted the appropriate rights for administering the computers and attributes that are required as part of their job but are prevented from accessing or changing computer settings outside their areas of responsibility.

Delegated Administration

Server Suite enables administrators to explicitly delegate management tasks to the appropriate users and groups on a zone-by-zone basis.

Password Policy Enforcement

Server Suite enables you to use existing Active Directory password policy rules, such as the minimum password length, complexity requirements, expiration, and allowed number of logon failures to allow before locking an account for both Windows and UNIX users.

Privileged Account Management

Server Suite enables you define rights, roles, and role assignments to control what users can do and who can execute privileged commands. You can also map privileged local accounts to Active Directory accounts to ensure better password security for those accounts. For example, the local root user account has full access to all data and can manipulate all settings on a UNIX computer. Mapping the local root user to an Active Directory user account enforces the Active Directory password policies on the account and makes it more difficult for an unauthorized user to obtain escalated privileges on the UNIX computer.

Understanding Service Desk Operations

Active Directory and Server Suite simplify help desk and service desk operations by:

- Enabling centralized administration for tasks such as adding new users or granting access to new computers.
- Consolidating user passwords and reducing the need for password resets.
- Simplifying troubleshooting for log on failures for UNIX users.

You should provide help desk staff with troubleshooting instructions to help them diagnose and resolve failed authentication or authorization tickets.

Understanding Capacity Management Activities

During the deployment of Server Suite Agents, you should monitor and analyze network traffic and domain controller replication to determine how well your environment handles the extra load of UNIX users and computers in Active Directory. In general, Server Suite software is configured to use minimal system resources and network bandwidth. In practice, however, you should monitor and evaluate the volume of traffic to determine its impact on performance across the network and the performance experienced by users logging on to UNIX workstations and servers.

If the network traffic or resource usage exceeds your expectations, you may want to modify the default configuration to better suit your network topology. For example, Server Suite provides numerous group policies and configuration parameters that you can modify to optimize network activity or control how much data is stored locally on individual computers.

Determining Whether You Need More Resources

In most cases, deploying Server Suite software does not noticeably affect the performance of the network or domain controllers. However, if you have a widely distributed network or replication delays, you should analyze your network's capacity to handle the additional load of UNIX users and computers to determine whether you need to make changes to ensure optimal performance and availability. For example, the following factors may require you to allocate additional resources:

- If the UNIX computers are in a different physical location than the domain controllers that they access, you may want to install a domain controller on a computer that is physically closer to the UNIX computers to reduce long-distance network traffic and the chance of replication delays.
- If you need to ensure availability in the event of a network or server failure, you should ensure that you have an adequate number of domain controllers to support the UNIX computers when they need to fail-over to a backup domain controller.
- If you add a large number of UNIX users to the Active Directory domain, apply your standard method for balancing domain controllers per number of users.
- If you add a large number of UNIX computers to the Active Directory domain, apply your standard method for balancing domain controllers per numbers of computers.
- If you move a large number of UNIX users and groups from a local directory (/etc/passwd and /etc/group) to Active Directory, you may need additional network bandwidth because authentication and authorization requests are now done over the network.

For more information about modifying configuration parameters, see the *Configuration and Tuning Reference Guide*.

Understanding How Caching Facilitates Lookups

Server Suite Agents store credentials in a local cache to reduce the network traffic required to look up information in the directory. For example, if a user executes the directory listing command in a UNIX command shell (such as with the ls -l command), the command looks up and displays a listing of files along with their attributes, such as the owner of each file.

However, a file's owner is stored as a number—the user's UID—on UNIX-based computers, but because the ls command displays the owner as a name and not a number, the ls command must look up the actual user name associated with the file owner's UID. Because UNIX UIDs and user names are stored in Active Directory, this lookup request must be serviced by Active Directory. If a large number of files are displayed when the ls command is run, this creates a substantial amount of lookup traffic between the UNIX computer and the Active Directory domain controller.

Server Suite reduces this traffic by caching the lookups so that the information does not have to be retrieved from the Active Directory each time a lookup is required. Commands such as ls check the local cache first for the relevant information instead of retrieving the information from Active Directory every time.

Troubleshooting Logon Failures

If a user attempts to log on to a computer that is in a Server Suite zone and the logon fails, the problem is typically caused by one of the following:

- Users attempting to log on to a computer they are not authorized to use.
- Users have an incomplete profile in the zone where the computer they are attempting to use is located.
- Users have not been assigned an appropriate role that allows logon access.
- Users have typed their non-Active Directory password or typed the wrong password more times than allowed.
- Local or group policy settings are applied to the computer to prevent access.

To investigate these potential problem areas:

1. Check whether the local UNIX computer can connect to the Active Directory domain controller.
    - Log on to the computer using a locally authenticated user, such as the local root user.
    - Run the ping command with the name of an appropriate domain controller in the forest.

      For example, if the local computer is joined to the snowline.org forest, the command might look similar to this:

      ```
      su -
      Password:
      ping shasta.snowline.org
      ```

      If the command receives a reply from the domain controller, the DNS service is functioning and the local computer is able to locate the domain controller on the network. If the ping command does not generate a reply, you should check your DNS configuration and check whether the local computer or the domain controller is disconnected from the network.
2. Check Active Directory information by running the adinfo command. The output from this command should appear similar to the following:

   ```
   Local host name: magnolia
   Joined to domain: snowline.org
   Joined as: magnolia.snowline.org
   Current DC: shasta.snowline.org
   Preferred site: Default-First-Site-Name
   Zone: snowline.org/Acme/Zones/cascade
   Last password set: 2017-12-21 11:37:22 PST
   CentrifyDC mode: connected
   ```

   If the mode is disconnected, check whether adclient is running and network connectivity. On a slow network adclient may drop the connection to Active Directory if there is a long delay in response time.

   If the output displays an <unavailable> error, you should try running the adleave command to leave Active Directory, re-run the adjoin command, then re-run the adinfo command. For example:

   ```
   adleave --force
   adjoin --user skip --zone cascade snowline.org
   Password:
   adinfo
   ```

   If a problem still exists, check the DNS host name of the local computer and the domain controller, the user name joining the domain, and the domain name you are using.
3. Check the clock synchronization between the local UNIX computer and the Active Directory domain controller.

If the clocks are not synchronized, reset the system clock on the UNIX computer using the date command.

4. Check for denied users and groups in the /etc/centrifydc/centrifydc.conf file or the Login Controls group policy. For example, open the centrifydc.conf file in a text editor, such as vi:

   vi /etc/centrifydc/centrifydc.conf

   - Search for the pam.deny.users line and make sure that the user who is trying to log on is not listed.
   - Search for the pam.deny.groups line and make sure that the user who is trying to log on is not a member of any group that is listed on this line.

5. Check the contents of the system log files or the centrifydc.log file after the user attempts to log on. You can use information in this file to help determine whether the issue is with the configuration of the software or with the user's account.

6. Check for conflicts between local user accounts and the user profiles in Active Directory by running the getent command. For example:

   getent passwd

   This command displays a list of local and Active Directory users with access to the computer. If the user's name is not listed but other Active Directory users are listed, the problem may be in the user's Active Directory account settings or UNIX profile.

   If no Active Directory users are listed in the output of the command, check whether adclient is running and whether the Active Directory domain controller is available.

7. Check the user's Active Directory account settings using Access Manager or Active Directory Users and Computers. For example:

   - Check whether the user has a UNIX profile for the local computer's zone.
   - If the user has a UNIX profile in the zone, check whether the profile is currently enabled.
   - If the user has an enabled UNIX profile, check the user's group membership to determine whether it is a local group defined in a different domain than the computer account.
   - Check whether the user's account has been disabled or locked.
   - Check whether any user-based group policies have been applied to the user account that may prevent access to the UNIX computer.

8. Enable logging of adclient activity using the addebug command. For example:

   /usr/share/centrifydc/bin/addebug on

   This command enables extensive logging of each operation performed by the adclient process in the /var/log/centrifydc.log file. You can use the information in this file to further diagnose the cause of any problems or to enable Server Suite's support staff to assist with resolving any issues.

Evaluating Additional Services And Integrations

After you have deployed Server Suite Agents to implement an Active Directory-based security and directory services, you may want to explore other ways to take advantage of Active Directory's infrastructure. In evaluating ways to extend your security and directory services, you must first understand:

- How the UNIX servers and workstation that are joining the domain are used
- Which applications are accessed locally and which applications are accessed by remote users
- How the servers and workstations are managed, and whether administrators are local users or remote users
- Whether there are specific additional IT services you want to enable
- Whether there are specific controls you want to apply

As a starting point, you should consider whether computers joining the domain are workstations that primarily support local logon sessions or servers that require few, if any, local logon sessions. In many cases, UNIX computers have few interactive users but are frequently used as application servers that host database or web applications. For those computers, you should determine whether Active Directory authentication and authorization is primarily for administrators who manage the server or for users who log in to access the application.

Some of the ways you can extend and evolve the deployment of Server Suite software include:

- Adding authentication service for applications
- Adding custom reports for auditing UNIX properties
- Adding group policies
- Adding support for NIS clients
- Using programs optimized for Kerberos authentication
- Integrating with products from other vendors

Adding Authentication Service for Applications

Because Active Directory and Server Suite use Kerberos and LDAP standards, many Kerberos-enabled or PAM-enabled applications can use Active Directory for authentication and authorization service with little or no configuration. One way you can evolve your deployment is to add support for single sign-on to additional applications.

Supporting Single Sign-on for Kerberos-enabled Applications

The primary way that Server Suite supports single sign-on is through Kerberos. Kerberos provides a ticket-based authentication mechanism that is the default method for authentication in Active Directory. When a user logs on to a computer that uses Active Directory authentication, a Kerberos ticket is issued to the user and that ticket allows the user to access data, applications, other computers, and other sessions without having to present credentials again. This silent authentication that takes place in the background as users browse network shares or run applications is the key to enabling a single sign-on experience.

Many applications are Kerberos-enabled by default or can be configured to support the use of Kerberos tickets. By default, when a computer joins an Active Directory domain, Kerberos requests are forwarded and serviced by the Kerberos Key Distribution Server on the Active Directory domain controller. Therefore, in most cases, existing Kerberos-enabled applications can authenticate and authorize access without any modification.

If you use an application that is not configured to use Kerberos authentication by default, however, you may need to modify configuration options or use specific command line options to support single sign-on.

In addition, users must be assigned to a role with the **Non-password (SSO) login is allowed** system right. This right is enabled in the predefined UNIX Login role. If you create custom roles and want to allow single sign-on, you should select this system right when defining the role.

Supporting Single Sign-on for PAM-aware Applications

Pluggable Authentication Modules (PAM) provide a flexible mechanism for authenticating users regardless of the underlying authentication system. Most programs and applications that rely on user authentication use PAM.

The agent uses its own PAM module, pam_centrifydc.so, to direct PAM requests to Active Directory. Therefore, in most cases, existing PAM-enabled applications can authenticate and authorize access without any modification and support single sign-on without any special configuration.

One known exception, however, is that most database applications support PAM authentication, but do not enable it by default. To support single sign-on for database applications, you should modify the database configuration to enable PAM authentication.

In addition, users must be assigned to a role with the **Non-password (SSO) login is allowed** system right. This right is enabled in the predefined UNIX Login role. If you create custom roles and want to allow single sign-on, you should select this system right when defining the role.

Supporting Active Directory Authentication for Apache and Java Applications

Most Web and J2EE platforms provide their own native authentication and authorization services for Web developers to use. With Server Suite, you can choose to extend the native interfaces to enable web applications to provide single sign-on capability or redirect authentication requests to Active Directory instead of a native authenticator.

Supporting Database Server Applications

Most database servers provide their own native authentication and authorization services. With Server Suite, you can choose to extend the native interfaces to enable supported database servers to provide single sign-on capability or redirect authentication requests to Active Directory instead of a native authentication service.

Adding Custom Reports for Auditing Unix Properties

Server Suite includes several default reports that you can use to monitor and audit access to the computers in your environment. The default reports provide detailed information about your UNIX users, groups, computers, zones, and licenses, and enable you to verify which users have access to specific computers, zones, or applications. Default reports also provide easy access to the information that you require for auditing, business planning, and regulatory compliance. After you generate a report, you can save the report in the following formats:

- Microsoft Excel (.xls)
- Microsoft Word (.doc)

- Adobe Acrobat (.pdf)
- XML document (.xml)

For example, after generating a report with information about the users in each zone, you can save it as a Microsoft Excel spreadsheet (.xls), and import the information into an Excel Workbook to create a Charge Back report on account usage for each department.

One of the most common ways to evolve the Server Suite deployment is to create custom reports that are specifically tailored to your organization and auditing requirements. The Access Manager console includes a Report Wizard that allows you select the specific Active Directory objects and properties and the relationships on which you want to base the report.

For information about creating and generating custom reports, see the *Administrator's Guide for Linux and UNIX*.

Adding Group Policies

For many companies, centralized policy management and configuration control is just as important as centralized identity management. With Server Suite, you can apply group policy settings from Active Directory to the non-Windows computers and UNIX users.

Evaluating Existing Policy Settings

If you have applied any domain-wide policies in the Active Directory forest, you should review what the policy settings are and where they are enforced for Windows-based computers. You should then evaluate which policy settings, if any, are applicable for computers running UNIX, Linux, or Mac OS X operating systems. For example, most organizations establish a policy for password complexity. You can view your current password policy settings by clicking **Domain Security Policy** under **Administrative Tools** to open the **Default Domain Security Settings**, then select **Password Policy**.

If you enable any password policy settings for the domain, they automatically apply to UNIX users and managed computers because Active Directory uses these settings when authenticating users. If you enable or change any of the default domain policy settings, you should consider how they affect UNIX users and computers. For information about the standard Windows group policies that apply for UNIX, see the Group Policy Guide.

Adding Server Suite-specific Group Policies to a GPO

You can add Server Suite-specific configuration settings to any Group Policy Object applied to any site, domain, or organizational unit in the Active Directory forest. You can then manage the specific policies enabled and settings applied centrally through the Group Policy Object Editor on Windows.

Each GPO can consist of configuration information that applies to computers, configuration information that applies to users, or sections of policy that apply specifically either to users or to computers. You link a GPO to an Active Directory organizational unit, domain, or site. Windows then applies the policy settings based on an established hierarchical order.

The Server Suite-specific group policy settings available for users and groups are defined separate administrative templates (.adm or .xml files) that can be added to any GPO. If you enable any of the policy settings, they are written to a virtual registry on the UNIX computer. The Server Suite Agent then runs a set of local mapping programs that read the virtual registry and modify local configuration files to implement the setting defined by the group policy. You can also create your own custom administrative template and mapper programs to implement custom group policies.

For more detailed information about creating and managing Server Suite-specific group policies, see the *Group Policy Guide* and Active Directory documentation.

Adding Support for NIS Clients

You can extend Server Suite software to provide NIS service from a Server Suite-managed computer, acting as a NIS server, to NIS client requests using Active Directory as the central data store for NIS maps.

There are many scenarios in which adding the Server Suite Network Information Service (adnisd) to your infrastructure can enable you to integrate Server Suite and Active Directory with other enterprise solutions. For example, the adnisd Network Information Service and Server Suite zones can be used to centrally manage and map multiple UNIX identities to a Windows user account for access resources stored on EMC Celerra Network Servers or Network Appliance Filers. Active Directory remains the central identity store and zones remain the primary way of mapping UNIX profiles to a user account, but the Server Suite Network Information Service enables you to deliver the appropriate information to servers and devices across the network.

Using the Server Suite Network Information Service in conjunction with the Server Suite Agent is a scenario like this provides the following advantages:

- **Redundancy.** As an NIS client, the Celerra Network Server can find NIS servers by broadcasting on the local subnet. If a subnet hosts more than one Server Suite-managed computer acting as a NIS server, the Celerra or NetApp server can fail over from one NIS server to another NIS server on that subnet, thus enabling multiple NIS paths to the same data held within Active Directory.

- **Multi-domain support.** The Server Suite NIS service can provide user mapping data to NIS clients who may have an account anywhere within an Active Directory forest, including remote or child domains. Through the Active Directory Global Catalog, Server Suite Agents can find user mapping information for users anywhere across the forest.

Extending your deployment with the Server Suite Network Information Service also enables you to centrally manage network information and publish custom information to NIS clients throughout the network without modifying the underlying Active Directory schema.

Using Programs Optimized for Kerberos Authentication

As a management platform, Server Suite provides its own versions of commonly-used open source programs. For example, the following packages have been optimized to work with Server Suite software and Active Directory:

- Standard MIT Kerberos utilities, such as kinit and kdestroy, are installed with the agent to support Kerberos keytab management for accounts in Active Directory.
- Kerberos-enabled client programs such as OpenSSH, support Kerberos authentication and single sign-on for secure connections between Server Suite-managed computers.
- An enhanced version of PuTTY supports Kerberos authentication for secure, remote access from Windows computers to Server Suite-managed computers.

Integrating with Products from Other Vendors

Server Suite software also integrates with products from many other vendors, such as Splunk, IBM DB2, SAP Netweaver and Secure Network Communication (SNC), and Quest ActiveRoles Server. In addition to Active Directory, you can use Server Suite software to extend other Microsoft services such as Services for Network File System (NFS), Microsoft Identity Integration Server (MIIS), and Microsoft Active Directory Federation Services (ADFS).

For more information about add-on packages, integration with other systems, or configuring Server Suite software to work with other products, see the Resource Center on the Delinea website.

Getting Assistance from Support

It is recommended that you take the following steps if you need assistance with an issue or have questions about the operation of Server Suite components:

1. Check the Support Portal on the Delinea website to search the Knowledge Base to see if your problem is a known issue or something for which there is a recommended solution.
    - Open http://www.centrify.com/support/login.asp in a Web browser.
    - Log in using your customer account information and password.
    - Click **Find Answer** and type one or more key words to describe the issue, then click **Find** to view potential answers to your question. For example, to search for known issues, type known issues and click **Find** to see articles related to the known issues in different releases.

      If your issue is not covered in an existing Knowledge Base article or the Server Suite documentation set, you should open a case with Delinea Support.
2. Click **Log a Case** to open a new case using the Delinea Support Portal.

   Alternatively, you can contact Delinea Support by email or telephone, if you prefer. Worldwide contact information is available in the "How to open a case and collect information for Delinea Support" Knowledge Base article (KB-0301).
3. Provide as much information as possible about your case, including the operating environment where you encountered the issue, and the version of the Delinea product you are working with, then click **Submit** to open the case.

Before or after opening a support case, you may need to collect additional information about your environment. To help ensure your issue gets resolved quickly and efficiently, you should take the following steps to gather as much information as possible:

1. Verify the Server Suite Agent is running on the computer where you have encountered a problem. For example, run the following command:

   ps –ef | grep adclient

   If the adclient process is not running, check whether the watchdog process, cdcwatch, is running:

   ps –ef | grep cdcwatch

The cdcwatch process is used to restart adclient if it stops unexpectedly.

2. Enable logging for the Server Suite Agent. For example:

   /usr/share/centrifydc/bin/addebug on

3. Create a log file for the Mac OS X Directory Service. For example:

   killall –USR1 DirectoryService

4. Run the adinfo command to generate a report that describes the domain and current environment. For example:

   adinfo --diag --output filename

5. Duplicate the steps that led to the problem you want to report. For example, if an Active Directory user can't log in to a Server Suite managed computer, attempt to log the user in and confirm that the attempt fails. Be sure to make note of key information such as the user name or group name being, so that Delinea Support can identify problem accounts more quickly.

6. Verify that log file /var/log/centrifydc.log or /var/adm/syslog/centrifydc.log exists and contains data.

7. Generate information about Active Directory domain connectivity and configuration files by running the following command:

   adinfo --support

   This command writes output to the file /var/centrify/tmp/adinfo_support.txt.

8. If there is a core dump during or related to the problem, save the core file and inform Delinea Support that it exists. Delinea Support may ask for the file to be uploaded for their review.

   If the core dump is caused by an agent process or command, such as adclient or adinfo, open the /etc/centrifydc/centrifydc.conf file and change the adclient.dumpcore parameter from never to always and restart the agent:

   /etc/init.d/centrifydc restart

9. If there is a cache-related issue, Delinea Support may want the contents of the /var/centrifydc directory. You should be able to create an archive of the directory, if needed.

10. If there is a DNS, LDAP, or other network issue, Delinea Support may require a network trace. You can use Ethereal to create the network trace from Windows or UNIX. You can also use Netmon on Windows computers.

11. Create an archive (for example, a .tar or .zip file) that contains all of the log files and diagnostic reports you have generated, and add the archive to your case or send it directly to Delinea Support.

12. Consult with Delinea Support to determine whether to turn off debug logging. If no more information is needed, run the following command:

    /usr/share/centrifydc/bin/addebug off

Templates and Sample Forms

This section provides templates and samples that you can customize and use in the deployment process. These templates represent documents that are commonly used, such as change control requests and email notifications of software changes. Your organization may require you to use organization-specific versions of these documents.

Simplified Environment Analysis and Zone Design Template

This template provides a framework for the information that the deployment team should collect, analyze, and document in evaluating the existing network infrastructure and how it will change after deployment. Depending on your environment and requirements, you might need to collect additional information, but this template describes the most common elements with examples that you can adapt to your organization.

1. Introduction

   Use this section to provide a brief overview of the deployment plan. For example, document the features you plan to deploy, any primary goals that might affect design decisions, and any dependencies or special considerations, such as activities that require change control approval or enhanced permissions.

2. Network architecture

   Use this section to capture details about your existing network configuration and Active Directory architecture. For example, you might want to record information about the Active Directory site, forest, and domain controllers, including trust relationships and domain and forest functional levels, if applicable.

   You might also include details about your DNS configuration, including whether you have more than one DNS namespace and any port requirements, firewall restrictions, and any network connectivity issues. For details about the default ports used, see Default ports for network traffic and communication.

3. Server Suite-managed computers

   Use this section to provide details about the existing UNIX, Linux, and Mac OS X computers on which you plan to deploy the Server Suite Agent.

4. Provisioning process

   Use this section to describe the process for provisioning computers, groups, and users.

5. Rights, roles, and role assignments

   Use this section to describe the rights, roles, role assignments, and configuration policies you require. For example, if you use the sudo program and the sudoers file, use this section to document how rights and roles defined in the sudoers file and whether the sudoers file is managed locally on each computer or in a central location.

6. Zone architecture

   Use this section to identify the Active Directory schema you are using and where Server Suite-related objects are located in the Active Directory forest.

7. Deployment preparation in Active Directory

   Use this section to summarize the deployment of Server Suite components into the existing Active Directory forest and domain.

8. Windows installation

   Use this section to describe how zones will be created and configured.

9. UNIX deployment

   Use this section to describes the deployment of Server Suite Agents on UNIX computers.

10. Group Policies

    Use this section describes the group policies that will be deployed for UNIX computers.

Change Control Request Form

Delinea

Most larger organizations require a formal change request to be submitted for any changes to Active Directory. The purpose of this template is to illustrate a request for creating new Active Directory organizational units, groups, and users. If the deployment team is not allowed to add UNIX groups and group members to Active Directory after the organizational structure if created, it is likely the project will experience delays.

Change Requested:

Approved By:

Test Case Matrix Sample

To validate the pilot deployment, most organizations execute at least some formal testing of features and functionality. The purpose of this template is to suggest a basic set of test cases to execute that apply to most environments. These test activities apply to setting up your environment, installing the software, and performing common administrative tasks. You can skip any activities that don't apply to your organization.

Testing Matrix

Create the OU Structure with a script or manually	Active Directory setup activities	
Create the OU Permissions with a script or manually		
Create Security Groups with a script or manually		
Create Distribution Groups with a script or manually		
Create the Zones Container with the Setup Wizard, a script, or manually		
Create the Licenses Container with the Setup Wizard, a script, or manually		
Create the service account for the Zone Provisioning Agent		
Update the local or domain policy to allow the Zone Provisioning Agent service to Log on as a service right		
Deploy the agent on computers		
Create a zone with a script or Access Manager console	Access Manager console activity	
Delegate zone control with a script or using the Delegate Zone Control Wizard		
Pre-Create Computer account		
Import UNIX groups from group files or group NIS maps		
Resolve mapping issues		
Import UNIX users from passwd files or passwd NIS maps		
Assign interactive users to the UNIX Login role	Authorization activities	
Assign users who need profile but not access to the listed role		
Join computers to the domain using adjoin	You should prepare for migration and create one or more initial zones before you join the domain.	

Configure root-equivalent rights		
Configure root-equivalent replacement role		
Add an Active Directory group for the role		
Test role access		
Test role privileges control		
Identify current management process (manual or automated)	UID consolidation activities	
Document the new management process		
Define the business rule for assigning UIDs (for example, SID)		
Identify active users to preserve, migrate, and keep		
Run adfixid to change file ownership		
Identify current management process (manual or automated)	GID consolidation activities	
Document the new management process		
Define the business rule for assigning the primary GID values (for example, GID)		
Identify the Active Directory groups for primary GID assignments	Domain Users	
Validate Active Directory log on credentials	User login activities	
Validate successful access to UNIX, Linux, Mac OS X		
Validate successful application usage		
Validate password complexity policy		
Validate account lockout policy		
Validate role enforcement		
Validate single sign on		
Validate password reset		
Test period users validated	Clean up activities	
Test period groups validated		
Test period roles validated		
Run adrmlocal to remove local accounts		

Preliminary Software Delivery Notification Email Template

The purpose of this template is to notify users that they are scheduled to receive new software that will be delivered to their computers. This email notice

should include a specific delivery date or a time frame estimate, if possible. Although you can delete this information from the email message you send out in your organization, this notice is most effective if users know specifically when the change is scheduled to occur. You can also customize the specific requirements or objectives that Server Suite is helping your organization achieve.

Colleagues:

The *[Department Testing Server Suite]* has successfully completed testing of the Server Suite software and is ready to begin the deployment portion of the project. The target date for deployment is *[Scheduled time]*.

Deployment of this software will greatly enhance our ability to comply with multiple industry requirements to include *[List objectives, such as: PCI, Sarbanes-Oxley compliance, Internal/External Security Audit, specific organization initiatives]*. These requirements are in alignment with prioritized corporate business objectives.

The Server Suite software enables the streamlining of authentication, access controls and privileges, and auditing for all corporate IT systems. For the most part, deployment and streamlined authentication and authorizations services occurs "behind the scenes" with minimal, if any, user disruption. You should not notice any operational changes when the software is deployed to your computer.

Thank you for your cooperation,

[IT Department Signature]

Department-specific Announcement and Instructions Email Template

The purpose of this template is to notify users in a specific department that they are scheduled to transition to using Server Suite for authentication and authorization. This email notification indicates that you plan to join the computers in the department to an Active Directory domain during down time. Depending on your organization's policies, this email may suggest users log on with their Active Directory credentials or explicitly state that they can continue to log on with their existing credentials.

Colleagues:

The *[Specific department you are deploying to, such as: Accounting Department]* is scheduled to begin the transition to Server Suite next week. In order to ensure a smooth transaction we simply ask that you log off of all systems before leaving for the weekend. When you return to work the following week, you should *[be able to log on with your current user name and password]*.

If you experience any difficulties logging on, or with application connectivity, please submit a ticket or contact the support desk immediately. Several members of each department helped the IT team perform successful testing and validation of this new solution, and we anticipate a smooth transition.

Thank you for your cooperation,

[IT Department Signature]

General Announcement and Deployment Schedule Email Template

The purpose of this template is to notify a broader user community of the deployment schedule for multiple departments across the company. This sample also illustrates the type of notes you can incorporate into the email message to keep other groups informed of their status. The general announcement may also include portions of the other two email templates. For example, you may want to include the objectives the transition to Server Suite helps the company achieve or the instructions to use current or Active Directory credentials after migration.

Colleagues:

At the completion of the week, the *[Server Suite Deployment Project Team]* will allocate first response resources to the next department scheduled for deployment.

This is the schedule coordinated with the Department Heads throughout the company:

9 May 2017	Information Technology	
16 May 2017	Accounting	
23 May 2017	Marketing	Pending EOQ Reports

30 May 2017	Security	
6 Jun 2017	Sales	
13 Jun 2017	Executive	
20 Jun 2017	PMO	
27 Jun 2017	Data Warehouse	Pending EOQ Reports
3 Jul 2017	Training	
10 Jul 2017	Business Development	
17 Jul 2017	Audit	

The IT Department would like to thank everyone to date for their work on this project, and look forward to a successful deployment. If you have any questions, please submit them to the *[Server Suite_project]* distribution list and include your contact information. We will respond with answers or contact you directly for more information.

Sincerely,

[IT Department I Server Suite Deployment Project Team]

Deployment Team Task Checklist

Before you install the pilot deployment, you should prepare a deployment checklist to ensure you have the information you need to successfully complete the deployment. For example, you should review port requirements, verify DNS resolution, and create one or more spreadsheets that describe the user and group accounts to be imported and any special relationships, such as membership in specific groups that need to be preserved or any special configuration you want to implement.

Creating a deployment checklist is optional, but can help you to collect detailed information about each of the computers targeted for deployment.

The following example illustrates information you can collect and record in a deployment team task checklist.

	Operating system, version, and patch level for target computers
	Host name and IP address for target computers
	Current disk space for target computers
	Review the details of the current DNS configuration For example: Is the address resolved through a UNIX DNS server, Windows DNS server, or settings in the /etc/hosts and /etc/resolv.conf files? Is the computer using a DNS server that has SRV records for Active Directory domain controllers? Are UNIX subnets registered and associated with Sites in Active Directory? Are you using a disjointed DNS namespace, where a UNIX computer name may be server.company.com but the Active Directory domain name is server.windows.company.com? Are you using DNS aliases and do they resolve correctly? Are there multiple network interfaces (NIC) in use?
	Current network time provider (NTP) For example, does the computer use a different server to determine the time than the Active Directory domain controller?
	Current firewall configuration For example, are there any firewalls blocking required ports between the UNIX computer and the Active

	Directory domain controllers for the registered sites?
	Current applications and services For example, do you have Perl, Samba, or OpenSSH deployed? Are the versions you have compatible with the Server Suite Agent or—if a Server Suite version is available—to be replaced by versions provided by Server Suite? Do you have existing authentication providers deployed? Are existing applications and services Kerberos-enabled or PAM-enabled? Are there other applications that require local users or groups?
	Current source of user and group information For example, are the /etc/passwd and /etc/group files the only source of user information for the users who access this computer or other identity stores, such as existing LDAP servers or NIS domains, used? Are there any specific users or groups that should remain locally defined?
	Current NSS configuration For example, have you reviewed the contents of the nsswitch.conf file to check for other sources of user and group information?
	Connectivity between this computer and the domain controller For example, is there a reply from the domain controller when you run the ping command?
	User names and UIDs checked for conflicts across the target group
	Zone requirements analyzed for the target group
	Zone identified for this computer
	Server Suite Agent installed and the computer joined to the domain
	Groups allowed or denied access identified for this computer
	Existing users and groups for this computer imported into Active Directory
	Imported user and group profiles mapped to Active Directory accounts
	Allowed or denied groups configured using parameter values or group policy

If you use a deployment checklist, you can also include additional notes and details about the activities performed. For example, a partially completed checklist might look something like this:

	Operating system: Sun Solaris 10 with all patches applied (17-April-2017)
	Host name and IP address: aspen, 177.29.10.10
	Current DNS configuration: Resolved through the enterprise DNS server, spider.ajax.org
	Current time source is NTP server: ntpd on solstice.ajax.org Change for deployment: Use SNTP on the Active Directory domain controller
	Current firewall configuration: No port issues
	Existing OpenSSH version to be replaced, no other issues found.

	Current source of user and group information: /etc/passwd, /etc/group, and NIS domain nwest03 have users who access aspen
	Connectivity with the domain controller: Verified by JR (2-May-2011).
	User names and UIDs checked for conflicts across the target group: Analyzed by JR and DC (4-May-2017).
	Zone requirements analyzed for the target group: Zones required for the target group are nwest01, swest02, corp-main, and nwest03 (9 May 2017). SF to recommend new extended zone descriptions for approval.
	Zone identified for this computer: nwest03
	Server Suite Agent installed and the computer joined to the Active Directory domain: dc3colorado.ajax.org, OU: US-UNIX-Computers
	Groups allowed r denied access identified for this computer: Allowed access group—all_employees, oracle_sys Denied access—consultants, temps
	Existing users and groups for this computer imported into Active Directory: Completed by DC (20-May-2017).
	Imported user and group profiles mapped to Active Directory accounts: Work complete for users and groups that already had matching Active Directory candidates. Work in progress for the remaining profiles without any matching Active Directory candidate. Target date for completion: 31-May-2017
	Allowed or denied groups configured using parameter values or group policy: TBD

Permissions Required for Administrative Tasks

This chapter describes the permissions required to perform administrative tasks that affect Centrify-specific objects in Active Directory. You can set these permissions manually for individual users and groups who manage Centrify zones in Active Directory. However, setting permissions manually can be time-consuming and error-prone. In most cases, you should use the Zone Delegation Wizard to authorize users to perform specific tasks.

At a minimum, all Access Manager actions require users to have generic Read permission. This permission is typically granted to all Authenticated Users by default.

Because Authenticated Users have read access, they can run reports in the Report Center. No additional rights need to be granted to enable users to run reports.

How Permissions Are Set

Access Manager requires specific rights for administrators to work with objects such as UNIX users, groups, and computers within Active Directory. As part of your deployment planning process, you should review the rights required to set up and manage Centrifyspecific objects and be familiar with how to manually assign rights for managing Centrify objects, if needed.

Built-in Windows groups, such as Domain Admins and Domain Users, have default permissions, which might be customized for your organization. In general, the administrators for the forest root domain have broad authority to set permissions for all other users and groups, including the administrators of other domains. Therefore, whether you can modify the permissions for specific users and groups within your Active Directory environment will depend on the policies of your organization.

If you have the appropriate authority, there are several ways you can access, verify, and modify the permissions assigned to specific users and groups.

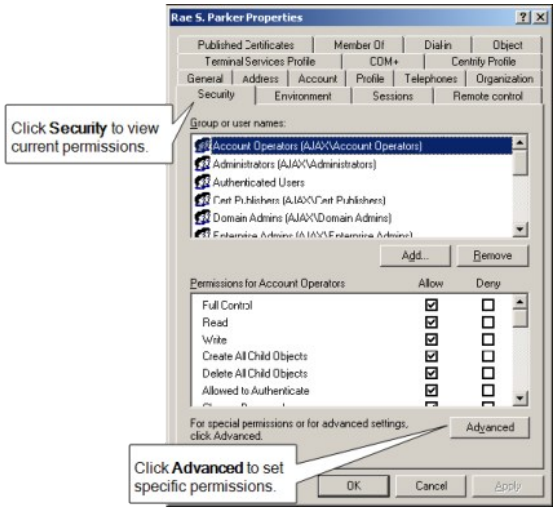
For example, you can view and modify permissions in the following ways:

- Use **ADSI Edit** to directly modify any Active Directory attributes.
- Use **Active Directory Users and Computers** to set basic or advanced permissions on any Active Directory object through the **Security** tab.

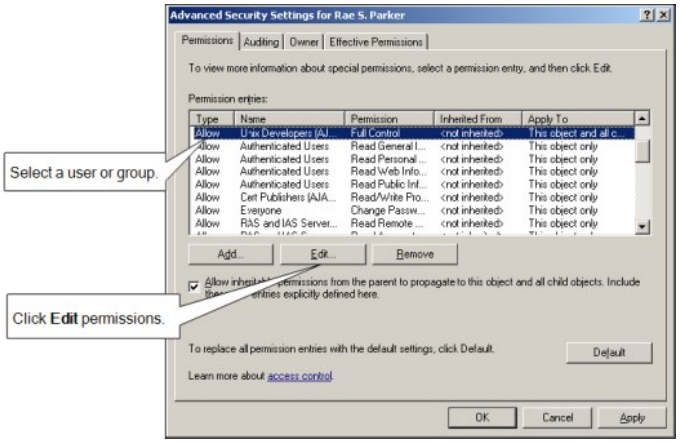
  To display the Security tab, select **View > Advanced Features**. To access some permissions, however, your user account must have **Create all child objects** or **Write all properties** permissions.
- Run the **Zone Delegation Wizard** to set the appropriate permissions for specific users or groups to perform specific tasks within a zone.
- Click **Permissions** when viewing Zone Properties in Access Manager to set basic or advanced permissions on any zone object.
- Click **Permissions** when viewing the Centrify Profile for a user in Access Manager to set basic or advanced permissions on any user object.

The following steps illustrate how you can set permissions from Active Directory Users and Computers:

1. Open the console and connect to the Active Directory domain.
2. Select an Active Directory object, such as a user or computer, rightclick, then click **Properties**.
3. Click the **Security** tab, then click **Advanced**.



4. Select the user or group to which you want to assign rights, then click **Edit**.

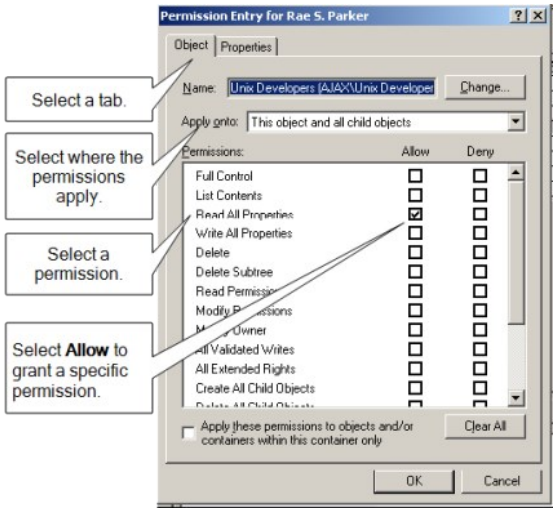


If the user or group to which you want to assign permissions isn't listed, click **Add** to find the account.

5. In the Permission Entry dialog box, click the **Object** or **Properties** tab, as needed.

   Selecting Object or Properties and where the permission should be applied varies depending on the task you are allowing a user or group to perform.

6. Select the specific rights you want to assign by scrolling to find the permission, then clicking the **Allow** check box.



7. When you are finished setting the appropriate permissions, click **OK**.

   For more specific information about how to set permissions on Active Directory objects and properties and how to view, modify, and remove permissions, see your Active Directory documentation.

Permissions Required to Use the Setup Wizard

In most cases, you run the Setup Wizard to guide you through the configuration of Active Directory for Centrify. The Setup Wizard updates Active Directory with Centrify-specific objects and properties, including zone and license containers that are required for proper operation.

To successfully perform initialization tasks, the user account that runs the Setup Wizard must have specific rights. Because some of these rights might be reserved for administrative accounts, some users might be prevented from performing certain steps in the Setup Wizard.

To allow other user accounts to run the Setup Wizard, you can manually create the appropriate container objects, then assign to those objects only the specific permissions needed to correctly complete the configuration of Centrify-specific objects. Users can then use the Setup Wizard to select the appropriate container objects and perform all of the necessary steps without being members of an administrative group.

Licenses Container Permission Requirements

The following table describes the minimum rights that must be applied to the Centrifyspecific container objects or other users to successfully complete the configuration of Centrify software.

Licenses container	Read all properties Create classStore Objects Modify permissions	This object only
	Write Description property Write displayName property	This object and all child objects
	The Setup Wizard requires you to create or select at least one parent container for license keys. By default, this container object is: domain/Program Data/Centrify/Licenses You can create additional License containers, if needed, through the Manage Licenses dialog box. By default, all Authenticated Users have read and list contents permission for the Licenses container and all of its child objects. You can change these permissions if you want to restrict access to Access Manager.	

Zones container or any container used as a destination for a new zone	Read all properties Create classStore Objects Create container objects	This object only
	Write displayName property	This object and all child objects
	The Setup Wizard requires you to create or select a parent container object for creating new zones. By default, this container object is: domain/Program Data/Centrify/Zones You can use other containers for zones, if needed. For example, if you have created a separate high-level organizational unit called UNIX as the parent container: domain/UNIX/Zones	
ZoneName/Computers container	Create group objects Write Description property	This object only
	These permissions are only needed if you are supporting “agentless” authentication in a zone.	
Computers container For example, the generic Computers container: domain.com/Computers	Write operatingSystem property Write operatingSystemVersion property Write operatingSystemHotfix property Write operatingSystemServicePack property	SELF on Computer objects
	These permission are granted to each computer’s SELF account when you select the Grant computer accounts in the Computers container permission to update their own account information option in the Setup Wizard.	

Licenses Container Permissions

The following table describes the minimum rights that must be applied to the Centrify Licenses container that stores the license keys for your installation.

Licenses container	Read all properties Create classStore Objects Modify permissions	This object only
	Write Description property Write displayName property	This object and all child objects

The Setup Wizard requires you to create or select a parent container for license keys. The default location for the parent container for license keys depends on the organizational structure you deploy. For example, if you use the recommended organizational structure, the default location for licenses would be domain/Centrify/Licenses.

You must have at least one parent container for license keys in the forest. You might want to create more than one license container objects to give you more granular control over who has access to which licenses.

By default, all Authenticated Users have Read and List Contents permission for the Licenses container and all of its child objects. These permissions are required to use Access Manager. You can change who has these permissions if you want to prevent users from using Access Manager.

Zones Container Permissions

The following table describes the minimum rights that must be applied to the Centrify Zones container.

Zones container or any container used as a destination for a new zone	Read all properties Create classStore Objects Create container objects	This object only
	Write displayName property	This object and all child objects
Change the default zone container	Delete	Previous zone container

The Setup Wizard requires you to create or select a parent Zones container object for new zones. The default location for the parent container for new zones depends on the organizational structure you deploy. For example, if you use the recommended organizational structure, the default location for new zones would be domain/Centrify/Zones. You can use other containers for zones or create multiple parent containers for zones to separate administrative duties for different groups.

Computers Container Permissions

The following table describes the minimum rights that must be applied to the generic Computers container (domain/Computers).

Computers container	Write operatingSystem property Write operatingSystemVersion property Write operatingSystemHotfix property Write operatingSystemServicePack property	SELF on Computer objects

These permission are granted to each computer's SELF account when you select the **Grant computer accounts in the Computers container permission to update their own account information** option in the Setup Wizard.

Computers Container Within a Zone Permissions

The following table describes the minimum rights that must be applied to the Computers container in a named zone if you are supporting "agentless" authentication in that zone.

ZoneName/Computers container	Create group objects Write Description property	This object only

Creating Parent Containers Manually

Some organizations prefer to create and manage Active Directory objects manually to ensure tight control over the objects and their related attributes. For example, you might want to manually create separate Zones or Licenses parent containers for different business units or geographic locations so that you can manually set different sets of permissions and related properties on those containers. Creating objects manually also enables you to have precise control over who has access to the objects.

You can create the container objects anywhere in the forest's directory structure, but you must have at least one parent Zones container object and at least one parent Licenses container object.

Optional Administrative Tasks

By default, Centrify does not require you to be an enterprise administrator or domain administrator of the forest root domain to install or configure Centrify-specific properties. However, some optional configuration tasks do require you to be an enterprise administrator or a domain administrator of the forest root domain.

These optional tasks involve:

- Creating display specifiers for Centrify profiles to enable access to the Centrify Profile properties page in Active Directory Users and Computers.
- Registering the administrative notification handler to ensure data consistency if users delete Centrify objects using Active Directory Users and Computers.

- Setting permissions for zones objects to enable maximum control over the placement of and rights associated with Centrify-related objects within Active Directory.

In most cases, if you want to perform any of these tasks, you must use an account that is an enterprise administrator or a domain administrator of the forest root domain.

Creating Display Specifiers for Centrify Profiles

To display the Centrify Profile properties in Active Directory Users and Computers, you must be an enterprise administrator or a domain administrator for the forest root domain because adding the Centrify Profile to Active Directory Users and Computers requires you to add display specifiers to Active Directory.

> **Note**: A display specifier is an Active Directory object that allows you to add components to the Active Directory Users and Computers (ADUC) Microsoft management console (MMC) snap-in.

If you want to make the Centrify Profile available in Active Directory Users and Computers, an enterprise administrator can manually define the display specifiers (under domain/Configuration/DisplaySpecifiers/LanguageID/) for computer, group, and user properties by modifying the adminPropertyPages attribute with the appropriate GUID. For example, if the Active Directory domain is ajax.org and the language you support is US-English (CN=409), you would define the display specifiers in:

ajax.org/Configuration/DisplaySpecifiers/409

> **Note**: Adding the display specifiers for Centrify properties is an optional step you can perform manually using ADSI Edit or by running the displayspecifier.vbs script. If you manage all Centrify objects through Access Manager, you do not need to perform this task.

To use the displayspecifier.vbs script to set up the display specifiers:

1. Log on using an enterprise administrator account or a domain administrator for the forest root domain.
2. Open a Command Prompt window and change to the Centrify installation directory. For example:

   cd C:\Program Files\Centrify\Access Manager
3. Run the displayspecifier.vbs script.

   If you want to manually add the display specifiers to display property pages in Active Directory Users and Computers, you must create the following entries using ADSI Edit, where n is the next number in the index of values for the attribute:

computer-Display displaySpecifier	adminPropertyPages	n,
group-Display displaySpecifier	adminPropertyPages	n, {0CDC9AD0-E870-483f-8D16-17EAB3B7F881}
user-Display displaySpecifier	adminPropertyPages	n, {543DBFE3-317D-4493-8D00-84591E4EDCDE}
inetOrgPerson-Display	adminPropertyPages	n, {543DBFE3-317D-4493-8D00-84591E4EDCDE}

For example, if the Active Directory domain is ajax.org and the language you support is US-English (CN=409), you would add these entries to the objects in:

ajax.org/Configuration/DisplaySpecifiers/409

In most cases, you only need to set up the display specifiers once for the Active Directory forest. If you support multiple languages, you can manually add the display specifiers to each language you support. For example, if your organization supports US-English (CN=409), Standard French (CN=40C), and Japanese (CN=411), you would add the display specifiers to these three containers. Once you have updated Active Directory by running the displayspecifier.vbs script or by manually adding the display specifiers, you can access the Centrify Profile properties using Active Directory Users and Computers.

Registering the Administrative Notification Handler

The administrative notification handler provides services to ensure data integrity in the Active Directory forest. You can register the notification handler automatically through the Setup Wizard the first time you start Access Manager, but this requires an account that is an enterprise administrator or a domain administrator in the forest root domain.

Registering the administrative notification handler is optional, but doing so helps to ensure that no orphan UNIX data is left in the directory if a user, group, or computer is deleted using Active Directory Users and Computers. When registered, the notification handler automatically deletes any service connection point (SCP) dependencies on a directory object if the directory object is deleted. Without this service, deleting a directory object such as a computer or user account in Active Directory might leave an orphan service connection point for the object in the directory.

If you don't want to perform this step in the Setup Wizard, you can manually configure the administrative notification handler using ADSI Edit or you can choose not to register the administrative notification handler for Centrify. If you choose not to register the administrative notification handler, however, you should periodically run the Analyze command to check for orphan data in the Active Directory forest.

To manually set up the administrative notification handler for Centrify, add the following entry using ADSI Edit under domain/Configuration/DisplaySpecifiers/LanguageID/ where n is the next number in the index of values for the attribute:

DS-UI-Default-Settings	dSUIAdminNotification	n,

For example, if the Active Directory domain is ajax.org and the language you support is US-English (CN=409), you would add this entry to the object in:

ajax.org/Configuration/DisplaySpecifiers/409

Granting Permissions For Administrative Tasks

The easiest way to grant permissions to perform administrative tasks is to use the Zone Delegation Wizard. The Zone Delegation Wizard enables you to delegate specific administrative tasks to specific users and groups. For each task you delegate to a specific user or group, you are providing that user or group with a specific set of permissions for working with objects in Active Directory.

The user who creates a zone has full control on the zone's serviceConnectionPoint. That user has exclusive permission to delegate administrative tasks to other users. The user who creates a zone is also the only user who can add NIS maps to the zone because creating NIS maps requires permission to create containers in Active Directory. The zone creator can, however, grant other users permission to add, remove, or modify NIS map entries.

The following table summarizes the permissions that can be assigned through your selections in the Zone Delegation Wizard. In addition to the permissions listed, however, the basic Read permission is required to perform any action. The Read permission is granted to Authenticated Users by default.

All	Permissions to perform all of the actions listed in the Zone Delegation Wizard and described below. This option allows a designated user or group to perform all of the other actions. Only the user who creates a zone can grant this permission to other users and groups for the zone.
Change zone properties	List contents on the ZoneName object container. Read all properties on the ZoneName object container. Write name on the ZoneName object container. Write Name on the ZoneName object container. Write Description property on the ZoneName object container.
Add users	List contents on the ZoneName/Users object container. Read all properties on the ZoneName/Users object container. Create serviceConnectionPoint objects on the ZoneName/Users object container.
Add groups	List contents on the ZoneName/Groups object container. Read all properties on the ZoneName/Groups object container. Create serviceConnectionPoint objects on the ZoneName/Groups object container.
Add local users	List contents on the ZoneName/Local Users object container. Read all properties on the ZoneName/Local Users object container. Add local users to the zone.
Add local groups	List contents on the ZoneName/Local Groups object container. Read all properties on the ZoneName/Local Groups object container. Add local groups to the zone.
Join computers to the zone	List contents on the ZoneName/Computers object container. Read all properties on the ZoneName/Computers object container. Create serviceConnectionPoint objects on the ZoneName/Computers object container. **Note** Joining the domain requires additional permissions on the Active Directory computer object, but the join command performs the necessary operations without requiring the additional permissions to be granted to the user or group you are designating as a trustee.

Remove zones	List contents on the ZoneName object container. Read all properties on the ZoneName object container. Allow Delete on the ZoneName object container. Allow Delete Subtree on the ZoneName object container.
Remove users	List contents on the ZoneName/Users object container. Read all properties on the ZoneName/Users object container. Delete serviceConnectionPoint objects on the ZoneName/Users object container.
Remove groups	List contents on the ZoneName/Groups object container. Read all properties on the ZoneName/Groups object container. Delete serviceConnectionPoint objects on the ZoneName/Groups object container.
Remove local users	List contents on the ZoneName/Local Users object container. Read all properties on the ZoneName/Local Users object container. Remove local users from the zone.
Remove local groups	List contents on the ZoneName/Local Groups object container. Read all properties on the ZoneName/Local Groups object container. Remove local groups from the zone.
Remove computers from the zone	List contents on the ZoneName/Computers object container. Read all properties on the ZoneName/Computers object container. Delete serviceConnectionPoint objects on the ZoneName/Computers object container.
Modify user profiles	List contents on the ZoneName/Users object container. Read all properties on the ZoneName/Users object container. Write cn on the serviceConnectionPoint object. Write name on the serviceConnectionPoint object. Write Name on the serviceConnectionPoint object. Write keywords on the serviceConnectionPoint object. For RFC 2307-compliant zones, modifying the user's UNIX profile also requires the following rights on the serviceConnectionPoint object of the UNIX user object: Write uid. Write uidNumber. Write loginShell. Write gidNumber. Write gecos. Write unixHomeDirectory. The additional rights for RFC 2307-compliant zones are applied to the posixAccount object associated with the serviceConnectionPoint for the UNIX user object.
Modify group profiles	List contents on the ZoneName/Groups object container. Read all properties on the object containers. Write name on the serviceConnectionPoint object. Write Name on the serviceConnectionPoint object. Write keywords on the serviceConnectionPoint object. For RFC 2307-compliant zones, modifying the group's UNIX profile also requires the following rights applied to the posixGroup object associated with the serviceConnectionPoint object of the UNIX group object: Write gidNumber.
Modify local user profiles	List contents on the ZoneName/Local Users object container. Read all properties on the ZoneName/Local Users object container. Modify local users in the zone. Parameters that can be modified are: User name (the UNIX login name). The user identifier (UID). The user's primary group profile numeric identifier (GID). The default home directory for the user. The default login shell for the user. General information about the user account (GECOS). State.
Modify local group profiles	List contents on the ZoneName/Local Groups object container. Read all properties on the object containers. Modify local groups in the zone. Parameters that can be modified are: Group name. Group members. Group identifier (GID). State.
Modify computer profiles	List contents on the ZoneName/Computers container object. Read all properties on the ZoneName/Computers container object. Write description on the ZoneName/Computers container object if the zone is a hierarchical zone. Write keywords on the serviceConnectionPoint object. Write displayName on the serviceConnectionPoint object. Write cn on the serviceConnectionPoint object. Write name on the serviceConnectionPoint object.
Allow computers to respond to NIS client requests	List contents on the ZoneName/Computers/zone_nis_servers group object. Read all properties on the ZoneName/Computers/zone_nis_servers group object. Write member property of group object on the ZoneName/Computers/zone_nis_servers group object.
	List contents on the ZoneName/Users and ZoneName/Groups container object. Read all properties on the ZoneName/Groups container object. Create serviceConnectionPoint on the ZoneName/Users and ZoneName/Groups container objects. Write cn on the

Import users and groups to zone	serviceConnectionPoint object. Write name on the serviceConnectionPoint object. Write managedby on the serviceConnectionPoint object. Write displayName on the serviceConnectionPoint object. Write keywords on the serviceConnectionPoint object. For RFC 2307-compliant zones, importing users also requires the following rights on the serviceConnectionPoint object of the UNIX user object ZoneName/Users: - Write uid. - Write uidNumber. - Write loginShell. - Write gidNumber. - Write unixHomeDirectory. - Write gecos. For RFC 2307-compliant zones, importing groups also requires the following right on the serviceConnectionPoint object of the UNIX group object under ZoneName/Groups: - Write gidNumber.
Manage roles and rights	List contents on the AzTask container and all child objects. Read all properties on the AzTask container and all child objects. Create msDS-AzTask objects Delete msDS-AzTask objects Write msDS-AzApplicationData on the msDs-AzTask object. Write cn on the msDs-AzTask object. Write name on the msDs-AzTask object. Write description on the msDs-AzTask object. Write msDs-OperationsForAzTask on the msDs-AzTask object. List contents on the AzOperation container and all child objects. Read all properties on the AzOperation container and all child objects. Create msDS-AzOperation objects Delete msDS-AzOperation objects Write msDs-AzApplicationData on the msDs-AzOperation object. Write cn on the msDs-AzOperation object. Write name on the msDs-AzOperation object. Write description on the msDs-AzOperation object. List contents on the msDS-AzAdminManager object. Read all properties on msDS-AzAdminManager object. Write msDs-AzApplicationData on msDS-AzAdminManager object.
Manage role assignments	List contents on the msDS-AzAdminManager object and all child objects. Read all properties on the msDS-AzAdminManager object and all child objects. Create msDS-AzRole objects. Delete msDS-AzRole objects. Write msDS-AzApplicationData on the msDS-AzRole object. Write msDS-TasksForAzRole on the msDS-AzRole object. Write msDS-MembersForAzRole on the msDS-AzRole object. Write displayName on the msDS-AzRole object. Write msDS-AzApplicationData on the msDS-AzAdminManager object.
Modify computer roles	List contents on the ZoneName object and all child objects. Read all properties on the ZoneName object and all child objects. Write msDS-AzApplicationData Write msDS-AzScopeName Write description
Add or remove NIS map entries	List contents on the ZoneName/NISMaps object container. Read all properties on the ZoneName/NISMaps object container. Create classStore Objects on the ZoneName/NISMaps object container. Write name on the ZoneName/NISMaps object container. Write Name on the ZoneName/NISMaps object container.
Modify NIS map entries	List contents on the ZoneName/NISMaps object container. Read all properties on the ZoneName/NISMaps object container. Write adminDescription on the classStore object. Write Description on the classStore object. Write wWWHomePage on the classStore object.
Remove NIS maps	List contents on the ZoneName/NISMaps object container. Read all properties on the ZoneName/NISMaps object container. Allow Delete on the MapName object. Allow Delete Subtree on the MapName object.

Note: In some cases, the permissions granted through the Zone Delegation Wizard are a subset of the complete permissions required to perform some tasks. For information about the complete permissions required to perform a specific task, see the section that describes the permissions for performing that task. For example, for information about setting permissions for NIS maps, see Setting permissions for NIS maps.

Setting permissions for zones

The user who creates a zone has full control over zone properties and administrative tasks. Only the zone owner can delegate administrative tasks to other users and groups through the Zone Delegation Wizard. In most cases, the users who are allowed to create zones have domain administrator privileges and sufficient permissions to perform all administrative tasks and to delegate administrative tasks to other users.

If you manually set permissions to allow domain users to create zones, however, you should also manually set the permissions to allow those users to manage rights and roles or notify zone administrators that they should run the Zone Delegation Wizard and assign those tasks to their own account or to appropriate users and groups. At least one administrator must have permission to add an authorization store, define rights and roles, and manage role assignments in each zone. All users must have at least one valid role assignment to access a zone.

Creating a Zone

To create new zones, your user account must be set with the following permissions:

Parent container for new zones you created or selected in the Setup Wizard. For example: domain/UNIX/Zones	On the **Object** tab, select **Allow** to apply the following permission to this object and all child objects: Create Container Objects Create Organizational Unit Objects **Note** Both permissions are required if you want to allow zones to be created as either container objects or organizational unit objects.
Parent container for Computers in the zone	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create group objects Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Write Description property These permissions are only needed if you are supporting "agentless" authentication in the new zone.

Opening Zones

To open an existing zone, your user account must be set with the following permissions:

Parent container for new zones For example: domain/UNIX/Zones	On the **Object** tab, select **Allow** to apply the following permission to this object: List contents
Container for the individual zone For example, a ZoneName container object, such as: domain/UNIX/Zones/arcade	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read allowedAttributes Read allowedAttributesEffective Read canonicalName Read Description Read displayName Read name Read objectClass
Parent container for Users in the zone	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectClass
Parent container for Groups in the zone	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectClass

Modifying Zone Properties

To modify zone properties for a zone, your user account must be set with the following permissions:

Container for an individual zone For example, a ZoneName container object: domain/UNIX/Zones/arcade	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read Name Read name Read Description Read displayName Write Description **Note** You can grant these permission to specific users or groups by selecting the **Change zone properties** task in the Zone Delegation Wizard. These permissions also enable you to change the parent zone for a selected zone object.

Renaming a Zone

To rename a zone, your user account must be set with the following permissions:

Container for an individual zone For example, a ZoneName container object, such as: domain/UNIX/Zones/arcade	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Write name property Write Name property **Note** You can grant this permission to specific users or groups by selecting the **Change zone properties** task in the Zone Delegation Wizard.

Deleting a Zone

To delete a zone from Active Directory, your user account must be set with the following permissions:

Container for an individual zone For example, a ZoneName container object, such as: domain/UNIX/Zones/arcade	On the **Object** tab, select **Allow** to apply the following properties to this object only: Delete Delete Subtree Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read Name Read name Read displayName **Note** You can grant this permission to specific users or groups by selecting the **Delete zone** task in the Zone Delegation Wizard.

Managing Roles and Rights in a Zone

To manage rights and roles in a zone, including creating and deleting role definitions and updating time constraints, your user account must be set with the following permissions:

Container for the authorization store For example: domain/UNIX/Zones/arcade/Authorization	On the **Object** tab, select **Allow** to apply the following properties to this object and all child objects: List contents Read all properties Click the **Properties** tab and select **Allow** to apply the following properties to the msDS-AzAdminManager object: Write msDS-AzApplicationData
AzTaskObjectContainer	On the **Object** tab, select **Allow** to apply the following properties to this object and all child objects: List contents Read all properties Create msDS-AzTask objects Delete msDS-AzTask objects Click the **Properties** tab and select **Allow** to apply the following properties to msDS-AzTask objects: Write msDS-AzApplicationData Write cn Write name Write description Write msDs-OperationsForAzTask
AzOpObjectContainer	On the **Object** tab, select **Allow** to apply the following properties to this object and all child objects: List contents Read all properties Create msDS-AzOperation objects Delete msDS-AzOperation objects Click the **Properties** tab and select **Allow** to apply the following properties to msDS-AzOperation objects: Write msDS-AzApplicationData Write cn Write name Write description

Managing Role Assignments in a Zone

To manage role assignments in a zone, your user account must be set with the following permissions:

Container for the authorization store For example: domain/UNIX/Zones/arcade/Authorization	On the **Object** tab, select **Allow** to apply the following properties to this object only: List contents Read all properties Create all child objects Delete all child objects Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Write msDS-AzApplicationData Click the **Properties** tab and select **Allow** to apply the following properties to msDS-AzRole objects: Write displayName Write msDS-AzApplicationData Write msDS-TasksForAzRole Write msDS-MembersForAzRole
Computers container in the zone	On the **Object** tab, select **Allow** to apply the following properties to this object only: Create Container Right This permission is required to allow a delegated user to make the first role assignment after a computer is joined to Active Directory.
AzRoleObjectContainer	On the **Object** tab, select **Allow** to apply the following properties to the msDS-AzApplication object and all child objects: List contents Read all properties Create msDS-AzRole objects Delete msDS-AzRole objects Click the **Properties** tab and select **Allow** to apply the following properties to msDS-AzRole objects: Write displayName Write msDS-AzApplicationData Write msDS-TasksForAzRole Write msDS-MembersForAzRole Click the **Properties** tab and select **Allow** to apply the following properties to msDS-AzAdminManager objects: Write msDS-AzApplicationData
AzOpObjectContainer	On the **Object** tab, select **Allow** to apply the following properties to this object only: Read all properties Create msDS-AzOperation objects Delete msDS-AzOperation objects Create msDS-AzRole objects Delete msDS-AzRole objects Click the **Properties** tab and select **Allow** to apply the following properties to msDS-AzRole objects: Write displayName Write msDS-AzApplicationData Write msDS-TasksForAzRole Write msDS-MembersForAzRole Click the **Properties** tab and select **Allow** to apply the following properties to msDS-

	AzOperation objects: Read name Read Name Write msDS-AzApplicationData Write name Write description

Changing Computer Role Properties in a Zone

To manage computer role properties in a zone, your user account must be set with the following permissions:

Container for the authorization store For example: domain/UNIX/Zones/arcade/Authorization/guid The *guid* object is a globally unique identifier (GUID) for the Authorization object. For example: CN=cab186af-61a0-4d54-a0dd...	On the **Object** tab, select **Allow** to apply the following properties to this object only: Read all properties Click the **Properties** tab and select **Allow** to apply the following properties to msDS-AzScope objects: Read name Read Name Write msDS-AzApplicationData Write msDS-AzScopeName Write description

Setting Permissions to Join or Leave the Domain

To join a UNIX computer to an Active Directory domain without predefining a computer account, your Active Directory user account must be set with the following permissions:

Parent container object for computer accounts For example: domain/UNIX/Servers	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint Objects **Note** You can grant this permission to specific users or groups by selecting the **Join computers** task in the Zone Delegation Wizard.

To join a UNIX computer to an Active Directory domain and place the computer account in a specific organizational unit (OU), the Active Directory account used to join the domain must be set with the following permissions:

Parent container object for the computer accounts	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint Objects Create Computer Objects

To join a UNIX computer to an Active Directory domain when you are using a predefined computer account, your Active Directory user account must be set with the following permissions:

Parent container object for the computer account	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint Objects
Computer account object in Active Directory For example, if the computer account is AJAX in the default Active Directory Computers container: domain/Computers/AJAX	On the **Object** tab, select **Allow** to apply the following permission to this object only: Full Control This permission is required for enabling or disabling a computer account.

To remove a UNIX computer from an Active Directory domain, your Active Directory user account must be set with the following permissions:

Parent container object for the computer account	On the **Object** tab, select **Allow** to apply the following permission to this object only: Delete serviceConnectionPoint Objects If you are deleting a computer account, you also need the Delete Computer Objects permission.

Note: This setting only gives the user or group permission to leave an Active Directory domain. If you want to grant permission for a user or group

to delete a computer account, you also need the Delete Computer Objects permission.

Setting Permissions for Zone Computers

Although joining or leaving a domain is the primary task for working with computer accounts in Active Directory, there are also specific permissions required to list computers or modify computer properties. The objects and permissions can also vary depending on the type of zone the computer account is associated with and the task to be performed. In most cases, you can grant the required permissions to specific users or groups by selecting the appropriate task in the Zone Delegation Wizard.

In most cases, you can grant the required permissions to specific users or groups by selecting the appropriate task in the Zone Delegation Wizard instead of assigning the permissions manually.

Joining a Computer to a Zone

To join a computer to a zone, your user account must have the following permission:

Parent container object for the computer account in the zone For example, in a classic zone, the ZoneName/Computers container object: domain/UNIX/Zones/acme/Computers	Click the **Object** tab and select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint Objects
Computer account object in Active Directory For example, if the computer account name is AJAX: domain/UNIX/Servers/AJAX	Click the **Object** tab and select **Allow** for the Full Control permission for the user with permission to join the domain. The adjoin command grants the computer's SELF account the following permissions: Write operatingSystem Write operatingSystemVersion Write operatingSystemHotfix Write operatingSystemServicePack Write servicePrincipalName Write userAccountControl Write dnsHostName

Listing Computer Accounts

To list computers, your user account must have the following permission:

Parent container object for the computer account in Active Directory For example: domain/UNIX/Servers	On the **Object** tab, select **Allow** to apply the following permission to this object for each of the computers to be included in the list: List contents
Parent container object for the computer account in the zone For example, in a classic zone, the ZoneName/Computers container object: domain/UNIX/Zones/acme/Computers	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectClass
The serviceConnectionPoint object for the computer account For example, if the computer account name is AJAX, select: domain/UNIX/Servers/AJAX then select: serviceConnectionPoint objects	Click the **Properties** tab and select **Allow** to apply the following properties to this object for each of the computers to be included in the list: Read displayName Read keywords Read managedBy Read Name Read objectClass
Computer account object in Active Directory For example, if the computer account name is AJAX: domain/UNIX/Servers/AJAX	Click the **Properties** tab and select **Allow** to apply the following properties to this object for each of the computers to be included in the list: Read objectClass Read Operating System Read Operating System Version Read userAccountControl

Modifying Computer Properties

To modify any computer account properties for a UNIX computer, your user account must have the following permission:

Parent container object for the computer account in Active Directory For example: domain/UNIX/Servers	On the **Object** tab, select **Allow** to apply the following permission to this object only: List contents
The serviceConnectionPoint object for the computer account For example, if the computer account name is AJAX, select: domain/UNIX/Servers/AJAX then select: serviceConnectionPoint objects	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read allowedAttributes Read allowedAttributesEffective Read displayName Read keywords Read managedBy Read Name Read objectClass Write keywords
Computer account object in Active Directory For example, if the computer account is AJAX in the default Active Directory Computers container: domain/UNIX/Servers/AJAX	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectGUID Read objectSid Read objectClass Read Operating System Read Operating System Version Read userAccountControl

Responding to NIS Requests

If you are supporting "agentless" authentication or want to allow a computer to service NIS client requests in a zone, the computer must be a member of the zone_nis_servers group in the zone. Setting or unsetting the **Allow this computer to respond to NIS client requests** property requires the following permissions:

The zone_nis_servers group object For example, select: domain/UNIX/Zones/acme/Computers/zone_nis_servers	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: List contents Read all properties Write member property If the zone_nis_servers group does not already exist in the current zone, setting the **Allow this computer to respond to NIS client requests** property also requires the following permission on the ZoneName/Computers object: Create group objects

Changing the Computer Zone

If you need to change the zone for a computer account, your user account must have the following additional permissions:

All parent container objects for the original and new zones	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read name Read Name
The serviceConnectionPoint object for the computer account	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Write name Write Name **Note** The Name property is the common name (cn) of the serviceConnectionPoint object.
Original parent container for the computer account in the current zone For example, if you are moving a computer from the Finance zone to the Corporate zone, the target object would be: domain/UNIX/Zones/Finance/Computers	On the **Object** tab, select **Allow** to apply the following permission to this object only: Delete serviceConnectionPoint Objects Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectGUID
New parent container for the computer account in the new zone For example, if you are moving a computer from the Finance zone to the Corporate zone, and you use the default Computers container, the target object would be: domain/UNIX/Zones/Corporate/Computers	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint Objects Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectGUID

Note: You can set the permissions for modifying computer accounts by clicking the **Security** tab when you are viewing a computer's properties.

Preparing a Computer Object

To prepare a computer account in a zone before joining, the following permissions apply to the user or group you want to designate as the trustee for joining the domain.

The serviceConnectionPoint object for the computer account	Click the **Object** tab and select **Allow** to apply the following permission to this object only: Read all properties Write keywords property Write displayName property
Computer account object in Active Directory For example, if the computer account name is AJAX: domain/Computers/AJAX	Click the **Object** tab and select **Allow** to apply the following permission to this object only: Read Permission Reset Password Write userAccountControl Validated write to DNS host name Validated write to service principal name Write to service principal name Write msDS-SupportedEncryptionTypes Write Account Restrictions Write Description Write displayName Write computer name (Pre-Windows 2000) Delete Delete Subtree All Extended Rights

The adjoin command resets the computer account and grants the computer's SELF account the following permissions:

- Write operatingSystem
- Write operatingSystemVersion
- Write operatingSystemHotfix
- Write operatingSystemServicePack
- Write altSecurityIdentities

Creating The Computer Object Manually

If you use Active Directory Users and Computers to prepare the computer object instead of the Prepare Computer wizard, the following permissions must be granted on the computer for the trustee:

The serviceConnectionPoint object for the computer account	Click the **Object** tab and select **Allow** to apply the following permission to this object only: Read all properties Write keywords property Write displayName property
Computer account object in Active Directory For example, if the computer account name is AJAX: domain/Computers/AJAX	Click the **Object** tab and select **Allow** to apply the following permission to this object only: Read Permission Reset Password Write userAccountControl Validated write to DNS Host Name Validated write to service principal name Write Account Restrictions Write Description Write displayName Write computer name (Pre-Windows 2000) Write operatingSystem Write operatingSystemVersion Write operatingSystemHotfix Write operatingSystemServicePack Write altSecurityIdentities Write msDS-SupportedEncryptionTypes Delete Delete Subtree All Extended Rights

Modifying Computer Roles

If you use computer role assignments to control access to a computer, the following permissions are required to modify computer roles:

msDS-AzScope This object is listed under a globally unique identifier (GUID) for the Authorization object. For example: CN=cab186af-61a0-4d54-a0dd...	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read description Read msDS-AzScopeName Read msDS-AzApplicationData Write description Write msDS-AzScopeName Write msDS-AzApplicationData

Deleting Computer Roles

If you use computer role assignments to control access to a computer, the following permissions are required to delete computer roles:

msDS-AzScope This object is listed under a globally unique identifier (GUID) for the Authorization object.	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read Name Read name Read displayName Allow Delete Allow Delete Tree

Setting Permissions For Zone Users

The specific objects and permissions required to work with user accounts depend on the type of zone the user account is associated with and the task to be performed.

In most cases, you can grant the required permissions to specific users or groups by selecting the appropriate task in the Zone Delegation Wizard instead of assigning the permissions manually.

Adding Users To Standard Zones

In a standard Centrify zone when the functional level of the forest is Windows Server 2003 or later, adding a user account with an Active Directory security group as the primary group to a zone requires the following permissions:

Parent container object for the user profile For example, if you use classic zones, the default Users container in the Finance zone: domain/UNIX/Zones/Finance/Users	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint Objects This permission is required for both standard zones and RFC 2307compliant zones. For standard zones, you need to apply additional permissions. Click the **Properties** tab and select **serviceConnectionPoint objects** from the object list, then select **Allow** to apply the following properties to this object: Read Name Read name Read displayName
User account object in Active Directory For example: domain/Users/user_name	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectCategory Read objectClass Read objectGUID Read objectSid Read userAccountControl
Parent container object for the individual zone For example, if you are adding a user to the Finance zone: domain/UNIX/Zones/Finance	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectGUID Write Description

Modifying Users In Standard Zones

In a standard zone, modifying user account properties for a user with a standard Active Directory security group as the primary group requires the following permissions:

The serviceConnectionPoint object for the user account For example, if you are using classic zones and the UNIX user name is chris: domain/UNIX/Zones/Finance/Users/chris then select serviceConnectionPoint objects	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read allowedAttributesEffective Read objectGUID Write keywords If you are changing the UNIX user name for the user, you need the following additional permissions applied to this object: Read name Write name Write Name property **Note** The Name property is the common name (cn) of the serviceConnectionPoint object.

Note: You can set the permissions for modifying user accounts by clicking **Permissions** when you are viewing the Centrify Profile for a user.

Modifying Users In Rfc 2307-compliant Zones

In a standard RFC 2307-compliant zone, modifying user account properties for a user with an Active Directory security group as the primary group requires the following permissions:

The serviceConnectionPoint object for the user account For example, if you are using classic zones and the UNIX user name is chris: domain/UNIX/Zones/Finance/Users/chris then select serviceConnectionPoint objects	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read allowedAttributesEffective Write keywords Write uid Write uidNumber Write gidNumber Write loginShell Write unixHomeDirectory If you don't see some of these attributes listed for serviceConnectionPoint objects, change the object selected to **posixAccount objects**, then click **Allow** for the additional properties. The GECOS field in a user's UNIX profile is derived from the displayName attribute or the Name property (cn).

> **Note**: You can grant the required permissions to specific users or groups for any zone by selecting the **Modify users** task in the Zone Delegation Wizard.

Listing Users In Standard Zones

In a standard zone, listing user account information requires the following permissions:

The serviceConnectionPoint object for the user account	Click the **Properties** tab and select **Allow** to apply the following properties to this object for each user included in the list: Read displayName Read managedBy Read objectClass Read Name to display the UNIX name Read keywords to display the other UNIX attributes

Listing Users in RFC 2307-Compliant Zones

In a standard RFC 2307-compliant zone, listing user account information requires the following permissions:

The serviceConnectionPoint object for the user account	Click the **Properties** tab and select **Allow** to apply the following properties to this object for each user included in the list: Read displayName Read keywords Read managedBy Read objectClass Read uid to display the UNIX name Read uidNumber to display the UNIX UID Read gidNumber to display the GID of the user's primary group Read logonShell to display the default shell for the user Read unixHomeDirectory to display the user's home directory Read Public Information to display the userPrincipalName for the user

Removing Users from Zones

Removing a user account from a standard zone or RFC 2307-compliant zone requires the following permission:

The serviceConnectionPoint object for the user account	On the **Object** tab, select **Allow** to apply the following permission to this object only: Delete

Setting Permissions for Zone Groups

The specific objects and permissions required to work with group accounts can vary depending on the type of zone the group is associated with and the task to be performed.

In most cases, you can grant the required permissions to specific users or groups by selecting the appropriate task in the Zone Delegation Wizard instead of assigning the permissions manually.

Adding Security Groups to Zones

Adding an Active Directory group to a zone requires the following permissions:

Parent container object for the group For example, if you are using classic zones, the ZoneName/Groups container: domain/UNIX/Zones/acme/Groups	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint objects Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectClass **Note** You can grant the required permissions to specific users or groups by selecting the **Add or remove groups** task in the Zone Delegation Wizard.
Group account object in Active Directory For example: domain/UNIX/UNIX groups/group_name	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read groupType Read objectCategory Read objectClass Read objectGUID Read objectSid
Parent container object for the individual zone For example, if you are adding a group to the Finance zone: domain/UNIX/Zones/Finance	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectGUID Write Description

Modifying Groups in Standard Zones

In a standard zone, modifying a group profile in a zone requires the following permissions:

The serviceConnectionPoint object for the group account For example, if the UNIX group name is web-qa in the HKLab zone: domain/UNIX/Zones/HKLab/Groups/web-qa then select serviceConnectionPoint objects	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read allowedAttributesEffective Read objectGUID Read Name If you are changing the UNIX group name for a group, you need the following additional permissions applied to this object: Read name Write name Write Name **Note** The Name property is the common name (cn) of the serviceConnectionPoint object.

Modifying Groups in RFC 2307-Compliant Zones

In a standard RFC 2307-compliant zone, modifying a UNIX-enabled group in a zone requires the following permissions:

The serviceConnectionPoint object for the group account	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read allowedAttributesEffective Read objectGUID Read Name If you are changing the UNIX group identifier for a group, you need the following additional permissions applied to this object: Read gidNumber Write gidNumber **Note** If you don't see this attribute listed for the serviceConnectionPoint object, change the object selected to **posixGroup objects**. If you are changing the UNIX name for a group, you need the following additional permissions applied to this object: Read name Write name Write Name **Note** The Name property is the common name (cn) of the serviceConnectionPoint object.

Listing Groups in Zones

In a standard zone, listing group account information requires the following permissions:

The serviceConnectionPoint object for the group account	Click the **Properties** tab and select **Allow** to apply the following properties to this object for each group included in the list: Read displayName Read managedBy Read objectClass Read Name to display the UNIX group name Read keywords to display the UNIX GID

Listing Groups in RFC 2307-Compliant Zones

In a standard RFC 2307-compliant zone, listing group account information requires the following permissions:

The serviceConnectionPoint object for the user account	Click the **Properties** tab and select **Allow** to apply the following properties to this object for each user included in the list: Read displayName Read keywords Read managedBy Read objectClass Read objectGUID Read Name to display the group name Read gidNumber to display the group GID

Removing Groups from Zones

Removing an Active Directory group from a standard zone or RFC 2307-compliant zone requires the following permission:

The serviceConnectionPoint object for the group account	On the **Object** tab, select **Allow** to apply the following permission to this object only: Delete

Setting Permissions for License Keys

Starting Access Manager requires the following permissions on the container object for licenses:

The domain root object For example, if the root domain of the forest is arcade.com: DC=arcade,DC=com	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectClass
Parent container for the Licenses container object For example: domain/Centrify UNIX	On the **Object** tab, select **Allow** to apply the following permission to this object only: List contents
Parent container for license keys For example, the Licenses container object you created or selected in the Setup Wizard: domain/Centrify UNIX/Licenses	On the **Object** tab, select **Allow** to apply the following permission to this object only: List contents

To add and remove license keys, your user account must have the following permissions:

Parent container for license keys For example, the Licenses container object you created or selected in the Setup Wizard: domain/Centrify UNIX/Licenses	Click the **Properties** tab and select **Allow** to apply the following properties to this object and all child objects: Write Description

Setting Permissions for NIS Maps

You can delegate administrative permissions for all NIS maps in a zone or for any specific NIS map within a zone by selecting either the NIS Maps parent container object or the specific NIS map object you want to work with. If you select the NIS Maps parent container object, the permissions you set apply to all NIS maps you add to the zone. If you select the individual NIS map object, the permissions you set only apply to that individual NIS map.

To set permissions on NIS maps or NIS map entries

1. Open the ADSI Edit MMC snap-in and connect to the Active Directory domain.

   Note: For NIS maps, you must use the Zone Delegation Wizard or ADSI Edit to set Active Directory permissions.

2. In the console tree, navigate to the zone folder.

   For example, if you deployed using the recommended organizational structure, expand the domain, Centrify, Zones, and select a specific zone name.

3. Select **CN=NisMaps** to set permissions for all NIS maps in a zone, right-click, then select **Properties**.

   If setting permissions for an individual map, expand CN=NisMaps, then select the map object—such as CN=auto_master—right-click and select **Properties**.

4. Click the Security tab, then click **Advanced**.
5. Click **Add** to search for the user or group to which you want to give administrative privileges, select the user or group in the results, then click **OK**.
6. Scroll to locate the appropriate permissions for the object and its properties to allow the selected user or group to perform the administrative task, click **Allow**, then click **OK**.

In most cases, you can grant the required permissions to specific users or groups by selecting the appropriate task in the Zone Delegation Wizard instead of assigning the permissions manually.

Adding NIS Maps to a Zone

To add NIS maps to the NIS Maps parent container in a zone, the user account must have the following permissions:

Parent container for NIS Maps For example, if you are using classic zones: domain/UNIX/Zones/ZoneName/NISMaps	On the **Object** tab, select **Allow** to apply the following permissions to this object and all child objects: Create Container Objects

Deleting NIS Maps from a Zone

To delete NIS maps in a zone, the user account must have the following permissions:

Parent container for NIS Maps	On the **Object** tab, select **Allow** to apply the following permissions: Delete Container Objects applied to this object and all child objects. On the **Object** tab, set Apply onto to **Container objects**, then select **Allow** to apply the following permissions: Delete Subtree **Note** This permission is required if the map contains any entries.

Adding Map Entries to NIS Maps

To add entries to any NIS map in a zone, the user account must have the following permissions:

Parent container for NIS Maps	On the **Object** tab, set Apply onto to **Container objects**, then select **Allow** to apply the following permissions: Create classStore Objects

Modifying Map Entries in NIS Maps

To modify entries in any NIS map in a zone, the user account must have the following permissions:

Parent container for NIS Maps	Click the **Properties** tab, set Apply onto to **classStore objects**, then select **Allow** for the following properties: Write adminDescription Write Description Write wWWHomePage

Changing the Map Type for NIS Maps

To change the map type for any NIS map in a zone, the user account must have the following permissions:

Parent container for NIS Maps	Click the **Properties** tab, set Apply onto to **This object and all child objects**, then select **Allow** for the following properties: Write Description

Deleting Map Entries from NIS Maps

To delete entries from any NIS map in a zone, the user account must have the following permissions:

Parent container for NIS Maps	Click the **Properties** tab, set Apply onto to **classStore objects**, then select **Allow** for the following properties: Write name Write Name

Adding Entries to a Specific NIS Map

To add entries to a specific NIS map in a zone, the user account must have the following permissions:

Individual NIS map	On the **Object** tab, select **Allow** to apply the following permissions to this object and all child objects: Create classStore Objects

Modifying Entries in a specific NIS Map

To modify the entries in a specific NIS map in a zone, the user account must have the following permissions:

Individual NIS map	Click the **Properties** tab, set Apply onto to **classStore objects**, then select **Allow** for the following properties: Write adminDescription Write Description Write wWWHomePage

Changing the Map Type for a Specific NIS Map

To change the map type for a specific NIS map in a zone, the user account must have the following permissions:

Individual NIS map	Click the **Properties** tab, set the Apply onto to **This object and all child objects**, then select **Allow** for the following properties: Write Description

Deleting Map Entries from a Specific NIS Map

To delete entries from a specific NIS map in a zone, the user account must have the following permissions:

Individual NIS map	Click the **Properties** tab, set Apply onto to **classStore objects**, then select **Allow** for the following properties: Write name Write Name

Setting Permissions for Password Synchronization

If you want to use the Network Information Service, adnisd, and the Centrify Password Filter to support "agentless" authentication of NIS client requests, the computer that will service the requests must be a member of the zone_nis_servers group in the zone and must be able to access the Active Directory attribute that stores the password hash. The specific permissions required depend on the attribute being used to store the password hash.

Centrify Password Synchronization Service

If you are using the Centrify Password Filter synchronization service, the zone_nis_servers group requires the following permissions:

altSecurityIndentities	Read altSecurityIndentities
msSFU30Password	Read msSFU30Password
unixUserPassword	Read unixUserPassword All Extended Rights

Microsoft Password Synchronization Service

If you are using the Microsoft password synchronization service and the Centrify Network Information Service, adnisd, to authenticate NIS client requests, you must set the following permissions at the domain level, on the Users container object, or on another container that applies to all users.

Users container or a container that applies to all users	Click the **Object** tab, set the Apply onto to **User objects** and select **Allow** to apply the following permission: All Extended Rights You can apply this permission to Domain Computers or to a specific group of computers that contains the computer where the adnisd service is running.

For information about installing and configuring a Microsoft password synchronization service, see the Microsoft documentation for that service or refer to documentation on the Microsoft Web site.

Setting Permissions for Rights and Roles

If you define specific rights and establish role-based access controls on a zone-by-zone or computer-by-computer basis, you might want to manually assign permissions for users who can configure rights and roles.

In most cases, you can grant the required permissions to specific users or groups by selecting the appropriate task in the Zone Delegation Wizard instead of assigning the permissions manually.

Creating the Authorization Store

All of the information about rights, roles, and role assignments is held in an **authorization store** for each zone in Active Directory. The name of authorization store object is CN=Authorization under the zone object's DN. For example, the authorization store for the zone named EMEA_Territories in the Arcade.Net forest is:

cn=Authorization, cn=EMEA_Territories, cn=Zones, cn=UNIX, dc=Arcade, dc=Net

To create the authorization store for a zone, users must have the following permissions:

Parent container for an individual zone For example, a ZoneName container object, such as: domain/Centrify/Zones/arcade	On the **Object** tab, select **Allow** to apply the following permissions to this object and all child objects: List contents Read all properties Read Permissions Select **Allow** to apply the following permissions to this object only: Create msDS-AzAdminManager objects

Defining Rights And Roles in the Authorization Store

To configure rights, roles, and role assignments, users must have the following permissions for the authorization store:

Authorization	On the **Object** tab, select **Allow** to apply the following permissions to this object and all child objects: List contents Read all properties Write all properties
msDS-AzApplication This object is listed under a globally unique identifier (GUID) for the Authorization object. For example: CN=cab186af-61a0-4d54-a0dd...	On the **Object** tab, select **Allow** to apply the following permissions to this object (listed as CN=GUID under the Authorization object) and all child objects: Create and delete msDS-AzOperation objects Create and delete msDS-AzTask objects Create and delete msDS-AzRole objects Create msDS-AzScope objects **Note** You must grant these permissions on the CN=GUID object if you are granting permissions manually with ADSI Edit. The proper permissions are set automatically for the users when you delegate administrative tasks for a zone.

Configuring Authorization in Classic Zones

Unlike hierarchical zones, authorization is an optional feature in classic zones. You must be an administrator or the user who created a classic zone to initialize the authorization store in Active Directory, identify the users who should be allowed to configure rights, roles, and role assignments, and enable or disable the enforcement of the rights and role assignments you have configured.

To update the list of users and groups who are allowed to configure DirectAuthorize rights and roles, you must have the Modify permissions right on the Authorization container under the classic zone container applied to this object and all child objects. If you have this permission, you can click **Add** to add Windows users and groups to the list of users and groups who can configure rights and roles. If you have the Modify permissions right, you can also select a user or group in the list and click **Remove** a user or group from the list.

Adding Roles

To add roles for users or groups, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzTaskObjectContainer This object is listed under a globally unique identifier (GUID) for the Authorization object.	On the **Object** tab, select **Allow** to apply the following permissions to this object: Create msDS-AzTask objects Click the **Properties** tab, then select **Allow** for the following properties: Read objectClass

Modifying Roles

To modify roles for users or groups, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzTaskObjectContainer/CN=roleName This object is listed under a globally unique identifier (GUID) for the Authorization object and a specific role name.	Click the **Properties** tab, then select **Allow** for the following properties: Read Name Read name Read description Read msDS-AzApplicationData Write Name Write name Write description Write msDS-AzApplicationData

Deleting Roles

To delete roles for users or groups, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzTaskObjectContainer/CN=roleName This object is listed under a globally unique identifier (GUID) for the Authorization object and a specific role name.	Click the **Properties** tab, then select **Allow** for the following properties: Read Name Read name Allow Delete

Adding Rights

To add the definition for a right in a zone, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-OpObjectContainer This object is listed under a globally unique identifier (GUID) for the Authorization object.	On the **Object** tab, select **Allow** to apply the following permissions to this object: Create msDS-AzOperation objects Click the **Properties** tab, then select **Allow** for the following properties: Read objectClass

Modifying Rights

To modify right definitions in a zone, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzTaskObjectContainer/CN=roleName This object is listed under a globally unique identifier (GUID) for the Authorization object and a specific role name.	Click the **Properties** tab, then select **Allow** for the following properties: Read Name Read name Read description Read msDS-AzApplicationData Write Name Write name Write description Write msDS-AzApplicationData

Deleting Rights

To delete right definitions in a zone, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-

	AzApplicationData
msDS-AzOpObjectContainer/CN=pamrightName or msDS-AzOpObjectContainer/CN=pcrightName This object is listed under a globally unique identifier (GUID) for the Authorization object and a specific PAM access right name or privileged command name.	Click the **Properties** tab, then select **Allow** for the following properties: Read Name Read name Allow Delete

Adding or Removing Rights from Roles

To add or remove rights from a role in a zone, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzTaskObjectContainer/CN=roleName This object is listed under a globally unique identifier (GUID) for the Authorization object and a specific role name.	Click the **Properties** tab, then select **Allow** for the following properties: Read Name Read name Read msDS-OperationsForAzTask Write msDS-OperationsForAzTask

Adding Role Assignments

To add a role assignment, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzRoleObjectContainer This object is listed under a globally unique identifier (GUID) for the Authorization object.	On the **Object** tab, select **Allow** to apply the following permissions to this object: Create msDS-AzRole objects

Modifying Role Assignments

To modify role assignments, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzRoleObjectContainer This object is listed under a globally unique identifier (GUID) for the Authorization object.	On the **Object** tab, select **Allow** to apply the following permissions to this object: Create msDS-AzRole objects
msDS-AzRoleObjectContainer/CN=CRA_guid This object is listed under a globally unique identifier (GUID) for the Authorization object and a unique identifier for the role assignment.	Click the **Properties** tab, then select **Allow** for the following properties to allow changes to the assigned user or groups: Read Name Read name Allow Delete Click the **Properties** tab, then select **Allow** for the following properties to allow changes to the available time for a role assignment: Read Name Read name Read msDS-AzApplicationData Write msDS-AzApplicationData

Deleting Role Assignments

To modify role assignments, users must have the following permissions:

Authorization	Click the **Properties** tab, then select **Allow** for the following properties: Write msDS-AzApplicationData
msDS-AzRoleObjectContainer/CN=CRA_guid This object is listed under a globally unique identifier (GUID) for the Authorization object and a unique identifier for the role assignment.	Click the **Properties** tab, then select **Allow** for the following properties: Read Name Read name Allow Delete

Setting Permissions for Zone Provisioning

The Zone Provisioning Agent requires permission to create UNIX profiles, that is, the service connection points in each zone where it needs to perform provisioning operations. The service account that runs the Zone Provisioning Agent requires the Log on as a service right set as a local computer security policy, or in the default domain policy.

Supplemental Installation Notes

This document includes various notes about installing Server Suite on different operating system platforms.

Verifying the DNS Configuration on Linux

The Server Suite Authentication Service (DirectControl) uses DNS to locate domain controllers for the Active Directory forest. To verify the Active Directory domain controller can be located through DNS, try sending a ping request to the computer.

You can also run the adinfo --diag command to attempt to read the DNS records for the domain you want to join. For example:

adinfo --diag domain_name

If DNS is properly configured, the command should display the LDAP URLs for the domain controllers in the domain you want to join.

For more detailed information about configuring DNS or troubleshooting your DNS configuration, see the *Administrator's Guide for Linux and UNIX*.

Joining the Domain (Zoned Mode Only)

To join an Active Directory domain manually:

1. On the Linux computer, log in as or switch to the root user.
2. Run adjoin to join an existing Active Directory domain using a fully-qualified domain name.

   adjoin --zone <zone_name> --user <user_name><domain_name>

   The user account you specify must have permission to add computers to the specified domain and zone. If you don't specify a user name, the Administrator account is used by default.
3. Type the password for the specified user account.

   If the authentication service can connect to Active Directory and join the domain, a confirmation message is displayed. You can now enable existing Active Directory groups and users to work with this Unix computer.

For more information about the options you can specify when joining a domain, see the man page for the adjoin command or the *Administrator's Guide for Linux and UNIX*.

To step through common tasks and test scenarios, see the *Evaluation Guide for Linux and UNIX*.

Joining the Domain (Express mode)

To join an Active Directory domain manually:

1. On the UNIX computer, log in as or switch to the root user.
2. Run adjoin to join an existing Active Directory domain using a fully-qualified domain name.

   adjoin --workstation --user <user_name> <domain_name>

   The user account you specify must have permission to add computers to the specified domain. If you don't specify a user name, the Administrator account is used by default.
3. Type the password for the specified user account.

   If the authentication service can connect to Active Directory and join the domain, a confirmation message is displayed.

   For more information about the options you can specify when joining a domain, see the man page for the adjoin command or the *Administrator's Guide for Linux and UNIX*.

HPUX Installation Notes

This section describes the unique characteristics or known limitations that are specific to using authentication service on a computer with the HP-UX operating environment.

ia64 - Mapping Local HP-UX User Accounts to Active Directory Accounts

In most environments, you can map local user accounts to Active Directory accounts to manage the passwords for local users using your Active Directory password policies. On HP-UX, however, if an account is a valid Active Directory account but the authentication through Active Directory fails, the PAM module will attempt to authenticate the account locally and will allow the account to log on if the local authentication succeeds. Because users can still log on to HP-UX systems using their local account password, you cannot effectively use Active Directory or the User Map group policy to enforce your password policies for local HP-UX user accounts.

To enforce Active Directory password policies for local HP-UX users, you need to disable the local user accounts to prevent those local account names and passwords from being used to log on.

Entering an Incorrect Password on HP-UX

On HP-UX, if Server Suite-enabled users enter an incorrect password, they are normally prompted with a second "System password" prompt. This prompt is asking for a password for a local user, regardless of whether that user actually exists locally on the system. If the user exists locally, this prompt allows the user to log in using the local password. If the user does not exist locally, this prompt is unnecessary and will not allow the authentication service-enabled user to log in, regardless of the password entered.

This second prompt can be avoided by changing the options in /etc/pam.conf to the authentication modules. Two changes are necessary:

1. Add an option to the authentication service PAM module to prompt all users for a password (not just Active Directory users)
2. Add an option to the HP-UX UNIX login module to use the password obtained by the authentication service module.

   The lines which need to be modified appear like this in the file:

   service_name auth sufficient /usr/lib/security/libpam_centrifydc.1 debug

   service_name auth required /usr/lib/security/libpam_unix.1

   Where service_name is something like login, dtlogin, ftp, or similar. The pam_centrifydc.1 line needs the ask flag to prompt all users for passwords. The libpam_unix.1 line needs the use_first_pass option. For example:

   login auth sufficient /usr/lib/security/libpam_centrifydc.1 debug ask

   login auth required /usr/lib/security/libpam_unix.1 use_first_pass

   > **Note**: It is extremely important that the pam_centrifydc line appear before the pam_unix line in the file, or users will never be prompted for a password. Administrators should be extremely careful when editing this file. Any typographically errors in this file could prevent all users from logging on to the system and render the system unusable.

AIX Installation Notes

Support for AIX Capabilities Attribute

Support has been added for the AIX Capabilities user attribute, a feature that is only available on AIX 5.3 and later. To enable the feature, edit /etc/centrifydc/centrifydc.conf to add the following line:

lam.method.version: 520

This allows using methods that are only available with AIX 5.3 and later, and these methods are required to support the Capabilities attribute.

Use adquery to view capabilities for an Active Directory user:

adquery user -X aix.capabilities <ADuser>

Use adupdate to set capabilities for an Active Directory user:

adupdate modify user -X +aix.capabilities=CAPABILITIES <ADuser>

Where CAPABILITIES is a comma-separated list of capabilities to add for the user. For example:

CAP_NUMA_ATTACH, CAP_BYPASS_RAC_VMM, CAP_PROPOGATE

Currently there is no group policy support for capabilities, this may be implemented in a future release of authentication service.

Users Cannot Log in by way of FTP if They Have a Restricted Shell

On AIX 6.1, a user's login shell must appear in the shells attribute of the /etc/security/login.cfg file. Delinea Privilege Elevation Service does not add dzsh to this attribute so by default an ftp user who is using dzsh as their login shell cannot log in. To workaround this issue, add /usr/bin/dzsh to the shells attribute of /etc/security/login.cfg.

Starting and Stopping DirectControl on AIX

Because the authentication service daemon, adclient, is defined as an AIX system resource, you use the following commands to start, stop, and check the status of the daemon:

startsrc -s centrifydc

stopsrc -s centrifydc

lssrc -s centrifydc

Using the Server Suite Authentication Service LDAP Proxy on AIX

When using the LDAP Proxy on AIX you need the following line in the slapd configuration file at

/usr/share/centrifydc/etc/openldap/ldapproxy.slapd.conf
moduleload /usr/share/centrifydc/libexec/openldap/libback_centrifydc.a(libback_centrifydc.so.0)

> **Note**: This should be entered as a single line into the configuration file. This line may already be in the configuration file, but commented out, in which case you can just remove the leading "#" to uncomment it.

Setting the DNS Configuration Parameter to Join the Domain on SuSE Linux

To successfully join a Active Directory domain on computers running SuSE Linux, you must set the mdns option to off in the /etc/host.conf file. If your /etc/host.conf file does not include the following line, you should add it to the file:

mdns off

This setting is required to enable proper DNS resolution, and therefore, must be set to successfully join the domain, and to allow users to log on properly.

Mounting CIFS Shares

Common Internet File Systems (CIFS) provides an open and cross-platform protocol for requesting remote network server files and services. When a CIFS share is mounted on a Centrify Linux system, file ownership is listed incorrectly.

To correct this, apply the CentrifyDC-cifsidmap plug-in. The CentrifyDC-cifsidmap plug-in enables mapping AD User/Group Security IDs (SIDs) to User/Group IDs (UIDs/GIDs) configured in a zone and from UIDs/GIDs to AD User/Group SIDs correctly. This, in turn, allows the CIFS Client integration with DirectControl.

Use Cases

Mapping UIDs to SIDs is not always required when mounting CIFS shares. But it is needed when working with the files on the shares. For example, when modifying Access Control Links (ACLs). In version 5.8 and older, the cifs-utils package uses the winbind daemon for this mapping. Through winbind, the /usr/sbin/cifs.idmap binary was linked against libraries.

The /usr/sbin/cifs.idmap binary works in conjunction with the Samba winbind facility to map owner and group SIDs to UIDs and GIDs respectively.

With version 5.9 the winbind facility does not perform this mapping. Use the **CentrifyDC-cifsidmap** plug-in to ensure that:

- cifs-idmap translates the ownership on the SMB share correctly.
- the kernel determines who has rights to the CIFS share mount directories and files correctly.
- AD User/Group SIDs are mapped correctly and all the IDs are consistent and correct.

For example:

To see the incorrect file ownership: mount your CIFS share and display the ownership of the files in the mounted share.

1. Mount the share. This command requires root privileges.

   Syntax:

   sudo mount -t cifs *domain_ip/path /local/path/* -o username=*your_user_name*, *file_privilege*, password=*your_password*, domain=*domain_name*, cifsacl

   Example:

   sudo mount -t cifs //192.168.0.100/cifsshare /tmp/mntshare1/ -o username=cifsdemouser1,rw, password=My1Pass,domain=example.com,cifsacl

   The cifs type (-t cifs) requires the cifsacl option. See man mount.cifs for command usage.

2. List all the files on the mounted file system.

   If the CIFS share is owned by root, then you need to use sudo to view the files on the mounted directory, because the files you are verifying can only be seen with root privileges.

   sudo ls -al /mntshare1

   ... ... root root ... cifsdemouser1.txt
   ... root root ... cifsdemouser2.txt
   ... root root ... cifsdemouser3.txt

   If the AD user names are not listed, and only root is listed at the owner of the files, then you need to install the CentrifyDC-cifsidmap plug-in. Complete the steps in the following sections.

CentrifyDC-cifsidmap Plug-in Requirements

The Centrify CIFS idmap plug-in is available only for supported systems. The cifs.idmap-plugin requires:

Operating system versions:

- RedHat 7 or above
- Debian 8 or above

- SUSE 12 or above

cifs-utils version:

- cifs-util 5.9 or above

Prepare to Install the CentrifyDC-cifsidmap Plug-in

Prior to installing the CentrifyDC-cifsidmap plug-in, install and configure the following:

- Install the cifs-utils

  The cifs-utils are a package of tools used on CIFS filesystems. See your CIFS documentation.

- Install CentrifyDC

  See the Planning and Deployment Guide.

- Join the machine to AD

  See the Planning and Deployment Guide.

Install the CentrifyDC-cifsidmap Package

1. Verify cifs-utils package is installed. Install it, if it is not already installed. For example:

   It is possible to manually configure your system without cifs-utils, but the program /usr/sbin/cifs.idmap, is still required for the Centrify CIFS idmap plug-in to work.

   - SUSE or RedHat

     yum install cifs-utils

   - Debian

     apt-get install cifs-utils

2. Download the CentrifyDC-cifsidmap package and change to the download directory.

   The package contains the cifs-idmap-plugin.

   Example download package names

   - SUSE or RedHat

     CentrifyDC-cifsidmap-5.5.1-rhel5.x86_64.rpm

   - Debian

     CentrifyDC-cifsidmap-5.5.1-deb8-x86_64.deb

     Example download directory

     # cd /home/user1/Download/

3. Run the appropriate package install command from the download directory.

   - SUSE or RedHat

     # sudo rpm -i CentrifyDC-cifsidmap-5.5.1-rhel5.x86_64.rpm

   - Debian

     # sudo dpkg -i CentrifyDC-cifsidmap-5.5.1-deb8-x86_64.deb

4. Verify the CentrifyDC-cifsidmap package is installed correctly. Check the libcifsidmap.so location.

- SUSE or RedHat

  # ls /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so -al

  ... /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so

- Debian

  # ls /usr/share/centrifydc/lib/plugins/cifs/libcifsidmap.so -al

  ... /usr/share/centrifydc/lib/plugins/cifs/libcifsidmap.so

Configure cifs-utils for CentrifyDC-cifsidmap Plug-in

On Linux, the command, alternatives, is a tool for managing different software packages that provide the same functionality. The alternatives command, on different systems has different names and locations. For additional information on alternatives use, see your Linux documentation.

- RedHat

  /usr/sbin/alternatives

- SUSE and Debian

  /usr/sbin/update-alternatives

To configure the cifs-utils

1. Check the status of /etc/cifs-utils/idmap-plugin and note the priority level.

   For example on RedHat:

   # pwd

   /etc/cifs-utils

   # ls -al

   ... idmap-plugin -- /etc/alternatives/cifs-idmap-plugin

   # alternatives --display cifs-idmap-plugin

   ...
   /usr/lib64/cifs-utils/cifs_idmap_sss.so - priority 20
   ... Current 'best' version is /usr/lib64/cifs-utils/cifs_idmap_sss.so.

   In this example the cifs_idmap_sss.so plugin object has the highest priority and that priority is set to 20.

2. Configure cifs-utils to use the CentrifyDC-cifsidmap plug-in, cifs-idmap-plugin.

   Run the commands appropriate for your OS.

   Include a priority that is higher than the priority listed in Step 1. For example, the priority in Step 1 is 20, set this cifs-idmap-plugin priority to 21 or higher.

   - RedHat

     alternatives --install /etc/cifs-utils/idmap-plugin cifs-idmap-plugin /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so <*priority*>

     alternatives --set cifs-idmap-plugin /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so

   - SUSE or Debian

     update-alternatives --install /etc/cifs-utils/idmap-plugin cifs-idmap-plugin /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so <*priority*>

     update-alternatives --set cifs-idmap-plugin /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so

3. Verify the CentrifyDC-cifsidmap plug-in is configured correctly. Run the appropriate alternatives display option.

- RedHat

  alternatives --display cifs-idmap-plugin

- SUSE or Debian

  update-alternatives --display cifs-idmap-plugin

4. Verify the cifs-idmap-plugin location and priority. Review the alternative command response.

   The cifs-idmap-plugin priority needs to be higher than other listed idmaps. The Current 'best' version needs to point to the cifs-idmap-plugin location.

   For example on RedHat:

   # alternatives --display cifs-idmap-plugin

   ... /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so - priority 21
   Current 'best' version is /usr/share/centrifydc/lib64/plugins/cifs/libcifsidmap.so.

Mount the CIFS Share and Confirm File Ownership

Only mount CIFS shares as root user or use sudo.

1. Verify the receiving mount directory. Create a directory to receive the mount files, if you do not have one. For example:

   cd /tmp
   mkdir mntshare1
   ls -al /mntshare1

2. Optionally, verify that the user(s), you are expecting to be owners of CIFS shared files, are valid AD users. For example:

   adquery user cifsdemouser1

   cifsdemouser1:x:1019226236:1019226232:cifsdemouser1:home/cifsdemouser1:/bin/bash

3. If you previously mounted the CIFS share, and found that file ownership was incorrect, unmount it now. For example:

   sudo unmount /tmp/mntshare1/

4. Mount the share. This command requires root privileges.

   Syntax:

   sudo mount -t cifs *domain_ip/path /local/path/* -o username=*your_user_name*, *file_privilege*,
   password=*your_password*, domain=*domain_name*, cifsacl

   Example:

   sudo mount -t cifs //192.168.0.100/cifsshare /tmp/mntshare1/ -o username=cifsdemouser1,rw,
   password=My1Pass,domain=example.com,cifsacl

   The cifs type (-t cifs) requires the cifsacl option. See man mount.cifs for command usage.

5. List all the files on the mounted file system.

   If the CIFS share is owned by root, then you need to use sudo to view the files on the mounted directory, because the files you are verifying can only be seen with root privileges.

   sudo ls -al /tmp/mntshare1

   ... ... cifsdemouser1 root ... cifsdemouser1.txt
   ... cifsdemouser2 root ... cifsdemouser2.txt
   ... cifsdemouser3 root ... cifsdemouser3.txt

   Notice the AD users are listed as owners of the CIFS share files. This completes the task.

Delinea

Known Issues

Here are some known issues, organized by category.

Installation and Un-installation Issues

- Upgrading from the beta build to this version may result in offline MFA mode if there are multiple authentication servers registered in your AD forest. To resolve this, uninstall the beta build first and then install this new version. (Ref: CS-41915)
- The Centrify Common Component should be the last Server Suite component uninstalled. If the component is uninstalled before other component, it must be reinstalled by the uninstall process to complete its task. (Ref: 36226a)
- If you intend to install the software on the desktop with elevated privilege, you should not check the "Run with UAC restrictions" option when creating the desktop. (Ref: 39725b)
- When you double-click on the Server Suite Agent for Windows msi and select the "repair" option, the existing files are replaced irrespective of their version number, even when they are identical. As a result, a prompt to restart the system is displayed as files that were in use were replaced. However, if you use the Easy Installer to do the repair and a file on the disk has the same version as the file that is part of the installer package, the installed file will not be replaced. Therefore, there will not be any prompt to restart the system. (Ref: 26561a)
- If you uninstall the Server Suite Agent for Windows while the DirectAudit Agent Control Panel is open, files needed by the uninstall process may be blocked. You should close the DirectAudit Agent Control Panel for a successful conclusion to the uninstall process. (Ref: 25753a)
- Server Suite Agent for Windows and its installer are built on .NET. Therefore, .NET is always installed as a pre-requisite before the agent is installed. If .NET is removed from the system later, Server Suite Agent for Windows will not run properly. User will also experience problem when trying to remove Server Suite Agent for Windows from the system. To properly uninstall Server Suite Agent for Windows, please make sure Server Suite Agent for Windows is uninstalled before .NET. (Ref: 39051a)

Configuration Issues

- In a cross-forest environment, forest A user cannot enroll a device joined to forest B when forest A does not have a connector. (Ref: CS-44805)
- In Windows 2016 and Windows 10, during the login process, selecting SMS or using other mechanisms like Security Question/Phone call/Password/Email/Mobile for MFA and clicking the "Commit" button will be intermittently unresponsive. (Ref: CS-41699)
- In some large environment with multiple domain controllers, it may take up to one minute for the new zone setting in Server Suite Agent Configuration to take effect. (Ref: 58128b)
- If one of the Global Catalog servers is unavailable, user may not be able to configure the zone for Server Suite Agent for Windows. (Ref: 58621b)
- Microsoft normally automatically distributes and installs root certificates to the Windows system from trusted Certificate Authorities (CA) and users are seamlessly able to use a secure connection by trusting a certificate chain issued from the trusted CA. However, this mechanism may fail if the system is in a disconnected environment where access to Windows Update is blocked or this feature of automatic root certificate installation is disabled. Without updates on the certificate trust list (CTL), the default CTLs on the system may not be adequate for secure connections of multi-factor authentication especially for older versions of Windows such as Windows 7 and Windows Server 2008 R2. To ensure the success of multi-factor authentication, user may need manually distribute and install the latest CTLs and the required root certificate to systems in a disconnected environment. See Centrify KB-6724 for further information. (Ref: CS-39703)

Environment Issues

- On Windows 10 and Windows 2016 machines with Centrify Privilege Elevation Service, the following will occur (Ref: CS-43883):
  - Pop up an error dialog several seconds after clicking "Open file location" in the context menu of a shortcut on the start menu. Explorer windows will display correctly.
  - No responses to the following actions
    - Clicking "Open file location" in the context menu of a shortcut on desktop
    - Clicking "Open file location" in the context menu of a shortcut on the Centrify Start menu in the Privileged Desktop
    - Slow response to "OK", "Cancel" in the shortcut property page after "Open file location" in the general tab is clicked. The dialog will close after several seconds.
- On some Windows 10 computers, the smart card login option may not be displayed if another credential method has been recently used. To display the smart card login option, remove and insert a smart card into the reader. This will cause the login screen to reload and will display the smart card login option. (Ref: CS-41282)
- An environment with no Global Catalog is not supported. (Ref: 46577a)
- Centrify Privilege Elevation Service requires machine time to be synchronized with domain controller. VMware virtual machine has a known issue that its time may not be synchronized with domain controller. This problem occurs more often on an overloaded virtual machine host. If the system clocks on the local Windows computer and the domain controller are not synchronized, Centrify Privilege Elevation Service does not allow any domain users to login. You can try the following KB from VMware to fix the time synchronization issue. http://kb.vmware.com/selfservice/microsites/search.do?language=en_US&cmd=displayKC&externalId=1189 (Ref: 47795b)

RunAsRole Issues

- If you use the "RunAsRole.exe /wait" command to run a Python script, the input/output cannot be redirected for versions of Python below 3.0.0. (Ref: 45061a)
- The Run As Role menu is not available on the start screen in Windows 8 or Windows 2012 or later because Microsoft doesn't support any custom context menu on the start screen. User has to go to the Windows desktop in order to launch an application using Run As Role context menu. (Ref: 35487a)
- When running "RunAsRole.exe /wait sc.exe" with no argument provided to sc.exe, sc.exe will prompt
  - Would you like to see help for the QUERY and QUERYEX commands? [y I n]:
  - Typing 'y' or 'n' doesn't do anything because the input cannot be successfully redirected to sc.exe. (Ref: 47016b)
- It is not recommended to change zone via Run As Role since the role that is in use may no longer be available once after leaving from the previous zone during the change zone process. (Ref: 58043a)
- On Windows Server 2008 R2 and Windows 7, if the Agent machine has no internet connection and the .NET CLR settings (checkCertificateRevocationList) is set to True, the MFA authentication will be failed because the CLR is unable to verify the certificate through internet. The workaround is to enable the internet connection or turn off the CLR settings (set checkCertificateRevocationList to False which is also the default value). (Ref: CS-40147)

Desktop with Elevated Privileges issues

- On a desktop with elevated privileges, if you use "Control Panel > Programs > Programs and Features" to uninstall a program, you may see the following warning message and cannot uninstall the software.

  "The system administrator has set policies to prevent this installation."

  This issue happens when User Account Control (UAC) is enabled and when "Run with UAC restrictions" is selected when creating the new desktop. (Ref: 33384a)

- You cannot use the Start menu option "Switch User" while you are using a role-based, privileged desktop. To use the "Switch User" shortcut, change from the privileged desktop to your default Windows desktop. From the default desktop, you can then select Start > Switch User to log on as a different user. (Ref: 39011b)

Roles and Rights Issues

- There is no 'Require multi-factor authentication' system right for the predefined 'Windows Login' role. To define this system right for MFA, use the pre-defined Require MFA for logon role, or create a new custom role. (Ref: CS-40888)
- Windows Network Access rights do not take effect on a Linux or UNIX machines. If you select a role to start a program or create a desktop that contains a Network Access right, you can only use that role to access Windows computers. The Windows computers you access over the network must be joined to a zone that honors the selected role. The selected role cannot be used to access any Linux or UNIX server computers on the network. (Ref: 32980a)
- Network Access rights are not supported on the Windows 2008 R2 Terminal Server if "RDC Client Single Sign-On for Remote Desktop Services" is enabled on the client side. (Ref: 34368b)
- To elevate privileges to the "Run as" account specified in a Windows right, the "run as" account must have local logon rights. If you have explicitly disallowed this right, you may receive an error such as "the user has not been granted the requested logon type at this computer" when attempting to use the right. (Ref: 34266a)
- If your computer network is spread out geographically, there may be failures in NETBIOS name translation. If a NETBIOS name is used, Active Directory attempts to resolve the NETBIOS name based on the domain controller that the user belongs to, which in a multi-segment network might fail. Therefore, Network Access rights might not work as expected if the remote server is located using NETBIOS name. You may need to consult your network administrator to work around this issue. (Ref: 39087a)
- File hash matching criteria in the Application right is not supported for a file larger than 500MB. This is to make sure DirectAuthorize does not spend too much CPU and memory resources to calculate the file hash. User trying to import a file with the size larger than 500MB will see an empty value for the file hash field. (Ref: 56778a)
- For a small set of application, enabled matching criterion - "Product Name", "Product version", "Company", "File Version" or "File Description" of a Windows Application Right may fail to match after upgrading agent under the following conditions: - Any value for the enabled matching criteria is defined by either import from a process or file - The matching criteria is defined by 5.1.3 or 5.2.0 DirectManage Access Manager since the number of affected application is expected to be relatively low, proactively updating the defined matching criteria of Windows Application Right is not necessary. (Ref: 60053a)

Compatibility with Third Party Products Issues

- VirtualDesktop is not compatible with Server Suite Agent for Windows. Users should use the Centrify system tray applet to create virtual desktop instead. (Ref: 44641b)

- The startup path for “SharePoint 2010 Management Shell” and “Exchange Management Shell” may set to C:\Windows instead of user home directory if it is launched via RunAsRole.exe or from a desktop with elevated privilege. (Ref: 38814b, 46943b)
- Attempting to enable Kerberos authentication for Oracle databases will fail. This issue is being brought to the attention of Oracle Support for a resolution in upcoming releases. (Ref: 33835b)
- Some applications do not use the process token to check the group membership. They check the user’s group membership on its own. Therefore, any Windows rights configured to use a privileged group will not take effect in these applications. The workaround is to use a privileged user account instead of a privileged group. Here is the list of known application with this issue:
    - vCenter Server 5.1
    - SQL Server
    - Exchange 2010 or above
    - SCOM 2007

      (Ref: 45318a, 45218a, 43779a, 38016a)
- Users may notice an error and cannot install ActivClient after installing Server Suite Agent for Windows. During the installation of ActivClient, it attempts to change the local security setting. However, there is a known issue for Server Suite Agent for Windows of blocking the local security setting (Ref: 63609b). Therefore, users may not be able to install ActivClient successfully after installing Server Suite Agent for Windows. We suggest installing ActivClient before installing Server Suite Agent for Windows. If Server Suite Agent for Windows has been installed, please uninstall it and follow the installation sequence suggested. This issue happens on Windows 8.1 and Windows 2012 R2 only. (Ref: 76016b)

Application Manager Issues

Application Manager does not support the Server Core edition of Windows. (Ref: CS-40656)

Best Practices

This section, created by Delinea Systems Engineering in collaboration with Delinea Engineering and Delinea Professional Services, describes the deployment best practices for Server Suite. The goal of this document is to outline and document the actions customers can take to prevent unexpected service degradation with the Server Suite product.

Using our best practices that have evolved over many years, we have developed the Server Suite software to be extremely resilient to many types of Active Directory topologies, networks and environments. In addition, we have gathered data from our major deployments to provide the top items that a customer should do to ensure the Server Suite deployment is healthy. The best practices are organized by functional area.

Best Practices For Unix And Linux Systems With Server Suite

This section includes the following topics:

Upgrade Server Suite Agents And Administrative Tools

Many technologies are prone to introducing problems when upgrading to the latest and greatest version. Delinea technology has been around for 15 years and unlike common practice with other technologies of waiting to upgrade, Delinea recommends having the latest and greatest versions installed because these will provide greater stability and security. Delinea provides major releases and minor releases every year. The agent is continually receiving security, performance, and feature updates. The administrator tools (consoles, SDKs, APIs) are continually adding functionality that can be pushed to the agent and more support for automation.

Customers should review security updates from Delinea on a periodic basis.

One of the most important things a customer can do is to upgrade the Server Suite Agent once per year to take advantage of the additional functionality/stability offered with latest versions. Server Suite Agents and administrative tools are easy to upgrade, can be done in a modular fashion and are backwards and forwards compatible. The most recent releases can be found at the Downloads section of the Support Portal.

Customers should leverage Enterprise grade deployment framework (supported by technologies like Chef, Puppet, Bladelogic, etc) to automatically deploy the Server Suite Agent and updates. Leverage Chef/Puppet/BladeLogic to automatically deploy and maintain agent configuration parameters and to leverage the Delinea Repo to automatically upgrade target systems in a streamlined fashion. Another option is the Delinea Software Repo for streamlined installation and updates.

Enable NSCD

Nscd is a daemon that provides a cache for the most common name service requests. The default configuration file, /etc/nscd.conf, determines the behavior of the cache daemon. More information on NSCD can be found here.

We recommend enabling nscd on each Server Suite enabled server to maximize the caching performance. The default configuration of nscd will suffice.

Set Group Policies To Govern The Agent Behavior

One of the most powerful features in the Server Suite platform is the ability to centrally push out Group Policy to Linux systems. We recommend deploying at least 1 GPO to your systems so you have the means to centrally configure the agent behavior in your environment. Group policy settings are documented in the *Group Policy Guide*. In the event a change to the Centrify parameters is needed for the environment, a GPO change can quickly deploy the change to the systems.

Customers should use the “Set crontab entries” GPO to deploy a crontab entry that runs the program /usr/share/centrifydc/adedit/adsyncignore every week. This will assure Server Suite is not looking up in AD local users, not defined in AD. This is a very strong recommendation. Customers can choose another mechanism to deploy the crontab entry to systems if that makes more sense for their environment.

Set agent parameters

Exclusions of Domains

Server Suite provides robust support for complex active directory environments with varying trust relationships. Many agent parameters can be configured through Group Policy. We often see customers don't cleanup decommissioned domains or have domains in the environment not in scope for Server Suite. We recommend blacklisting the domains that are not in scope or whitelisting only the domains in scope for Server Suite.

An example of excluding, black listing, a domain in /etc/centrifydc/centrifydc.conf is:

adclient.excluded.domains: anvil.acme.com

An example of including, white listing, a domain in /etc/centrifydc.conf is:

adclient.included.domains: anvil.acme.com

Paged Control

To operate the best with the Microsoft Active Directory search optimizer, Server Suite provides a parameter called "adclient.schema.extensions.search.add.paged.control". We recommend setting this parameter to true to optimize AD lookups.

Suite 2016.1

If the version of the Server Suite Agent for *NIX running is version 5.3.1, part Suite 2016.1, we highly recommend configuring the parameter "adclient.altupn.update.interval: 90000000" in /etc/centrifydc/centrifydc.conf.

These parameters can be deployed via the GPO"Add centrifydc.conf properties" under Computer Configuration > Centrify Settings > DirectControl Settings. See the *Group Policy Guide* for additional information.

Use the Server Suite DB2 Plugin

DB2 systems normally authenticate users against the local Operating System. Therefore, most customers don't think about performance of authentication and lookups when they centralize authentication to Active Directory. However, as customers centralize authentication to Active Directory, performance considerations become more important since DB2 is very user lookup intensive. Customers that leverage DB2 in their environment should consider using the Server Suite DB2 user and group plugin since it delivers enhanced caching to improves the performance of lookups in a DB2 environment that leverages Active Directory for authentication/authorization.

Best Practices for Active Directory Environment

Index the UID Attribute

Many UNIX applications make requests for the uid attribute as part of their inner workings. If the uid attribute is not indexed and applications make frequent requests for uid data, this can have a negative effect on the performance of Domain Controllers. Centrify highly recommends customers index the uid attribute in Active Directory.

Windows Active Directory functional level and Windows Server version

Customers should maintain an upgrade strategy to use a stable and supported Active Directory functional level and the version of Windows server. As of this writing customers should be moving to Windows 2016 functional modes.

Maintain sites and services domain controller topology

A common issue customers come across is Centrify binding to the wrong Domain Controllers. For example, all the users in the US may be authenticating to a domain controller that is not geographically desirable. In most instances, this occurs because the AD Sites and Services definition does not include the subnets of the UNIX/Linux systems or is not updated on a consistent basis.

A process should be defined where the UNIX/Linux networking teams regularly interact with the AD team to assure subnets are added and removed from AD Sites and Services accordingly.

Centrify Access Model Best Practices

Proper definition of global/child zone structure.

A proper Centrify deployment should have a Global Zone with an appropriate number of Child Zones and Computer Roles to drive access across groups of systems. The general recommendation for defining profiles, roles and rights is:

- UNIX enable all users at the Global Zone level
- In addition, UNIX enable users at the child zone level, if attributes need to be different
- for users on the systems in the child zones (ie.different primary group)
- UNIX enable groups at the Child Zone vs. the Global Zone unless the groups need to be visible across all servers

- Always enable ZPA to automate UNIX profile provisioning across all Zones that will have user/group UNIX profiles
- Define Roles and Rights in the Global zone and assign roles at computer roles or zones if appropriate

A common mistake made is the use of too many Child Zones or use Child Zones incorrectly. Limit child zone sprawl. Child zones should be used for specific purposes like:

Segregating systems in different business units

Segregate the management of groups of systems to different administrative groups

Override the UNIX profiles of users and groups across groups of systems.

Another common mistake is managing roles and rights definition throughout the zone hierarchy which makes it difficult to find roles and rights when updates are needed.

Another mistake is using Zones to define access. Instead, use Computer roles to prevent lateral movement, drive an automated access model and to take advantage of performance benefits. Leverage Computer Roles and AD groups to manage system types by likeness of access and create AD user groups in a similar manner. This promotes automation because user access can be granted access/privileges by simply adding users to the right AD groups. Similarly, systems can be provisioned to the right AD group of computers. Computer roles can be defined by application types. For example, "App 1 DEV" App1 PROD", etc. The goal is to not have to use the access manager UI for provisioning access.

Analyze The Deployment Periodically

As a Server Suite deployment matures, customers should perform a periodic analysis using the Access Manager "Analyze" feature. The analysis highlights problem areas in the Server Suite deployment. For example, the analysis will identify orphaned objects.

Additionally, Centrify recommends periodically reviewing security updates available at our support portal.

Use the Centrify Zone Provisioning Agent

We highly recommend leveraging the Zone Provisioning Agent to automatically provision UNIX profiles for users. Additionally, we recommend two instances of ZPA in large environments. This provides redundancy in the provisioning process. The ZPA service should also be monitored to ensure it is operational.

Deploy Reporting Services and Security Information and Event Management (SIEM)

To maximize the investment, we highly recommend deploying Delinea Reporting Services and SIEM integration. These capabilities provide customers which insight into which users can access which system and security related events the Server Suite Agent reports on. See the following items for more information:

- *Report Administrator's Guide*
- SIEM documentation on the documentation portal
- A Delinea community article

Best Practices for the Audit and Monitoring Service

This section includes the following topics:

Manage the Audit Store Database Size

The Audit Store database needs to be managed according to the company's retention policy which often dictated by the security/compliance team. To assure the audit service performs and scales as required, we recommend keeping the active Audit Store database at most, between 250GB and 500GB in size. Perform a database rotation if your active Audit Store database is larger than 500GB. A database rotation takes the current active database and marks it inactive and makes a new database the active database. See the documentation for how to automate database rotation.

Another approach is to delete audit records and shrink the size of the active database. This approach works well as long as the indexes are also rebuilt. Otherwise, shrinking the database without indexing will lead to fragmented indexes and poor query performance. KB-8472 details how to shrink and re-build the database indexes.

Centrify recommends keeping only databases that are required for auditing purposes attached to the audit infrastructure. The databases that are not needed should be detached. Customers often forget to detach the databases that are outside the company's normal live data/retention policies. Too many attached Audit Store databases result into poor query performance and increased load on the Management database. Periodically review the list of attached Audit

Store databases and detach the ones that are no longer needed to be online as per the retention policy.

Maintain the audit store database index

It is recommended to maintain the audit store database's indexes regularly. This can be done by setting up a simple SQL job to reorganize the indexes if they are 5%-30% fragmented and rebuild the indexes if they're more than 30% fragmented. KB-8472 details how shrink and re-build the database indexes.

Configure SQL Server

There are several SQL specific configurations and server settings that can affect performance and operation.

Avoid deploying the Audit Store databases in a SQL availability group unless it's required by the company's compliance policies.

Configure SQL Server power settings to be set to Balanced instead of High Performance.

SQL Server has a setting called Max Server Memory that controls the maximum amount of physical memor that can be consumed by the SQL Server's buffer pool. An incorrectly configured Max Server Memory may either result into the SQL engine causing high IO or OS/other programs starving for more memory. Refer to the "configuring the maximum memory for audit store databases" section of the Auditing Administrator's Guide and always configure this value as recommended before the deployment begins.

If you're expecting a database server to get migrated/retired in the near future, it's better to create a CNAME alias in DNS for the current database server and specify the alias everywhere (e.g. when creating a new Management database) rather than specifying the actual host name. This will prevent scenarios where the database server is not found after a migration.

Audit and Monitoring Architecture

The audit architecture includes several components to ensure a smooth operating and secure audit environment. A Collector is the service that collects audit records from servers being audited and stores them in the audit store database. Avoid deploying the collector on the same machine as the active Audit Store database's SQL Server.

When using the Server Suite Agent for Windows to audit sessions, configure data capture at native color depth when auditing systems with many concurrent users (such as Citrix XenApp server). When not capturing at native color depth, the DirectAudit daemon has to transform the captured data to its target format which ends up consuming CPU cycles. To automatically set native color depth at installation time, see the documentation.

Grant Audit Installation Rights To Administrator Groups

Centrify Audit Administrators have specific privileges to manage and configure the Server Suite audit configuration. A common mistake is rights are assigned to specific AD accounts vs. AD groups or rights are not delegated at all. When employees leave the company and those AD accounts are disabled, the Audit services becomes inaccessible. To avoid this, Centrify recommends rights over the Audit installation are delegated to AD groups and administrators/auditors are placed into the proper AD groups. This will ensure that all administrators within that security group will have access to configure/modify the audit settings in the event that a specific employee leaves the organization.

Delinea Relationship Best Practices

Monthly Cadence Call with Delinea

Customers can schedule a monthly cadence call with Delinea Account Team, Support, and Engineering to ensure that best practices and customer requirements are consistently being communicated.

Customers should have the contact information of their account team (Account executive, customer success manager, and systems engineer). This account team can help escalate requests internally within Delinea, handle licensing questions and feature requests.

Get Your Annual Delinea Healthcheck

Customers are entitled to annual healthchecks provided by the Delinea account team. Delinea conducts healthchecks in varying scope. A basic healthcheck can be conducted by a Delinea Systems Engineer in a few hours and can provide insight into the usage of Centrify, risks and areas for improvement. Additionally, more advanced healthchecks can be provided in a 3 to 5 day paid engagement with Delinea professional services to delve deep into the environment to provide recommendations for security and operational improvement as well as address identified issues.

Attend Annual Delinea Update Meetings

Customers are entitled to annual update meetings with the Delinea Account and Product Management to understand new feature availability and to submit/track enhancements. Customers often find that Delinea has provided additional capability in a new release that addresses new requirements they are entitled to. Additionally, this helps customers to understand the product roadmap and direction for Delinea and promotes a partnership between Delinea and the customer.

This section describes how to install and use license management tools provided by Delinea to add, remove, monitor, and generate reports about Delinea licenses and license usage. The license management tools described here include the Delinea Licensing Service and the Licensing Report wizard. The license management tools described here allow you to manage licenses for access control, privilege management, and auditing.

This document is intended for administrators who are responsible for adding, removing, monitoring, and reporting on Delinea licenses. Readers should have administrator privileges to use the Delinea Licensing Service, the Licensing Report wizard, and the Access Manager and Audit Manager consoles.

Delinea licenses give you access to the following key features:

- Secure authentication and identity management
- Role-based access rights
- Delegation of authority
- Auditing of activity

These features can be used together or independently, depending on the type of licenses you purchase and the specific requirements of your organization.

Delinea License Management Tools

Delinea provides a set of tools that let you manage Delinea licenses and generate reports about the different types of Delinea licenses you have purchased.

The tool for adding and removing licenses, monitoring license usage, and configuring license usage notification is the *Delinea Licensing Service*. The licensing service works together with Server Suite components to monitor and report usage and activity for all types of Delinea licenses. For more information about using the licensing service, see Managing Licenses with the Licensing Service.

The tool for generating license reports is the *Delinea Licensing Report wizard*. The wizard generates a report summary and detailed system information about the computers where you have Delinea software deployed. Report information is formatted as comma-separated values (CSV) in a text file. The report is intended primarily for use by Delinea Support. If requested, you can send it to Delinea Support for analysis. You can also use the report for your own analysis. For more information about the Licensing Report wizard, see Creating Licensing Reports with the Licensing Report Wizard.

How Licensing Works

Delinea licensing is based on the number of servers and workstations you authorize for authentication and privilege elevation, and for audit and monitoring service. License validation and management are handled through the licensing service, the Access Manager console, and the Audit Manager console.

Delinea license management tools check for license keys when any of the following events occur:

- A manual or automatic refresh operation is performed through the licensing service.
- You start the Access Manager console.
- An agent-managed computer joins a zone.
- You start the Audit Manager console, the Audit Analyzer console, or the auditing session player; or when you rotate to a new auditing database using either PowerShell or the SDK.

Checking licenses for authentication and privilege elevation verifies that there are enough license keys installed for all UNIX and Windows computers with valid accounts in Active Directory.

Checking licenses for audit and monitoring service verifies that there are enough license keys installed for each computer that is connected to an audit and monitoring service collector.

If the number of licensed computers exceeds the total number of licenses you have purchased, a message is displayed with license usage details, and—if applicable—instructions to add license keys.

After you have installed enough license keys to cover all the configured UNIX, Linux, Mac OS X, or Windows computers, the applicable Delinea console will open at startup and allow you to perform all of the normal administrative tasks.

Understanding License Types

Licenses for authentication and privilege elevation (*also referred to as access control and privilege management*) are purchased and installed separately from licenses for *auditing*. You can use the licensing service to install and manage all types of licenses.

Licenses for access control and privilege management are issued based on how a computer is used. For example, a computer can be licensed as a UNIX or Windows workstation or as a standard UNIX or Windows server, or as an application server. The following types of licenses are available:

- **Workstation Licenses (UNIX or Windows)** permit a specific number of UNIX or Windows workstations to be available to Active Directory users. Workstation licenses are intended for computers that are used interactively by one or two concurrent users but that do not host applications accessed by multiple users. There are separate UNIX workstation and Windows workstation licenses.
- **Server Licenses (UNIX or Windows)** permit a specific number of servers to be available to Active Directory users accessing server-based

applications. Server licenses are for computers that are accessed by multiple concurrent users and typically host a specific type of application. There are separate UNIX server and Windows server licenses.

Licenses for audit and monitoring service are issued for each computer that will be connected to an audit and monitoring service collector. Auditing licenses are issued separately for UNIX and Windows computers.

Understanding License Keys

Depending on whether you have purchased software licenses, your license keys might provide limited *evaluation* usage of the software for a specific number of days, or *permanent* access to features for a specific number of computers. If you initially install using an evaluation license key, you must eventually replace that evaluation key with one or more permanent license keys to continue using the software.

Your capacity for enabling access for standard UNIX services or applications is defined by the total of all of the licenses you purchase and install. For example, if you install three valid license keys that each enable 100 workstations for UNIX access, you have a total of 300 workstation login licenses available.

Each license you purchase has a 24-character registration key that specifies:

- The type of license granted by the key.
- The total number of computers that may be enabled under this key's license. If this is an evaluation key, the number of computers is unlimited, but the license count is displayed as zero (0) to indicate no computers are licensed under the evaluation key.
- The time limit for the key. If the license is a permanent license key, the time limit is not applicable. If the license is an evaluation key, the time is set to a duration that is defined in the license key.

Because each license key specifies a set number of computers, it is common to receive multiple license keys. You can provide these license keys when you install Delinea software on a Windows computer or after installation using the licensing service. For information about using the licensing service to add licenses, see Managing Licenses with the Licensing Service.

How License Usage is Counted

How license usage is counted depends on these factors:

- Whether the license is for authentication and privilege elevation (that is, access control and privilege management), or for audit and monitoring service.
- Whether the licensed computer uses the Windows or UNIX operation system.
- Whether the license is a permanent license or an evaluation license.

Using Delinea Licenses in FIPS Environments

Each recently issued Delinea license supports both FIPS compliant and non-FIPS compliant environments. The Licensing Service control panel **DC/DZ Deployment** tab and **DA Deployment** tab show the FIPS status of the selected licensing service host computer.

If you install the licensing service on multiple host computers in the forest (for example, for availability and redundancy reasons), it is highly recommended that all hosts have the same FIPS compliance setting. That is, licensing service hosts should all be FIPS compliant, or should all be non-FIPS compliant.

In most situations, Delinea license management tools are installed by default when you install Server Suite. However, some license management tools also have standalone installers so that you can perform a manual installation, or modify an existing license management tool installation.

Installing the Delinea Licensing Service

The Delinea Licensing Service is installed by default when you install Server Suite. The default installation location is:

C:\Program Files\Centrify\Licensing Service

For details about installing Server Suite, see the *Planning and Deployment Guide* and the *Administrator's Guide for Windows*.

You can choose not to install the licensing service during Server Suite installation by deselecting the **Centrify Licensing Service** check box in the list of components to install when the Delinea Management Services installation wizard executes. For example, if the licensing service is already installed on one computer in the forest and you do not need to install it on other computers, you can deselect it from the list of installed components. However, you should ensure that the licensing service is installed on at least one computer in the forest before deselecting it during installation.

If you do not install the licensing service when you install Server Suite, you can install it separately as described in Performing a Standalone Licensing Service installation.

Performing a Standalone Licensing Service Installation

You can install the Licensing Service separately from Server Suite using the standalone Licensing Service installer.

To perform a standalone installation of the Licensing Service:

1. Log on to the Windows computer and insert the CD or navigate to the directory where you downloaded Delinea files. If the Getting Started page is not automatically displayed, double click the autorun.exe file to start the installation of the Delinea software.
2. On the Getting Started page, click **Centrify Licensing Service**.
3. At the Welcome page, click **Next**.
4. Review the terms of the license agreement, click **I accept the terms in the License Agreement**, then click **Next**.
5. Specify a location for installing licensing service components and click **Next**.
6. Click **Install** to begin the installation.
7. When the installation finishes, click **Finish**.

> **Note**: You can also install the licensing service by executing the following installer, which resides in the Licensing Service folder in the Server Suite installation folder:

Centrify_Licensing_Service-x.x.x-win64.msi

After the licensing service is installed and running, you can use the licensing service control panel to manage Delinea licenses as described in Managing licenses with the Licensing Service.

Modifying a Delinea Licensing Service Installation

You can change, repair, or remove an existing licensing service installation by executing the standalone Delinea Licensing Service installer as described in Performing a Standalone Licensing Service Installation after the licensing service is already installed.

You can select one of the following options:

- **Change.** Select this option to change installation parameters of the current installation.t
- **Repair.** Select this option to remove backup files, re-copy the licensing service program files to the default installation location, and reset registry entries.
- **Remove.** Select this option to remove the licensing service from the computer.

Verifying that the Delinea Licensing Service is Running

To verify that the licensing service is running, open the Services administrative tool on the computer where the licensing service is installed. The "Delinea Licensing Service" entry should have a status of **Started**.

Assigning a License Container to a Zone through Access Manager

If you choose to use more than one license container in the forest, you can assign a specific license container to an individual zone. This option is useful if you want to manage zones independently with each zone using its own set of license keys rather than having all zones use a common pool of licenses. If you assign a specific license container to a zone, however, only the license keys installed in that container can be used for the computers in that zone.

For example, if you create a license container object named ajax.org/Performix Licenses, add a license key for 10 Workstation license to that container, and assigned that container to the Performix Division zone, those 10 workstation licenses are available specifically for the computers you add to the PerformixD ivision zone.

To assign a license container to a zone:

1. Open the Access Manager console.
2. If prompted to connect to a forest, specify a domain controller, and, if needed, the user credentials for connecting to the domain controller, then click **OK**.
3. In the console tree, select **Zones** to display the list of zones.
4. Select a zone and right-click, then click **Properties**.
5. On the General tab, select a specific Licenses container from the list of available **License containers** for the zone to use, then click **OK**.

Installing the Licensing Report Wizard

The Licensing Report wizard is installed by default when you install Server Suite. The default installation location is C:\\Program Files\\Delinea\\Deployment Report.

You can optionally reinstall the wizard manually by executing the Licensing Report wizard standalone installer:

Centrify_Licensing_Report-x.x.x-win64.msi

The standalone installer is located in the DirectManage folder in the Server Suite installation folder.

Modifying a Licensing Report Wizard Installation

You can change, repair, or remove an existing Licensing Report wizard installation by executing the standalone installer:

Centrify_Licensing_Report-x.x.x-win64.msi

The standalone installer is located in the DirectManage folder in the Server Suite installation folder.

You can select one of the following options when you execute the standalone installer in an environment where the wizard is already installed:

- **Change.** Select this option to change installation parameters of the current installation.
- **Repair.** Select this option to remove backup files, re-copy the Licensing Report wizard program files to the default installation location, and reset registry entries.
- **Remove.** Select this option to remove the Licensing Report wizard from the computer.

After the Delinea Licensing Service is installed and running, you can use the Licensing Service control panel to manage Delinea licenses in these ways:

- **Open the Licensing Service control panel.** For more information, see Opening the Licensing Service Control Panel.
- **Start and stop the Centrify Licensing Service, and manually refresh license count information.** For more information, see Starting, Stopping, and Refreshing the Licensing Service.
- **Create license containers for Centrify licenses.** For more information, see Creating License Containers and Adding License Keys.
- **Add and remove licenses for Centrify products.** For more information, see Adding and Removing Centrify License Keys.
- **Monitor license usage for each Centrify product.** For more information, see Monitoring Centrify License Usage.
- **Manually refresh license usage information, and configure how often license usage information is refreshed automatically.** For more information, see Configuring Licensing Service Settings.
- **Configure license usage email notification.** You can configure the list of email recipients, the license usage percentage that triggers notification, whether certain environment details should be omitted from email notification, and outbound email sender details. For more information, see Configuring License Usage Email Notification.
- **View the current licensing service log and configure licensing service logging parameters.** For more information, see Configuring and Viewing Licensing Service Logs.

Opening the Licensing Service control panel

Use the Windows Start menu to open the Licensing Service control panel. If **Centrify Licensing Service Control Panel** is not pinned to the Start menu, use Start menu searching to locate and start the Centrify Licensing Service control panel.

The Licensing Service control panel contains the following tabs:

- **General.** Use this tab to monitor current licensing service status, start and stop the licensing service, and manually refresh license count information as described in Starting, Stopping, and Refreshing the Licensing Service.

  The Current Configuration area displays the name of the Active Directory forest that the licensing service manages, and the name of the computer where the licensing service is running.

  The Monitoring Details area displays the current status of license monitoring, the date of the last license usage update, and license status details. Current status can be one of the following:

  - **Idle.** The licensing service is running, and is available to perform a license usage update.
  - **Busy.** A license usage update is in progress, or the licensing service is starting.
  - **N/A.** The licensing service is not running or is otherwise unavailable.

    An additional field, **Service status**, displays whether the Licensing Service is running or stopped.

- **DC/DZ Deployment.** Use this tab to monitor usage details—including license counts—of authentication and privilege elevation (also known as *access control and privilege management*) licenses. See Monitoring Centrify License Usage for more information about using this tab.
- **DA Deployment.** Use this tab to monitor usage details—including license counts—of audit and monitoring service licenses. See Monitoring Centrify License Usage for more information about using this tab.
- **DC/DZ Licenses.** Use this tab to create license containers, and add or remove licenses for authentication and privilege elevation (also known as *access control and privilege management*). See Creating License Containers and Adding License Keys and Adding and Removing Centrify License Keys for more information about using this tab.
- **DA Licenses.** Use this tab to add or remove licenses for audit and monitoring service. See Adding and Removing Centrify License Keys for more information about using this tab.
- **Settings.** Use this tab to configure how often license usage information is automatically refreshed, and license usage email notification details. Email notification details that you can configure include the list of recipients, SMTP server settings, whether some system information is hidden in notification email, and the license usage threshold that triggers email notification. See Configuring Licensing Service Settings and Configuring License Usage Email Notification for more information about using this tab.
- **Troubleshooting.** Use this tab to manually refresh license usage information and manage licensing service logging. Logging parameters that you can configure include trace level of logged events and log file location. You can also view and save the current log from this tab. For more information, see

Configuring Licensing Service Settings and Configuring and Viewing Licensing Service Logs.

Starting, stopping, and refreshing the licensing service

Use the **General** tab in the Licensing Service control panel to start, stop, and restart the licensing service, and to refresh license count information manually.

To start and stop the licensing service:

1. Open the Licensing Service control panel **General** tab.
2. Click **Start**, or **Stop**, or **Restart**.

Whenever you start or restart the licensing service, license usage information is refreshed. See Monitoring Centrify License Usage for information about viewing license usage information.

Licensing service start and stop information can be logged in the licensing log file depending on the log trace level that is configured. See Configuring and Viewing Licensing Service Logs for information about viewing the licensing log and setting the log trace level.

Refreshing the License Count Manually

In some situations, you might want to refresh the license count information in the licensing service without refreshing all license usage information. When you refresh the license count information as described in this section, license keys are updated in the licensing service, but a complete license usage evaluation is not triggered.

For example, if you add or remove licenses through Access Manager or Audit Manager after the licensing service is installed, you should update the license count in the licensing service as described here so that the license changes that you made through Access Manager or Audit Manager are implemented immediately in the licensing service. If you do not update the license count as described here, license additions or removals that you perform through Access Manager or Audit Manager are not implemented until a regularly scheduled license update task executes.

If you need to refresh all license usage information, including license count, perform the procedure described in Refreshing license usage information.

To refresh the license count manually:

1. Open the Licensing Service control panel **General** tab.
2. Click **Refresh Now**.

Creating License Containers and Adding License Keys

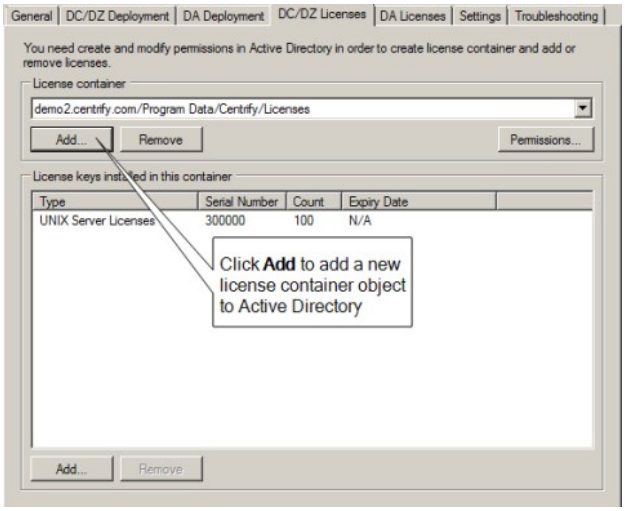
Before you can add Centrify authentication and privilege elevation license keys, you must create a Licenses container object in Active Directory because you must have at least one Licenses container in the forest into which you install license keys. It is also possible to add more License containers to the forest and use those additional containers to control who can use which license keys. For example, you may want to create one license container for application servers and another for workstation licenses. You can then set permissions on the container objects to prevent the workstation administrators from installing the application server license keys and the application server administrators from installing the workstation license keys in their respective containers.

> **Note:** You can also use Access Manager to assign a specific license container to an individual zone as described in Assigning a License Container to a Zone through Access Manager.

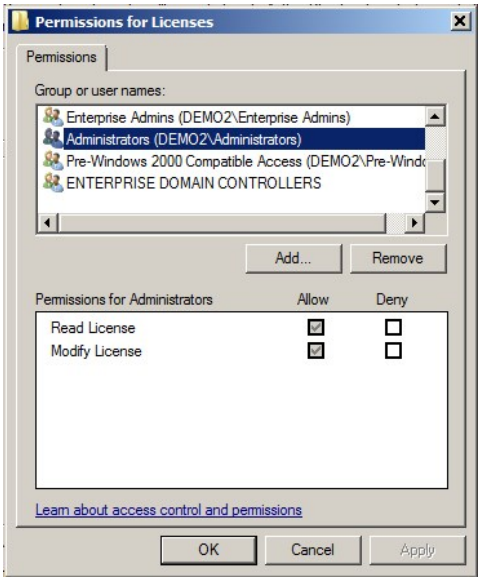
Creating License Containers

To add a new license container object for authentication and privilege elevation licenses:

1. Open the Licensing Service control panel **DC/DZ Licenses** tab.
2. In the License container section, click **Add**.



3. Browse to select a location for the new license container, then click **Create**. Select either container or organizational unit to indicate the type of object to create, and type a name for the new license container object and click **OK**.
4. Click **OK** to close the Browse for Container dialog box.
5. When prompted to confirm the creation of the container object, click **Yes** to add the license container to Active Directory.
6. Click **Permissions** to assign Read License and Modify License permissions to specific users or groups. The users or groups that you give the Modify License permission to can then add license keys to the new license container.



Adding and Removing Centrify License Keys

When you install Centrify software for authentication and privilege elevation, you must provide at least one licensing key that is specific to authentication and privilege elevation. Likewise, when you install audit and monitoring service, you must provide at least one license key that is specific to audit and monitoring service.

> **Note:** If you are using a valid evaluation license key for audit and monitoring service and install a permanent audit and monitoring service license key, the evaluation key is automatically removed from the audit and monitoring service installation. If you are using a valid permanent auditing license key and install an evaluation license key for audit and monitoring service, the evaluation key takes precedence as long as it has not expired.

To add license keys for authentication and privilege elevation:

1. Open the Licensing Service control panel **DC/DZ Licenses** tab.
2. In the **License container** section, select the appropriate License container from the list of available license containers.
3. At the bottom of the dialog box, in the **License keys installed in this container** section, click **Add**.
4. Type or paste the new license key string, then click **OK**.
5. Click **OK**.

To add license keys for audit and monitoring service:

1. Open the Licensing Service control panel **DA Licenses** tab.
2. In the **Installation** section, select the auditing installation for which you are adding a license.
3. Click **Add**.
4. Type or paste the new license key string, then click **OK**.
5. Click **OK**.

To delete a license key that you have previously installed:

1. Open the Licensing Service control panel **DC/DZ Licenses** tab or the **DA Licenses** tab.
2. In the **License keys installed in this container** section, highlight the license to delete, click **Remove**, and then click **OK**.

Monitoring Centrify license Usage

The Licensing Service control panel allows you to monitor how many Centrify licenses in the forest are in use, and how many are available. You can see usage information for access control and privilege management licenses, and for auditing licenses.

> **Note:** To generate a more comprehensive report of license usage, including detailed system information about the computers where you have Centrify software deployed, use the Licensing Report wizard. When you generate a license usage report with the wizard, information is formatted as comma-separated values (CSV) in a text file. See Creating Licensing Reports with the Licensing Report Wizard for more information.

To see usage information for authentication and privilege elevation licenses:

1. Open the Licensing Service control panel **DC/DZ Deployment** tab.

   The license usage information that is displayed when you first open the tab is from the last time you refreshed the information in the **DC/DZ Deployment** dialog box. If you restarted the Licensing Service or refreshed license usage information from the **Troubleshooting** tab, the latest license usage information is not displayed in the **DC/DZ Deployment** dialog box until you perform Step 2 and Step 3.

2. In the **Source** field, select the licensing service host computer for which to report license usage information.

   If you select **Last Updated Centrify Licensing Service**, the licensing service host computer containing the latest valid licensing information is selected.

3. Click **Refresh**.

   Information displayed in the dialog box is based on the most recent refreshing of license usage information, which is generated by a scheduled refresh, manual refresh, or starting the Licensing Service. That is, clicking **Refresh** here does not instruct the licensing service to check current license usage.

4. Optional: To display current license usage information:

   1. Perform a manual refresh from the **Troubleshooting** tab as described in Configuring Licensing Service Settings.
   2. Return to the **DC/DZ Deployment** tab and click **Refresh**.

To see usage information for audit and monitoring service licenses:

1. Open the Licensing Service control panel **DA Deployment** tab.

   The license usage information that is displayed is for all available audit and monitoring service installations (that is, global capacity and usage are shown).

2. In the **Source** field, select the licensing service host computer for which to report license usage information.

If you select **Last Updated Centrify Licensing Service**, the licensing service host computer containing the latest valid licensing information is selected.

3. In the **Installation** field, select an audit and monitoring service installation whose licensing information you want to see.
4. Click **Refresh**.

   Information displayed in the dialog box is based on the most recent refreshing of license usage information, which is generated by a scheduled refresh, manual refresh, or starting the licensing service. That is, clicking **Refresh** here does not instruct the licensing service to check current license usage.
5. Optional: To display current license usage information:
   1. Perform a manual refresh from the **Troubleshooting** tab as described in Configuring Licensing Service Settings.
   2. Return to the **DA Deployment** tab and click **Refresh**.

Configuring Licensing Service Settings

Use the **Settings** tab in the Licensing Service control panel to refresh license usage information and configure licensing email notification details.

Refreshing license usage information

You can use the licensing service to refresh license usage information in these ways:

- Start or restart the licensing service as described in Starting, Stopping, and Refreshing the Licensing Service.
- Configure an automatic refresh interval as described in this section.
- Perform a manual refresh of license count and usage as described in this section.

To configure an automatic refresh interval:

1. Open the Licensing Service control panel **Settings** tab.
2. In the Update Schedule section, click **Configure**.
3. Specify a start time and recurrence pattern (interval), and click **OK**.

To manually refresh license count and usage information:

1. Open the Licensing Service control panel **Troubleshooting** tab.
2. Click **Refresh Now**.

   Note: Manually refreshing license count and usage as described here updates both license count and license usage. If you want to update just the license count (for example, due to performance considerations), perform the procedure described in Refreshing the License Count Manually.

Configuring License Usage Email Notification

Email is sent to a list of recipients when a license is deployed. Routine notices are sent if license usage is below 90% (or a different threshold if you specify one). Warnings are sent if usage thresholds are exceeded. The default thresholds that trigger email warnings are 90%, 100%, and 120%.

Typical email notification appears as follows, and includes an attachment of the latest report generated by the Licensing Report wizard (not shown here):

`From: "Delinea Licensing Service" <licensingservice@domain.com>

To: "System Administrator" <sysadmin@domain.com>

Subject: Notice from Centrify: You are deploying 17% of your DirectControl/DirectAuthorize UNIX licenses, 20% of your DirectAuthorize Windows licenses, and 30% of your total DirectAudit licenses.

Date: Monday, October 31, 2016 12:00 AM

DirectControl/DirectAuthorize UNIX usage: 13 out of 75
DirectAuthorize Windows usage: 5 out of 25
Total DirectAudit usage: 15 out of 50

=== DirectControl/DirectAuthorize Usage Summary ===
UNIX Server: 5 used, 50 licensed
UNIX Workstation: 5 used, 25 licensed
UNIX without license type: 3 used
Windows Server: 2 used, 25 licensed
Windows Workstation: 3 used, 0 licensed
DirectControl/DirectAuthorize Evaluation: 0 licensed
DirectControl UNIX - Express: 0 used
Mac systems: 0 used
zLinux systems: 0 used

=== DirectAudit Usage Summary ===
UNIX Server: 5 used, 25 licensed
UNIX Workstation: 5 used, 0 licensed
UNIX without license type: 0 used
Windows Server: 2 used, 25 licensed
Windows Workstation: 3 used, 0 licensed
DirectAudit Evaluation: 0 licensed
zLinux systems: 0 used`

You can configure email notification details such as the list of recipients, SMTP server settings, whether to omit some system information from the report attached to the notification email, and one license usage threshold that replaces the default 90% threshold.

To configure license usage email notification:

1. Open the Licensing Service control panel **Settings** tab.
2. In the Notification section, click **Configure**.
3. To add or remove a user on the email recipient list:
    - To remove the user from the list of recipients, highlight the user name and click **Remove**.
    - To add a user to the list of recipients, click **Add** in the Recipients section. Type the email address and display name for the user and click **OK**.
4. To configure SMTP server settings:
    - Type the display name and email address of the user who is the email sender.
    - Type the host name or IP address of the outbound email server and specify a port number.
    - If the outbound email server requires secured password authentication for login, select **This server requires authentication** and type the name and password of a user with login permission. If the outbound email server does not require secured password authentication for login, leave this check box unchecked.
    - To optionally test the SMTP configuration, click **Test** and specify a recipient for the test email message.
5. To specify that a warning is sent when license usage exceeds a threshold other than 90%, select **Warn when the usage reached** and specify a threshold value from 1% to 89%. The threshold that you specify is used instead of the default 90% threshold.
6. The license usage report generated by the Licensing Report wizard is included as an attachment in email notification. To omit host, zone, and installation names from the attachment, select **Hide host, zone and installation names from the attached licensing report**.
7. Click **OK**.

    Note: Depending on how a recipient's email filters are configured, notification email might be redirected to a recipient's junk or spam folder. If a recipient is not receiving email as expected, check the recipient's junk or spam folder. If necessary, modify the recipient's email filters so that notification email is not directed to the junk or spam folder.

    Note: By default, if the license usage report is 10 MB or larger, the service sends the report as a .zip file instead of a plain text attachment. You can add the following registry setting to configure the size for which the service attaches the report as .zip file: HKLM\SOFTWARE\Centrify\Licensing Service\ReportNotificationCompressionThreshold as a DWORD registry setting. Enter the value as the number of MB for the file size threshold. For example, a value of 3 will make sure that licensing reports that are 3 MB or larger are sent as zip files.

Configuring and Viewing Licensing Service Logs

Detailed licensing service log files are created while the licensing service is running, and are saved in the following default location:

C:\\Program Files\\Common Files\\Centrify Shared\\Logs

In addition to viewing the current log file, you can edit the current file, configure which events are stored in log files (that is, the logging level) and specify the location where log files are stored.

To view and edit the current log file:

1. Open the Licensing Service control panel **Troubleshooting** tab.
2. To save the current log file without first opening it for viewing, click **Save As**, navigate to a folder location, specify a name for the log file, and click **Save**.
3. To open the log file for viewing and editing, click **View Log**. While the file is open for viewing, use the **File** and **Edit** menus to save the file to a name and location of your choice, select parts of the file for copying, or clear the file.
4. To save a zipped version of the log file to a location of your choice, click **Export Diagnostics Data**, specify a folder location, and click **OK**.

To configure licensing service event logging level:

1. Open the Licensing Service control panel **Troubleshooting** tab.
2. Click **Options**.
3. In the Log Settings dialog box, select one of the following categories of events to log:
    - No log messages
    - Error messages
    - Warning messages
    - Informational messages
    - All messages
4. Click **Apply**, then click **OK**.

To specify a different licensing service log file folder:

1. Open the Licensing Service control panel **Troubleshooting** tab.
2. Click **Options**.
3. In the **Log folder path** field, specify or browse to the folder where you want to store licensing service log files.
4. Click **OK**.

The Licensing Report wizard collects information about the Delinea software you have deployed, including how many licenses you have installed, where they are used, where they are inactive, and the number of licenses that remain available in the forest. Information is reported for audit and monitoring service, authentication and privilege elevation licenses.

The wizard is installed by default when you install Server Suite on a Windows computer. You can also download and install the wizard separately using a standalone setup program as described in Installing the Licensing Report Wizard.

Note: Depending on the version of your installed Delinea software, the following nomenclature caveats could apply:

- Licenses for authentication and privilege elevation might be shown as *DirectControl and DirectAuthorize* licenses in examples and command output.
- Licenses for audit and monitoring service might be shown as *DirectAudit* licenses in examples and command output.

Permissions Required to Generate a Licensing Report

You must have the following privileges to generate a licensing report:

Centrify Express for UNIX/Linux	A user account in a domain that is trusted by other domains in the forest, or an account that can search and read information from all of the domains in the forest.
Authentication & Privilege	A user account in a domain that is trusted by other domains in the forest, or an account that can search and read information from all of the domains in the forest.
Audit & Monitor	A user account with the permissions required for Authentication & Privilege plus the “Manage License” or “View” permission for the audit and monitoring service installation.

You can specify different user accounts when you run the wizard, if needed. For example, you might need to use different accounts to collect information about one or more audit and monitoring service installations.

Information Required to Produce the Licensing Report

Before you run the wizard, verify that you have the following information available:

Folder location	The Licensing Report wizard can be installed with Server Suite or downloaded and installed as a separate executable file. If you download the file from the Centrify website, it is saved by default in your Downloads folder. This folder is usually located on the drive where Windows is installed in a folder with your user name. For example, the path to the file might be similar to this: C:\Users\your_name\Downloads
Domain controller	Centrify products are licensed for the entire forest. Therefore, the wizard must be able to connect to a domain controller that can access Active Directory information for the entire forest. You are prompted to specify the domain controller and credentials for connecting to the domain when you start the wizard. Alternatively, you can specify the name of a domain that is trusted to access other domains in the forest.
User credentials for authentication and privilege elevation (*DirectControl and DirectAuthorize*)	The wizard must be able to read license and deployment information from the domain controller that has access to all domains in the forest. By default, your logon account credentials are used to connect to the domain controller. If your logon account does not have the List Objects permission to access the domain controller, you can specify a different user name and password when prompted to specify the account credentials for connecting to the domain.

User credentials for audit and monitoring service (*DirectAudit*)	The licensing report wizard attempts to retrieve usage information from Active Directory before attempting to retrieve information from audit store databases. The wizard attempts to connect to audit store databases only if the information is not found in Active Directory. If the wizard needs to connect to an audit store database, user credentials and the "Manage License" or "View" permission for each installation are required. By default, the same user credentials are used to get all deployment information. However, if the user account does not have the "Manage License" or "View" permission, you can specify a different user name and password for audit installations when prompted.
Report output configuration	You need to specify the file name and folder location for the licensing report generated by the wizard. You must also decide whether the report output should show or hide information about the computers where you have deployed Centrify software. If you choose to hide zone, computer, and installation names, the information will be replaced with a one-way hash of the text to prevent the computers from being identified in the report. If you choose this option, you will not be able to review and validate license information for specific computers. The report output is saved as comma-separated values (CSV) in a text file.

Preparing to run the Licensing Report wizard

To keep the report output concise, Delinea recommends that you check for and remove orphaned computer accounts and decommissioned computers before generating a licensing report.

To check for and remove orphaned and decommissioned computers:

1. Open Active Directory Users and Computers and delete the computer objects associated with the decommissioned computers.
2. Open Access Manager.
3. Right-click **Centrify Access Manager** in the navigation pane, then select **Analyze**.
4. Select **Orphan zone data objects and invalid data links**, then click **Next**.
5. Click **Finish**.
6. Select Analysis Results to check whether any orphan information was found.

   If there are deleted computer objects with an orphan zone profile listed in the Analysis Results, select the issue, right-click, then select **Remove orphan profile**.

Running the Licensing Report Wizard

After you have installed the Licensing Report wizard as part of Server Suite or as a separate standalone installation package, you can run the wizard to generate a licensing report. You can start the wizard from within Access Manager or by navigating to it from the Start menu.

To run the wizard from within Access Manager:

1. Open Access Manager.
2. Right-click **Centrify Access Manager**, then select either **Centrify Licensing Report (DirectControl)** or **Centrify Licensing Report (DirectControl & DirectAudit)**.

   If you select DirectControl, the licensing report utility automatically checks the current forest for authentication and privilege elevation information using your current account credentials. If you need to specify different credentials or check audit and monitoring service licenses, select **Centrify Licensing Report (DirectControl & DirectAudit)** or from the Start menu select **Centrify Licensing Report**.
3. Click **Next** to accept the default domain controller and your current credentials to retrieve deployment information.

If necessary, you can specify a different domain controller and select the option to specify a different user if your current account does not have permissions to retrieve deployment information, then click **Next**.

4. If the Audit Management service is not running, or if DirectManage Audit version 2015.1 or earlier is installed, or if you do not have the necessary audit and monitoring service permissions, you are prompted to specify credentials to retrieve audit installation information.

   If you see this prompt, click **Next** to use your current credentials to retrieve audit installation information.

   If necessary, you can select the option to specify a different user, then specify a different user name and password if your current account does not have the "Manage Licenses" or "View" permission for the audit Installation, then click **Next**.

   If you do not see this prompt, go to Step 6 and continue from there.

5. If the Audit Management service is not running, or if DirectManage Audit version 2015.1 or earlier is installed, or if you do not have the necessary audit permissions, you are prompted to specify whether your current credentials can be used to retrieve audit and monitoring service installation information.

   If you see this prompt, click **Next** if the credentials specified in Step 4 can retrieve information for all of the audit installations listed.

   If necessary, you can select an audit and monitoring service installation and click **Change Credentials** to specify a different user name and password for connecting to a specific installation, then click **Next**.

   If you do not see this prompt, go to Step 6 and continue from there.

6. Specify the name and folder location for the licensing report and whether to hide host, zone, and installation names in the report output, then click **Next**.

   - By default, the licensing report output is located in your Documents folder with a name in the format of Centrify_Licensing_Report_yyyymmdd.txt, where yyyymmdd is the year, month, and date indicating when you are generating the report. If a report of the same name already exists in that location, a version number suffix is added to the default report name.
   - Select the option to **Hide host, zone, and installation names from the report** to keep this information private. The wizard will generate random strings to replace host, zone, and installation names in the report output. Note that selecting this option does not obfuscate the Active Directory forest name. The forest name is required to send the report output to Delinea. All other names included in the report can be replaced with random strings.

7. Review the output location and file name, then click **Next** to generate the report.

8. To preview the report before saving it or sending it to Delinea, click **Preview Report**.

   To open the report for editing or to save it as a different file name, leave the **Open the output report** option selected and click **Exit**.

   To send the report output directly to the Delineay Support portal, click ***Send to Delinea**.

9. Click **OK** to acknowledge that the report will be sent and continue.

   You will be given a reference number for communicating with support about the report and prompted to log in using your Delinea account user name and password. After logging in, click **Continue** to display details about your report.

Running the utility as a separate package

You can access the shortcut for the licensing report executable directly from the Start menu. If **Licensing Report** is not pinned to the Start menu, use Start menu searching to locate and start the licensing report utility. After you open the utility, the steps for generating the report are the same as the steps in the previous section. Follow the instructions in the wizard to generate the report output.

Running the utility from the command line.

As an alternative to running the licensing report utility as a wizard, you can use the command-line interface to run the wizard in a Command Prompt window. To use the command-line interface for the utility, navigate to the directory where the CentrifyDeploymentReport.exe file is located (the default location is C:\Program Files\Centrify\Deployment Report). Open a Command Prompt window, and execute the command using the following syntax:

```
CentrifyDeploymentReport.exe [/standardmode]    [/server=server] [/plaindata] [/silent /output=filepath  [/force]] [/help] [/?]
```

You can use the following options with the utility:

/standardmode	Run CentrifyDeploymentReport.exe with standard edition support only.
/server=server	Specify the name of a domain controller in the forest for which you want to run the report.
/plaindata	Include host, zone, and installation names in the report. By default, host, zone, and installation names are not included in the report.
/silent	Run CentrifyDeploymentReport.exe in silent mode. You can use this option when generating the report for Server Suite standard edition using the /standardmode option, or without the /standardmode option to generate an report that includes audit and monitoring service information.
/output=filepath	Specify output file path and file name of the licensing report. You can use this option only when you are using the /silent option.
/force	Force the generation of a new licensing report even if the output file specified already exists. You can use this option only when you are using the /silent option.
/help, /?	Display command syntax and usage information.

Reviewing the licensing report output

The Licensing Report wizard generates a report formatted as a set of comma separated values (CSV) in a text file. The report contains two main sections:

- The first section contains summary information about the counted computers where you have Delinea software deployed.
- The second section contains detailed information about the computers where you have Delinea software deployed, including separate areas for counted and uncounted computers. If a computer is uncounted, a comment explains the reason why it is uncounted.

> **Note:** See How Computers are Counted for Licensing Reports for more information about which computers in the forest are counted, and how their licenses count against the total number of available licenses.

The first and second report sections are separated from each other as follows:

Just before the end of Section 1, a checksum is included to validate the authenticity of the report. For example:

```
Checksum,1,"frACfH0SRjhEDxPFU5ZAbfoZ5ISMKm1ZFqssWG79V4Wr3QC4Fp1wneQG03U26C+lU0608J5PdrV2vuH0nMJLxcdi6cV4nerrZPhmhlIf7MU="
```

Editing the checksum or any other part of Section 1 invalidates the report. If you make any changes in this section, you will need to generate a new report.

You should also note that the last lines in the report are a report identifier string and the version number of the Licensing Report wizard that generated the report. For example, you might see lines similar to this at the end of the report:

```
Report ID,"8OY5i6p0LZtePMYTAg0PqcImIZA="
Version,"5.4.0.118"
```

You should not modify or delete the report identifier or the version number.

How Computers are Counted for Licensing Reports

To generate a report, the licensing report software first determines which computers in the forest are validly using Centrify software. These “valid usage” computers are considered “counted” computers. Licenses for counted computers are subtracted from the total number of available permanent workstation or server licenses, and their licensing summary information is reported in Section 1 of the licensing report.

Counted Computer Scenarios

A computer is counted if the following scenarios are true:

- The computer's zone status is **Auto Zone** or **Zoned**. This scenario applies only to computers where authentication and privilege elevation features are installed.
- The computer has a status of **Active**.

Uncounted Computer Scenarios

Uncounted computers are included (together with counted computers) in Section 2 of the licensing report, but are not shown in Section 1 because their licenses are not subtracted from the total number of available licenses.

A computer is uncounted if any one of the following scenarios is true:

- The computer's zone status is **Express** or **Zoneless**. This scenario applies only to computers where authentication and privilege elevation features are installed.
- The computer is using an authentication and privilege elevation license, and is joined to the **Null Zone**. Note that computers using audit and monitoring service licenses are counted even if they are joined to the null zone.
- The computer has a status of **Inactive**.
- The computer is using an authentication and privilege elevation license, and is **Orphaned** (the computer profile exists in the zone but the corresponding Active Directory computer object has been removed). Note that computers using audit and monitoring service licenses are counted even if they are orphaned.
- The computer has a **Duplicated** audit and monitoring service license (the audit and monitoring service agent was migrated from one installation to another, and the time stamp of the agent from the earlier installation has not expired).
- The computer has an **Unknown logon time** (the computer has never joined the domain).

License Type Information for Managed and Audited Computers

If you have authentication and privilege elevation features or audit and monitoring service features deployed, the summary in report Section 1 includes information about the type of Delinea license in use on each computer.

License type can be one of the following values:

- **Server**
- **Workstation**
- **None** (The license type cannot be determined from the Active Directory object, as is the case when the computer is orphaned, or the agent is from a release earlier than 2015.1.)

See Understanding License Types for more information about license types.

Zone information for managed computers

If you have authentication and privilege elevation features deployed, report Section 1 includes zone mode information in the "DirectControl/DirectAuthorize Agent Type" string shown in Example 2: Zone Mode and Number of Agents.

> **Note:** Zone mode applies only to computers where authentication and privilege elevation features are installed. Zone mode does not apply to computers using audit and monitoring service licenses.

Depending on the nature of your deployment, the zone mode information displays one of the following values:

- **Auto Zone** if the computer is in a Centrify Auto Zone.

  You cannot use Centrify rights and roles on computers joined to an Auto Zone.

  If the Zone mode for a computer is Auto Zone, the computer is included in the authentication service (DirectControl) license count.

- **Zoned** if the computer is in a standard Centrify zone.

  All authentication and privilege elevation features are supported for computers in Centrify zones on most platforms. However, the Centrify Agent for Mac OS does not support Centrify rights and roles.

  If the Zone mode for a computer is Zoned, the computer is included in the authentication service (DirectControl) license count.

- **Express** if the computer has a Centrify Express agent installed.

  Computers with a Centrify Express agent have limited functionality. For example, you cannot apply group policies or use Centrify rights and roles on

computers with the Centrify Express agent.

If the Zone mode for a computer is Express, the computer is not included in the authentication service (DirectControl) license count.

- **Zoneless** if a computer has the Centrify Agent installed but is not connected to a zone.

  This agent type is primarily for computers that use Centrify MFA for Windows login authentication.

  If the Zone mode for a computer is Zoneless, the computer is not included in the authentication service (DirectControl) license count.

- **Null Zone** if a computer is joined to the null zone.

  If the Zone mode for a computer is Null Zone, the computer is not included in the authentication service (DirectControl) license count.

See Example 2: Zone Mode and Number of Agents for details about how zone mode information is displayed in the report.

Status information for managed and audited computers

If you have authentication and privilege elevation features or audit and monitoring service features deployed, the counted/uncounted information in report Section 2 indicates the status of the computer as **Active** or **Inactive**:

- **Active** if the computer has been used for authentication and privilege elevation, or for audit and monitoring service, within 45 days prior to the date that the report was run.

  Computers with an active status are included in the license count.

  For authentication and privilege elevation licenses, the time stamp of the managed computer logon to the domain controller is monitored if the functional level of the domain controller is Windows Server 2003 or later. The licensing report uses the time stamp of the LastLogonTimestamp attribute to determine whether there has been logon activity within 45 days prior to the date that the report was run.

  For audit and monitoring service licenses, the licensing report uses the most recent time that the managed computer has communicated with a collector to determine whether there has been auditing activity within 45 days prior to the date that the report was run.

- **Inactive** if the computer has not been used for authentication and privilege elevation, or for audit and monitoring service, within 45 days prior to the date that the report was run.

  Inactive computers are not included in the license count.

See Example 6: Counted Identity and Privilege Elevation Computers for an example of computer status information.

Remarks for Managed and Audited Computers

If you have authentication and privilege elevation features or audit and monitoring service features deployed, the counted/uncounted information in report Section 2 includes remarks about the following computers:

- Uncounted computers with authentication and privilege elevation licenses.
- Counted and uncounted computers with audit and monitoring service licenses.

Remarks provide additional information about why a computer is uncounted, and other significant information to be aware of. See Example 7: Counted Audit and Monitoring Service Computers and Example 8: Uncounted Computers of All License Types for examples of remarks strings.

The Remarks string can have the following values:

- **Duplicated** if an audit and monitoring service agent was migrated from one installation to another (such as during an upgrade), and the time stamp of the agent from the earlier installation has not expired.

  Computers with duplicated licenses are not counted. That is, the license is only counted once.

- **Excluded due to null zone** if the computer was not counted because it is joined to the null zone.

  Computers with authentication and privilege elevation features (DirectControl and DirectAuthorize licenses) are not counted if they are joined to the null zone.

  Computers with audit and monitoring service features (DirectAudit licenses) are included in the auditing license count even if they are joined to the null

zone.

- **Excluded due to zoneless mode** if the computer has a zone mode of Zoneless (that is, the computer has the Centrify Agent installed but is not connected to a zone).
- **Excluded due to express mode** if the computer has a Centrify Express agent installed.
- **Inactive** if the computer has a status of Inactive as described in Status Information for Managed and Audited Computers.
- **None** if no additional information is required.
- **Orphaned** if the computer profile exists in the zone but the corresponding Active Directory computer object has been removed.

  Orphaned computers with authentication and privilege elevation features (DirectControl and DirectAuthorize licenses) are not included in the license count. You can use Access Manager to delete orphan profiles as described in Preparing to run the Licensing Report wizard.

  Orphaned computers with audit and monitoring service features (DirectAudit licenses) are included in the auditing license count if the computer has communicated with a collector within 45 days prior to the date that the report was run.
- **Unknown logon time** if the computer has never joined the domain. This situation typically occurs when you use Access Manager to prepare a UNIX computer prior to joining the computer to the domain. Computers with an unknown logon time are not included in the license count.
- **Vault-based systems** are your Windows, UNIX, and/or network devices that are managed by and audited by the Server Suite.

Evaluation Licenses for Managed and Audited Computers

If a computer has a valid evaluation license, the detailed section of the licensing report (Section 2) indicates the licensing status as Evaluation (Valid). In the case of valid evaluation licenses, the summary section of the report (Section 1) might show the "Available" licenses as a negative number. You can ignore negative available licenses if you have valid unlimited evaluation licenses. However, if the licensing status indicates an expired evaluation license, you should remove the expired evaluation license key.

Status Information for Zoneless Computers

If a computer has the Centrify Agent installed but is not connected to a zone, its agent type is listed as *Zoneless* in the licensing report. This agent type is primarily for computers that use Centrify MFA for Windows login authentication.

Examples

This section contains examples of a hypothetical licensing report.

Depending on the version of your installed Centrify software, the following nomenclature caveats could apply:

- Licenses for authentication and privilege elevation are shown as *DirectControl and DirectAuthorize* licenses.
- Licenses for audit and monitoring service are shown as *DirectAudit* licenses.

> **Note:** "Join Time" is the point in time when the computer joined to the zone. Because Join Time is a feature introduced in Release 2020, if the agent is older than Release 2020, the Join Time displays as "Unknown."

Example 1: Agent, License Type and Count

The following example shows the first portion of report Section 1, containing summary system information. Colored lines indicate how entries in each section relate to each other. Different line colors are for readability only.

Note that this example shows the agent (DirectControl, DirectAudit, and/or DirectAuthorize), the license type (UNIX, Windows, or combined UNIX and Windows), licenses found, licenses used, and licenses available.

Depending on what types of Centrify licenses you have in your environment, your own licensing report could contain fewer entries than the example shown here.

Example 2: Zone Mode and Number of Agents

The following example shows the next portion of report Section 1, displaying the deployment quantities for each type of DirectControl/DirectAuthorize agent based on zone mode. This example shows the layout of this section rather than example data. Depending on what types of Centrify licenses you have in your environment, your own licensing report might not use all of the layout entries shown here.

Example 3: Zone Names and Deployment Details

The following example shows the next portion of report Section 1. Information for DirectControl/DirectAuthorize deployments is sorted by zone. Information

for DirectAudit deployments is sorted by agent type and by installation. This example shows the layout of this section rather than example data. Depending on what types of Centrify licenses you have in your environment, your own licensing report might not use all of the layout entries shown here.

```
Number of Zones,#
------------------------------------------------------------

"2y8grBYVHP","1.3 or earlier","OK",#
...
```

Example 4: License Detail Summaries

The following example shows the final portion of report Section 1. It displays a summary for authentication and privilege elevation (DirectControl/DirectAuthorize) licenses, and a summary for audit and monitoring service (DirectAudit) licenses.

The Count string in this section is especially useful to check the total number of installed licenses. Other details include license keys, serial numbers, and expiration dates.

If the Shared string displays Yes, the license key is being shared by more than one audit and monitoring service installation.

At the end of Section 1 is a checksum that validates the authenticity of the report. Do not edit the checksum or any other content preceding it before sending the report to Centrify for analysis. This example shows the layout of this section rather than example data. Depending on what types of Centrify licenses you have in your environment, your own licensing report might have more or fewer entries than the layout shown here.

```

Example 6: Counted Identity and Privilege Elevation Computers

The following example shows the next portion of report Section 2, containing information about counted computers where authentication and privilege elevation (DirectControl and DirectAuthorize) features are used. Information includes the system name, the timestamp of the most recent Active Directory update, OS and agent versions, zone mode (see Zone Information for Managed Computers), status (see Status Information for Managed and Audited Computers), current zone, and license type (see License Type Information for Managed and Audited Computers.

Information about these counted computers is collected and reported in Section 1 of the report, as shown in Example 1: Agent, License Type and Count through Example 4: License Detail Summaries.

This example shows the layout of this section and example data. Depending on what types of Centrify licenses you have in your environment, your own licensing report might not use all of the layout entries shown here.

```
System Report of Counted Usage for DirectControl/DirectAuthorize
---------------------------------

...
```

Example 7: Counted Audit and Monitoring Service Computers

The following example shows the next portion of report Section 2, containing information about counted computers where audit and monitoring service (DirectAudit) features are used. Information includes the system name, the timestamp of the most recent communication with a collector, OS and agent versions, status (see Status Information for Managed and Audited Computers), license type (see License Type Information for Managed and Audited Computers), and remarks (see Remarks for Managed and Audited Computers).

Vault-based systems are your Windows, UNIX, and/or network devices that are managed by and audited by the Server Suite.

Note that the remarks string for one computer states "Orphaned," but the computer is still counted because audited computers are counted even when they are orphaned (unlike DirectControl/DirectAuthorize computers).

Information about these counted computers is collected and reported in Section 1 of the report, as shown in Example 1: Agent, License Type and Count through Example 4: License Detail Summaries.

This example shows the layout of this section and example data. Depending on what types of Centrify licenses you have in your environment, your own licensing report might not use all of the layout entries shown here:

```

...
```

Example 8: Uncounted computers of all license types

The following example shows the last portion of report Section 2, containing information about uncounted computers (considered "invalid usage" computers) where authentication and privilege elevation (DirectControl, DirectAuthorize) features, and audit and monitoring service (DirectAudit) features might be deployed.

DirectControl and DirectAuthorize information includes the system name, the timestamp of the most recent Active Directory update, OS and agent versions, zone mode (see Zone Information for Managed Computers), current zone, license type (see License Type Information for Managed and Audited Computers), and remarks (see Remarks for Managed and Audited Computers).

Note that the Remarks string shows that DirectControl and DirectAuthorize computers were not counted because the were inactive, had an unknown logon time, were orphaned, or were joined to the null zone.

DirectAudit information includes the system name, the timestamp of the most recent Active Directory update, OS and agent versions, license type (see License Type Information for Managed and Audited Computers), and remarks (see Remarks for Managed and Audited Computers).

Note that the Remarks string shows that DirectAudit computers were not counted because they were inactive or duplicated.

> **Note:** The Active Directory attribute of postalAddress is repurposed to store the agent join date as well as additional information for UNIX/Linux systems. The postalAddress field does not store data such as zip codes. Because postalAddress is a multi-value string, the format displayed in the report is like "JoinTime:xxxxx;LicenseType:xxxx".

This example shows the layout of this section and example data. Depending on what types of Centrify licenses you have in your environment, your own

licensing report might not use all of the layout entries shown here:

System Report of Uncounted Usage for DirectControl/DirectAuthorize

```

Example 9: List of Zones and Special Profiles

The following examples show the additional sections of the report that show detailed information about zones and special user profiles.

The Zone report lists detailed information about each zone. Below is a sample.

```
Zone Report

----------------------

CN,Type,Parent Zone,Tenant ID,Tenant URL,Is ZPA provisiong,Is agentless client supported,Number of user profiles,Number of group profiles,Number of local user profiles,Number of local group profiles,Number of local Windows user profiles,Number of local Windows group profiles,Number of cross domain users,Number of cross forest users,Number of NIS maps,Number of roles,Number of PAM rights,Number of Command rights,Number of Windows Desktop rights,Number of Windows Application rights,Number of Windows Network Access rights,Number of role assignments,Number of computer roles,Number of roles with "MFA required",Number of roles with "audit if possible",Number of roles with "audit required",Number of roles with "audit not required"

keJg5xag6R,$CimsZoneVersion7,FbiyaZP2IT,AAQ0527,http://xxxxxxxxxx,

Yes,No,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#,#

...
```

In the next section of the licensing report lists the Special AD User Profiles Defined Report. This report lists out any special user profiles (SCP) that have been defined; profiles are detected based on pattern matching such as "oracle", "hadoop", "hdfs", "hive", and so forth.

You can configure the pattern match my modifying the registry value (value name: "SpecialUserProfilePattern"; type: multi string). Each row stands for a defined name pattern (from all zones).

If there is no name pattern configured, this section is not displayed in the report.

```
Special AD User Profiles defined Report

----------------------------------------

"oracle": #

"hadoop": #

"hdfs": #

"hiv$": #

...
```

The next section of the licensing report is the Special Local User Profiles Defined Report, which is very similar to the previous section. This report lists out any special local user profiles (SCP) that have been defined; profiles are detected based on pattern matching, such as "oracle", "hadoop", "hdfs", "hive", and so forth.

You can configure the pattern match my modifying the registry value (value name: "SpecialUserProfilePattern"; type: multi string). Each row stands for a defined name pattern (from all zones).

If there is no name pattern configured, this section is not displayed in the report.

```
Special Local User Profiles defined Report
------------------------------------------

"oracle": #
"hadoop": #
"hdfs": #
"hiv$": #
...
```

The guide provides the following information:

Preparing For An Upgrade

This chapter provides an overview of the upgrade process and a summary of the compatibility requirements between the core components of Server Suite software. You should review the information in this chapter before upgrading any components on the computers where Delinea software is installed.

Upgrading the Operating System

Upgrading the operating system (OS) on a managed computer can make major changes to the configuration files and utilities installed on it, In many cases, operating system upgrades and operating system patches can changes affect the behavior of Delinea software. If the behavior of Delinea software is modified because of an operating system upgrade, it is possible for users to be locked out and unable to access to computer resources. To prevent this from happening, Delinea recommends that you first remove any Delinea packages you have installed before upgrading the operating system, then reinstall the packages after the operating system upgrade has been completed and the computer has been verified to be operating normally.

You should note that removing Delinea software prior to applying operating system patches or upgrading the operating system is not required in most cases. However, because operating system changes can affect authentication and authorization services, it is considered a best practice to ensure the upgrade does not interrupt services for any users.

Upgrading Computers Accessed by Multiple Users

In most cases, you can upgrade Delinea software on computers that are accessed by multiple users without entering single-user mode. However, upgrading authentication, authorization, and auditing services on a computer can potentially prevent users from logging on or using computer resources. If possible, you should perform upgrades when other users who might access the computer are logged off, then reboot the computer after completing the upgrade.

You should note that having all users logged off and rebooting the computer after an upgrade are not required steps, but are best practices to ensure the upgrade does not interrupt services for any users. In most cases, users who are already logged on are not affected by the upgrade. However, users who attempt to log on while files are being replaced during the upgrade process might be temporarily locked out of the managed computer you are upgrading.

Compatibility Between Versions of Delinea Software

In most cases, newer versions of Delinea software releases are backward-compatible with previous versions, enabling you to mix and match components from different versions and upgrade components over time when it is convenient to do so. However, there are some limitations to take into account when mixing and matching versions, and these limitations might influence which components you upgrade and how quickly you upgrade from one version to another.

In most organizations, the agents you install on managed computers are upgraded on a staggered schedule while administrative tools are upgraded at a set time to take advantage of new features.

To ensure flexibility of the upgrade process:

- Agents are always backward-compatible with older versions of the administrative console.

  However, using an older version of the administrative console with a newer agent limits the features and functionality available. If you are using an administrative console from version 2.x to manage zones, agents from version 4.x and 5.x must use the --compat option to join 2.x-compatible zones.

- Agents are always forward-compatible with the administrative console for one version.

  You can upgrade the administrative console without upgrading agents at the same time. However, there are limitations to features and functionality when using older agents with an upgraded console. For example, agents from version 4.x cannot be included in hierarchical zones. In addition, some features require an upgrade. For example, if you want to use the Delinea Agent for Windows for access control and privilege management, you must either upgrade or remove the Delinea auditing service for Windows.

- Group policies are not guaranteed to be compatible with different agent and administrative console versions.

  New group policies cannot be enforced on computers with an agent from a previous version of Delinea software. If a group policy is applied to a computer that has an older version of the agent, the policy is ignored. You should only apply group policies that are supported in both the agent and administrative console versions you are using.

Finding Upgrade Packages

You can find Server Suite and agent packages for all supported operating systems on the Delinea Customer Download Center. From the Customer Download Center, you can choose to download individual agent packages one at a time or download an archive that includes agents for all operating systems at once.

At a minimum, you should download the Delinea Agent Installer and the ADCheck Diagnostic Tool. You can then use the install.sh shell script interactively or with the centrify-suite.cfg configuration file to install and enable features on the computers you want to upgrade. Delinea recommends that you use the install.sh shell script to install or upgrade all Delinea packages on managed computers, especially if you have multiple Delinea packages installed that you wish to upgrade. The install.sh installation script performs a thorough set of pre-installation and post-installation steps to ensure a successful installation or upgrade with minimal disruption to your environment.

Alternatively, you can use the native package manager for your operating system to upgrade the components you have installed. If you want to use a native package manager, see Using a native package manager on Linux computers for Linux computers or Using a native package manager on UNIX computers for UNIX computers.

Disabling Command-line Auditing

If you have auditing enabled on a computer you are upgrading, you should check whether auditing is configured for individual commands or all user activity. If you have enabled auditing for specific commands, you should temporarily disable auditing on the managed computer before upgrading, then restart the auditing of individual commands after completing the upgrade. If you are auditing all user activity on a managed computer, you do not need to stop the auditing service. There will be a brief interruption while files are replaced, then auditing will continue without requiring you to manually restart it.

Upgrading Delinea Management Services on Windows Computers

This section describes how to upgrade Authentication & Privilege and Audit & Monitoring administrative components on Windows computers. It includes a more detailed discussion about compatibility between components.

> **Note**: In releases before 2017.2, you installed the DirectManage Access and DirectManage Audit sets of components. Those component areas have been renamed and are now called Authentication & Privilege and Audit & Monitoring,respectively.

What Should You Upgrade First?

You are not required to upgrade Delinea software components in any particular order. Depending on where you have components installed and how they are distributed, you might update components used for auditing before updating components for access control and privilege management. Alternatively, you might update one set of agents immediately, followed by one administrative console, then update other components at a later time.

Although there's no technical requirement to upgrade components in a specific order, most organizations upgrade one or more administrative consoles and components that might require changes to a database first—for example, Access Manager if upgrading access control and privilege management—then deploy upgraded agent software after upgrading all of other components.

Similarly, if you upgrading the auditing infrastructure, you might upgrade Audit Manager, the management database, and the audit store before upgrading collectors and agents.

Updating Administrative Components

As noted in General compatibility between versions of Delinea software, most organization upgrade the administrative consoles at a set time, often as part of planned maintenance, then upgrade agents opportunistically over a period of time. It is common, therefore, to have a mix of components from different versions of Delinea software within certain limits.

To help you plan for the upgrade, you should identify which versions of different components you currently have installed and which components will require an upgrade.

Depending on whether you are upgrading Authentication & Privilege, Audit & Monitoring, or both feature sets, you might have different compatibility requirements.

Access Control and Privilege Management Compatibility

You can upgrade to Server Suite—with Access Manager, version 5.1.x or later—to manage zones and agents (adclient) from version 3.x, 4.x, or 5.x. If you have agents from version 2.x, you must manage them using a console from version 4.x or earlier. If you use an older version of the console, you cannot take advantage of any features or enhancements introduced in newer versions of the console. If you upgrade to the latest release, you can continue to manage all of your currently deployed agents but must upgrade those agents to take full advantage of any new features.

You must upgrade UNIX, Linux, or Mac agents to 5.0 or later to use hierarchical zones. If you have zones from a previous release of Delinea software, you can use admigrate to convert those zones to hierarchical zones.

To manage Windows computers with Access Manager, the Delinea Agent for Windows must be version 3.0 or later.

Auditing Infrastructure Compatibility

You can upgrade to Server Suite—with Audit Manager, Audit Analyzer, and Collector service version 3.1.x or later—to manage auditing on UNIX, Linux, and Windows computers from version 2.x or 3.x. If you have agents from version 1.x, you must manage them using a console from version 1.x.

You must update the collector service to version 3.x to receive audit data from Windows computers with 3.x Windows agents.

Because the auditing infrastructure is a multi-tiered architecture that collects information to be preserved, reviewed, and archived, Delinea recommends a more formal upgrade process than for other components. This is especially true for larger organizations that collect a great deal of audit data. If you are upgrading the auditing infrastructure, therefore, see Upgrading the auditing infrastructure for more detailed information about the process to follow.

Access Control and Privilege Management Compatibility

You can upgrade to Server Suite—with Access Manager, version 5.1.x or later—to manage zones and agents (adclient) from version 3.x, 4.x, or 5.x. If you have agents from version 2.x, you must manage them using a console from version 4.x or earlier. If you use an older version of the console, you cannot take advantage of any features or enhancements introduced in newer versions of the console. If you upgrade to the latest release, you can continue to manage all of your currently deployed agents but must upgrade those agents to take full advantage of any new features.

You must upgrade UNIX, Linux, or Mac agents to 5.0 or later to use hierarchical zones. If you have zones from a previous release of Delinea software, you can use admigrate to convert those zones to hierarchical zones.

To manage Windows computers with Access Manager, the Delinea Agent for Windows must be version 3.0 or later.

Auditing Infrastructure Compatibility

You can upgrade to Server Suite—with Audit Manager, Audit Analyzer, and Collector service version 3.1.x or later—to manage auditing on UNIX, Linux, and Windows computers from version 2.x or 3.x. If you have agents from version 1.x, you must manage them using a console from version 1.x.

You must update the collector service to version 3.x to receive audit data from Windows computers with 3.x Windows agents.

Because the auditing infrastructure is a multi-tiered architecture that collects information to be preserved, reviewed, and archived, Delinea recommends a more formal upgrade process than for other components. This is especially true for larger organizations that collect a great deal of audit data. If you are upgrading the auditing infrastructure, therefore, see Upgrading the auditing infrastructure for more detailed information about the process to follow.

Upgrading Components Interactively

You can upgrade components on any Windows computer interactively by clicking the links on the Server Suite Getting Started page. If the setup program detects components are installed, you have the option to update, modify, or remove those components. You can then follow the prompts displayed to review the components to be updated and complete the upgrade.

If the setup program detects components are installed, you are prompted to confirm that you want to continue with the upgrade. You can then follow the prompts displayed to review the components to be updated and complete the upgrade.

Upgrading Auditing Components Silently on Windows

If you want to perform a "silent" or unattended installation of the Delinea auditing components, you can do so by specifying the appropriate command line options and Microsoft Windows Installer (MSI) file to deploy. You can also use an unattended installation to automate the installation or upgrade on remote computers if you use a software distribution product, such as Microsoft System Center Configuration Manager (SCCM), to deploy software packages.

If you have the physical CD or ISO image for Delinea software, you can find the Microsoft Windows Installer (MSI) files for auditing components in subdirectories under the DirectAudit folder.

Before running the Microsoft Windows Installer (MSI) for any component, you should verify the computers where you plan to install meet the prerequisites described in the *Auditing Administrator's Guide*.

To install the auditing components silently:

1. Open a Command prompt window or prepare a software distribution package for deployment on remote computers.

   For information about preparing to deploy software on remote computers, see the documentation for the specific software distribution product you are using. For example, if you are using Microsoft System Center Configuration Manager (SCCM), see the Configuration Manager documentation.

2. Select the appropriate package for the auditing component you want to upgrade.

   For example, locate the following file to install the audit management server on 64-bit operating systems:

   Centrify DirectAudit Audit Management Server64.msi

3. Run the installer with no user interface and specify the package for the auditing component you want to upgrade.

   For example, to upgrade an agent on 64-bit operating systems, run the following command:

   msiexec /qn /i "Delinea Agent for Windows64.msi"

Upgrading Auditing Infrastructure

This chapter describes the recommended steps for upgrading auditing-related components to ensure you can continue auditing activity throughout the upgrade process. Keep in mind that upgrading the auditing infrastructure might require updates to the existing database, but, in most cases, should not require any computers to be shutdown or restarted to complete the upgrade.

Delinea

Why Are There Formal Steps for Upgrading an Audit Installation

In most organizations that deploy auditing, the auditing infrastructure—the installation—consists of components on multiple computers that must be able to communicate with each other to collect, transfer, and store information about user and computer activity. This multi-tiered architecture might be widely distributed and might include hundreds or thousands of computers that must be monitored. Upgrading all of those computers without interrupting ongoing auditing service requires a formal upgrade process that allows computers from different versions to continue communicating for a period of time.

Upgrading Auditing Components in a Specific Order

Because the upgrade process is expected to take a period of time—the length of time depends on the size and complexity of your installation—there are specific rules about the configurations supported and the order in which you should upgrade auditing components. To ensure auditing continues uninterrupted during the upgrade period, you should upgrade audit installation components in the following order:

1. Audit store databases
2. Management server databases
3. Consoles and collectors and the management server service
4. Agents

By following this upgrade order, you can ensure components can continue to communicate while you upgrade the rest of the audit installation. For example, an upgraded audit store can continue to receive audit date from collectors and respond to requests from the management server and consoles that have not be updated.

Be sure to upgrade all of your audit store databases before upgrading other components. You can upgrade the database without upgrading other components from a Command window by running the following command:

```
setup.exe /database
```

Unsupported Configurations

If you upgrade auditing components in a different sequence than the one described in Upgrading auditing components in a specific order, you might end up with an unsupported configuration that requires you to upgrade the remaining components immediately or suspend auditing of user activity until you can complete the upgrade.

You might encounter this situation if you upgrade the Audit Manager and Audit Analyzer consoles or a collector before upgrading the management and audit store databases.

Updating Auditing-Related Databases

If an upgrade requires an update to the database, you are prompted to run the database maintenance wizard and to select the databases to upgrade. If the wizard can connect to the databases selected and the database upgrade is successful, no further action is required.

You can upgrade audit store databases and the management database interactively using the Database Maintenance Wizard or by running the following command:

```
setup.exe /database
```

Upgrading the auditing databases, however, requires specific Windows and database permissions. Before attempting to upgrade the database, verify that you have a user account that meets the following requirements:

- The Windows account you use to update the database with the Database Maintenance Wizard must be an Active Directory domain user and a local administrator on computer where you are running the setup.exe program.
- Your Windows or SQL login account must be either a member of sysadmin fixed server role or a member of db_owner database role on each of the database instances being upgraded. If the account is a member of db_owner database role, you must also have the EXTERNAL ACCESS ASSEMBLY permission on each of the database servers hosting the management database and audit store databases.

You can use the following SQL statement to grant the EXTERNAL ACCESS ASSEMBLY permission to a specific user:

GRANT EXTERNAL ACCESS ASSEMBLY TO [DOMAIN\user]

For example, to grant this permission to the account john@acme.com, you might execute the following SQL statement:

GRANT EXTERNAL ACCESS ASSEMBLY TO [ACME\john]

Updating Agents Out of Sequence

The recommended upgrade steps suggest that you to update deployed agents last. However, upgrading the agent is much simpler than upgrading the audit store or management database. which might require a database administrator to be involved. In most cases, it is safe to update the agent at any point in the upgrade process. If there are restrictions that would prevent a new agent from using an older collector, those restrictions are documented in the release notes.

Restarting Computer After Agent Upgrade

If a computer has both Delinea Privilege Elevation Service and Delinea Audit & Monitoring Service enabled, you must restart the computer after upgrading the agent. If a computer only has Delinea Audit & Monitoring Service, there's no requirement to restart.

Delinea

Best Practices for Upgrading Large Audit Installations

When upgrading the Delinea Audit & Monitoring Service environment to a newer version, always follow this order for minimal service disruption:

1. Upgrade the audit databases.
2. Upgrade the audit collectors.
3. Upgrade the agents.
4. Upgrade remaining components (such as the consoles, PowerShell cmdlets, SDK, Audit Management server and so forth).
5. Delinea recommends using the Database Maintenance Wizard to "Generate the SQL scripts" for upgrading the databases rather than letting the Database Maintenance wizard perform an in-process upgrade.
6. When performing a database upgrade by manually running the scripts, follow this order for minimal service disruption:
    - Upgrade the "Active" audit store database(s).
    - Upgrade the remaining audit store databases.
    - Upgrade the audit management database.
7. To upgrade the audit databases, typically the sysadmin rights on the database server are needed. This is because some of the operations performed during the database upgrade (such as marking an assembly with EXTERNAL ACCESS) requires permissions that are typically only assigned to the users with sysadmin rights. If the database environment is hardened and the user cannot run the upgrade scripts as a sysadmin, here's a minimum set of permissions that the user must have in order to upgrade the databases:
    - User must have db_owner rights
    - User must have the EXTERNAL ACCESS ASSEMBLY rights
8. If the user is unsure whether the user has necessary rights to run the database upgrade or not, we recommend that the user generate the SQL scripts for database upgrade and hand them over to the database administrator for execution.
    - The audit database upgrade scripts are idempotent, which means accidentally running them multiple times will not cause any harm.
9. The database upgrade scripts sometimes log warning messages (for example, for exceeding key length). These warnings can be safely ignored. However, if any errors are received while running the database upgrade scripts, please notify Centrify support. This information is also available in KB-32276.

Upgrading Managed Computers

This chapter describes how to update Delinea software on managed Linux and UNIX computers. You can also upgrade Delinea software on Mac OS X computers using the install.sh shell script in a Terminal application or by downloading, unpacking, and running the latest Mac OS X installer. For more information about upgrading Delinea software on Mac OS X computers, see the **Administrator's Guide for Mac**.

> **Note**: When you upgrade agents installed on Linux computers, the upgrade process does not automatically enable desktop auditing on those systems. For information about enabling desktop auditing on supported Linux systems, see the **Auditing Administrator's Guide**.

Configuring install.sh to Run Without User Interaction

You can use the install.sh shell script to upgrade computers silently without user interaction. When you run install.sh without user interaction, you have the same upgrade options that you have when using install.sh interactively. When using install.sh without user interaction, however, you specify the type of upgrade on the command line and in a configuration file.

--std-suite upgrades authentication and privilege elevation features. Any other Delinea packages you have installed are unchanged as long as they are compatible with the version being upgraded.

--ent-suite upgrades authentication, privilege elevation, Delinea-enabled OpenSSH, and auditing features. Any other Delinea packages you have installed are unchanged as long as they are compatible with the version being upgraded.

In both cases, you can customize the upgrade by modifying the default centrify-suite.cfg configuration file. With the default centrify-suite.cfg configuration file, the install.sh script upgrades the Delinea Agent access control and privilege management features or the Delinea access control, privilege management, and auditing features.

If you have already installed OpenSSH before you upgrade, either upgrade option also upgrades the OpenSSH packages.

All other packages available are left unchanged. For more detailed information about configuring a silent upgrade using the configuration file, see “Setting the parameters in a custom configuration file for the installation script” and the details for the INSTALL parameter in the Planning and Deployment Guide.

Using the install.sh Shell Script to Update Packages

The Delinea Agent installation script, install.sh, is a shell script that you can run interactively or configure to run silently on any supported UNIX, Linux, or Mac OS X computer.

You can use the install.sh shell script to upgrade any installed Delinea software except Delinea sudo. If you have the Delinea sudo package, you can upgrade the package before or after you upgrade the Delinea Agent and other packages.

To use the install.sh script interactively:

1. Unzip and extract the contents of the file you downloaded from the Delinea Customer Download Center. For example:

   gunzip centrify-infrastructure-services-*<release>*-platform-arch.tgz
   tar -xvf centrify-infrastructure-services-*<release>*-platform-arch.tar

2. Run the install.sh script to start the update on the local computer's operating environment. For example:

   ./install.sh

   The installer checks that it is possible to update Delinea software on the local computer. For example, it will check that the computer is a supported platform and that any required patches are installed. For more information about the ADCheck diagnostic tool, see the *Planning and Deployment Guide*.

3. Specify the type of upgrade you want to perform.

   - (E) option: This option upgrades Server Suite access control, privilege management, secure shell, and auditing features. Any other Delinea packages you have installed are unchanged as long as they are compatible with the version being upgraded.
   - (S) option: This option upgrades Server Suite access control, privilege management, and secure shell (Centrify-enabled OpenSSH) features. Any other Delinea packages you have installed are unchanged as long as they are compatible with the version being upgraded.
   - Custom (C) option: This option allows you to select the Delinea packages located in the current directory and choose whether to erase (E), update (U), reinstall (R), keep unchanged (K) each package. If there is a package available for which there is no corresponding version already installed, you can choose to install the package.
   - (X) option: This option installs or upgrades the access control and privilege management components as unlicensed Delinea Express components.

     If you want to install or upgrade additional packages such as the Delinea Network Information Service (adnisd) or the Delinea LDAP proxy service, you should use the custom install option and select the packages to install.

Using a Native Package Manager on Linux Computers

When you upgrade using the install.sh shell script, the script manages all dependencies and compatibility issues for you. If you want to upgrade Delinea software packages using the native package manager, you should first determine whether there are any compatibility issues or dependencies between the packages you have installed. For details about specific version compatibility requirements and upgrade scenarios, see Compatibility for Additional Packages.

As of version 5.4.0, the core Delinea Agent bundle consists of four packages that must always be upgraded to the same version simultaneously: Delinea, CentrifyDC-openssl, centrify-openldap, and CentrifyDC-curl. When fixes and patches are released, you can update individual packages of the core bundle, as long as the version is the same version as the other core packages.

After you have determined whether you have any version dependencies, you can use the native package manager to upgrade packages simultaneously. You can also use the native package manager to remove old packages individually or remove all packages simultaneously.

If you want to install or upgrade software packages using common native package installers, such as the Red Hat or Debian package manager, you should note that the software packages are signed with a GNU Privacy Guard (GPG) key. You need to import the key to verify the package authenticity before installing or upgrading the package. To import the key, download the RPM-GPG-KEY-centrify file from the Delinea Download Center then run the appropriate command for the package manager. For example:

```
rpm --import RPM-GPG-KEY-centrify
```

If you are not using a native package manager, you can use any other installation program you have available for the local operating environment. For example, if you use another program, such as SMIT, YAST, APT, or YUM to install and manage software packages, you can use that program to install Server Suite software packages.

Upgrading Packages on a Linux Computer

You do not need to stop any running Delinea process to perform the upgrade. While you do not usually need to restart Delinea processes or reboot your computer after upgrade, you may need to restart other processes that depend on PAM or NSS modules. Rebooting the computer after upgrade is recommended as a best practice.

It is best to install all Delinea packages simultaneously, if you are upgrading individual packages, however, you might see warnings from the package manager about package dependencies or version conflicts. If you see that a dependency is generated because of a package you have yet to upgrade, it is safe to ignore the warning.

Fresh Installation Using RPM

If you are performing a fresh installation on a Linux computer that supports the Red Hat Package Manager (rpm), you can install the packages individually. For example, to install the Delinea Audit & Monitoring Service package you would enter commands similar to the following:

```
rpm -i CentrifyDA-5.4.0*-platform.arch.*rpm
```

The platform and architecture you specify in the file name on the command line should identify the specific operating system you are using, for example Centrify-5.4.0-rhel4.x86_64.rpm or centrify-5.4.0-suse10.ia64.rpm. After the package manager updates the packages installed, you can optionally restart Delinea processes or reboot the computer.

You can verify the Delinea packages that were installed using the following command:

```
rpm -qa CentrifyDC-\*
```

Upgrading Existing Packages Using RPM

If you are upgrading an existing installation of an agent package on a Linux computer that supports the Red Hat Package Manager (rpm), you should add all of the packages you want to upgrade to a directory of your choice, and issue a single command similar to this:

```
rpm -Uhv my_dir/\*.rpm
```

Where my_dir is a directory that you specify.

Fresh Installation Using the Debian Package Manager

On a Debian, Ubuntu, or Linux MINT computer, the order that you install the core package depends on whether you are performing a fresh installation or upgrading an existing installation. Any Delinea packages other than the core packages can be listed after the core bundle in any order.

For example, to perform a fresh installation of the core authentication service package, you would enter commands similar to the following:

```
dpkg -i ./centrifydc-openssl-5.4.0-platform-arch.deb
./centrifydc-openldap-5.4.0-platform-arch.deb
./centrifydc-curl-5.4.0-platform-arch.deb
./centrifydc-5.4.0-platform-arch.deb
```

Upgrading Packages Using the Debian Package Manager

If you are upgrading an existing installation, the order of the core packages is different than that in a fresh installation. Delinea packages other than the core packages can be listed after the core bundle in any order.

For example, if you were updating all of the Delinea Agents, you would enter commands similar to the following, noting that the packages in **bold** are the core agent packages, and must be entered in the order below:

```
dpkg -i --force-confnew --force-confmiss
\--ignore-depends=centrifydc-nis
\--ignore-depends=centrifydc-ldapproxy
\--ignore-depends=centrifyda./centrifydc
__./centrifydc-5.4.0-***platform-arch***.deb__
**./centrifydc-openssl-5.4.0-***platform-arch***.deb**
**./centrifydc-openldap-5.4.0-***platform-arch***.deb**
**./centrifydc-curl-5.4.0-** *platform-arch***.deb**
./centrifydc-ldapproxy-5.4.0-*platform-arch*.deb
./centrifydc-nis-5.4.0-*platform-arch*.deb
./centrifyda-3.4.0-*platform-arch*.deb
```

> **Note**: If you are upgrading the core agent package from version 5.4.0 or later, to any later version, you must include Delinea in the list of packages to ignore. If you do not have centrifydc-nis, centrify-ldapproxy, or centrifyda installed, the --ignore-depends command for those packages is not necessary.

The platform and architecture you specify on the file name in the command line should identify the specific operating system you are using, for example centrifydc-5.4.0-deb7-i386.deb. After the package manager updates the packages installed, you can optionally restart Delinea processes or reboot the computer.

You can verify the Delinea packages that were upgraded using the following command:

```
dpkg -s CentrifyDC-\*
```

Using a Native Package Manager on UNIX Computers

When you upgrade using the Delinea install.sh shell script, the script manages all dependencies and compatibility issues for you. If you want to upgrade Delinea software packages using the native package manager, you should first determine whether there are any compatibility issues or dependencies between the packages you have installed. You can then upgrade packages individually or simultaneously. For details about specific version compatibility requirements and upgrade scenarios, see Compatibility for additional packages.

After you have determined whether you have any version dependencies, you can use the native package manager to upgrade all packages simultaneously. You can also use the native package manager to remove old packages individually or remove all packages simultaneously.

Upgrading Packages Individually on a UNIX Computer

With the exception of Solaris computers, you do not need to stop any running Delinea process to perform an upgrade on UNIX machines. On Solaris computers, you should stop all Delinea processes before upgrading. You should note that while rebooting the computer or restarting agent services after an upgrade is not required for Delinea processes in most cases, you may need to reboot the computer or restart any processes that rely on PAM or NSS modules after you complete the upgrade to ensure that the upgraded binaries and libraries are being run. Rebooting the computer after upgrade is recommended as a best practice.

To upgrade Delinea software using the native package manager, follow these basic steps:

- Stop all Delinea processes running on Solaris computers.

  For example:

  /usr/share/centrifydc/bin/centrifydc stop
  /etc/init.d/centrify-sshd stop
  /etc/init.d/adfsagent stop

- Upgrade the core agent packages using the native package manager. The four core packages must be upgraded together.
- Upgrade other Delinea packages using the native package manager.
- Restart Delinea processes or reboot the computer.

Depending on the order in which you are upgrading individual packages, you might see warnings from the package manager about file dependencies. If you see that a dependency is generated because of a package you have yet to upgrade, it is safe to ignore the warning.

The next sections illustrate the commands to use on different platforms. The actual file name that you specify on the command line—including a specific build number, platform, and architecture—will identify the specific operating system you are updating, for example centrifydc-5.4.2-sol8-sparc-local.tgz or centrifydc5.4.2aix53ppc-bff.gz.

Performing Upgrades on UNIX Computers

The process for simultaneous upgrades on UNIX computers is similar to that for Linux computers. However, the native package managers on different platforms vary in their ability to perform simultaneous upgrades.

This section includes the following topics:

Upgrading Packages on Solaris Computers

On Solaris computers, it is necessary to spool all packages that are to be installed simultaneously. The package manager can then take the spooled packages and install them all at once using one command. Before upgrading on Solaris computers, however, you should stop all Delinea processes that are running.

> **Note**: On Solaris 10 computers that use Solaris zones, you should upgrade the core agent packages as a separate step. You can then upgrade other Delinea packages using a simultaneous upgrade.

To perform upgrades on Solaris computers:

1. Stop existing Delinea processes.

   For example, if you are upgrading the core agent, Delinea-enabled OpenSSH, and Delinea NIS packages, you would enter commands similar to the following:

```
/usr/share/centrifydc/bin/centrifydcstop
etc/init.d/centrify-sshd stop
/etc/init.d/adnisd stop (on Solaris 9)
svcadm disable centrifydc_server (on Solaris 10 or later)
```

2. Create a new admin file.

   If you are upgrading an existing installation, make a copy of the system default admin file (/var/sadm/install/admin/default) and modify it to ignore dependencies. In the examples below, this file is called my_admin. It should look like this:

   mail=
   instance=overwrite
   partial=nocheck
   runlevel=nocheck **idepend=nocheck** rdepend=quit
   space=quit
   setuid=nocheck **conflict=nocheck** action=nocheck basedir=default

   If you are performing a fresh installation, you can use the original system admin file and keep the default settings.

3. Unzip and extract each package into a temporary directory, for example, my_tmp_dir.

   To unzip and extract the agent core packages, you would enter commands similar to the following:

   ```
   gunzip centrifydc-5.4.0-*platform-arch*-local.tgz
   tar xvf centrifydc-5.4.0-platform-arch-local.tar

   gunzip centrifydc-openssl-5.4.0-*platform-arch*-local.tgz
   tar xvf centrifydc-openssl-5.4.0-*platform-arch*-local.tar

   gunzip centrifydc-openldap-5.4.0-*platform-arch*-local.tgz
   tar xvf centrifydc-openldap-5.4.0-*platform-arch*-local.tar

   gunzip centrifydc-curl-5.4.0-*platform-arch*-local.tgz
   tar xvf centrifydc-curl-5.4.0-*platform-arch*-local.tar
   ```

4. Spool the packages.

   Spool the packages to a specified directory, for example, my_spool_dir.

   To spool the core packages, you would run commands similar to the following:

   ```
   pkgadd -s /my_spool_dir -d /my_tmp_dir/CentrifyDC CentrifyDC
   pkgadd -s /my_spool_dir -d /my_tmp_dir/CentrifyDC-openssl CentrifyDC-openssl

   pkgadd -s /my_spool_dir -d /my_tmp_dir/CentrifyDC-openldap
   CentrifyDC-openldap
   pkgadd -s /my_spool_dir -d /my_tmp_dir/CentrifyDC-curl CentrifyDC-curl
   ```

5. Upgrade the packages.

   To upgrade the core packages, you would enter commands similar to the following:

   ```
   /usr/sbin/pkgadd -a my_admin -n -d /my_spool_dir CentrifyDC-openssl
   /usr/sbin/pkgadd -a my_admin -n -d /my_spool_dir CentrifyDC-openldap
   CentrifyDC-curl
   /usr/sbin/pkgadd -a my_admin -n -d /my_spool_dir CentrifyDC
   ```

6. Restart Centrify processes after the upgrade is complete.

7. Verify the upgrade.

   To verify that the upgrade was successful, run the following command:

   ```
   /usr/bin/pkginfo \| grep -i Centrify
   ```

Upgrading Packages on HP-UX Computers

On HP-UX computers, it is necessary to spool all packages that are to be installed. The package manager can then take the spooled packages and install them all at once using one command.

To perform upgrades on HP-UX computers

1. Copy and unzip all depot.gz packages into a temporary directory, for example, my_dir.

   To unzip and extract the agent core packages, enter commands similar to the following:

   ```
   gunzip centrifydc-5.4.0-*platform-arch*.depot.gz
   gunzip centrifydc-openssl-5.4.0-*platform-arch*.depot.gz
   gunzip centrifydc-openldap-5.4.0-*platform-arch*.depot.gz
   gunzip centrifydc-curl-5.4.0-*platform-arch*.depot.gz
   ```

2. Spool each package.

   On HP-UX computers, you can use the default spool directory, but you must create a working directory, for example my_dir.

   To spool the agent core packages to my_dir, enter commands similar to the following:

   ```
   swcopy -s /full_path/my_dir/centrifydc-openssl-5.4.0-*platform-arch*.depot
   CentrifyDC-openssl
   swcopy -s /full_path/my_dir/centrifydc-openldap-5.4.0-*platform-arch*.depot
   CentrifyDC-openldap
   swcopy -s /full_path/my_dir/centrifydc-curl-5.4.0-*platform-arch*.depot
   CentrifyDC-curl
   swcopy -s /full_path/my_dir/centrifydc-5.4.0-*platform-arch*.depot
   CentrifyDC
   ```

3. Upgrade the packages.

   Use a single command to upgrade all packages. For example, to update the core agent packages, enter a command similar to the following:

   ```
   swinstall -s CentrifyDC-openssl CentrifyDC-openldap CentrifyDC-curl
   CentrifyDC
   ```

4. Verify the upgrade.

   Verify that the upgrade was successful by running the following commands:

   ```
   swlist \l grep -i Centrify
   swverify CentrifyDC
   ```

Upgrading Packages on AIX Computers

On AIX computers, it is necessary to unzip all packages that are to be installed. The package manager can then take the unzipped packages and install them all at once, using one command.

To perform upgrades on AIX computers do the following:

1. Copy and Unzip the packages to a directory, for example, my_dir.

   If you are upgrading the core agent packages, you would run commands similar to the following:

   ```
   gunzip centrifydc-5.4.0-*platform-arch*-bff.gz
   gunzip centrifydc-openssl-5.4.0-*platform-arch*-bff.gz
   gunzip centrifydc-openldap-5.4.0-*platform-arch*-bff.gz
   gunzip centrifydc-curl-5.4.0-*platform-arch*-bff.gz
   ```

2. Upgrade the packages.

   You can now upgrade the packages using commands similar to the following:

   ```
   inutoc .
   installp -aY -d my_dir all
   ```

Upgrading Agents on Solaris Systems

Before upgrading agents on Solaris systems you'll need the installation packages appropriate for your Solaris system, as listed in the table below.

Solaris Agent Installation Packages

Solaris 10	svr4	x86	centrify-server-suite-2021.1-sol10-x86.tgz
Solaris 10	svr4	Sparc	centrify-server-suite-2021.1-sol10-sparc.tgz
Solaris 11	svr4	x86	centrify-server-suite-2021.1-sol10-x86.tgz
Solaris 11	svr4	Sparc	centrify-server-suite-2021.1-sol10-sparc.tgz
Solaris 11	IPS	x86	centrify-server-suite-2021.1-sol11-i386.tgz
Solaris 11	IPS	Sparc	centrify-server-suite-2021.1-sol11-sparc.tgz

To upgrade the Solaris svr4 packages:

- Follow the instructions here: Using the install.sh shell script to update packages or Performing upgrades on UNIX computers

Upgrading and Migrating Solaris svr4 Packages to IPS on Solaris 11

If you have a Solaris 11 system on which you've installed a previous release of the Delinea Agent for *NIX and you want to upgrade and use Solaris IPS, you do the upgrade in 3 steps:

1. Run the install-last-svr4.sh script.

   This upgrades your previous agent to a temporary, in-between version 9.9.9.

2. Run the install-last-svr4.sh script again and uninstall the version 9.9.9 packages.

   This prepares the system so that you can install the IPS packages.

3. Run the IPS-specific install script, install-ips.sh to install the Solaris IPS packages.

These steps assume that there aren't any child zones configured on this Solaris system.

You'll need the IPS specific tgz file and also the svr4 tgz for your system in order to perform these steps.

Before you upgrade:

- Make sure that the agents components that are installed before you upgrade are the same ones that you want to have installed after the upgrade. It's easier to do the upgrade in place this way.

  For example, if you have the audit agent currently installed but you don't want it installed in the new version, remove it before upgrading. Or, if you don't have the ldap proxy component installed but you do want it installed in the new version, install it first (the same version as the other agent components that are already installed).

To upgrade and migrate the Solaris svr4 packages to IPS on Solaris 11:

1. Log on or switch to the root user.
2. Change to the appropriate directory that contains the Delinea Agent package you want to install.

   For example, change to the Agent_Unix directory.

   If you downloaded individual agent packages from the Delinea Download Center, unzip and extract the contents. For example, you'll need the following two .tgz files:

centrify-infrastructure-services-2021.1-sol11-i386.tgz

centrify-infrastructure-services-2021.1-*SolarisVersion-platform-arch*.tgz

For each package, extract them; here's an example:

gunzip -d centrify-infrastructure-services-*<release>*-platform-arch.tgz

tar -xf centrify-infrastructure-services-*<release>*-platform-arch.tar

3. Change to the /lastsvr4 sub-directory and run the install-last-svr4.sh script to prepare the previous installation for upgrade:
    1. The script prompts you, "Do you want to continue and upgrade to v.9.9.9?"

       Enter Y for yes.
    2. The script prompts you to confirm your selection:

       Enter Y to continue (or enter N to change the settings).

       The script unpackages the files and installs the new packages.
4. Run the install-last-svr4.sh script a 2nd time and uninstall the 9.9.9 version components:
    1. The script prompts you, asking if you want to erase, reinstall, or keep the current package.

       Enter E to erase.
    2. The script prompts you to confirm your selection to uninstall the package.

       Enter Y to continue.

       The script uninstalls and removes the version 9.9.9 files.
    3. You can run the following command to verify the Solaris agent package svr4 installation status:

       pkginfo | grep -i Centrify

       Note that there is no space between "pkg" and "info"; if you search for "pkg info" you'll be searching for IPS packages.
5. Change to the directory (up one level) that contains the installation packages and run the install-ips.sh script.
    1. The script will list that it found previously installed svr4 packages and prompts you, asking if you want to continue.

       Enter Y for yes.
    2. The script will list out the package versions to install and prompts you to confirm.

       Enter Y to confirm and continue.

       The script installs the IPS packages.
6. You can run the following command to verify the Solaris agent package IPS installation status:

   pkg info | grep -i Centrify

   Note: The space between "pkg" and "info"; if you search for "pkginfo" you'll be searching for svr4 packages.

Delinea

Upgrading Managed Mac OS X Computers

In most cases, you can update agents on Mac OS X computers by simply installing the new agent either directly or remotely on top of an existing agent. As a best practice, you should perform in-place upgrades using a local Mac administrative (admin) account or any other user account that has local administrative rights and reboot the computer after completing the upgrade. In most cases, you should not perform the upgrade while you are logged on as an Active Directory user in a currently active session.

In rare cases, you might be advised to run adflush to clear the Active Directory cache before performing an in-place upgrade. For example, if you are updating agents from version 4.x, or earlier, to 5.1.x, run adflush first to ensure a smooth upgrade. It is highly unusual for an upgrade to require you to leave and rejoin a managed Mac computer to the domain.

Compatibility for Additional Packages

In general, Delinea software packages are not version-dependent on each other. However, there are compatibility limitations in some situations. This chapter describes specific compatibility requirements for packages that are not part of the core agent packages or have been added to or removed from the core agent packages. If you are only upgrading the core agent packages and have no other packages installed, you can skip this chapter.

Should You Be Concerned About Compatibility?

Compatibility issues are managed automatically when you use the install.sh shell script to upgrade packages. If you plan to update packages using a native package manager, however, you should be aware of potential compatibility issues and be able to manually manage dependencies between packages. Depending on the version of Delinea software you currently have installed, the version you are upgrading to, and which packages you have installed, you might have many or no compatibility concerns. The first step is to identify which software packages and versions you have deployed.

The core agent package for access control and privilege management for versions before version 5.4.0 is CentrifyDC. For all releases after and including 5.4.0, the core agent package is split into four distinct packages:

CentrifyDC

CentrifyDC-openssl
CentrifyDC-openldap
CentrifyDC-curl

The core agent package for auditing is CentrifyDA. Other packages you might have installed include:

CentrifyDC-nis
CentrifyDC-krb5
CentrifyDC-ldapproxy
CentrifyDC-openssh
CentrifyDC-web
CentrifyDC-apache
CentrifyDC-adbindproxy

> **Note**: When you upgrade to version 5.4.0 of the Delinea Agent, you must also upgrade all of the other Delinea packages you have installed to version 5.4.0 as well. If you fail to upgrade a package other than the core packages, and attempt to upgrade the core agent packages to 5.4.0, the upgrade will fail. For agent versions after 5.4.0, you may not be required to simultaneously upgrade each of the packages other than the core agent packages.

Removing the CentrifyDC-samba Package

If you are upgrading the core agent package for access control and privilege management and have Delinea Samba installed, you should remove the Delinea Samba CentrifyDC-samba) package, install open-source Samba, and install the Delinea adbindproxy package (CentrifyDC-adbindproxy). See the **Samba Integration Guide** for details about that procedure.

Compatibility for CentrifyDC-nis Package

If you are upgrading the core agent packages and have the CentrifyDC-nis package installed, you should also upgrade the CentrifyDC-nis package. The CentrifyDC-nis package must have the same major version number as the core agent packages. The version number for the CentrifyDC-nis package should never be higher than the version number of the core agent packages.

> **Note**: Some platforms, the adnisd package might prevent the ypbind service from starting properly because of the order in which services are started. For example, if ypbind is configured to start before the adnisd service, the bind will fail. This issue does not occur if you are installing new packages. However, to prevent unintended changes to the existing startup sequence during an upgrade, upgrading the adnisd package will not modify your existing startup configuration. You can manually correct the startup sequence after an upgrade by manually running the chkconfig script. For example, run the following command after the adnisd upgrade:

```
chkconfig adnisd on
```

Compatibility for CentrifyDC-krb5 Package

The Delinea Kerberos client tools are no longer packaged with the Server Suite agent or available from the Delinea Download Center. The client tools were formerly provided as a separate software package or as part of the core agent package to support Kerberos-based authentication on older operating systems. The package is no longer relevant on currently-supported operating systems.

Compatibility for CentrifyDC-ldapproxy Package

If you are upgrading the core agent packages and have the CentrifyDCldapproxy package installed, you should also upgrade the CentrifyDCldapproxy package. The CentrifyDCldapproxy package must have the same major version number as the core agent package. The version number for the CentrifyDCldapproxy package should never be higher than the version number of the core agent package. If you upgrade the core agent packages to a version number that is higher than the CentrifyDCldapproxy package version, the installation script removes the CentrifyDCldapproxy package. To retain the CentrifyDCldapproxy package when you upgrade the core agent packages, you must make sure that both packages are upgraded to the same version number.

Compatibility for CentrifyDC-openssh Package

In most cases, the core agent packages and the CentrifyDCopenssh packages are installed and upgraded together. Therefore, in most cases, they will have the same major version number. If you have the CentrifyDCopenssh package installed and are upgrading the core agent to version 5.1.2 or later, you must also upgrade the CentrifyDCopenssh package. If you use the installation script to upgrade, it enforces this compatibility requirement.

Delinea

Compatibility for CentrifyDC-Apache and CentrifyDC-Web Packages

If you are upgrading the core agent packages to 5.x and have Delinea for Apache or Java applications installed, the CentrifyDC-apache or CentrifyDC-web package should be version 4.x or later. For example, CentrifyDC_apache-4.2.0-nnn is compatible with CentrifyDC version 5.x.

Upgrading Version-Dependent Packages

If you are upgrading a computer that has one or more Delinea software packages that are version-dependent on one another, you should either:

- Remove the Delinea packages that are version-dependent before upgrading the core agent packages, upgrade the core agent packages, then re-install the new versions of the version dependent packages.
- Simultaneously upgrade the core agent packages and all of the additional packages that are version-dependent.

If you are upgrading a computer where there are no version dependencies, Delinea recommends you upgrade all packages simultaneously, if possible.

Working with Classic Zones After an Upgrade

Server Suite supports both classic and hierarchical zones. After you upgrade the agents, you can choose to either migrate your classic zones into a hierarchical zone structure or maintain them as classic zones. If you want to convert your classic zones into hierarchical zones, you can use the admigrate program. For details about using the admigrate program to migrate a classic zone to a new parent or child hierarchical zone, see the man page for admigrate.

> **Note**: You can only migrate classic zones to hierarchical zones if you have upgraded the Delinea Agent to version 5.x or later.

You are not required to migrate any existing classic zones. If you choose to maintain your existing zones as classic zones, however, you should be aware that the authorization model in classic zones differs from the authorization model used in hierarchical zones. For example:

- In classic zones, any user with a profile in a zone is automatically granted login access to all computers joined to the zone.
- In hierarchical zones, a user with a profile in a zone must be assigned to a role with login rights and PAM access rights before being able to login to a computer joined to a zone.

In addition, there are configuration parameters, commands, APIs, and features that are only applicable in classic zones and other parameters, commands, APIs, and features that are only applicable in hierarchical zones. For example, authorization is an optional feature that can be enabled or disabled in classic zones, so there is a configuration parameter and a zone property option to support the feature in classic zones. For hierarchical zones, authorization is required for access to any managed computer, so the configuration parameter and zone property option are not visible in hierarchical zones.

What To Do If There Are Problems During an Upgrade

In most cases, upgrading Delinea software is a seamless process that does not interrupt services. If you are not able to complete an upgrade successfully, however, there are a few steps you can take to restore your working environment. This chapter covers the steps to take if you have problems during the upgrade process.

Delinea

Remove and Re-install Authentication and Privilege

If you have problems upgrading any Authentication & Privilege components, such as Access Manager, you should use the Control Panel application to uninstall the software, then rerun the setup program to install the components cleanly.

If you want to restore an older version of the software rather than attempt a fresh installation of the latest version—run the setup program for that version of the software.

Remove and Re-install Delinea Audit and Monitoring Service

If you have problems upgrading any Delinea Audit and Monitoring Service components, such as Audit Manager or Audit Analyzer, you should do the following:

- Use the Control Panel application to remove the auditing infrastructure components from the local computer.
- Use ADSI Edit to remove the service connection point for the installation. If you publish this information in more than one location, remove all of the service connection points from the forest.
- Rerun the setup program to install the components cleanly.

If you want to restore an older version of the software rather than attempt a fresh installation of the latest version—run the setup program for that version of the software.

Remove and Re-install Agent Features

If you have problems upgrading any agent features, such as access control and privilege management or auditing services, you should do the following:

- Log on as root and disable auditing on UNIX computers where auditing is enabled:
    1. dacontrol -d
- Use the adleave command to remove the UNIX computer from its current zone and Active Directory domain.
- Use the Delinea Privilege Elevation Service settings to remove the local Windows computer from its current zone, then use the Windows Control Panel application to remove the agent services from the local computer.
- Rerun the install.sh script or the agent setup program to install the agent cleanly.
    1. You can join the domain from the installation script on UNIX computers or join a zone from the agent configuration wizard on Windows computers.
- Log on as root and enable auditing on UNIX computers where you want auditing enabled.
    1. dacontrol -e

Delinea

Known Issues

The following are known issues organized by category.

Installation and Uninstallation Issues

- Upgrading from the beta build to this version may result in offline MFA mode if there are multiple authentication servers registered in your AD forest. To resolve this, uninstall the beta build first and then install this new version. (Ref: CS-41915)
- The Delinea Common Component should be the last Server Suite component uninstalled. If the component is uninstalled before other component, it must be reinstalled by the uninstall process to complete its task. (Ref: 36226a)
- If you intend to install the software on the desktop with elevated privilege, you should not check the "Run with UAC restrictions" option when creating the desktop. (Ref: 39725b)
- When you double-click on the Delinea Agent for Windows msi and select the "repair" option, the existing files are replaced irrespective of their version number, even when they are identical. As a result, a prompt to restart the system is displayed as files that were in use were replaced. However, if you use the Easy Installer to do the repair and a file on the disk has the same version as the file that is part of the installer package, the installed file will not be replaced. Therefore, there will not be any prompt to restart the system. (Ref: 26561a)
- If you uninstall the Delinea Agent for Windows while the DirectAudit Agent Control Panel is open, files needed by the uninstall process may be blocked. You should close the DirectAudit Agent Control Panel for a successful conclusion to the uninstall process. (Ref: 25753a)
- Agent for Windows and its installer are built on .NET. Therefore, .NET is always installed as a pre-requisite before the agent is installed. If .NET is removed from the system later, Delinea Agent for Windows will not run properly. User will also experience problem when trying to remove Delinea Agent for Windows from the system. To properly uninstall Delinea Agent for Windows, please make sure Delinea Agent for Windows is uninstalled before .NET. (Ref: 39051a)

Configuration Issues

- In a cross-forest environment, forest A user cannot enroll a device joined to forest B when forest A does not have a connector. (Ref: CS-44805)
- In Windows 2016 and Windows 10, during the login process, selecting SMS or using other mechanisms like Security Question/Phone call/Password/Email/Mobile for MFA and clicking the **Commit** button will be intermittently unresponsive. (Ref: CS-41699)
- In some large environment with multiple domain controllers, it may take up to one minute for the new zone setting in Delinea Agent Configuration to take effect. (Ref: 58128b)
- If one of the Global Catalog servers is unavailable, user may not be able to configure the zone for Delinea Agent for Windows. (Ref: 58621b)
- Microsoft normally automatically distributes and installs root certificates to the Windows system from trusted Certificate Authorities (CA) and users are seamlessly able to use a secure connection by trusting a certificate chain issued from the trusted CA. However, this mechanism may fail if the system is in a disconnected environment where access to Windows Update is blocked or this feature of automatic root certificate installation is disabled. Without updates on the certificate trust list (CTL), the default CTLs on the system may not be adequate for secure connections of multi-factor authentication especially for older versions of Windows such as Windows 7 and Windows Server 2008 R2. To ensure the success of multi-factor authentication, user may need manually distribute and install the latest CTLs and the required root certificate to systems in a disconnected environment. See Delinea KB-6724 for further information. (Ref: CS-39703)

Environment Issues

- On Windows 10 and Windows 2016 machines with Delinea Privilege Elevation Service, the following will occur (Ref: CS-43883):
  - Pop up an error dialog several seconds after clicking "Open file location" in the context menu of a shortcut on the start menu. Explorer windows will display correctly.
  - No responses to the following actions * Clicking "Open file location" in the context menu of a shortcut on desktop * Clicking "Open file location" in the context menu of a shortcut on the Delinea Start menu in the Privileged Desktop * Slow response to "OK", "Cancel" in the shortcut property page after "Open file location" in the general tab is clicked. The dialog will close after several seconds.
- On some Windows 10 computers, the smart card login option may not be displayed if another credential method has been recently used. To display the smart card login option, remove and insert a smart card into the reader. This will cause the login screen to reload and will display the smart card login option. (Ref: CS-41282)
- An environment with no Global Catalog is not supported. (Ref: 46577a)
- Delinea Privilege Elevation Service requires machine time to be synchronized with domain controller. VMware virtual machine has a known issue that its time may not be synchronized with domain controller. This problem occurs more often on an overloaded virtual machine host. If the system clocks on the local Windows computer and the domain controller are not synchronized, Delinea Privilege Elevation Service does not allow any domain users to login. You can try the following KB from VMware to fix the time synchronization issue. http://kb.vmware.com/selfservice/microsites/search.do?language=en_US&cmd=displayKC&externalId=1189 (Ref: 47795b)

RunAsRole Issues

- If you use the "RunAsRole.exe /wait" command to run a Python script, the input/output cannot be redirected for versions of Python below 3.0.0. (Ref: 45061a)
- The Run As Role menu is not available on the start screen in Windows 8 or Windows 2012 or later because Microsoft doesn't support any custom context menu on the start screen. User has to go to the Windows desktop in order to launch an application using Run As Role context menu. (Ref: 35487a)
- When running "RunAsRole.exe /wait sc.exe" with no argument provided to sc.exe, sc.exe will prompt
  - Would you like to see help for the QUERY and QUERYEX commands? [y | n]:
  - Typing 'y' or 'n' doesn't do anything because the input cannot be successfully redirected to sc.exe. (Ref: 47016b)
- It is not recommended to change zone via Run As Role since the role that is in use may no longer be available once after leaving from the previous zone during the change zone process. (Ref: 58043a)
- On Windows Server 2008 R2 and Windows 7, if the Agent machine has no internet connection and the .NET CLR settings (checkCertificateRevocationList) is set to True, the MFA authentication will be failed because the CLR is unable to verify the certificate through internet. The workaround is to enable the internet connection or turn off the CLR settings (set checkCertificateRevocationList to False which is also the default value). (Ref: CS-40147)

Desktop with Elevated Privileges Issues

- On a desktop with elevated privileges, if you use “Control Panel > Programs > Programs and Features” to uninstall a program, you may see the following warning message and cannot uninstall the software.

  "The system administrator has set policies to prevent this installation."

  This issue happens when User Account Control (UAC) is enabled and when “Run with UAC restrictions” is selected when creating the new desktop. (Ref: 33384a)

- You cannot use the Start menu option “Switch User” while you are using a role-based, privileged desktop. To use the “Switch User” shortcut, change from the privileged desktop to your default Windows desktop. From the default desktop, you can then select Start > Switch User to log on as a different user. (Ref: 39011b)

Roles and Rights Issues

- There is no 'Require multi-factor authentication' system right for the predefined 'Windows Login' role. To define this system right for MFA, use the pre-defined Require MFA for logon role, or create a new custom role. (Ref: CS-40888)
- Windows Network Access rights do not take effect on a Linux or UNIX machines. If you select a role to start a program or create a desktop that contains a Network Access right, you can only use that role to access Windows computers. The Windows computers you access over the network must be joined to a zone that honors the selected role. The selected role cannot be used to access any Linux or UNIX server computers on the network. (Ref: 32980a)
- Network Access rights are not supported on the Windows 2008 R2 Terminal Server if "RDC Client Single Sign-On for Remote Desktop Services" is enabled on the client side. (Ref: 34368b)
- To elevate privileges to the "Run as" account specified in a Windows right, the "run as" account must have local logon rights. If you have explicitly disallowed this right, you may receive an error such as "the user has not been granted the requested logon type at this computer" when attempting to use the right. (Ref: 34266a)
- If your computer network is spread out geographically, there may be failures in NETBIOS name translation. If a NETBIOS name is used, Active Directory attempts to resolve the NETBIOS name based on the domain controller that the user belongs to, which in a multi-segment network might fail. Therefore, Network Access rights might not work as expected if the remote server is located using NETBIOS name. You may need to consult your network administrator to work around this issue. (Ref: 39087a)
- File hash matching criteria in the Application right is not supported for a file larger than 500MB. This is to make sure DirectAuthorize does not spend too much CPU and memory resources to calculate the file hash. User trying to import a file with the size larger than 500MB will see an empty value for the file hash field. (Ref: 56778a)
- For a small set of application, enabled matching criterion - "Product Name", "Product version", "Company", "File Version" or "File Description" of a Windows Application Right may fail to match after upgrading agent under the following conditions: - Any value for the enabled matching criteria is defined by either import from a process or file - The matching criteria is defined by 5.1.3 or 5.2.0 DirectManage Access Manager since the number of affected application is expected to be relatively low, proactively updating the defined matching criteria of Windows Application Right is not necessary. (Ref: 60053a)

Compatibility with Third Party Products Issues

- VirtualDesktop is not compatible with Delinea Agent for Windows. Users should use the Delinea system tray applet to create virtual desktop instead. (Ref: 44641b)
- The startup path for "SharePoint 2010 Management Shell" and "Exchange Management Shell" may set to C:\Windows instead of user home directory if it is launched via RunAsRole.exe or from a desktop with elevated privilege. (Ref: 38814b, 46943b)
- Attempting to enable Kerberos authentication for Oracle databases will fail. This issue is being brought to the attention of Oracle Support for a resolution in upcoming releases. (Ref: 33835b)
- Some applications do not use the process token to check the group membership. They check the user's group membership on its own. Therefore, any Windows rights configured to use a privileged group will not take effect in these applications. The workaround is to use a privileged user account instead of a privileged group. Here is the list of known application with this issue:
    - vCenter Server 5.1
    - SQL Server
    - xchange 2010 or above
    - SCOM 2007

      (Ref: 45318a, 45218a, 43779a, 38016a)
- Users may notice an error and cannot install ActivClient after installing Delinea Agent for Windows. During the installation of ActivClient, it attempts to change the local security setting. However, there is a known issue for Delinea Agent for Windows of blocking the local security setting (Ref: 63609b). Therefore, users may not be able to install ActivClient successfully after installing Delinea Agent for Windows. We suggest installing ActivClient before installing Delinea Agent for Windows. If Delinea Agent for Windows has been installed, please uninstall it and follow the installation sequence suggested. This issue happens on Windows 8.1 and Windows 2012 R2 only. (Ref: 76016b)

Application Manager Issues

Application Manager does not support the Server Core edition of Windows. (Ref: CS-40656).

Configuration

- Unix Configuration Guide
- Group Policy Admin Guide
- NIS Admin Guide
- Smart Card Configuration Guide

The *Configuration and Tuning Reference Guide* provides reference information for Server Suite configuration parameters. You can set configuration parameters locally on Linux, UNIX, and Mac OS X computers to fine tune the operation of Server Suite components and subsystems. Server Suite is an integrated software solution that delivers secure access control and centralized identity management through Microsoft Active Directory. With Server Suite software, your organization can improve IT efficiency, regulatory compliance, and security for on-premise, mobile, and hosted resources.

Intended Audience

This guide is intended for administrators who want to customize the operation of Server Suite components and subsystems by modifying locally-defined configuration parameters. Many of these operations can also be configured remotely using group policies. This guide is intended as a supplement to the main Server Suite documentation set. It assumes that you have a working knowledge of Server Suite components and administration.

For information about planning a deployment and installing components, see the *Planning and Deployment Guide*. For information about performing administrative tasks using Access Manager, see the *Administrator's Guide for Linux and UNIX*.

Limitations of this Guide

This guide is updated with every major release of Server Suite. Because the supported configuration parameters can change from one release to another, have different default values between releases, or be designed to address very specific conditions, you should consider the configuration files (centrifydc.conf and centrifyda.conf for example) included with the software to be the definitive source of information for the parameters in the version of the software you are using. If there are differences between the information in the configuration files and this guide, you should consider the comments in the configuration file itself to be the most current or accurate for your environment.

The sections in this guide are as follows:

Working with Parameters and Agent Configuration Files

The Delinea Agent configuration files, centrifydc.conf and centrifyda.conf, can be used to customize and control the operation of Server Suite components and subsystems on a local host computer. This section provides an introduction to using the configuration file and setting values for the configuration parameters defined in the file.

Controlling agent operations

The Delinea configuration file for access control and privilege management is /etc/centrifydc/centrifydc.conf. The Delinea configuration file for auditing is /etc/centrifyda/centrifyda.conf. Depending on the deployment options selected when you install the agent, one or both of these files might be available on each Delinea-managed computer. The configuration files contain parameters that specify how Delinea components and subsystems operate on the local computer. They can be used to tune operations to suit your environment, for example to address bandwidth or latency constraints or address specific requirements, for example, to prevent the storage of a password hash. Many of the operations controlled locally by configuration parameters can also be controlled remotely using group policies. For information about customizing operations using group policies, see the *Group Policies Guide*.

You only have to edit the /etc/centrifydc/centrifydc.conf or /etc/centrifyda/centrifyda.conf file if you want to set custom values for one or more configuration parameters. For most organizations, the default values are appropriate. However, if you decide that you want to use a custom value for any parameter, you can uncomment the parameter name in the appropriate configuration file, then set an appropriate parameter value in place of the default value.

> **Note**: In most cases, you only modify settings in the configuration files if you want to customize specific behavior locally on an individual computer. For most parameters, you can make changes, then run the adreload command to have the changes take effect immediately. Some parameters, however, require you to restart the agent (adclient). Similarly, if you make changes to the configuration parameters used by the Delinea Network Information Service (adnisd), you may need to run the adreload command or restart that service.

Basic syntax used in configuration files

Configuration parameter are defined using a key/value pair that identifies the configuration parameter name and the value assigned to that parameter. If a configuration parameter is not explicitly set in the configuration file, the Delinea Agent assumes a default value for that parameter.

A key/value pair in the configuration file typically takes the following form:

parameter_name: value

where parameter_name is the name of the configuration parameter that describes the component the setting applies to or the purpose of the parameter, and value is the value assigned to that parameter. Variations in the formatting of the key/value pair are allowed. For example, the parameter name can be followed by a colon (:), equal sign (=), or a space:

parameter_name=value

parameter_name value

Setting configuration parameter names

In most cases, parameter names are fixed strings that are defined in the default centrifydc.conf file and commented out to illustrate the default value or how to configure a setting. In some cases, however, the parameter name itself must be customized to enable a setting. For example, the configuration parameter pam.mapuser.localuser must include the specific local user name you are mapping to an Active Directory account. For example, to map the local user joan7 to the Active Directory user joan.adams, you must set the parameter name to pam.mapuser.joan7 to specify that the mapping is for the local user joan7:

pam.mapuser.joan7: joan.adams

Setting configuration parameter values

Depending on the configuration parameter you are setting, the parameter value can be a string, a numeric value, or a Boolean value. For example, user names and group names defined in Active Directory are specified as strings using a valid Active Directory form, such as user[@domain]. In some cases, string parameter values can include environment variables.

In general, you can specify user names in the configuration file with any of the following valid formats:

- Standard Windows format: domain\user_name
- Universal Principal Name (UPN): user_name@domain
- Alternate UPN: alt_user_name@alt_domain
- UNIX user name: user

However, you must include the domain name in the format if the user account is not in the local computer's current Active Directory domain. In addition, if you are specifying an Active Directory logon name that contains spaces, you should use quotes around the string. For example:

adclient.hash.allow: 'marco sanchez@arcade.com'

Using special characters

Configuration parameter values can include the following special characters that are often used in UNIX scripts:

- The dollar sign ($) signifies an environment variable that can be resolved to an appropriate value if recognized by the agent. Valid environment variable names can consist of alphanumeric characters and underscores.
- A backslash (\) signifies that the next character is a literal, and is used, among other things, to specify a trailing space (\ ) or a single backslash (\\).

Boolean values are case-insensitive. The permissible values are true, yes, false, and no.

If a parameter can take multiple values, those values are separated from each other by a comma or a space. Spaces preceding or trailing each value are ignored.

Using environment variables

The values in key/value pairs can include standard shell environment variables. The variables are resolved to their current value when the Centrify Agent reads the configuration file. For example, you can use the environment variable $HOSTNAME to include the local computer's host name in any parameter value setting:

example_parameter: test_$HOSTNAME

If the name of the current managed computer is host1, the configuration parameter example_parameter takes the value test_host1.

In addition to standard environment variables, you can use the following Centrify-specific environment variables in the configuration file:

- $ZONE is the name of the host computer's Centrify zone.
- $JOINNAME is the name of the host computer's account name in Active Directory.
- $DOMAIN is the name of the Active Directory domain to which the host computer is joined.
- $SITE is the name of the Active Directory site for the host computer.

Rereading parameter values after making changes

In most cases, you can either run the adreload command or restart the agent (adclient) to have changes to any configuration parameter take effect. Running the adreload command or restarting the adclient process forces the Delinea Agent to reread the configuration parameters that have been defined, including any values that have changed since the last time the configuration file was read.

For most configuration parameters, you can run the adreload command to have changes take effect without restarting the adclient process. There are a few configuration parameters, however, that cannot be reloaded by running the adreload command. If you want to ensure that the agent rereads all configuration parameters, you should restart the adclient process. For example, to ensure all changes to adclient-related configuration parameters take effect, you can restart the adclient process.

Similarly, if you make changes to the configuration parameters used by the Delinea Network Information Service (adnisd), you can either run the adreload command or restart the adnisd service to ensure those changes take effect. If you change LRPC- or NSS-related parameters, you should restart both the adclient and adnisd processes if both are running when you make the change.

Securing parameter settings

By default, the configuration files—centrifydc.conf and centrifyda.conf—are owned by root. In most cases, therefore, the parameter settings you specify are secure because they can only be set or modified by the root user and access to the root account is tightly controlled. However, there are many parameters that allow you to specify settings in an external file. For example, the pam.allow.groups parameter allows you to specify a list of groups in an external file, then set the parameter value to use the file: keyword and the file path and file name of that external file.

If you are using an external file to configure parameter settings, you should ensure that the external file meets the following security requirements:

- The external file is owned by root or an equivalently-protected account.
- The external file is not group or world writable.
- The path you specify to the external file is not a symbolic link.

Using group policies to configure settings

Many configuration parameter values can be controlled by enabling and applying corresponding Delinea group policies through the Group Policy Management Editor. When you use group policies to set configuration parameters, the group policy setting overrides any local configuration setting and the group policy setting is reapplied if the computer is rebooted and periodically when the group policy is automatically refreshed. Therefore, if a group policy exists for configuring a specific setting, in most cases, you should use the group policy rather than edit the local configuration file.

If no group policy exists for a configuration parameter you want to change or if no group policy is applied to the local computer, you can customize the local configuration file to set configuration parameter values as needed.

To determine whether a group policy exists to configure a specific setting, and which group policies affect which settings, see the *Group Policy Guide*. When you open the Group Policy Guide PDF file, use the PDF reader search function to search for a setting (for example, adclient.cache.expires.gc). If the setting can be configured with a group policy, the setting is referred to in the group policy description.

Note: It is possible for an Active Directory administrator to override virtually any setting in the local configuration file using group policies applied to a local computer. This effectively gives administrators with permission to enable or disable group policies root-level access to computers in the zones they manage. There is no way to effectively prevent settings from being changed, except by disabling user, computer, or all group policies in the local centrifydc.conf or centrifyda.conf file or by strictly controlling who has permission to enable and apply group policies to computers that join an Active Directory domain.

For information about disabling the application of group policies using settings in the local centrifydc.conf file, see Customizing group policy configuration for more information about enabling and applying group policies rather than setting configuration parameters locally on a computer, see the *Group Policy Guide*.

Parameters and values are subject to change

Configuration parameters are added, updated, and retired with each release of the Delinea Agent. In addition, some parameters are intended only for specific circumstances and are intentionally not documented in this guide. If a configuration parameter setting is recommended by Delinea Support, but not documented in this guide, you should consider the recommendation made by Support to be authoritative. You should also consider the comments in the configuration file to be the most authoritative reference for the release of the software you are using. Because parameters are often created to address specific issues in specific environments, the default values and recommendations for changes to the default values are also subject to change from one release to another.

Customizing adclient Configuration Parameters

This section describes the configuration parameters that affect the operation of the core agent (adclient) process on the local host computer.

adclient.altupns

This configuration parameter specifies a UPN suffix that adclient will recognize as a valid UPN suffix even if it is a realm unknown by Kerberos.

The default value is “mil”.

For example, to specify “biz” as a suffix to recognize:

adclient.altupns: biz

You can also use multiple UPN suffixes separated by a space. For example, to specify “biz” and “mil” as suffixes to recognize:

adclient.altupns: biz mil

This parameter does not support wildcards (*.acme.com) or preceding dots (.acme.com).

adclient.autoedit

This configuration parameter specifies whether the agent is allowed to automatically edit the NSS and PAM configuration files on the local computer.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value is set to true to allow the files to be edited or false to prevent the files from being edited. The following example allows both the NSS and PAM configuration files to be edited automatically:

adclient.autoedit: true

In most cases, this parameter should be set to true to allow the agent to maintain configuration files automatically. When this parameter is set to true, you can further control the specific individual files to be automatically edited in different operating environments through additional configuration parameters. For example, you can use the adclient.autoedit.nss to enable or disable automatic editing of the nsswitch.conf file or the adclient.autoedit.pam to enable or disable automatic editing of the PAM configuration file. These additional configuration parameters are ignored if the adclient.autoedit parameter is set to false. For more information about the configuration parameters to control the editing of specific files on different platforms, see Enabling automatic editing for specific files.

If you set the adclient.autoedit parameter to false, you must manually edit the appropriate configuration files to enable agent operation. For example, if you set this parameter to false, you should manually edit the nsswitch.conf and /etc/pam.d/systemauth or /etc/pam.d files to include Delinea information or authentication through Active Directory will fail and you may disable login access entirely.

If you want to manually edit the configuration files, you should first make a backup copy of the existing files. After you make a backup copy of the files, you can use the following examples to manually update the files with the configuration information for the agent.

> **Note**: If the adclient.autoedit parameter is not defined in the configuration file, its default value is true.

Enabling automatic editing for specific files

If you set the adclient.autoedit parameter to true, you can use the following parameters to identify the specific files to be automatically edited in different operating environments:

adclient.autoedit.nss	Specify whether you want to automatically edit the Name Service Switch configuration (nsswitch.conf) file on **HP-UX**, **Solaris**, and **Linux** computers. For example: adclient.autoedit.nss: true You can also use group policy to set this parameter.
adclient.autoedit.pam	Specify whether you want to automatically edit the PAM configuration (pam.conf file or pam.d directory) on **AIX**, **HP-UX**, **Solaris**, **Mac OS X**, and **Linux** computers. For example: adclient.autoedit.pam: true You can also use group policy to set this parameter.
adclient.autoedit.centrifypam	Specify whether to activate the Delinea authorization plug-in and add it to the authorization mechanism every time adclient starts. The default value is true. For example: adclient.autoedit.centrifypam: true
adclient.autoedit.centrifypam.restart.securityagent	Specify whether to restart SecurityAgent after the authorization database is edited. The default value is true. For example: adclient.autoedit.centrifypam.restart.securityagent: true If this parameter is set to false, you must restart the SecurityAgent process or reboot the computer manually after the authorization database is edited. If you do not restart SecurityAgent or reboot, users might not be able to log in.
adclient.autoedit.nscd	Specify whether you want to disable automatic editing of the nscd passwd and group cache (nscd.conf) on **Solaris** and **Linux** computers. By default, this parameter is set to false, which means automatic editing is disabled. Setting this parameter to true enables automatic editing. It is recommended that you change the default setting and enable automatic editing of the nscd caches; doing so reduces NSS response time substantially for large volumes of repeated queries.

Note: Some operating systems do not install nscd by default; be sure that nscd is installed before configuring this setting. For example: adclient.autoedit.nscd: false You can also use group policy to set this parameter. | | adclient.autoedit.methods | Specify whether you want to automatically edit the Loadable Authentication Module (LAM) methods.cfg configuration file on **AIX** computers. For example: adclient.autoedit.methods: true You can also use group policy to set this parameter. | | adclient.autoedit.user | Specify whether you want to automatically edit the /etc/security/user file. The default value is true. For example: adclient.autoedit.user: true You can also use group policy to set this parameter. | | adclient.autoedit.user. root | Specify whether root login is controlled by the Centrify authentication mechanism. If this parameter is set to true, the root stanza 'SYSTEM = "compat"' in /etc/security/user will be commented out and root login must go through theCentrify authentication mechanism. The default value is false (so that by default, root login does not go through the <MadCap:variable name="server-company-vars.company-short-name" /> authentication mechanism). For example: adclient.autoedit.user.root: false | | adclient.autoedit.pwgrd | Specify whether you want to automatically edit the password and group hashing and caching daemon (pwgrd) on **HP-UX** computers. For example: adclient.autoedit.pwgrd: true You can also use group policy to set this parameter. |

Note that if you make any changes to any adclient.autoedit.* parameter, you must restart the adclient process for the change to take effect. Restarting adclient is required whether you set the parameters manually in the configuration file or by enabling a group policy.

Related topics

Editing the NSS configuration manually

Editing the PAM configuration manually

Editing the NSS configuration manually

To manually edit the NSS configuration, modify the /etc/nsswitch.conf file to include centrifydc as the first entry for the password and group lines as appropriate for your environment. For example:

passwd: centrifydcfiles
shadow: centrifydcfiles
group: centrifydcfiles

By placing centrifydc at the beginning of each line, you ensure that Active Directory authentication takes precedence over other forms of authentication.

Editing the PAM configuration manually

In most cases, you should not manually edit the PAM configuration on a computer unless absolutely necessary because changes can produce unexpected and undesirable results. If you choose to edit the file manually, you should use caution and limit the changes you make.

To manually edit the PAM configuration to use Delinea and Active Directory, you need to add several lines to the top of the appropriate PAM configuration file for the local operating environment.

For example, on Linux you need to add the following lines to the top of the /etc/pam.d/system-auth file:

auth sufficient pam_centrifydc.so debug
auth requisite pam_centrifydc.so deny debug
account sufficient pam_centrifydc.so debug
session sufficient pam_centrifydc.so homedir
password sufficient pam_centrifydc.so try_first_pass
password requisite pam_centrifydc.so deny

On Solaris and other platforms, you need to add the following lines to the top of the /etc/pam.conf file:

rlogin auth sufficient pam_centrifydc.so debug
rlogin auth requisite pam_centrifydc.so deny debug
login auth sufficient pam_centrifydc.so debug
login auth requisite pam_centrifydc.so deny debug
passwd auth sufficient pam_centrifydc.so try_first_pass debug
passwd auth requisite pam_centrifydc.so deny debug
other auth sufficient pam_centrifydc.so debug
other auth requisite pam_centrifydc.so deny debug
cron account sufficient pam_centrifydc.so debug
other account sufficient pam_centrifydc.so debug

other password sufficient pam_centrifydc.so debug
other session sufficient pam_centrifydc.so debug

> **Note**: In most operating environments, when new users log on successfully, the Delinea Agent automatically attempts to create the user's home directory. In Solaris environments, however, the home directory is often automounted over NFS, so the attempt to automatically create a new home directory for new users typically fails. If you use NFS to automount home directories, you can turn off the automatic creation of the home directory by setting the pam.homedir.create parameter in the centrifydc.conf file to false. For more information about setting this parameter, see pam.homedir.create.

By adding the appropriate lines to the beginning of the PAM configuration file, you ensure that Active Directory authentication takes precedence over other forms of authentication.

Editing the LAM configuration manually

To manually edit the LAM configuration for AIX computers, you need to add Delinea specific information to the /usr/lib/methods.cfg and /etc/security/user files.

In the /usr/lib/methods.cfg file, add the following lines to enable authentication through the Delinea Agent and Active Directory:

CENTRIFYDC:
program = /usr/lib/security/CENTRIFYDC program_64 = /usr/lib/security/CENTRIFYDC64
options = noprompt

In the /etc/security/user file, you need to change the SYSTEM attribute for your users. The easiest way to do this is to change the SYSTEM attribute in the "default" stanza. For example:

...
SYSTEM = "CENTRIFYDC OR CENTRIFYDC[NOTFOUND] AND compat"
...

In addition, if any user has an explicit setting for the SYSTEM attribute, you should remove the setting. For example, by default, the root account has an explicit SYSTEM setting, so you should delete this line or comment it out.

adclient.binding.dc.failover.delay

This configuration parameter specifies the time, in minutes, to wait before adclient fail over to the next domain controller when the currently-connected domain controller is either down or not responding. The default is fail over immediately.

> **Note**: This configuration parameter only takes effect when adclient is running. If the domain controller stored in kset is down when adclient is not running, starting up adclient will force adclient to lookup a healthy domain controller.

adclient.binding.idle.time

This configuration parameter specifies the maximum number of minutes to allow as idle time when binding to Active Directory.

For example, to allow a maximum idle time of 5 minutes during a bind operation:

adclient.binding.idle.time: 5

adclient.binding.ldapsearch.statistic.interval

Use this parameter to specify how much time passes before adclient resets the LDAP search statistics.

The default is 30 minutes.

You can see these statistics by running the following command or by viewing the messages sent to the Unix syslog (centrifydc.log):

adinfo --sysinfo adagent

The adclient.heartbeat.interval parameter controls the heartbeat log messages.

adclient.binding.refresh.force

This configuration parameter specifies whether to force LDAP bindings to be refreshed even if the current binding is to a local (preferred) Active Directory site. Under some conditions, binding to a different site can help facilitate load balancing between servers.

If you set this parameter to true, the agent will attempt to connect to another local domain controller when the period specified in adclient.binding.refresh.interval expires.

By default, this configuration parameter is set to false. For example:

adclient.binding.refresh.force: false

adclient.binding.refresh.interval

This configuration parameter specifies how often to refresh the LDAP bindings to the preferred Active Directory site under these conditions:

- If the computer is currently bound to a local domain controller, bindings are refreshed only if adclient.binding.refresh.force is set to true.
- If the computer is currently bound to a domain controller in another site, bindings are refreshed regardless the adclient.binding.refresh.force setting.

If the agent is unable to communicate with a local domain controller, it automatically connects to an available domain controller in another site until a domain controller in its preferred site becomes available. To determine when a domain controller in the preferred site is available, the agent periodically attempts to re-connect to domain controllers in its preferred site whenever it is connected to a backup domain controller in another site. This parameter controls how frequently the agent performs the attempt to re-connect to the preferred site.

The parameter value specifies the number of minutes between refresh attempts. It must be an integer greater than zero. The following example sets the interval time to 60 minutes:

adclient.binding.refresh.interval: 60

If this parameter is not defined in the configuration file, its default value is 30 minutes.

In changing this parameter, you should consider your network and site topology and the reliability of your servers. If you have highly reliable network links and very good connections between sites, you may find it safe to increase this value, but if communication between sites is slow you should keep this interval short to ensure the agent communicates with domain controllers in its preferred site as soon as possible.

adclient.get.builtin.membership

This configuration parameter determines whether the agent checks for valid users in built-in Active Directory groups, such as Administrators. By default, this parameter's value is false, in which case, the adclient process ignores members of built-in groups.

To include members of built-in groups, set this parameter to true in the configuration file:

adclient.get.builtin.membership: true

adclient.cache.cleanup.interval

This configuration parameter specifies how often the agent should clean up the local cache. At each cleanup interval, the agent checks the cache for objects to be removed or expired, and at every 10th interval, the agent rebuilds local indexes. This parameter's value should be less than the values specified for the adclient.cache.negative.lifetime, adclient.cache.flush.interval, and adclient.cache.object.lifetime parameters.

The default cleanup interval is 10 minutes.

For example:

adclient.cache.cleanup.interval: 10

adclient.cache.encrypt

This configuration parameter specifies whether you want to encrypt the local cache of Active Directory data. If you set this parameter to true, all of the Active Directory data stored in the cache is encrypted and the cache is flushed each time the agent starts up. If you set this parameter to false, the cache is not encrypted and is not flushed when the agent starts up.

For example, to encrypt all data in the cache:

adclient.cache.encrypt: true

If this parameter is not defined in the configuration file, its default value is false.

adclient.cache.encryption.type

This configuration parameter specifies the type of encryption to use when encrypting the local cache. The encryption type you specify must be a type supported in the Kerberos environment. For example, Windows Server 2003 Kerberos supports the following cryptographic algorithms: RC4-HMAC, DES-CBC-CRC and DES-CBC-MD5.

For example:

adclient.cache.encryption.type: des-cbc-md5

This configuration parameter is only used if adclient.cache.encrypt is set to true. If the adclient.cache.encrypt parameter is set to false, this configuration parameter is ignored.

adclient.cache.expires

This configuration parameter specifies the number of seconds before an object in the domain controller cache expires. This parameter controls how frequently the agent checks Active Directory to see if an object in the cache has been updated.

Every object retrieved from Active Directory is stamped with the system time when it enters the domain controller cache. Once an object expires, if it is needed again, the agent contacts Active Directory to determine whether to retrieve an updated object (because the object has changed) or renew the expired object (because no changes have been made). To make this determination, the agent checks the highestUSN for the expired object. If the value has changed, the agent retrieves the updated object. If the highestUSN has not changed, the agent resets the object's timestamp to the new system time and retrieves the object from the cache.

If the agent is unable to contact Active Directory to check for updates to an expired object—for example because the computer is disconnected from the network—the agent returns the currently cached object until it can successfully contact Active Directory.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you aren't using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time to 600 seconds (10 minutes):

adclient.cache.expires: 600

If this parameter is not defined in the configuration file, its default value is 3600 seconds (1 hour).

> **Note**: The adclient.cache.expires parameter defines the default cache expiration time for all objects types. You can override this default value for specific object types by appending the object type to the parameter name. For example, if you want to explicitly override the default expiration time for computer objects, you can define a different value for the adclient.cache.expires.computer parameter. The valid object types you can append to the parameter name to override the default value are: computer, extension, gc, group, search, user, user.membership and zone. Note that adclient.cache.expires.gc, if not set, does not default to the value of adclient.cache.expires, but has its own default value.

adclient.cache.expires.computer

This configuration parameter specifies the number of seconds before a computer object in the domain controller cache expires. If this parameter is not specified, the generic object cache expiration value is used.

Every computer object retrieved from Active Directory is stamped with the system time when it enters the domain controller cache. Once an object expires, if it is needed again, the agent contacts Active Directory to determine whether to retrieve an updated object (because the object has changed) or renew the expired object (because no changes have been made). To make this determination, the agent checks the highestUSN for the expired object. If the value has changed, the agent retrieves the updated object. If the highestUSN has not changed, the agent resets the object's timestamp to the new system time and retrieves the object from the cache.

If the agent is unable to contact Active Directory to check for updates to an expired object—for example because the computer is disconnected from the network—the agent returns the currently cached object until it can successfully contact Active Directory.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for computer objects to 600 seconds (10 minutes):

adclient.cache.expires.computer: 600

> **Note**: The default cache expiration time for all objects types is defined with the adclient.cache.expires parameter. If you explicitly set the adclient.cache.expires.computer parameter, its value overrides the default value for cached objects.

adclient.cache.expires.extension

This configuration parameter specifies the number of seconds before an extension object in the domain controller cache expires. If this parameter is not specified, the generic object cache expiration value is used.

Every object retrieved from Active Directory is stamped with the system time when it enters the domain controller cache. Once an object expires, if it is needed again, the agent contacts Active Directory to determine whether to retrieve an updated object (because the object has changed) or renew the expired object (because no changes have been made). To make this determination, the agent checks the highestUSN for the expired object. If the value has changed, the agent retrieves the updated object. If the highestUSN has not changed, the agent resets the object's timestamp to the new system time and retrieves the object from the cache.

If the agent is unable to contact Active Directory to check for updates to an expired object—for example because the computer is disconnected from the network—the agent returns the currently cached object until it can successfully contact Active Directory.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for extension objects to 1800 seconds (30 minutes):

adclient.cache.expires.extension: 1800

> **Note**: The default cache expiration time for all objects types is defined with the adclient.cache.expires parameter. If you explicitly set the adclient.cache.expires.extension parameter, its value overrides the default value for cached objects.

adclient.cache.expires.gc

This configuration parameter specifies the number of seconds before information in the global catalog cache expires. The global catalog cache contains the distinguished name (DN) for each object that has been looked up in Active Directory. The primary purpose of the global catalog cache is to store the results from paged object searches. Object attributes are stored in the domain controller cache.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for global catalog objects to 3600 seconds (60 minutes), which is the default value:

adclient.cache.expires.gc: 3600

> **Note**: If you do not define the adclient.cache.expires.gc parameter in the configuration file, it has a default value of 3600 seconds (1 hour). Unlike the default value for other object types, the default value for adclient.cache.expires.gc is not dependent on the value of adclient.cache.expires.

adclient.cache.expires.group

This configuration parameter specifies the number of seconds before a group object in the domain controller cache expires. The domain controller cache contains object attributes including the object's Active Directory properties, memberships, indexes and other parameters. If this parameter is not specified, the generic object cache expiration value is used.

Every group object retrieved from Active Directory is stamped with the system time when it enters the domain controller cache. Once an object expires, if it is needed again, the agent contacts Active Directory to determine whether to retrieve an updated object (because the object has changed) or renew the expired object (because no changes have been made). To make this determination, the agent checks the highestUSN for the expired object. If the value has changed, the agent retrieves the updated object. If the highestUSN has not changed, the agent resets the object's timestamp to the new system time and retrieves the object from the cache.

If the agent is unable to contact Active Directory to check for updates to an expired object—for example because the computer is disconnected from the network—the agent returns the currently cached object until it can successfully contact Active Directory.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for group objects to 1800 seconds (30 minutes):

adclient.cache.expires.group: 1800

> **Note**: The default cache expiration time for all objects types is defined with the adclient.cache.expires parameter. If you explicitly set the adclient.cache.expires.group parameter, its value overrides the default value for cached objects.

adclient.cache.expires.group.membership

This configuration parameter specifies the number of seconds before a group membership object in the domain controller cache expires. The domain controller cache contains object attributes including the object's Active Directory properties, memberships, indexes and other parameters. If this parameter is not specified, the generic object cache expiration value is used.

Every group membership object retrieved from Active Directory is stamped with the system time when it enters the domain controller cache. Once an object expires, if it is needed again, the agent contacts Active Directory to determine whether to retrieve an updated object (because the object has changed) or renew the expired object (because no changes have been made). To make this determination, the agent checks the highestUSN for the expired object. If the value has changed, the agent retrieves the updated object. If the highestUSN has not changed, the agent resets the object's timestamp to the new system time and retrieves the object from the cache.

If the agent is unable to contact Active Directory to check for updates to an expired object—for example because the computer is disconnected from the network—the agent returns the currently cached object until it can successfully contact Active Directory.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for group objects to 1800 seconds (30 minutes):

adclient.cache.expires.group: 1800

> **Note**: The default cache expiration time for all objects types is defined with the adclient.cache.expires parameter. If you explicitly set the adclient.cache.expires.group.membership parameter, its value overrides the default value for cached objects.

adclient.cache.expires.search

This configuration parameter specifies the number of seconds before the results of an Active Directory search expire.

Search expiration is handled separately from object expiration because a search result may include objects that have been deleted or be missing objects that have been added that meet the search criteria.

You can set this configuration parameter by manually adding it to the centrifydc.conf configuration file and specifying the maximum number of seconds for a search result to be kept in the local cache.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for search to 1800 seconds (30 minutes):

adclient.cache.expires.search: 1800

> **Note**: The default cache expiration time for all objects types is defined with the adclient.cache.expires parameter. If you explicitly set the adclient.cache.expires.search parameter, its value overrides the default value for cached objects.

adclient.cache.expires.user

This configuration parameter specifies the number of seconds before a user object in the domain controller cache expires. If this parameter is not specified, the generic object cache expiration value is used.

Every user object retrieved from Active Directory is stamped with the system time when it enters the domain controller cache. Once an object expires, if it is needed again, the agent contacts Active Directory to determine whether to retrieve an updated object (because the object has changed) or renew the expired object (because no changes have been made). To make this determination, the agent checks the highestUSN for the expired object. If the value has changed, the agent retrieves the updated object. If the highestUSN has not changed, the agent resets the object's timestamp to the new system time and retrieves the object from the cache.

If the agent is unable to contact Active Directory to check for updates to an expired object—for example because the computer is disconnected from the network—the agent returns the currently cached object until it can successfully contact Active Directory.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for user objects to 1800 seconds (30 minutes):

adclient.cache.expires.user: 1800

> **Note**: The default cache expiration time for all objects types is defined with the adclient.cache.expires parameter. If you explicitly set the adclient.cache.expires.user parameter, its value overrides the default value for cached objects.

adclient.cache.expires.user.membership

This configuration parameter specifies the number of seconds before a user's group membership information in the domain controller cache expires. If this parameter is not specified, the user object cache expiration value (adclient.cache.expires.user) is used.

Every user object retrieved from Active Directory is stamped with the system time when it enters the domain controller cache. Once an object expires, if it is needed again, the agent contacts Active Directory to determine whether to retrieve an updated object (because the object has changed) or renew the expired object (because no changes have been made). To make this determination, the agent checks the highestUSN for the expired object. If the value has changed, the agent retrieves the updated object. If the highestUSN has not changed, the agent resets the object's timestamp to the new system time and retrieves the object from the cache.

If the agent is unable to contact Active Directory to check for updates to an expired object—for example because the computer is disconnected from the network—the agent returns the currently cached object until it can successfully contact Active Directory.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time for user objects to 1800 seconds (30 minutes):

adclient.cache.expires.user.membership: 1800

> **Note**: The default cache expiration time for all objects types is defined with the adclient.cache.expires parameter. If you explicitly set the adclient.cache.expires.user.membership parameter, its value overrides the default value for cache objects.

adclient.cache.flush.interval

This configuration parameter specifies how frequently, in hours, to flush all objects from the domain controller cache. The domain controller cache contains object attributes including the object's Active Directory properties, memberships, indexes and other parameters.The parameter value must be a positive integer. Unlike the other cache management parameters, which flush objects selectively, this parameter removes all objects in the cache at the interval you specify.

Specify the interval, in hours, using an integer value. The default value is 0, which disables the complete flushing of the cache.

For example, the following setting flushes all values in the cache every 12 hours:

adclient.cache.flush.interval: 12

adclient.cache.negative.lifetime

This configuration parameter specifies how long, in minutes, a negative object should remain in the domain controller cache. The domain controller cache contains object attributes including the object's Active Directory properties, memberships, indexes and other parameters. A negative object is returned when an object is not found in a search result. This configuration parameter determines how long that negative result should remain in the cache, regardless of the object type or object expiration time. By storing this negative result in the cache, the agent does not need to connect to Active Directory to look for an object that was previously not found.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be a positive integer. The default period of time for keeping negative results is 5 minutes. Setting the parameter value to 0 keeps negative objects in the cache indefinitely.

The following example sets the lifetime for negative objects to 10 minutes:

adclient.cache.negative.lifetime: 10

adclient.cache.object.lifetime

This configuration parameter specifies how long, in hours, an Active Directory object should remain in the domain controller cache. Setting the parameter value to 0 keeps objects in the cache indefinitely. When you set this parameter to 0, objects remain in the cache until they are deleted from Active Directory or the cache is manually flushed with the adflush command. If you don't want objects to remain in the cache indefinitely, you can use this parameter to set the maximum amount of time an object should be available in the cache.

For example, if you want to set the maximum time for an object to be held in the cache to 12 hours, you can set this configuration parameters as follows:

adclient.cache.object.lifetime: 12

With this setting, object values can be retrieved from the local domain controller cache for 12 hours. At the end of the 12 hour period, however, the object is removed from the local cache and must be retrieved from Active Directory if it is needed again.

If this parameter is not defined in the configuration file, its default value is 0.

adclient.cache.refresh

This configuration parameter specifies the maximum number of seconds an object can be read from the domain controller cache before it needs to be refreshed. This parameter allows an object to be read from the cache if the age of the object in the cache is less than the parameter value.

This parameter is useful in cases where reading objects from Active Directory may result in duplicate object requests. For example, the PAM-enabled login process is designed to always retrieve the user object from Active Directory first to ensure that the most recent version of the user object is available for logging on. It only retrieves the user object from the cache if Active Directory is unavailable. Logging on, however, may require this same information to be requested from Active Directory more than once.

To prevent sending the duplicate object requests during the login process, the Delinea Agent checks this parameter. If the age of the object in the cache is less than the refresh time specified by this configuration parameter, the object is allowed to be read from cache. If the object in the cache is older than the refresh interval, the login process retrieves the information from Active Directory.

The parameter value must be a positive integer. The default value is 5 seconds. For example:

adclient.cache.refresh: 5

> **Note**: This configuration parameter applies to generic objects in the domain controller cache and becomes the default refresh period for all object types. You can set separate refresh periods for specific objects types using the object-specific configuration parameters. For example, you can set different refresh times for computer objects and user objects using the adclient.cache.refresh.computer, and adclient.cache.refresh.user configuration parameters. This generic object refresh setting applies to any object for which you do not set an object-specific refresh period.

adclient.cache.refresh.computer

This configuration parameter specifies the maximum number of seconds a computer object can be read from the domain controller cache before it needs to be refreshed. This parameter allows a computer object to be read from the cache if the age of the object in the cache is less than the parameter value.

This parameter is useful in cases where reading objects from Active Directory may result in duplicate object requests. For example, the PAM-enabled login process is designed to always retrieve the user object from Active Directory first to ensure that the most recent version of the user object is available for logging on. It only retrieves the user object from the cache if Active Directory is unavailable. Logging on, however, may require this same information to be requested from Active Directory more than once.

To prevent sending the duplicate object requests during the login process, the Delinea Agent checks this parameter. If the age of the object in the cache is less than the refresh time specified by this configuration parameter, the object is allowed to be read from cache. If the object in the cache is older than the refresh interval, the login process retrieves the information from Active Directory.

The parameter value must be a positive integer. The default value is 5 seconds. For example:

adclient.cache.refresh.computer: 5

> **Note**: The default refresh time for all objects types is defined with the adclient.cache.refresh parameter. If you set the adclient.cache.refresh.computer parameter, its value overrides the default value for objects.

adclient.cache.refresh.extension

This configuration parameter specifies the maximum number of seconds an extension object can be read from the domain controller cache before it needs to be refreshed. The domain controller cache contains object attributes including the object's Active Directory properties, memberships, indexes and other parameters. This parameter allows an extension object to be read from the cache if the age of the object in the cache is less than the parameter value.

This parameter is useful in cases where reading objects from Active Directory may result in duplicate object requests. For example, the PAM-enabled login process is designed to always retrieve the user object from Active Directory first to ensure that the most recent version of the user object is available for logging on. It only retrieves the user object from the cache if Active Directory is unavailable. Logging on, however, may require this same information to be requested from Active Directory more than once.

To prevent sending the duplicate object requests during the login process, the Delinea Agent checks this parameter. If the age of the object in the cache is less than the refresh time specified by this configuration parameter, the object is allowed to be read from cache. If the object in the cache is older than the refresh interval, the login process retrieves the information from Active Directory.

The parameter value must be a positive integer. The default value is 5 seconds. For example:

adclient.cache.refresh.extension: 5

> **Note**: The default refresh time for all objects types is defined with the adclient.cache.refresh parameter. If you set the adclient.cache.refresh.extension parameter, its value overrides the default value for objects.

adclient.cache.refresh.gc

This configuration parameter specifies the maximum number of seconds an entry can be read from the global catalog cache before it needs to be refreshed. This parameter allows an object to be read from the cache if the age of the object in the cache is less than the parameter value.

This parameter is useful in cases where reading objects from Active Directory may result in duplicate object requests. For example, the PAM-enabled login process is designed to always retrieve the user object from Active Directory first to ensure that the most recent version of the user object is available for logging on. It only retrieves the user object from the cache if Active Directory is unavailable. Logging on, however, may require this same information to be requested from Active Directory more than once.

To prevent sending the duplicate object requests during the login process, the Delinea Agent checks this parameter. If the age of the object in the cache is less than the refresh time specified by this configuration parameter, the object is allowed to be read from cache. If the object in the cache is older than the refresh interval, the login process retrieves the information from Active Directory.

The parameter value must be a positive integer. The default value is 5 seconds. For example:

adclient.cache.refresh.gc: 5

> **Note**: The default refresh time for all objects types is defined with the adclient.cache.refresh parameter. If you set the adclient.cache.refresh.gc parameter, its value overrides the default value for refreshing objects.

adclient.cache.refresh.group

This configuration parameter specifies the maximum number of seconds a group object can be read from the domain controller cache before it needs to be refreshed. This parameter allows a group object to be read from the cache if the age of the object in the cache is less than the parameter value.

This parameter is useful in cases where reading objects from Active Directory may result in duplicate object requests. For example, the PAM-enabled login process is designed to always retrieve the user object from Active Directory first to ensure that the most recent version of the user object is available for logging on. It only retrieves the user object from the cache if Active Directory is unavailable. Logging on, however, may require this same information to be requested from Active Directory more than once.

To prevent sending the duplicate object requests during the login process, the Delinea Agent checks this parameter. If the age of the object in the cache is less than the refresh time specified by this configuration parameter, the object is allowed to be read from cache. If the object in the cache is older than the refresh interval, the login process retrieves the information from Active Directory.

The parameter value must be a positive integer. The default value is 5 seconds. For example:

adclient.cache.refresh.group: 5

> **Note**: The default refresh time for all objects types is defined with the adclient.cache.refresh parameter. If you set the adclient.cache.refresh.group parameter, its value overrides the default value for refreshing objects.

adclient.cache.refresh.search

This configuration parameter specifies the maximum number of seconds search results can be read from the domain controller cache before it needs to be refreshed. This parameter allows the search results to be read from the cache if the age of the object in the cache is less than the parameter value.

This parameter is useful in cases where reading objects from Active Directory may result in duplicate object requests. For example, the PAM-enabled login process is designed to always retrieve the user object from Active Directory first to ensure that the most recent version of the user object is available for logging on. It only retrieves the user object from the cache if Active Directory is unavailable. Logging on, however, may require this same information to be requested from Active Directory more than once.

To prevent sending the duplicate object requests during the login process, the Delinea Agent checks this parameter. If the age of the object in the cache is less than the refresh time specified by this configuration parameter, the object is allowed to be read from cache. If the object in the cache is older than the refresh interval, the login process retrieves the information from Active Directory.

The parameter value must be a positive integer. The default value is 5 seconds. For example:

adclient.cache.refresh.search: 5

> **Note**: The default refresh time for all objects types is defined with the adclient.cache.refresh parameter. If you set the adclient.cache.refresh.search parameter, its value overrides the default value for refreshing objects.

adclient.cache.refresh.user

This configuration parameter specifies the maximum number of seconds a user object can be read from the domain controller cache before it needs to be refreshed. This parameter allows a user object to be read from the cache if the age of the object in the cache is less than the parameter value.

This parameter is useful in cases where reading objects from Active Directory may result in duplicate object requests. For example, the PAM-enabled login process is designed to always retrieve the user object from Active Directory first to ensure that the most recent version of the user object is available for logging on. It only retrieves the user object from the cache if Active Directory is unavailable. Logging on, however, may require this same information to be requested from Active Directory more than once.

To prevent sending the duplicate object requests during the login process, the Delinea Agent checks this parameter. If the age of the object in the cache is less than the refresh time specified by this configuration parameter, the object is allowed to be read from cache. If the object in the cache is older than the refresh interval, the login process retrieves the information from Active Directory.

The parameter value must be a positive integer. The default value is 5 seconds. For example:

adclient.cache.refresh.user: 5

> **Note**: The default refresh time for all objects types is defined with the adclient.cache.refresh parameter. If you set the adclient.cache.refresh.user parameter, its value overrides the default value for refreshing objects.

adclient.cache.upn.index

This configuration parameter specifies whether to index user principle names (UPNs) that are stored in the Delinea user cache. You can use this parameter to differentiate between two users when the UPN of one user is equal to the SAM@domain_name of another user, and both user objects are stored in the user cache.

To enable UPN indexing, set this parameter to true. For example:

adclient.cache.upn.index: true

By default, this parameter is set to false, and UPNs are not indexed.

adclient.client.idle.timeout

This configuration parameter specifies the number of seconds before the agent will drop a socket connection to an inactive client.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be an integer greater than zero. The following example sets the inactive client timeout to 900 seconds:

adclient.client.idle.timeout: 900

If you set this parameter to zero, the agent will never drop the socket connection. Therefore, you should always specify a value greater than zero.

If this parameter is not defined in the configuration file, its default value is 5 seconds.

> **Note**: You must restart adclient for changes to this parameter to take effect. There is a Group Policy setting for this property but changing it has no effect until adclient is restarted on the affected computers. (Ref: CS-18792c)

adclient.clients.listen.backlog

This configuration parameter specifies the number of backlog connections to maintain when all threads are busy. Through operating system services, the agent maintains a queue of pending connection requests that are received from the processes that need the services of the agent. This configuration parameter controls the maximum number of pending requests to hold in the queue.

Decreasing the value of this parameter may prevent processes from performing tasks that require adclient services, for example, a login request may be unable to authenticate a user. Increasing the value of this parameter may reduce the chance of service request failure, but may waste system memory resources and impact system performance.

For example:

adclient.clients.listen.backlog: 50

If you change this parameter, you must restart the adclient process for the change take effect.

adclient.clients.socket

This configuration parameter specifies the named socket through which clients communicate with the agent.

The parameter value must be the name of the socket. For example:

adclient.clients.socket: /var/centrifydc/daemon

If this parameter is not defined in the configuration file, its default value is daemon.

adclient.clients.threads

This configuration parameter specifies the number of threads the agent pre-allocates for processing client requests.

The parameter value must be an integer zero or greater. If you set this parameter to zero, the agent processes requests sequentially. For example:

adclient.clients.threads: 4

If this parameter is not defined in the configuration file, its default value is 4 threads.

If you change this parameter, you must restart the adclient process for the change take effect.

adclient.clients.threads.max

This configuration parameter specifies the maximum number of threads the agent will allocate for processing client requests. This parameter value should be greater than or equal to the number of pre-allocated threads specified by the adclient.clients.threads parameter. The default value is 20 threads. For example:

adclient.clients.threads.max: 20

If you change this parameter, you must restart the adclient process for the change take effect.

adclient.clients.threads.poll

This configuration parameter specifies the number of milliseconds the agent waits between checks to see if a client's request has been completed.

Request completion polling is necessary to eliminate race conditions in operating environments such as Linux that don't have pselect implemented in the kernel. This polling mechanism should be disabled if the operating system has an atomic pselect.

The parameter value must be an integer zero or greater. A value of zero turns off polling. For example:

adclient.clients.threads.poll: 100

If this parameter is not defined in the configuration file, its default value is 100 milliseconds.

adclient.cloud.auth.token.max

This configuration parameter specifies the maximum number of cloud authentication requests that can be processed simultaneously. The default is 10 requests.

If you change this parameter, you must restart the adclient process. When the number of simultaneous connection requests exceeds this setting, the next authentication request will fail. If an authentication request times out waiting for a response, the connection is closed and the token is cleared to allow a new request

The default value of this parameter is 10 simultaneous requests. For example:

adclient.cloud.auth.token.max: 10

adclient.cloud.cert.store

Use this configuration parameter to specify the file in which to store the certificate that verifies cloud server connections.

By default, if there is no set file location, adclient will automatically locate the certificate.

> **Note**: The agent searches the following locations by default:

- /etc/ssl/certs/ca-certificates.crt
- /etc/pki/tls/certs/ca-bundle.crt
- /user/share/ssl/certs/ca-bundle.crt
- /usr/local/share/certs/ca-root-nss.crt
- /etc/ssl/cert.pem

This configuration parameter should only be used if adclient.cloud.skip.cert.verification.

For example:

adclient.cloud.cert.store: /etc/ssl/ca-bundle.crt

adclient.cloud.connector

This configuration parameter specifies a cloud connector to use in the current Active Directory forest. This parameter enables you to explicitly designate the cloud connector to use for connections between Delinea-managed Linux and UNIX computers and the cloud instance providing cloud authentication services.

By default, adclient will automatically select the most appropriate cloud connector to use based on network topology. You can use this parameter, however, to manually specify the IP address or fully-qualified domain name of the cloud connector you want connections to go through. By designating a cloud connector, adclient will use that cloud connector and won't do automatic discovery to other connectors.

For example, to specify the cloud connector by IP address:

adclient.cloud.connector: 192.168.1.61:8080

To specify the cloud connector using the fully-qualified domain name:

adclient.cloud.connector: connector.mydomain.com:8080

Note that port 8080 is the default port for cloud connectors to use.

adclient.cloud.connector.refresh.interval

This configuration parameter specifies how frequently adclient contacts its cloud connector. The refresh task is a background process that searches for and selects the nearest available cloud connector to use for connectivity between the Active Directory forest and the cloud service. By default, the process runs every 8 hours. You can use this group policy to modify that interval.

For example, to set the cloud connector refresh interval to 12 hours:

adclient.cloud.connector.refresh.interval: 12

adclient.cloud.skip.cert.verification

Use this configuration parameter to skip verification of the security certificate for cloud connections.

By default, this parameter is set to false, and certificate verification is required.

For example:

adclient.cloud.skip.cert.verification: false

adclient.cloud.connector.subnet.preference.enabled

This configuration parameter specifies whether or not to enable the ability to select subnet preferences when the agent connects to a cloud connector.

By default, this option is not enabled (false), which means that the agent selects the cloud connector based on the closest Active Directory site.

If you enable this option, the agent selects the cloud connector located in the same subnet as the client within the current Active Directory site, then in different subnets within the current Active Directory site, and then in an Active Directory site that's different than the current one.

adclient.custom.attributes

This configuration parameter enables you to add Active Directory attributes to the Delinea authentication cache that are not retrieved by default. You can specify computer, user, or group attributes by using the appropriate form of the parameter:

adclient.custom.attributes.**computer**:attributeNameadclient.custom.attributes.**user**:attributeNameadclient.custom.attributes.**group**:attributeName

Separate multiple attributes by a space. For example, to specify the user attributes comment and company and the group attributes info and telephoneNumber:

adclient.custom.attributes.user: comment company
adclient.custom.attributes.group: info telephoneNumber

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

> **Note**: You can use the adquery --dump command to see a list of the attributes that adclient caches for users or groups.

adclient.deploy.report.update.interval

The adclient.deploy.report.update.interval configuration parameter specifies how often adclient updates the postalAddress attribute of computer objects. You specify a number to represent how many hours the update interval is.

By default, this parameter is 1, so that the postalAddress is updated every hour.

Within a computer object's postalAddress are the following sub-attributes:

- CurrentDC (the current domain controller)
- AdclientProcessElapseTime (how long since adclient started, in seconds)
- ComputerUpTime (how long the computer has been up and running, "xxx days, hh:mm" format)
- DCUpdateTime (the timestamp when the domain controller was last updated with this information, in Windows UTC time format)
- CurrentConnector (the current connector in use)
- ConnectorUpdateTime (the timestamp when the connector was last updated with this information, in Windows UTC time format)

For example, to set the interval to 8 hours:

adclient.deploy.report.update.interval:8

adclient.disk.check.free

This configuration parameter specifies the size, in KB, of disk space available for the local cache that should generate a warning message. The agent will check the availability of free disk space at the interval specified with the adclient.disk.check.interval parameter. If the disk space available at any interval is less than the value you set for the adclient.disk.check.free parameter, the agent stops saving data in the local cache and displays a warning message to indicate that you should free up disk space. At the next interval when the available disk space exceeds the size you set for this parameter, the agent resumes normal operation and saving data to its cache.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value must be an integer of zero or greater. A value of zero disables the display of a warning message about the available disk space. The default minimum of available disk space that triggers a warning message is 51200 KB. For example:

adclient.disk.check.free: 51200

> **Note**: Keep in mind that the value you set for this parameter can affect the recovery of a system. The agent will only resume saving data in its local cache if there is more disk space available than what you have specified to generate the warning. For example, if you have specified that the agent issue a warning when the available disk space falls to 51200 KB, there must be more than 51200 KB of disk space available for the agent to return to normal operation and write to the cache.

adclient.disk.check.interval

This configuration parameter specifies how frequently the agent should check the disk space available for the local cache. The default interval checks the available disk space every 5 minutes. If the disk space available at any interval is less than the value you set for the adclient.disk.check.free parameter, the agent will stop saving data in the local cache and will discard any new data until you free up enough disk space for it to resume saving data in the local cache.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value must be an integer zero or greater. A value of zero disables checking for available disk space. For example:

adclient.disk.check.interval: 5

> **Note**: Keep in mind that the value you set for this parameter can affect the recovery of a system after the agent stops writing data to the local cache. If you set this parameter to 0, the agent will not check for available disk space so it will not return to normal operation when disk space is freed up. In addition, setting this parameter to 0 or to a long interval may cause the agent to consume too much of the disk for its local cache and make the computer unstable or unusable. Therefore, you should keep the interval for checking the available disk space relatively short. Keeping the interval short will also help to ensure that the agent resumes normal operation and saving data to its cache at the earliest opportunity.

adclient.dns.cache.timeout

> **Note**: This parameter has been deprecated in favor of dns.cache.timeout.

This configuration parameter specifies the amount of time, in seconds, before a cached DNS response expires.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be a positive integer. For example, the default values expires a cached DNS response after 300 seconds:

adclient.dns.cache.timeout: 300

adclient.dns.cachingserver

Cache-only DNS servers cannot provide sufficient authoritative responses to DNS requests directly. They refer to authoritative servers, such as a Windows server and then relay the answer to the DNS request. This means, for some cache-only DNS servers, DNS requests, sent to cache-only DNS server, need to have recursive flag. For example dnscache. Other cache-only DNS servers do not require setting the recursive flag. See your DNS server specifications.

Examples of cache-only DNS servers, include:

- dnsmasq
- dnscache
- tinyDNS
- pdnsd
- unbound
- dnrd

The adclient.dns.cachingserver configuration parameter determines whether to send recursive DNS requests or not. When set to true, this parameter sends recursive DNS requests, as apposed to the standard non-recursive requests. Default is false.

To use a cache-only DNS server, in the centrifydc.conf file, set in the adclient.dns.cachingserver parameter to true. There might be some DNS functionality loss in adclient, when this parameter is set to true.

Parameter syntax:

adclient.dns.cachingserver: false

The default setting is false.

When set to true, recursive DNS requests are allowed.

Optionally, the install.sh script also provides an option for handling cache-only DNS servers with adcheck.

install.sh [--dns_cache]

This invokes adcheck with option -r and allows DNS recursion with cache-only DNS servers.

adclient.dumpcore

This configuration parameter specifies whether the agent should be allowed to dump core.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The value you set for this parameter overrides the default ulimit setting. The parameter value must be one of the following valid options:

- never to specify that the agent never dump core.
- once to specify that the agent should dump core only when there is no existing core dump file.
- always to specify that the agent dump core on every crash.

For example:

adclient.dumpcore: never

adclient.dynamic.dns.command

This configuration parameter specifies the parameters to use for the addns command if it is launched by adclient (see adclient.dynamic.dns.enabled).

For example, the default setting is:

adclient.dynamic.dns.command: /usr/sbin/addns -U -m

The -U option creates or updates the IP address and domain name pointer (PTR) records in the DNS server for the local computer.

The -m option uses the local computer account's Active Directory credentials to establish a security context with the DNS server.

> **Note**: UNIX computers that act as a gateway between networks may require you to specify the network adapter IP address in the addns command line. To ensure that you register the correct network address with the Active Directory DNS server, set adclient.dynamic.dns.command with a command line that uses the correct IP address for the network interface you want to use. (Ref: CS-20319c)

adclient.dynamic.dns.enabled

This configuration parameter specifies whether adclient will automatically launch the addns command. The addns command dynamically updates DNS records on an Active Directory-based DNS server in environments where the DHCP server cannot update DNS records automatically.

> **Note**: In most cases, you do not need to use the addns command if a host's IP address is managed by a Windows-based DNS server and the host obtains its IP address from a Windows-based DHCP server because the DHCP server updates the DNS record for the host automatically. If you are not using a Windows-based DNS server, you should use nsupdate or a similar command appropriate to the operating environment of the DNS server to update DNS records.

The addns command is launched with the parameters specified by the adclient.dynamic.dns.command configuration parameter.

The default value for Mac OS X computers is True

The default value for all other platforms is False.

adclient.dynamic.dns.refresh.interval

This configuration parameter specifies whether or not dynamic DNS records are periodically updated for this host and, if there are updates, the interval between updates. The parameter takes an integer of 0 or greater. If set to 0, it turns the DNS update feature off. If set to 1 or greater, it specifies the number of seconds between DNS update attempts.

The default value for this parameter is 0 (off).

adclient.excluded.domains

This configuration parameter specifies a list of domains to exclude from the list of trusted domains.

For example, you might want to exclude specific domains that are contained within a trusted forest. To specify domains to exclude, enter one or more domain names in dotted-name format, separated by spaces, For example:

adclient.excluded.domains: eng.acme.com qa.acme.com

The Delinea Agent does not probe any excluded domains and consequently ignores users from these domains.

The default value for this parameter is the empty list, which does not exclude any domains.

adclient.exit.on.incomplete.zone.hierarchy

This configuration parameter specifies whether or not the agent stops if it can't load the complete zone hierarchy.

Adclient loads the zone hierarchy during startup only. There might be some situations where not all zones can be loaded: for example, if this is the first time loading zones since running adjoin. Normally, adclient will run with an incomplete or incorrect zone hierarchy.

The parameter value must be a boolean value of true or false. For example:

adclient.exit.on.incomplete.zone.hierarchy: true

If this parameter is not defined in the configuration file, its default value is false.

adclient.fetch.object.count

This configuration parameter specifies the number of objects to obtain in a single LDAP request. You can use this parameter to optimize the number of objects to suit your environment.

The parameter value must be a positive integer. For example:

adclient.fetch.object.count: 5

With this parameter, there is a trade-off here between speed and memory usage as well as bandwidth and latency. As you increase the number of objects included in an LDAP request, you may improve the overall performance by decreasing the number of connections to Active Directory and reducing the overall demand on the server, but you increase the RAM used by the agent. If you decrease the number of objects included in an LDAP request, you may reduce overall performance because of the additional network traffic, but decrease the memory used by the agent.

On faster networks, you can safely retrieve a small number of objects. On slower networks or when retrieving information for large groups (for example, groups with more than 1000 users), you may want to increase the value for this parameter.

adclient.force.salt.lookup

This configuration parameter specifies that you want to force the Delinea Agent to look up the complete principal name, including the Kerberos realm used as the key salt, from the KDC. Setting this parameter to true is required if you remove arcfour-hmac-md5 from the list of encryption types specified for the adclient.krb5.tkt.encryption.types parameter and if you change a userPrincipalName attribute in Active Directory without changing the user's password.

The parameter value can be true or false. The default value is true. For example:

adclient.force.salt.lookup: false

> **Note**: When this parameter value is set to true it may cause "pre-authrequired" warning messages to appear in the Active Directory event log.

adclient.gc.locator.shortcut

If set to true, the adclient.gc.locator.shortcut configuration parameter specifies to use a shortcut to the global catalog on the domain controller, as long as the domain controller is also a valid global catalog server.

This process bypasses the usual DNS lookup for the global catalog. Setting this parameter to true can be useful in situations where the root domain is blocked, thereby also blocking the global catalog.

By default, the adclient.gc.locator.shortcut configuration parameter is set to false.

adclient.get.primarygroup.membership

This configuration parameter specifies whether zone users are added as members of a primary group.

By default, Active Directory users are not members of their primary Active Directory group. This parameter is used to control whether zone users are added as members of this primary group.

The parameter value can be true or false. If you set this parameter to true, zone users are added to the primary group. If you set this parameter to false, zone users are not added to the primary group.

Setting this parameter to true can have performance implications when you query the group (for example, by using the adquery group command) because adclient has to search for all Active Directory users who have has this group as their primary group.

The default value is false. For example:

adclient.get.primarygroup.membership: false

adclient.gmsa

Use this configuration parameter to specify the gMSA (Microsoft group Managed Service Accounts on Windows) that adclient will treat either as Active Directory or Unix user accounts.

adclient.gmsa: **<gmsa>**

When you specify a gMSA, it is recommended to not use a field or format that uses special characters. Special characters have to be formatted with escape sequences and they're likely to cause errors. For example, if you use CN (CommonName), DisplayName, UPN (UserPrincipalName), those are fine, but samAccountName$ can be problematic because of its use of the $ character.

For each gMSA that you specify, you also need to specify the location where the password is stored using the following format:

<gmsa>.krb5.keytab: **<file_path>**

Example:

adclient.gmsa: serviceXYZ

serviceXYZ.krb5.keytab: /some/secure/location/serviceXYZ.keytab

adclient.hash.allow

This configuration parameter specifies the list of users you want to allow to have their password hash stored. By default, the Delinea Agent stores a UNIX-style SHA256 hash of each user's password in the cache when the user is authenticated during login. Storing the password hash allows previously authenticated users to log on when the computer is disconnected from the network or Active Directory is unavailable.

Although the default behavior is to store the password hash for all users, you can use this parameter to explicitly list the users whose hashed passwords are stored in the cache. If you use this parameter, only the users you specify can log on when the computer is disconnected from the network or Active Directory is unavailable.

The parameter value can be one or more user names. If more than one name, the names can be separated by commas or spaces. For example:

adclient.hash.allow: jdoe bsmith

If no user names are specified or the parameter is not defined in the configuration file, the password hash is stored for all users.

adclient.hash.deny

This configuration parameter specifies the list of users you want to prevent from having their password hash stored. By default, the Delinea Agent stores a UNIX-style SHA256 hash of each user's password in the cache when the user is authenticated during login. Storing the password hash allows previously authenticated users to log on when the computer is disconnected from the network or Active Directory is unavailable.

Although the default behavior is to store the password hash for all users, you can use this parameter to explicitly list the users whose hashed passwords must not be stored in the cache. If you use this parameter, the users you specify cannot log on when the computer is disconnected from the network or Active Directory is unavailable. All other users are permitted to have their password hash stored and allowed to log on when the computer is disconnected from the network or Active Directory is unavailable.

The parameter value can be one or more user names. If more than one name, the names can be separated by commas or spaces. For example:

adclient.hash.deny: jdoe bsmith

If no user names are specified or the parameter is not defined in the configuration file, the password hash is stored for all users.

adclient.hash.expires

This configuration parameter specifies the number of days the password hash for any user can be stored in the cache before it expires.

The parameter value must be a positive integer. A value of zero (0) specifies that the password hash should never expire. For example, to set this parameter so that the password hash expires after 7 days:

adclient.hash.expires: 7

If this parameter is not defined in the configuration file, its default value is 0.

adclient.heartbeat.interval

The adclient.heartbeat.interval configuration parameter specifies how often (in minutes) adclient will send an INFO message to the UNIX syslog.

By default, this parameter is set to zero (0), which means that this task is disabled.

For example, to set the interval to 5 minutes:

adclient.heartbeat.interval:5

adclient.ignore.setgrpsrc

This configuration parameter specifies whether adclient accesses the ~/home/.setgrpsrc file when a user issues commands such as groups and id that return information about users' group membership.

Whenever it accesses the ~/home/.setgrpsrc file, adclient mounts the specified user's home directory. This behavior can be problematic because it makes it difficult for administrators to control mounts to file servers. For example, moving a file server requires removing all mounts, so before doing so, an administrator must scan for mounts that may have been created by running groups or id. In addition, the extra NFS mounts generated by this behavior reduce the number of reserved ports available on Red Hat systems and can slow system performance.

You can set this parameter's value to either true or false. When true, adclient ignores the ~/home/.setgrpsrc file when a user issues commands such as groups and id, and does *not* mount the specified user's home directory. When false, adclient does check the ~/home/.setgrpsrc file when a user issues commands such as groups and id, and does mount the specified user's home directory.

The default value is false.

To change the value to true, such that adclient does not check the ~/home/.setgrpsrc file and mount a user's home directory when checking for group membership, set this parameter's value to true in the configuration file:

adclient.ignore.setgrpsrc: true

After setting this parameter, you must run adreload to reload the configuration file.

> **Note**: Setting this parameter does not affect the use of the adsetgroups command by the current user to view or change group membership. For a logged on user, the home directory is already mounted.

adclient.included.domains

This configuration parameter specifies a list of domains to include as trusted domains.

If this parameter specifies any domains (that is, is not empty), only the specified domains and the joined domain will be trusted. For example, you might want to specify specific domains to trust in a trusted forest, rather than trust all domains in the forest.

> **Note**: Alternately, you may use the adclient.excluded.domains parameter to exclude from the trusted list specific domains that are contained within a trusted forest.

To specify domains to include, enter one or more domain names in dotted-name format, separated by spaces, For example:

adclient.included.domains: eng.acme.com qa.acme.com

In this example, the only trusted domains are eng.acme.com, qa.acme.com, and the domain to which the computer is joined.

The Delinea Agent does not probe any domains that are not on the list (except the joined domain) and consequently ignores users from other domains.

The default value for this parameter is the empty list, which has no effect on determining which domains to trust.

adclient.ipv4.port.range.low / high

You can use the adclient.ipv4.port.range.low and adclient.ipv4.port.range.high parameters to specify the low and high ends of the range of IP ports for adclient and adnisd to use. These parameters control the outbound connection port for both TCP and UDP connections.

By specifying an IP port range, you can then configure your firewall to allow traffic through that port range only.

The typical port number is between 1024 and 65535. Setting this parameter does require a restart of adclient.

adclient.iterate.private.groups

This configuration parameter specifies whether adclient iterates through users to look for private groups when searching for groups.

The adclient process may receive periodic requests from processes such as adnisd for all zone-enabled users and groups. adclient queries Active Directory for those users and groups. By default, adclient queries only for group objects when searching for groups. When dynamic private groups are turned on (using the configuration parameter auto.schema.private.group), it creates private groups with a single user where the primary GID of the private group is set to the user's UID. When dynamic private groups are present, adclient must search through user objects as well as group objects when looking for groups.

This parameter's value must be either true or false. When true, adclient iterates through user objects in Active Directory when searching for groups. When false, adclient does not iterate through user objects when searching for groups.

Note that iterating through users isn't noticeably slower than iterating only through groups until the numbers of users get into tens or hundreds of thousands. In these numbers, iteration may take more time.

If this parameter is not defined in the configuration file, its default value is initially false. Once adclient encounters a private group, it sets this parameter's value to true for the rest of adclient's process lifetime or until a user sets this parameter in the configuration file.

adclient.krb5.principal.lower

This configuration parameter converts the principal in Kerberos tickets to lowercase for compatibility with some third-party applications.

Set to true to change the principal in Kerberos tickets to lowercase.

Set to false to leave the case unchanged for the principal in Kerberos tickets.

The default value is false.

> **Note**: Use this parameter when a machine is joined to classic zones or hierarchical zones. When a machine is in Auto Zone, please use auto.schema.name.lower instead.

adclient.krb5.conf.domain_realm.anysite

This configuration parameter specifies whether or not to search for all domain controllers in a kerberized realm or just the domain controllers within the current, preferred site.

If this parameter is set to true, then the system will list all reachable domain controllers in a kerberized realm, regardless of which site they're located in.

If this parameter is set to false, then only the domain controller in the current, preferred site is listed.

For example:

adclient.krb5.conf.domain_realm.anysite: true

If this parameter is not defined in the configuration file, its default value is false.

adclient.ldap.packet.encrypt

This configuration parameter specifies the LDAP encryption policy you use. For example, if your organization has a security policy that does not allow unencrypted LDAP traffic, you can use this parameter to specify that all connections to Active Directory are encrypted. If your organization isn't concerned with the encryption of LDAP data and you want better performance, you can force all connections to be unencrypted.

The parameter value must be one of the following valid options:

- Allowed to allow both encrypted and unencrypted LDAP traffic.
- Disabled to prevent encrypted LDAP traffic.
- SignOnly to require all LDAP traffic to be signed to ensure packet integrity, but not encrypted.
- Required to require all LDAP traffic to be signed and encrypted. If you select this setting and a server doesn't support encryption, the connection will be refused.

For example:

adclient.ldap.packet.encrypt: Allowed

If this parameter is not defined in the configuration file, its default value is Allowed.

adclient.ldap.socket.timeout

This configuration parameter specifies the time, in seconds, the agent will wait for a socket connection timeout during LDAP binding.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer greater than zero. For example:

adclient.ldap.socket.timeout: 30

If this parameter is not defined in the configuration file, its default value is 5 seconds.

adclient.ldap.timeout

This configuration parameter specifies the time, in seconds, the agent will wait for a response from Active Directory before it gives up on the LDAP connection during fetch, update, or delete requests.

If a request is made to Active Directory and a response is not received within the number of seconds specified by this parameter, that request is retried once. For the second request, the agent will wait up to twice as long for a response. If the second request is not answered within that amount of time, the connection to that specific domain controller is considered disconnected. For example, if you set this parameter value to 7, the agent waits 7 seconds for a response from Active Directory to a fetch, update, or delete request. If the request isn't answered within 7 seconds, the agent retries the request once more and waits up to 14 seconds for a response before switching to disconnected mode. This results in a maximum elapsed time of 21 seconds for the agent to determine that Active Directory is unavailable.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. For example:

adclient.ldap.timeout: 10

If this parameter is not defined in the configuration file, its default value is 7 seconds.

adclient.ldap.timeout.search

This configuration parameter specifies the time, in seconds, the agent will wait for a response from Active Directory before it gives up on the LDAP connection during search requests.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. For example:

adclient.ldap.timeout: 10

If this parameter is not defined in the configuration file, its default value is double the value specified for the adclient.ldap.timeout parameter.

adclient.ldap.trust.enabled

This configuration parameter specifies whether you want to allow the agent to query trusted domains and forests for transitive trust information. The parameter's value can be true or false. If you set this parameter to true, the adclient process generates a krb5.conf that includes information from all trusted forests and can be used to authenticate cross-forest users to Kerberos applications. If you set this parameter to false, the agent does not query external trusted domains or forests for information.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be true or false. The default value is true. For example:

adclient.ldap.trust.enabled: true

> **Note**: Querying external trusted forests can take a significant amount of time if the other forests are blocked by firewalls. You may want to set this parameter to false if your trust relationships, network topology, or firewalls are not configured properly for access.

adclient.ldap.trust.timeout

This configuration parameter specifies the maximum number of seconds to wait for responses from external forests and trusted domains when attempting to determine trust relationships. If your trusted domains and forests are widely distributed, have slow or unreliable network connections, or are protected by firewalls, you may want to increase the value for this parameter to allow time for the agent to collect information from external domains and forests.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be a positive integer. For example, to time out if a response is not received in within two minutes, you can set this parameter value to 120:

adclient.ldap.trust.timeout: 120

The default value is 5 seconds. Before changing this setting, you should consider your network topology, the reliability of network connections, and the network bandwidth, speed, and latency for connecting to external forests and domains. If the value is set too low to consistently receive a response, you may be unable to search trusted external domains.

adclient.legacyzone.mfa.background.fetch.interval

This configuration parameter specifies how often the Delinea Agent updates the cache with the list of groups in classic zones and Auto Zones specified in the following parameters:

adclient.legacyzone.mfa.required.groups

This is a background process that updates the cache periodically according to the interval specified. Enabling this configuration parameter will improve multi-factor authentication performance.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy, or to temporarily override group policy.

For example, to set the parameter interval to 45 minutes:

adclient.legacyzone.mfa.background.fetch.interval: 45

To disable this process, set the parameter value to 0.

The default parameter value is 30 minutes.

adclient.legacyzone.mfa.cloudurl

This configuration parameter specifies which cloud instance URL the agent will accesses in order to implement multi-factor authentication for users in classic zones and Auto Zones.

If all of the cloud connectors in the Active Directory forest use a single cloud instance URL, the agent will use this instance for multi-factor authentication by default, and you do not have to specify the URL using this parameter. If you have access to more than one cloud instance URL, you must specify the URL you would like use for multi-factor authentication for the zone using this parameter or the group policy that modifies this parameter.

If you have access to more than one cloud instance URL, but do not specify which one should be used for multi-factor authentication, you will not be able to configure the zone to use multi-factor authentication.

In most cases, you set this configuration parameter using group policy. If you are manually setting this parameter, the parameter value must be a URL in the following format:

https://tenantid.domainfqdn:port/

For example:

adclient.legacyzone.mfa.cloudurl: https://abc0123.mydomain.com:8080/

adclient.legacyzone.mfa.enabled

This configuration parameter specifies whether multi-factor authentication is enabled for a classic zone or an Auto Zone. If you enable multi-factor authentication, users must be authenticated using more than one method. For example, users might be required to provide a password and respond to a text message or a phone call, or answer a security question. To enable multi-factor authentication, set this parameter to true. Set the parameter to false if multi-factor authentication is not required for any users.

In most cases, you set this configuration parameter using group policy. If you are manually setting this parameter, the parameter value must true or false. For example:

adclient.legacyzone.mfa.enable: true

If this parameter is not defined in the configuration file, its default value is false.

adclient.legacyzone.mfa.required.groups

This configuration parameter specifies a list of Active Directory groups in a classic zone or an Auto Zone that are required to use multi-factor authentication when logging on or using privileged commands. For example, if you want to require all members of the Qualtrak Admin group to use multi-factor authentication when they log on to computers that host sensitive information, you can add that group to this parameter.

Groups specified in this parameter must be security groups; distribution groups are not supported.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy, or to temporarily override group policy.

By default, multi-factor authentication is not enabled for groups in classic or Auto Zones.

You can separate each group by a space or a comma and you can use double quotes or escape characters to included spaces or special characters in group names. For example:

adclient.legacyzone.mfa.required.groups: centrify_users, “Qualtrak Admins”, Domain\ Users

Supported group name formats

You can specify groups by name or you can list the group names in a file in the following formats:

- SAM account name: sAMAccountName
- SAM account name of a group in a different domain: sAMAccountName@domain
- canonicalName: domain/container/cn

Specifying the parameter value in a separate file

To specify a file that contains a list of Active Directory group names, you can set the parameter value using the file: keyword and a file location. For example:

adclient.legacyzone.mfa.required.groups: file:/etc/centrifydc/legacy_user_groups_mfa.require

In the etc/centrifydc/legacy_user_groups_mfa.require file, you would type each group name on its own line using any of the supported name formats. For example:

server_users
“Qualtrak Admins”
Domain\ Users
group4@domain.com

adclient.legacyzone.mfa.required.users

This configuration parameter specifies a list of Active Directory users in a classic zone or an Auto Zone that are required to use multi-factor authentication when logging on or using privileged commands. For example, if you want to require Bill Hill to use multi-factor authentication to log on to a computer that hosts sensitive information, you can add her to this parameter.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy, or to temporarily override group policy.

By default, multi-factor authentication is not enabled for users in classic or Auto zones.

You can separate each user name by a space or a comma and you can use double quotes or escape characters to include spaces or special characters in user names.

For example, to specify that multi-factor authentication is required for users bill hill and tetsu.xu to log on to computers in an Auto Zone you would define the parameter value in the following way:

adclient.legacyzone.mfa.required.users: “bill.hill”, tetsu.xu@ajax.org

Supported user name formats

You can specify users by name or you can list the user names in a file in the following formats:

- SAM account name: sAMAccountName
- SAM account name of a user in a different domain: sAMAccountName@domain
- User Principal Name: name@domain
- Canonical Name: domain/container/cn
- Full DN: CN=commonName,...,DC=domain_component,DC=domain_component
- An asterisk (*), which includes all Active Directory users.

Specifying the parameter value in a separate file

To specify a file that contains a list of Active Directory user names, you can set the parameter value using the file: keyword and a file location. For example:

adclient.legacyzone.mfa.required.users: file:/etc/centrifydc/legacy_user_users_mfa.require

In the etc/centrifydc/legacy_user_users_mfa.require file, you would type each user name on its own line using any of the supported name formats. For example:

tetsu.xu
jane/ doe@ajax.org
Domain Users

adclient.legacyzone.mfa.rescue.users

This configuration parameter specifies a list of Active Directory users who can log on to computers in a classic zone or an Auto Zone when multi-factor authentication is required, but the agent cannot connect to the Delinea cloud service. You should specify at least one user account for this parameter to ensure that someone can access the computers in the event that multi-factor authentication is required but not available.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy, or to temporarily override group policy.

You can separate each user by a space or a comma and you can use double quotes or escape characters to include spaces or special characters in user names.

For example, to specify that user amy adams has the ability to log on to a computer in an Auto Zone if she is required but unable to authenticate using multi-factor authentication, you would define the parameter value in the following way:

adclient.legacyzone.mfa.rescue.users: amy.adams

Supported user name formats

You can specify users by name or you can list the user names in a file in the following formats:

- SAM account name: sAMAccountName
- SAM account name of a user in a different domain: sAMAccountName@domain
- User Principal Name: name@domain
- Canonical Name: domain/container/cn
- Full DN: CN=commonName,...,DC=domain_component,DC=domain_component
- An asterisk (*), which includes all Active Directory users.

Specifying the parameter value in a separate file

To specify a file that contains a list of Active Directory user names, you can set the parameter value using the file: keyword and a file location. For example:

adclient.legacyzone.mfa.rescue.users: file:/etc/centrifydc/legacy_user_users_mfa.rescue

In the etc/centrifydc/legacy_user_users_mfa.rescue file, you would type each user name on its own line using any of the supported name formats. For example:

tetsu.xu
amyadams
jane/ doe@ajax.org
user1@domain.com

adclient.legacyzone.mfa.tenantid

This configuration parameter specifies which Delinea Platform instance ID (also known as the tenant ID) the agent will access in order to implement multi-factor authentication for users in classic zones and Auto Zones.

By default, this parameter is empty and the agent uses the adclient.legacyzone.mfa.cloudurl parameter to locate Delinea Connectors.

For example:

adclient.legacyzone.mfa.tenantid: ABC1234

adclient.local.account.manage

This configuration parameter specifies whether the agent manages local user and local group accounts on computers where the agent is installed.

When this parameter is set to true:

- The agent gets the local user and local group profiles from the zone, and updates the local /etc/passwd and /etc/group files using the information defined in the zone.
- You can view and manage local users and groups in Access Manager as described in the *System Administrator's Guide for Linux and UNIX*.

The default value of this parameter is false, unless you upgraded from an Server Suite release in which local account management was enabled (in which case, it is set to true).

You can also set this configuration parameter using group policy.

adclient.local.account.manage.strict

This configuration parameter applies enforcement mode for local account management. The default is false and it is defined as not strict.

The following are sub-parameters for this configuration parameter:

- adclient.local.account.manage.strict.passwd: false
- adclient.local.account.manage.strict.group: false

When enabled in strict mode for user (except user with UID 0) any unmanaged local user's password entry is removed from /etc/passwd. If /etc/shadow file exist, shadow entry is removed as well. If user's extended attributes exist, those are removed.

When enabled in strict mode for group (except user with GID 0), any unmanaged local group entry is removed from /etc/group. If group's extended attributes exist, those are removed as well.

After switching to strict enforcement of local account management, switching back to non strict local account management does not restore the unmanaged local user or group.

adclient.local.account.notification.cli

This configuration parameter lets you define a command to process changes to local account profiles after the agent synchronizes local user and group profiles with profiles defined in a zone.

For example, if new local users are added, removed, or have their enabled/disabled status changed locally, the command that you define in this parameter is executed. Typical activities that this command might perform include setting the password for new or updated local accounts, or notifying password vault about changes to local accounts and defining actions to take regarding those accounts.

When this parameter is enabled, the agent invokes the defined command in another process and passes a comma separated UNIX name list to the command for further processing.

By default, this parameter's value is empty (that is, no command is defined). This parameter takes effect only when local account management is enable through group policy, or when the adclient.local.account.manage parameter is set to true.

You can also set this configuration parameter using group policy.

adclient.local.account.notification.cli.arg.length.max

This configuration parameter specifies the maximum argument length for the command that you define in the adclient.local.account.notification.cli parameter.

To determine the default argument length for your environment, execute getconf ARG_MAX.

After determining the default argument length for your environment, you can set this parameter to the same value to ensure that the agent's setting is consistent with the environment setting.

The default value of this parameter is 131072, which is 128KB. This parameter takes effect only when the adclient.local.account.manage parameter is set to true.

adclient.local.forest.altupn.lookup

This configuration parameter specifies whether or not to perform the local forest altupn lookup. The default is true. If you set this parameter to false, the local forest altupn lookup is skipped.

adclient.local.group.merge

This configuration parameter determines whether to merge local group membership from the /etc/group file into the zone group membership for groups that have the same name and GID. For example, if the Delinea Agent retrieves the membership list of kwan, emily, and sam for the group profile with the group name performx1 and GID 92531 from Active Directory and there is also a local group named performx1 with the GID 92531 with users wilson and jae, the merged group would include all five members (kwan,emily,sam,wilson,jae).

By default, this parameter value is set to false to prevent unexpected results. For example:

adclient.local.group.merge: false

Setting this parameter to true violates normal NSS behavior and, therefore, may have unexpected side effects. You should analyze your environment carefully before changing this parameter to true. If you determine you can safely merge local and Active Directory group profiles, you can uncomment this parameter and change its value.

> **Note**: If you set this parameter to true, you must run adreload to detect changes in the local group file.

adclient.logonhours.local.enforcement

This configuration parameter determines whether the agent and Active Directory both check for user logon hour restrictions, or whether only Active Directory checks for logon hour restrictions. This parameter is useful in cases where users are in time zones that are different from the time zone that the agent is in.

When this parameter is set to true, the agent and Active Directory both check for local logon hour restrictions. If the agent and user are in different time zones, and one time zone recognizes Daylight Savings Time while the other does not, the user may not be able to log on during permissible hours. (Ref: CS-33553 a)

When this parameter is set to false, only Active Directory checks for local hour restrictions, so there is no Daylight Savings Time conflict with the agent.

The default value for this parameter is true.

You should set this parameter to false if you have users that are not in the same time zone as the agent.

For example:

adclient.logonhours.local.enforcement: false

adclient.lookup.sites

This configuration parameter specifies a list of sites, and optionally a domain, to search for domain controllers and the global catalog if they are not found in the preferred site.

> **Note**: You can specify the preferred site in the adclient.preferred.site configuration parameter, and the preferred site is displayed when you execute the adinfo command.

The format for this parameter is:

adclient.lookup.sites: site1 [site2] [site3]...

The agent performs the following steps whenever it attempts to connect to a DC or GC:

1. Discover the preferred site.
2. From DNS, get a list of DCs or GCs in the preferred site and attempt to connect to each one until a connection is successful or the list is exhausted.
3. If unable to connect to a DC or GC in the preferred site, try to connect to a DC or GC in any site.

By using this configuration parameter, you can restrict step 3 to a specific set of alternate sites to search for DCs or GCs. Run Active Directory Sites and Services to see a list of sites for your environment. Sites are searched in the list order that you specify.

You can use any legal Active Directory site name when you set this parameter. For example:

adclient.lookup.sites USTEXAS USCALIFORNIA

You can optionally specify a domain suffix in this parameter, so that the site list is searched only in the domain that you specify. Use the following format to specify a domain:

adclient.lookup.sites.domainsuffix: site1 [site2] [site3]...

For example:

adclient.lookup.sites.example.com: USTEXAS USCALIFORNIA

If this configuration parameter is not configured, the agent tries to connect to a DC or GC in any site, as described in step 3 above. By default, this configuration parameter is not configured.

> **Note**: Do not add the preferred site to this list, as the preferred site will be searched anyway.

adclient.lrpc2.receive.timeout

This configuration parameter specifies how long, in seconds, the agent should wait to receive data coming from a client request.

In most cases, you set this configuration parameter using group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. For example:

adclient.lrpc2.receive.timeout: 30

If this parameter is not defined in the configuration file, its default value is 30 seconds.

adclient.lrpc2.send.timeout

This configuration parameter specifies the maximum number of seconds the agent should wait for reply data to be sent in response to a client request.

In most cases, you set this configuration parameter using group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. For example:

adclient.lrpc2.send.timeout: 30

If this parameter is not defined in the configuration file, its default value is 30 seconds.

adclient.next.closest.site.lookup.enabled

The adclient.next.closest.site.lookup.enabled configuration parameter specifies whether or not the Microsoft "Try Next Closest Site" is enabled. If it is enabled, the agent locates a domain controller according to the following order:

1. Tries to find a domain controller in the same site.
2. If there isn't a domain controller in the same site, the agent tries to find a domain controller in the next closest site.
   A site is closer if it has a lower site-link cost than another site with a higher site-link cost.
3. If no domain controller is available in the next closest site, the agent tries to find a domain controller in the domain.

By default, this parameter is set to true.

For example: adclient.next.closest.site.lookup.enabled:true.

adclient.nss.statistic.interval

The adclient.nss.statistic.interval configuration parameter specifies how much time passes before adclient updates the NSS query statistics information. The value represents the number of minutes.

By default, this parameter is set to 30 minutes.

For example: adclient.nss.statistic.interval:30.

adclient.ntlm.domains

This configuration parameter allows you to manually map Active Directory domain names to NTLM domains. This parameter is useful in cases where you need to use NTLM authentication because firewalls prevent Kerberos authentication and when firewall constraints prevent the automatic discovery of Active Directory to NTLM domain mapping.

You can specify the parameter's value as one or more domain name pairs, separated by a colon (:), or using the file: keyword and a file location. For example, you can set the parameter value using the format ActiveDirectory_DomainName:NTLM_DomainName to specify a list of domain name pairs:

adclient.ntlm.domains: AJAX.ORG:AJAX FIREFLY.COM:FIREFLY

To specify a file that contains a list of colon-separated values in the form of ActiveDirectory_DomainName:NTLM_DomainName, you can set the parameter value using the file: keyword and a file location:

adclient.ntlm.domains: file:/etc/centrifydc/domains.conf

Keep in mind that you must manually define how Active Directory domains map to NTML domains. If you define this information in a separate file, such as domains.conf, the file should consist of entries similar to the following:

AJAX.ORG:AJAX

FIREFLY.COM:FIREFLY

HR1.FIREFLY.COM:HR1

After you have manually defined the mapping of Active Directory domains to NTLM domains, you can use the pam.ntlm.auth.domains parameter to specify the list of domains that should use NTLM authentication instead of Kerberos authentication. For more information about defining the domains that should use Kerberos authentication, see pam.ntlm.auth.domains.

Alternatively, you can set the group policy, **Computer Configuration >Delinea Settings > DirectControl Settings > Network and Cache Settings > Specify AD to NTLM domain mappings**.

adclient.ntlm.separators

This configuration parameter specifies the separators that may be used between the domain name and the user name when NTLM format is used. For example, the following setting:

adclient.ntlm.separators: +/\\

allows any of the following formats (assuming a user joe in the acme.com domain):

acme.com+joe
acme.com/joe
acme.com\joe

> **Note**: The backslash character (\) can be problematic on some UNIX shells, in which case you may need to specify domain\\user.

The first character in the list is the one that adclient uses when generating NTLM names.

The default values are +/\\, with + being the adclient default.

adclient.one-way.x-forest.trust.force

Use this configuration parameter, adclient.one-way.x-forest.trust.force, to specify a list of two-way trusted domains that need to be treated as one-way trusted domains. This is useful when two-way trusted domains are not accessible from currently joining machine, for example, they are behind a firewall. Configuring this parameter allows x-forest users to authenticate onto the trusting machines.

The options are:

- An empty list (default)
- A list of forests or domains to be treated as one-way trusted.

  Specify a list of two-way trusted forests, and domains that have two-way external trust relationship with the local domain, to be treated by DirectControl Agent as one-way trusted forests or domains.

This parameter is likely to be used together with the configuration parameters, pam.ntlm.auth.domains and adclient.ntlm.domains, if these forests and domains are not accessible from the currently joining machine.

- Use the pam.ntlm.auth.domains parameter to specify the list of domains that use NTLM authentication instead of Kerberos authentication.
- Use the adclient.ntlm.domains parameter to map AD domains to NTLM domains.

Alternatively, you can set the group policy **Computer Configuration > Centrify Settings > DirectControl Settings > Adclient Settings > Force domains and forests to be one-way trusted**.

adclient.os.name

This configuration parameter specifies the name of the operating system for the local computer. This information is dynamically determined by the uname command and stored in the Active Directory computer object. The configuration parameter value can be manually overridden by defining a different value, if desired. If you change the value, however, you must restart adclient for the change to take effect.

For example, to set the parameter value manually to Linux:

adclient.os.name: Linux

adclient.os.version

This configuration parameter specifies the version of the operating system for the local computer. This information is dynamically determined by the uname command and stored in the Active Directory computer object. The configuration parameter value can be manually overridden by defining a different value, if desired. If you change the value, however, you must restart adclient for the change to take effect.

For example, to set the parameter value manually to 3.0-125:

adclient.os.version: 3.0-125

adclient.os.version.use.win7prefix

This configuration parameter specifies whether the operating system version prefix (6.1:) should be added automatically to the computer object's operatingSystemVersion attribute when a computer joins the domain. This prefix is used to indicate whether a computer supports FIPS encryption. The valid values are:

- 1 to add the prefix only when FIPS encryption is enabled.
- 2 to add the prefix regardless of FIPS encryption.

Depending on the version of the agent you have installed, the default value might be either of these values. The recommended setting for this parameter is 2. For example, to always add the prefix:

adclient.os.version.use.win7prefix: 2

adclient.paged.search.max

This configuration parameter specifies the maximum number of items included in each page of a paged LDAP search.

The parameter value must be a positive integer. For example:

adclient.paged.search.max: 100

If this parameter is not defined in the configuration file, its default value is 100 items.

Before changing this parameter setting, you should consider its impact on your environment. As you decrease the number of items included in each LDAP page, you increase the number of connections made to Active Directory and the added demand that increased traffic places on the server, but you decrease the RAM used by the agent. If you increase the number of items included in each LDAP page, you decrease the number of connections to Active Directory and reduce the overall demand on the server, but you increase the RAM used by the agent.

adclient.prefer.cache.validation

This configuration parameter instructs adclient to authenticate the user using the cached credentials first regardless of the current connectivity state with the Active Directory domain controller.

The parameter value is either true or false. The default is false; for example

adclient.prefer.cache.validation: false

Set this option to true to reduce traffic on slow networks. However, if the Active Directory credentials are not synchronized with the cached credentials, you run the risk of undesired side affects when the computer is online.

You can also set this configuration parameter using group policy.

adclient.preferred.login.domains

This configuration parameter enables you to specify the domain names against which to authenticate SAM account names. Use this parameter if your environment contains identical SAM account names on multiple domains, and you want to authenticate against a specific domain.

If you use this parameter, the adclient.cache.upn.index parameter must be set to true.

To use this parameter, type a space-separated list of domains as the parameter value. For example:

adclient.preferred.login.domains: demo1.acme.com demo2.acme.com

adclient.preferred.site

This configuration parameter enables you to identify a specific site to use to locate available domain controllers. By default, the adclient process uses CLDAP NETLOGON requests to automatically discover its site based on how sites are configured using Active Directory Sites and Services. This default behavior enables adclient to select domain controllers in the same site as preferred domain controllers because they are likely to provide the best performance and least replication delays. This configuration parameters enables you to override the site returned by Active Directory and use a specific site.

If you don't define a value for the parameter, adclient continues to discover sites based on how sites are configured using Active Directory Sites and Services.

If you want to define a specific site to use, you can use the following override options:

- You can specify a "universal" site override that does not include an Active Directory forest in the parameter name. The override applies to all Active Directory domains that do not have a forest-specific override.
- You can specify one or more "forest-specific" site overrides that includes the name of an Active Directory forest in the parameter names. This type of override limits the domain controllers to the domain controllers in the specified forest-specific site.

Forest-specific site overrides take precedence over universal site overrides. Depending on your requirements, you can use the site override options to override sites for all forests, specific forests, or a combination of the two.

The following is an example a "universal" site override that applies to all forests that do not have a forest specific override:

adclient.preferred.site: my-preferred-site

To specify a forest-specific site override, you specify the configuration parameter using the following format:

adclient.preferred.site.forest_name: my-forest-site

The following example illustrates how you would define the configuration parameters to use the USNORTH Active Directory site for all forests except the ocean-site forestspecific site.

adclient.preferred.site: USNORTH
adclient.preferred.site.ocean.net: ocean-site

adclient.prevalidate.allow.groups

This configuration parameter specifies the groups that are prevalidated to access the local UNIX computer using Active Directory credentials when the computer is offline even if users in the group have not previously logged onto the computer.

Under normal circumstances, only users who have previously logged on to a computer can be authenticated when the computer is disconnected from the network. For those users, authentication is based on the password hashes stored during the previous log-on. In some cases, however, you may require users who have never logged on to a particular computer to be authenticated when the computer is disconnected from the network. For example, you may have an administrative group that requires access to computers that are disconnected from the network but on which they have never previously logged in. To accommodate the users in that group, you can configure the group for prevalidation.

In most cases, you set this configuration parameter using group policy.

If you are manually setting this parameter, the parameter value must be a comma-separated list of UNIX group names. Enclose group names with spaces in double quotes, for example:

adclient.prevalidate.allow.groups: performx,qualtrak,"domain admins

Using this parameter with other prevalidation parameters

If you do not specify any groups for this parameter, then no group accounts are prevalidated to access the local computer. If you specify either the adclient.prevalidate.allow.users or adclient.prevalidate.allow.groups parameters, only those users and groups are prevalidated, with the exception of any users or groups specified by adclient.prevalidate.deny.users and adclient.prevalidate.deny.groups parameters. For example, to allow all users in the admins group to be prevalidated, except the users who are also members of the outsource group, you could set the adclient.prevalidate.allow.groups and adclient.prevalidate.deny.groups parameters like this:

adclient.prevalidate.allow.groups: admins
adclient.prevalidate.deny.groups: outsource

To allow prevalidation for all users in the zone without any exceptions, you can set the adclient.prevalidate.allow.groups parameter to all@zone. For example:

adclient.prevalidate.allow.groups: all@zone

For users or groups of users to be prevalidated, their accounts must be active accounts with permission to log on to the local computer and have a service principal name (SPN) set in the form of:

preval/username

Where preval is the service name specified by the adclient.prevalidate.service parameter and username is the user logon name, which can be either of the following:

- the name part of the user's UPN, if the domain part matches the user's domain
- samAccountName, if the UPN is empty or the UPN's domain part is different from the user's domain

Registering service principal names

To enable prevalidation for a user, you can use the Windows setspn.exe utility to add a service principal name for the user. For example, to register the service principal name for the user kai@arcade.com using preval as the service name, you could type a command similar to the following in a Windows Command Prompt window:

setspn -A preval/kai kai

This setspn command registers the SPN in Active Directory for the preval service for the specified user account, the Active Directory user kai. On the computers where this user is allowed to be prevalidated, the user can be authenticated without having logged on previously.

If you are allowing prevalidation for an administrative group, you must register a service principal name (SPN) for each member of the group. For example, if you are allowing prevalidation for the admins group and this group has five members, you would use the setspn.exe utility to register a Service Principal Name for each of those members.

Specifying the supported encryption types

All prevalidated users must have their Active Directory msDSSupportedEncryptionTypes attribute set to 0x18 (for just AES128 and AES256 support) or above to be able to login when disconnected. The parameter value represents the sum of the encryption types supported. Use the sum of the following encryption type values to determine the parameter value:

DES_CBC_CRC = 0x01
DES_CBC_MD5= 0x02
RC4_HMAC_MD5 = 0x4
AES128_CTS_HMAC_SHA1_96 = 0x08
AES256_CTS_HMAC_SHA1_96 = 0x10

For example, 0x1c indicates support for RC4_HMAC-MD5, AES128_CTS_HMAC_SHA1_96, and AES256_CTS_HMAC_SHA1_96.

Refreshing prevalidated credentials

To ensure their validity, the credentials for prevalidated users and groups are periodically retrieved from Active Directory. For example, the credentials are refreshed whenever you do the following:

- Reboot the local computer.
- Start or restart the adclient process.
- Run the adflush command to clear the cache.
- Changes a password from the local system.

The credentials are also periodically refreshed at the interval defined by the adclient.prevalidate.interval parameter to ensure that prevalidation will continue working after password changes.

adclient.prevalidate.allow.users

This configuration parameter specifies the users that are prevalidated to access the local UNIX computer using Active Directory credentials when the computer is offline even if they have not previously logged onto the computer.

Under normal circumstances, only users who have previously logged on to a computer can be authenticated when the computer is disconnected from the network. For those users, authentication is based on the password hashes stored during a previous log on. In some cases, however, you may require users who have never logged on to a particular computer to be authenticated when the computer is disconnected from the network. For example, you may have administrative users who require access to computers that are disconnected from the network but on which they have never previously logged in. To accommodate those users, you can configure them for prevalidation.

In most cases, you set this configuration parameter using group policy.

If you are manually setting this parameter, the parameter value must be a comma-separated list of UNIX user names. Enclose user names with spaces in double quotes, for example:

adclient.prevalidate.allow.users: jesse,rae,tai,"sp1 user"

sing this parameter with other prevalidation parameters

If you do not specify any users for this parameter, then no specific user accounts are prevalidated to access the local computer. If you specify either the adclient.prevalidate.allow.users or adclient.prevalidate.allow.groups parameters, only those users and groups are prevalidated, with the exception of any users or groups specified by adclient.prevalidate.deny.users and adclient.prevalidate.deny.groups parameters. For example, to allow all users in the admins group and the users ali, kai, and tanya who are not members of the admins group to be prevalidated, but prevent the users jorge and maurice from being prevalidated, you could set the allow and deny parameters like this:

adclient.prevalidate.allow.groups: admins
adclient.prevalidate.allow.users: ali,kai,tanya
adclient.prevalidate.deny.users: jorge,maurice

For users or groups to be prevalidated, their accounts must be active accounts with permission to log on to the local computer and have a Service Principal Name (SPN) set in the form of:

preval/username

Where preval is the service name specified by the adclient.prevalidate.service parameter and username is the user logon name, which can be either of the following:

- the name part of the user's UPN, if the domain part matches the user's domain
- samAccountName, if the UPN is empty or the UPN's domain part is different from the user's domain

Registering service principal names

To enable prevalidation for a user, you can use the Windows setspn.exe utility to add a service principal name for the user. For example, to register the Service Principal Name for the user kai@arcade.com using preval as the service name, you could type a command similar to the following in a Windows Command Prompt window:

setspn -A preval/kai kai

This setspn command registers the SPN in Active Directory for the preval service for the specified user account, the Active Directory user kai. On the computers where this user is allowed to be prevalidated, the user can be authenticated without having logged on previously.

Specifying the supported encryption types

All prevalidated users must have their Active Directory msDSSupportedEncryptionTypes attribute set to 0x18 (for just AES128 and AES256 support) or above to be able to login when disconnected. The parameter value represents the sum of the encryption types supported. Use the sum of the following encryption type values to determine the parameter value:

DES_CBC_CRC = 0x01
DES_CBC_MD5= 0x02
RC4_HMAC_MD5 = 0x4

AES128_CTS_HMAC_SHA1_96 = 0x08
AES256_CTS_HMAC_SHA1_96 = 0x10

For example, 0x1c indicates support for RC4_HMAC-MD5, AES128_CTS_HMAC_SHA1_96, and AES256_CTS_HMAC_SHA1_96.

Refreshing prevalidated credentials

To ensure their validity, the credentials for prevalidated users and groups are periodically retrieved from Active Directory. For example, the credentials are refreshed whenever you do the following:

- Reboot the local computer.
- Start or restart the adclient process.
- Run the adflush command to clear the cache.
- Changes a password from the local system.

The credentials are also periodically refreshed at the interval defined by the adclient.prevalidate.interval parameter to ensure that prevalidation will continue working after password changes.

adclient.prevalidate.deny.groups

This configuration parameter specifies the groups that cannot be prevalidated to access the local UNIX computer. If you allow any groups or users to be prevalidated, you can use this parameter to define exceptions for any groups that should be prevented from prevalidation. In most cases, you would use this parameter to exclude a subset of users that are in a member group of an allowed group. For example, to allow all users in the admins group to be prevalidated, except the users who are members of the outsource subgroup, you could set the adclient.prevalidate.allow.groups and adclient.prevalidate.deny.groups parameters like this:

adclient.prevalidate.allow.groups: admins
adclient.prevalidate.deny.groups: outsource

In most cases, you set this configuration parameter using group policy.

If you are manually setting this parameter, the parameter value must be a comma-separated list of UNIX group names. Enclose group names with spaces in double quotes, for example:

adclient.prevalidate.deny.groups: performx,qualtrak,"domain admins"

adclient.prevalidate.deny.users

This configuration parameter specifies the users that cannot be prevalidated to access the local UNIX computer. If you allow any groups or users to be prevalidated, you can use this parameter to define exceptions for any users who should be prevented from prevalidation. In most cases, you would use this parameter to exclude a subset of users that are members of an allowed group. For example, to allow all users in the admins group except the users jorge and maurice who are members of the admins group to be prevalidated, you could set the allow and deny parameters like this:

adclient.prevalidate.allow.groups: admins
adclient.prevalidate.deny.users: jorge,maurice

In most cases, you set this configuration parameter using group policy.

If you are manually setting this parameter, the parameter value must be a comma-separated list of UNIX user names. Enclose user names with spaces in double quotes, for example:

adclient.prevalidate.deny.users: jesse,rae,tai,"sp1 user"

adclient.prevalidate.interval

This configuration parameter specifies the interval, in hours, for refreshing the credentials for prevalidated user and group accounts. The credentials for prevalidated users must be periodically refreshed to ensure they are in sync with Active Directory and that prevalidation will continue working after password changes.

The parameter value should be a positive integer. A value of 0 disables all prevalidation of users. For example, to refresh the credentials for prevalidated users every 8 hours:

adclient.prevalidate.interval: 8

In most cases, you set this configuration parameter using group policy.

adclient.prevalidate.service

This configuration parameter specifies the service name to use for prevalidated users and groups. You must use the name you specify in this parameter when you register the Service Principal Name (SPN) for a user or group with the setspn.exe utility.

For example, to set the service name to preval:

adclient.prevalidate.service: preval

In most cases, you set this configuration parameter using group policy.

adclient.random.password.generate.try

This configuration parameter specifies the maximum number of times that the agent attempts to generate a random Active Directory password. Depending on the complexity requirements of your environment, you may need to set this value higher than the default to ensure an appropriately complex password is generated.

The default value is 10.

For example:

adclient.random.password.generate.try: 10

adclient.random.password.complexity.pattern

This configuration parameter specifies the complexity requirements for the generation of a random Active Directory password. Each complexity requirement is assigned a numeric value:

English uppercase characters (A through Z) = **1**

English lowercase characters (a through z) = **2**

Base 10 digits (0 through 9) = **4**

Special, non-alphanumeric characters (!, $, #, %, etc...) = **8**

The parameter value is the additive value assigned to the different complexity requirements you require of the password.

For example, if you wanted to require the generated password to include at least one uppercase letter, at least one lower case letter, and at least one digit, you would set the value at 1 + 2 + 4 = **7**; or:

adclient.random.password.complexity.pattern: 7

The default value for this configuration parameter is 7.

adclient.random.password.length.min

This configuration parameter specifies the minimum character length of a randomly generated Active Directory password.

The default value is 15 characters. For example:

adclient.random.password.length.min: 15

adclient.random.password.length.max

This configuration parameter specifies the maximum character length of a randomly generated Active Directory password.

The default value is 21 characters. For example:

adclient.random.password.length.max: 21

adclient.samba.sync

This configuration parameter specifies whether you want to have the Delinea Agent work in conjunction with Samba. The parameter value can be either true or false. You should set this parameter to false if you do not want any interaction between Delinea and Samba.

If you want the agent to work with Samba, you may need to make changes to your environment or configure additional settings. For Delinea and Samba to operate in the same environment, you need to do the following:

- Check that the samba.base.path configuration parameter specifies the correct path to the Samba binaries.
- Check that the samba.winbind.listen.path configuration parameter specifies the correct path to the Samba winbindd listen path.
- Check that Samba is configured for ADS security.
- Check that Samba belongs to the same REALM as the Delinea Agent.
- Verify that Samba and the Delinea Agent share an Active Directory computer object.
- Set the adclient.samba.sync configuration parameter to true.

For example:

adclient.samba.sync: true
samba.base.path: /usr
samba.windbindd.listen.path: /run/samba/windbindd

For more information about installing and configuring Samba to work with Delinea software, see the *Samba Integration Guide* available on the Delinea web site.

adclient.server.try.max

This configuration parameter specifies the maximum number of servers per domain the agent should attempt to connect to before going into disconnected mode. This parameter is used if the agent is unable to connect to it's primary domain controller to enable it to query DNS for a list of other domain controllers and try each server in the list up to the maximum number of servers you specify. For example, if you have a large number of replica domain controllers for a given domain, you may want to use this parameter to limit the number of servers for the agent to try in order to limit network traffic and improve performance.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer or 0. Setting the parameter value to 0 means that the agent attempts to connect to every server in the list until successful.

The default value is 0.

For example, to allow the agent to attempt to contact up to five domain controllers before going into disconnected mode:

adclient.server.try.max: 5

This parameter is ignored if you have defined a master domain controller for the zone to which the computer belongs because the computer only connects to that domain controller.

> **Note**: This parameter is deprecated for versions of adclient from 4.4.3 to 5.0.*x*. It is available in version 5.1.0 and later.

adclient.skip.inbound.trusts

This configuration parameter specifies whether you want adclient to skip probing inbound trusts for the domaininfomap.

Options are:

- false: If set to false, when building domaininfomap, both two-way and incoming trusts are probed. (Default)
- true: If set to true, when building domaininfomap, only two-way trusts are probed.

Set adclient.skip.inbound.trusts in the centrifydc.conf file. For example:

adclient.skip.inbound.trusts: true

To apply this configuration parameter while adclient is running, follow the recommended sequence:

1. Perform adreload.
2. Rebuild the domaininfomap. Choose a method:
    - Run adflush -t to rebuild the domaininfomap manually.
    - Wait for the next rebuild cycle from adclient.

adclient.skip.unused.outbound.trusts

This configuration parameter specifies whether you want to prevent the agent from sending network queries to outbound trust domains that do not have users in Delinea zones.

If you set this parameter to true, the agent will only send network queries to outbound trust domains that have users in Delinea zones.

If you are manually setting this parameter, the parameter value must be true or false. For example:

adclient.skip.unused.outbound.trusts: true

If the parameter is not explicitly defined in the configuration file or by group policy, its default value is false.

adclient.sntp.enabled

This configuration parameter specifies whether you want to use the Windows Time Service to keep the local system clock in sync with the domain the computer has joined.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be true or false. For example:

adclient.sntp.enabled: true

If the parameter is not explicitly defined in the configuration file or by group policy, its default value is true.

adclient.sntp.poll

This configuration parameter specifies the interval between SNTP clock updates when you are using the Windows Time Service to keep the local system clock in sync with the domain the computer has joined.

In most cases, you set the polling interval using group policy.

If you are manually setting this parameter, the value is the base 2 logarithm of the time in seconds. For example, setting this parameter value to 6 sets the update interval to 64 seconds (26), and a value of 15 sets the update interval to 32768 seconds, or 9.1 hours. For example, to set the update interval to 256 seconds:

adclient.sntp.poll: 8

If the parameter is not explicitly defined in the configuration file or by group policy, its default value is 15 (9.1 hours).

dclient.tcp.connect.timeout

This parameter specifies the timeout of all TCP port probing used in adclient. This parameter default is ten seconds.

adclient.udp.timeout

This configuration parameter specifies the maximum number of seconds to allow to complete UDP binding. The agent will attempt to bind twice. If the first bind request is not complete within the period specified by this parameter, the agent sends a second request with a timeout period that is double the setting of this parameter. If both bind requests fail to complete within the allotted time, the agent sets its status to disconnected.

For example, if you set this parameter to 10 seconds and the bind request is not complete within 10 seconds, the agent sends a second bind request and waits a maximum of 20 seconds for the bind to complete before assuming the computer is disconnected from the network or Active Directory is unavailable.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be a positive integer. The default value for this parameter is 15 seconds. For example:

adclient.udp.timeout: 15

adclient.update.os.interval

This configuration parameter specifies the number of seconds to wait before updating operating system information after adclient starts in disconnected mode.

If you are manually setting this parameter, the parameter value should be a positive integer. The default value for this parameter is 30 seconds. For example:

adclient.update.os.interval: 30

adclient.use.all.cpus

This configuration parameter specifies whether to use all processors on a multi-processor system. The parameter value can be true or false. Setting this parameter to true allows the adclient process to use additional CPUs on a computer to process background tasks in parallel when logging on and can significantly decrease the startup time in sites with a large number of domain controllers.

For example:

adclient.use.all.cpus: true

If the parameter is not explicitly defined in the configuration file, its default value is true. If you change this parameter, you must restart the adclient process for the change take effect.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

adclient.use.tokengroups

This configuration parameter specifies whether the agent should attempt to use the Active Directory tokenGroups attribute on the user object to determine a user's group membership when the Kerberos Privilege Attribute Certificate (PAC) is not available.

In most cases, allowing the agent to use this attribute when necessary is desirable and the default setting for this attribute is true. For example:

adclient.use.tokengroups: true

In mixed-mode domains with both Windows 2000 and Windows 2003 computers, however, the tokenGroups attribute can include Universal groups in the user's group membership list. If you have Universal groups in mixed-mode domains and want to prevent those Universal groups from being included in the user's group membership list, you can set this parameter value to false. Setting this value to false will force the agent to use a slower mechanism for finding group membership instead of the tokenGroups attribute and can result in a slower user login experience, but the results will be consistent with what would be retrieved using the Kerberos PAC.

adclient.user.computers

This configuration parameter specifies whether to allow computer principals to be treated as users with login capabilities when added to the zone. The parameter value can be true or false. The configuration parameter must be set to true to allow Distributed File System support for Samba. Setting this to true may impact performance, however, in domains with heavily-loaded domain controllers or large user and computer populations.

For example:

adclient.user.computers: true

adclient.user.lookup.cn

This configuration parameter specifies whether you want to allow users to be found by their common name (cn) attribute. The parameter value can be true or false.

By default, you can allow users to login using their UNIX profile name, Active Directory displayName, or Active Directory cn attribute. However, allowing users to log on using these additional attributes can require the agent to perform multiple searches to locate a user account in Active Directory. In environments with domain controllers under heavy load or with large user populations, searching Active Directory multiple times might negatively impact performance.

If you want to prevent the agent from attempting to access to user information by the common name, you can set this configuration parameter to false. For example:

adclient.user.lookup.cn: false

The default value for Mac OS X computers is false.

The default parameter value for all other platforms is true.

adclient.user.lookup.display

This configuration parameter specifies whether you want to allow users to be found by their display name (displayName) attribute. The parameter value can be true or false.

By default, you can allow users to login using their UNIX profile name, Active Directory displayName, or Active Directory cn attribute. However, allowing users to log on using these additional attributes can require the agent to perform multiple searches to locate a user account in Active Directory. In environments with domain controllers under heavy load or with large user populations, searching Active Directory multiple times might negatively impact performance.

If you want to prevent the agent from attempting to access to user information by the displayName attribute, you can set this configuration parameter to false. For example:

adclient.user.lookup.display: false

The default value for Mac OS X computers is false.

The default parameter value for all other platforms is true.

adclient.user.name.max.exceed.disallow

When this parameter is set to false, users with a login name longer than eight characters are permitted to log in. When set to true, users with a login name longer than eight characters are not permitted to log in. This configuration parameter applies to local account management in that a local user with rights in addition to the platform-specified limit is not be added to the system.

adclient.version2.compatible

This configuration parameter is used to maintain compatibility with zones created using version 2.0 or 3.0 of Access Manager. The default is true for zones created using the 2.0 or 3.0 console. The default is false for zones created with the 4.x or later console.

If you do not have users or groups that were given access to UNIX computers using an older console, having this parameter set to false results in a performance improvement on Windows 2000 domain controllers. Setting the value to true decreases login performance on Windows 2000 domain controllers.

For example:

adclient.version2.compatible: false

If you have users or groups that were given access to UNIX computers using an older console, you may want to upgrade those users and groups to take advantage of the performance improvements.

To determine whether you have zones and users from an older version of Delinea software , open the console and click **Analyze**. You can then review the Analysis Results and attempt to update user properties, if needed.

adclient.watch.cpu.utilization.info.threshold

When adclient's CPU usage is higher than the value specified by this parameter, cdcwatch will write a message to the INFO log.

The default value is -1, which means that no threshold is set.

If the adclient.use.all.cpus parameter is set to true, the CPU utilization will be divided by the total number of CPUs.

For example, the setting below sets the info CPU utilization threshold to 10%:

adclient.watch.cpu.utilization.info.threshold: 10

adclient.watch.cpu.utilization.warning.threshold

When adclient's CPU usage is higher than the value specified by this parameter, cdcwatch will write a message to the WARN log.

The default value is -1, which means that no threshold is set.

If the adclient.use.all.cpus parameter is set to true, the CPU utilization will be divided by the total number of CPUs.

For example, the setting below sets the warn CPU utilization threshold to 20%:

adclient.watch.cpu.utilization.warn.threshold: 20

adclient.watch.slow.lookup.info.threshold

This configuration parameter specifies the adclient threshold (in milliseconds) for the time spent on a complete NSS request. When a NSS request exceeds this threshold, the NSS module writes information to a message to the INFO log file.

By default, this parameter is set to -1, which means that there is no threshold.

For example, the example below specifies that information goes into the INFO log if the request exceeds 20 milliseconds:

```
adclient.watch.slow.lookup.info.threshold:20
```

adclient.watch.slow.lookup.info.threshold.group

This configuration parameter specifies the adclient threshold (in milliseconds) for the time spent on a complete NSS request categorized by group. When a NSS request exceeds this threshold for the user category, the NSS module writes to a message to the INFO log file.

The group category indicates the following NSS calls: getgrnam* getgrgid*

The nss.watch.slow.lookup.info.threshold.group setting overrides that set by the adclient.watch.slow.lookup.info.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: adclient.watch.slow.lookup.info.threshold.group:35.

adclient.watch.slow.lookup.info.threshold.user

This configuration parameter specifies the adclient threshold (in milliseconds) for the time spent on a complete NSS request categorized by user. When a NSS request exceeds this threshold for the user category, the NSS module writes to a message to the INFO log file.

The user category indicates the following NSS calls: getpwnam* getpwuid* getgrouplist

The nss.watch.slow.lookup.info.threshold.user setting overrides that set by the adclient.watch.slow.lookup.info.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: adclient.watch.slow.lookup.info.threshold.user:15.

adclient.watch.slow.lookup.warn.threshold

This configuration parameter specifies the adclient threshold (in milliseconds) for the time spent on a complete NSS request. When a NSS request exceeds this threshold, the NSS module writes information to a WARN log file.

By default, this parameter is set to -1, which means that there is no threshold.

For example: adclient.watch.slow.lookup.warn.threshold:20.

adclient.watch.slow.lookup.warn.threshold.group

This configuration parameter specifies the adclient threshold (in milliseconds) for the time spent on a complete NSS request for the group category. When a NSS request exceeds this threshold, the NSS module writes information to a WARN log file.

The group category indicates the following NSS calls: getgrnam* getgrgid*

The nss.watch.slow.lookup.info.threshold.user setting overrides that set by the adclient.watch.slow.lookup.warn.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: adclient.watch.slow.lookup.warn.threshold.group:30.

adclient.watch.slow.lookup.warn.threshold.user

This configuration parameter specifies the adclient threshold (in milliseconds) for the time spent on a complete NSS request for the user category. When a NSS request exceeds this threshold, the NSS module writes information to a WARN log file.

The user category indicates the following NSS calls: getpwnam* getpwuid* getgrouplist

The nss.watch.slow.lookup.info.threshold.user setting overrides that set by the adclient.watch.slow.lookup.warn.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: adclient.watch.slow.lookup.warn.threshold.user:25.

adclient.zone.group.count

This configuration parameter provides a calculated value that controls the method used to determine group membership for users. If the calculated value for this parameter is larger than the number of groups a user is a member of, the Delinea Agent iterates over the user's group list to determine group membership. For example, if there are more group profiles defined for the zone than the number of groups the user is a member of, the agent uses the user's group list to determine group membership.

If the calculated value for this parameter is smaller than the typical number of groups a user is a member of, the agent iterates over all of the group profiles enabled for the zone to determine group membership. For example, if there are fewer group profiles defined for the zone than the number of groups the user is a member of, the agent uses the zone's group profile list to determine group membership.

Switching between the two methods for determining group membership may improve the log-in time for some users. You can use this configuration parameter to override the calculated value. For example, if you always want to use the user's group membership list rather than iterate through the list of group profiles defined for the zone, you can set this parameter to an artificially high value. If you always want to use the zone's group profile list rather iterate through the user's group membership list, you can set this parameter to an artificially low value.

For example:

adclient.zone.group.count: 6

addns.tcp.timeout

This configuration parameter controls the amount of time, in seconds, that the addns process waits for responses to its requests for updates.

The parameter value can be any positive integer. The default value of this parameter is 7 seconds:

addns.tcp.timeout: 7

addns.wait.time

This configuration parameter controls the amount of time, in seconds (default 60), that the addns process should wait for another addns process to exit before proceeding.

Because the addns process enables dynamic updates to DNS records on Active Directory-based DNS servers, it includes a mechanism to prevent two addns processes from running at the same time. This configuration parameter value controls how long a addns command request will wait for another addns process to complete its execution before proceeding.

The parameter value can be any positive integer. For example, to set the wait time to 45 seconds:

addns.wait.time: 45

adjust.offset

This configuration parameter specifies the time difference between the local host and the domain that should trigger an adjustment to the local computer's time-of-day setting.

The default parameter value is 5 minutes. With this setting, if the time difference between the local host and the domain controller is less than 5 minutes, the adclient process calls the adjtime function to update the local host time to match the Active Directory domain. If the offset between the local computer and the domain controller is more than 5 minutes, adclient process calls the settimeofday function to update local computer's time.

The parameter value can be any positive integer. For example:

adjust.offset.time: 5

audittrail.audited.command.with.args

This configuration parameter controls whether audit trails for audited command include command parameters. If set to true, the command name and parameters are displayed in the audit trail. If set to false, just the command name is displayed in the audit trail.

The default value is false.

audittrail.Centrify_Suite.Trusted_Path.machinecred.skipda

This configuration parameter specifies whether trusted path audit trail events are sent to the audit installation database in situations where the user is using a computer credential. The default value is true (that is, events are not sent to the audit database). For example:

audittrail.Centrify_Suite.Trusted_Path.machinecred.skipda: true

Events are sent to the system log even if this parameter is set to true.

audittrail.targets

This configuration parameter specifies the target for audit trail information. Possible settings are:

1. Audit information is not sent.
2. Audit information is sent to DirectAudit. This capability is supported by DirectAudit version 3.2 and later.
3. Audit information is sent to the local logging facility (syslog on UNIX systems, Windows event log on Windows systems).
4. Audit information is sent to both DirectAudit and the local logging facility.

If DirectAudit 3.2 or later is installed, the default value is 3 (local logging facility and DirectAudit). Otherwise, the default value is 2 (local logging facility only). For example:

audittrail.targets: 3

In most cases, you set this configuration parameter using group policy.

audittrail.

This parameter specifies whether to override the global audit trail targets. If this parameter is set, the system uses the targets value in the current component; otherwise, the system uses the global configured value.

There are two target settings that can be overridden:

- Whether the system sends the audit trail information to DirectAudit or not
- Whether the system sends the audit trail information to the local logging system or not. On UNIX systems, the local logging system is syslog and on Windows systems it's the Windows event log.

For this setting, you specify a single numeric value to represent where the system will send the audit trail information. (Setting one value to signify two settings is called a bit mask.) The possible settings are as follows:

0	No	No	There is no override to the audit trail target of the current component. The system uses the global audit trail target value.
1	Yes	No	The system overrides just the audit trail target for DirectAudit. This capability is supported by DirectAuditversion 3.2 and later.
2	No	Yes	The system overrides just the audit trail target for the local logging system. If you're using a DirectAuditversion prior to version 3.2, this is the default setting.
3	Yes	Yes	The system overrides both the audit trail targets for DirectAuditand the local logging system. If you're using DirectAuditversion 3.2 or later, this is the default setting.

In most cases, you set this configuration by way of group policy.

audittrail.

This parameter specifies how to calculate where the system sends the audit trail information for a particular component if you have also set the corresponding audittrail.<product>.<component>.overrides parameter.

There are two kinds of audit trail targets that can be overridden:

- Whether to enable the DirectAudit audit trail target for the component or not
- Whether to enable the local logging system audit trail target or not. On UNIX systems, the local logging system is syslog and on Windows systems it's the Windows event log.

For this setting, you specify a single numeric value to represent which audit trail targets are enabled for the component. The possible settings are as follows:

-1	No	No	Use the global audit trail target value. This is the default setting.
0	No	No	Neither the DirectAudit nor the local logging target are enabled for the component.
1	Yes	No	Enable only the DirectAudit audit trail target for the component. This capability is supported by DirectAudit version 3.2 and later.
2	No	Yes	Enable only the local logging audit trail target for the component.
3	Yes	Yes	Enable the audit trail targets for both DirectAudit and the local logging system.

In most cases, you set this configuration parameter using the **Computer Configuration > Policies > Administrative Templates Policy definitions (ADMX files) > Delinea Audit Trail Settings** group policy.

The system calculates the final audit trail targets for a component based on the following information:

- If audittrail.<product>.<component>.overrides is not specified, the system uses the global audit trail target value
- If audittrail.<product>.<component>.overrides is specified, for each target (DirectAudit and local logging), whether the audit trail information will be sent to this target is determined by the following:
    - If audittrail.<product>.<component>.targets is set to -1, or the setting is not overridden in audittrail.<product>.<component>.overrides, the system uses the global audit trail target value
    - If the target is overridden by audittrail.<product>.<component>.overrides and enabled by audittrail.<product>.<component>.targets, the system sends the audit trail information to this target

capi.cache.enabled

This configuration parameter specifies whether the in-process memory CAPI cache is enabled. If the cache is enabled, lookups are sent to the cache before being sent to adclient.

- If the object is found in the cache and has a valid TTL (as configured in the capi.cache.negative.ttl and capi.cache.ttl parameters), the object is returned.
- If the TTL has expired, the lookup is sent to adclient.
- If the object is not found in the cache, the lookup is sent to adclient.

If the object is found in adclient, the cache entry (that is, the key-value and acquisition time stamp) is updated.

If you set this parameter to true, the CAPI cache is enabled.

The following attributes are supported:

- Sid
- _UnixName
- sAMAccountName
- userPrincipalName
- Guid
- Unixid

The default value of this parameter is false. For example:

capi.cache.enabled: false

capi.cache.hash.table.size

This configuration parameter specifies the number of hash map buckets that are allocated if the in-memory CAPI SID cache is enabled through the capi.cache.enabled parameter.

The default value of this parameter is 769. For example:

capi.cache.hash.table.size: 769

capi.cache.log.interval

This configuration parameter specifies the number of seconds between log events that dump information about the performance of the in-memory CAPI SID cache. This parameter takes effect only if the in-memory CAPI SID cache is enabled through the capi.cache.enabled parameter.

- Summary information such as hits, misses, and so on are DEBUG level events.
- Details about the bucket distributions are TRACE level events.

Setting this parameter to 0 disables all hash map log dumps pertaining to the in-memory CAPI SID cache.

The default value of this parameter is 0. For example:

capi.cache.log.interval: 0

capi.cache.max.objects

This configuration parameter specifies the maximum number of objects that are kept in the in-memory CAPI SID cache if the cache is enabled through the capi.cache.enabled parameter. If the number is exceeded, cached objects that are the oldest are replaced with new objects.

The default value of this parameter is ten thousand objects. For example:

capi.cache.max.objects: 10000

capi.cache.negative.ttl

This configuration parameter specifies the number of seconds that a negative cached SID object remains in the in-memory CAPI SID cache before it is refreshed. This parameter takes effect only if the in-memory CAPI SID cache is enabled through the capi.cache.enabled parameter.

The default value of this parameter is 3,600 seconds. For example:

capi.cache.negative.ttl: 3600

capi.cache.ttl

This configuration parameter specifies the number of seconds that a positive cached SID object remains in the in-memory CAPI SID cache before it is refreshed. This parameter takes effect only if the in-memory CAPI SID cache is enabled through the capi.cache.enabled parameter.

The default value of this parameter is 3,600 seconds. For example:

capi.cache.ttl: 3600

db2.implement.pam.ignore.users

Starting with Delinea DB2 agent 5.2.3, this configuration parameter specifies whether the Delinea DB2 agent checks pam.ignore.users for a list of users to authenticate locally, without first attempting to authenticate those users in Active Directory.

By default, the Delinea DB2 agent authenticates users in Active Directory first. If users do not exist in Active Directory, the Delinea DB2 agent then authenticates users locally.

If you set this parameter to true, users defined in the pam.ignore.users list are authenticated locally only (that is, no attempt is made to authenticate them in Active Directory first). For example:

db2.implement.pam.ignore.users: true

To specify that an Active Directory authentication attempt should be made for all users, and that local authentication be attempted only for users not in Active Directory, set this parameter to false:

db2.implement.pam.ignore.users: false

If you change the setting of this parameter, restart the DB2 instance to activate the new setting.

db2.user.zone_enabled

This configuration parameter specifies whether to constrain the DB2 agent authentication to zone enabled Active Directory users only. By default, the DB2 agent authenticates all Active Directory users even if the Active Directory user is not in the zone. To constrain the authentication to zone enabled Active Directory users only, add the following parameter to the /etc/centrifydc/centrifydc.conf file:

db2.user.zone_enabled.db2_instance_name: true

In this parameter, db2_instance_name is the name of the DB2 instance (for example, db2inst1).

After you add this parameter, restart the DB2 instance to pick up the new setting.

db2.userpass.username.lower

This configuration parameter specifies whether the DB2 userpass plugin is used to convert the user name to lowercase before attempting authentication (true) or not make the conversion (false, the default).

dc.dead.cache.refresh

This configuration parameter specifies how long, in seconds, to keep in cache the fact that a domain controller is dead.

The default value is 60 seconds. For example:

dc.dead.cache.refresh: 60

dc.live.cache.refresh

This configuration parameter specifies how long, in seconds, to keep in cache the fact that a domain controller is alive.

The default value is 3600 seconds (one hour). For example:

dc.live.cache.refresh: 3600

dc.penalty.time

This configuration parameter controls how long a domain controller that has failed is considered less preferable to the other domain controllers in the forest that either have not failed or have failed farther back in time.

The default setting is 3600 seconds (one hour).

This parameter helps you avoid domain controllers that appear to be alive, but when they are selected exhibit higher level failures such as crashed, tombstoned, or dead netlogon service.

The value specifies the number of seconds. For example, the following specifies two hours:

dc.penalty.time: 7200

dns.alive.resweep.interval

This configuration parameter specifies the amount of time to wait, when DNS is active, before triggering a DNS server sweep to see if any DNS servers are responding faster than the current one.

The adclient process periodically checks in the background to see if any DNS servers are available with faster response times than the currently active DNS server. This parameter, dns.alive.resweep.interval, determines how often this check, or sweep, occurs. The default is one hour (3600 seconds).

For the sweep, the dns.sweep.pattern parameter determines the probe pattern that is used to find a live DNS server; that is, it sets:

- The protocol to use (TCP or UDP)
- The amount of time to wait for a response.

The DNS server that responds fastest is selected, is cached in memory, and is used for all DNS requests until one of the following occurs:

- It stops responding.
- A new server sweep discovers a faster DNS server and replaces it.
- Adclient is stopped and restarted.

If the newly selected server is different than the previous server, the kset.dns.server file is updated with the address of the newly selected server.

The default value for this parameter is 3600 seconds.

The parameter value must be a positive integer. For example:

dns.alive.resweep.interval: 3600

dns.block

This configuration parameter specifies the list of domain controllers that should be filtered out when resolving the domain controller to contact through DNS. This configuration parameter enables you to prevent the adclient process from attempting to contact domain controllers that are known to be inaccessible, for example, because they reside behind a firewall, or domain controllers that shouldn't be contacted, for example, because of their physical location or because they are no longer valid domain controllers for the site.

The parameter value can be one or more fully-qualified domain controller server names. If you are specifying more than one domain controller name, the names can be separated by commas or spaces. For example:

dns.block: ginger.ajax.org,salt.ajax.org,nc1.sea.ajax.org

In most cases, you set this configuration parameter using group policy.

If you don't specify a value for this parameter, access is not blocked for any domain controllers.

Delinea

dns.cache.negative

This configuration parameter specifies whether to cache negative DNS responses. A negative response is returned when a DNS server is not found. By storing a negative result in the cache, the agent does not look for a server that was previously not found.

Set this parameter to true to cache negative DNS responses or false to not cache negative responses. When this parameter is false, the system attempts to respond to all requests. A cached response expires after the amount of time specified by the dns.cache.timeout parameter (default value is 300 seconds).

The default is true; for example:

dns.cache.negative:true

dns.cache.timeout

This configuration parameter specifies the amount of time, in seconds, before a cached DNS response expires.

The default value is 300 seconds.

Specify a positive integer; for example:

dns.cache.timeout:300

dns.dc.domain_name

This configuration parameter can be used to specify the domain controller host names if your DNS is not configured to use Active Directory. In most cases, you should not use this configuration parameter in a production environment because Active Directory automatically updates DNS with fail-over and replica servers optimized for the Active Directory site configuration. This configuration parameter is used primarily for configuring an evaluation environment when the DNS server is on a UNIX computer and can't provide the _ldap service records.

To set this parameter, the Active Directory domain name must be specified as the last portion of the configuration parameter name, and the parameter value is the host name of the domain controller. For example, if the Active Directory domain is acme.com and the domain controller for that domain is coyote.acme.com:

dns.dc.acme.com: coyote.acme.com

> **Note**: You must specify the name of the domain controller, not its IP address. In addition, the domain controller name must be resolvable using either DNS or in the local /etc/hosts file. Therefore, you must add entries to the local /etc/hosts for each domain controller you want to use if you are not using DNS or if the DNS server cannot locate your domain controllers.

To specify multiple servers for a domain, use a space to separate the domain controller server names. For example:

dns.dc.lab.test: dc1.lab.test dc2.lab.test

dns.dead.resweep.interval

This configuration parameter specifies the amount of time to wait, in seconds, when DNS is down, before triggering a DNS server sweep to see if any DNS servers are alive.

If the current DNS server times out on a request (does not respond within the interval and number of retries specified by dns.tcp.timeout or dns.udp.timeouts), the agent attempts to acquire another DNS server. If it fails to find a live server, DNS is considered down and the agent waits for the interval specified by this parameter, dns.dead.resweep.interval, before attempting to acquire another DNS server.

The default is 60 seconds.

The parameter value must be a positive integer. For example:

dns.dead.resweep.interval: 60

dns.gc.domain_name

This configuration parameter can be used to specify the domain controller used as the global catalog if your DNS is not configured to use Active Directory. In most cases, you do not use this configuration parameter in a production environment. This configuration parameter is used primarily for configuring an evaluation environment when the DNS server is on a UNIX computer and can't provide the _gc service records.

To set this parameter, the Active Directory domain name must be specified as the last portion of the configuration parameter name, and the parameter value is the host name of the domain controller. For example, if the Active Directory domain is arcade.com and the domain controller for that domain is fire.arcade.com:

dns.gc.arcade.com: fire.arcade.com

> **Note**: You must specify the name of the domain controller, not its IP address. In addition, the domain controller name must be resolvable using either DNS or in the local /etc/hosts file. Therefore, you must add entries to the local /etc/hosts for each domain controller you want to use if you are not using DNS or if the DNS server cannot locate your domain controllers.

To specify multiple servers for a domain, use a space to separate the domain controller server names. For example:

dns.dc.lab.test: dc1.lab.test dc2.lab.test

dns.query.all.servers

This configuration parameter specifies whether the DNS subsystem should try all live DNS servers until either the lookup succeeds or the list is exhausted.

When this parameter is set to true (the default), DNS tries each server on the list of all DNS servers in /etc/resolv.conf (or dns.servers) one-by-one until either the list is exhausted or the object is resolved. By default, this configuration parameter is configured as true:

dns.query.all.servers: true

When this parameter is set to false, the DNS subsystem stops querying after the first "record not found" response.

This feature is useful in environments that contain multiple DNS servers that do not all hold the same records (and are therefore not all aware of the same AD domains).

dns.servers

This configuration parameter specifies a space separated list of IP addresses of DNS servers that are used to resolve domain controller names. Set this parameter if a computer running Mac OS X 10.7 or later cannot connect to a domain controller through a VPN connection.

Starting with Mac OS X 10.7, /etc/resolv.conf is no longer used for domain controller name resolution. Therefore, some VPN programs no longer update DNS server information in /etc/resolv.conf when signing on. On computers running Mac OS X 10.7 and later, this can result in the computer not being able to connect to a domain controller through a VPN if the DNS server locations are not specified as described here.

The following example shows the setting of two IP addresses for DNS servers:

dns.servers: 111.22.333.4 555.66.777.8

dns.sort

This configuration parameter determines whether to sort by speed during background sweeps or to pick the first DNS server that responds.

> **Note**: This parameter only applies to *background* sweeps. During *initial* sweeps, the first server to respond is always chosen, regardless of how dns.sort is set.

Generally, the first server in the list (as specified in /etc/resolv.conf or by the dns.servers parameter) responds first. However, if a server was previously chosen, and is still configured in /var/centrify/kset.dns.server, it is always tried first regardless of how dns.sort is set.

This parameter is useful if you have multiple DNS servers specified in /etc/resolv.conf, some of which are not compatible with DirectControl. If you list the DirectControl-compatible first, and set this parameter to false, an incompatible server will never be chosen unless the compatible servers are unavailable.

Set the value of this parameter to true to sort by speed. Set the value to false to select the first server that responds.

The default is to sort by speed (true); for example:

dns.sort: true

dns.sweep.pattern

This configuration parameter specifies a comma separated list to use when scanning for live DNS servers. For each item in the list, specify the type of scan (t for TCP; u for UDP) and the number of seconds to wait for a response.

For example, the following pattern:

dns.sweep.pattern: t1, u1,u2

specifies:

- A TCP scan with a one second wait for a response
- A UDP scan with a one second wait for a response
- Another UDP scan with a two second wait for a response

For each value, all known DNS servers are queried. If the kset.dns.server file exists, the server it defines is queried first.

For initial DNS server acquisition, the first DNS server to respond is chosen, at which point the sweep is terminated. Since the kset.dns.server file is queried first, the server it defines is most likely to be selected. Otherwise, the first server specified in /etc/resolv.conf responds first

For background DNS sweeps, the entire sweep pattern is completed, at which point the fastest server to respond is chosen and the sweep is terminated.

If a new DNS server is selected, the kset.dns.server file is updated with its address.

If the end of the list is reached and no DNS servers respond, DNS is considered down. A new sweep begins after the period of time specified by the dns.dead.resweep.interval.

The default pattern for Linux and Unix is:

dns.sweep.pattern: t1,u1,u1,t2,u2,u2

The default pattern for OS X is:

dns.sweep.pattern: u1,u1

dns.tcp.timeout

This configuration parameter specifies the amount of time, in seconds, to wait before re-sending a TCP request, when there is no response from the current DNS server. If the current server does not respond to this request, it is considered down, which triggers a sweep to acquire a new server as specified by the dns.sweep.pattern parameter. The new server becomes the selected server (it is cached in memory and its address is put in kset.dns.server), and it attempts to handle the DNS request.

The default value is 1 second. You may specify only one TCP retry.

Specify a positive integer; for example:

dns.tcp.timeout: 1

This parameter specifies the timeout values for TCP requests. Use dns.udp.timeouts to specify timeout values for UDP requests.

dns.udp.timeouts

This configuration parameter specifies the number of times to re-send a UDP request, and the number of seconds to wait for each, when there is no response from the current DNS server to a UDP request. Specify a comma separated list of values, up to three entries. If the current server does not respond to any of the requests, it is considered down, which triggers a sweep to acquire a new server as specified by the dns.sweep.pattern parameter. The new server becomes the selected server (it is cached in memory and its address is put in kset.dns.server), and it attempts to handle the DNS request.

The default value on Linux and Unix is three retries of 1, 2, and 4 seconds, respectively.

The default value on OS X is 1 second.

Specify a positive integer; for example:

dns.udp.timeouts: 1, 2, 4

This parameter specifies the timeout values for UDP requests. Use dns.tcp.timeout to specify timeout values for TCP requests.

domain.dead.cache.refresh

This configuration parameter specifies how long, in seconds, to keep in cache the fact that a domain is dead (that is, the domain does not contain any live domain controllers).

The default value is 60 seconds. For example:

domain.dead.cache.refresh: 60

domain.live.cache.refresh

This configuration parameter specifies how long, in seconds, to keep in cache the fact that a domain is alive (that is, the domain contains at least one live domain controller).

The default value is 3600 seconds (one hour). For example:

domain.live.cache.refresh: 3600

fips.mode.enable

This configuration parameter indicates whether FIPS 140-2 compliant algorithms are used in the authentication protocols. FIPS 140-2 compliance is available for authentication using Kerberos and NTLM with the following caveats and requirements:

- FIPS mode is available on Centrify Agents version 5.0.2 or later but only on specific UNIX platforms. See the NIST validation entry for the Centrify FIPS mode for the current list of supported platforms.
- Domain controllers must be at Windows 2008 domain functional level or greater. If the domain controller domain functional level does not meet the required level, adclient does not start and returns an error message.
- FIPS 140-2 compliance uses only the following algorithms: AES128-CTS or AES256-CTS encryption types, RSA for public key generation, DSA for digital signature generation and SHA1, SHA256, SHA384 or SHA512 for hashing.
- Inter-realm keys for the AES128-CTS or AES256-CTS encryption types must be established between any trusted domains to enable Active Directory users to log on to a joined computer (see the ksetup utility to set up inter-realm keys).
- FIPS mode only allows NTLM pass-through authentication over SChannel; FIPS mode is not available for 'NTLM authentication over SMB or SMB2.

In most cases, you set this configuration parameter using group policy. As long as the UNIX computer is running a supported platform, this policy sets the fips.mode.enable configuration parameter to true and restarts adclient.

> **Note**: The administrator must explicitly add the centrifydc_fips.xml or centrifydc_fips.adm group policy template on the domain controller to set fips.mode.enable. The template needs to be imported to just one domain controller in a forest.

If you are manually setting this parameter, the parameter value must be true or false. For example, to enable FIPS 140-2 compliant algorithms, set the following:

fips.mode.enable: true

The default is false.

After manually setting this parameter, you must restart adclient to enable FIPS mode.

There are several restrictions and rules governing the use of FIPS mode. For example:

- Prevalidated groups and users that use FIPS mode to log in when disconnected must have their Active Directory msDS-SupportedEncryptionTypes attribute set to at least 0x18 (prevalidated login for users in FIPS mode requires Kerberos AES 128- or 256-bit encryption).See adclient.prevalidate.allow.groups and adclient.prevalidate.allow.users for the full explanation of the Active Directory msDS-SupportedEncryptionTypes options.
- The value of the corresponding Windows policy (**Computer Configuration > Policies > Windows Settings > Security Settings > Local Policies > Security Option > System Cryptography: Use FIPS compliant algorithms for encryption, hashing, and signing**) has no effect on the Windows, Linux, UNIX, or Mac OS X computers managed through the Delinea Agent. You must use the configuration parameter or the Delinea policy to enable FIPS mode.

The following configuration parameters affect adclient operation when FIPS mode is enabled:

- adclient.krb5.keytab.clean.nonfips.enctypes: Set this configuration parameter to true to have adclient scan the computer's keytab file and remove all non-AES encryption keys for service principal names (SPNs) during startup. (The default is false.)
- adclient.krb5.permitted.encryption.types: If you include the arcfour-hmac-md5 encryption type in this configuration parameter AND adclient.krb5.extra_addresses is true, adclient generates the MD4 hash for the computer password and saves it in the keytab file.

For more information about using FIPS encryption, see the *Administrator's Guide for Linux and UNIX*.

log

This configuration parameter defines the level of detail written to the agent log file. The log level works as a filter to define the type of information you are interested in and ensure that only the messages that meet the criteria are written to the log. For example, if you want to see warning and error messages but not informational messages, you can change the log level from INFO to WARN.

The parameter value can be FATAL, ERROR, WARN, INFO, DEBUG, or TRACE. For example:

log: WARN

You can also modify this configuration parameter to define a different logging level for specific library messages. For example:

log: info
log.pam: debug

logger.facility.adclient

This configuration parameter defines the syslog facility to use for logging general adclient activity. You can specify separate syslog facilities for logging general adclient messages, adclient auditing messages, and adnisd messages. This parameter's value can be any valid syslog facility. For example, you can set this parameter to log messages to auth, authpriv, daemon, security, or localn facilities.

The default facility is auth. For example:

logger.facility.adclient: auth

> **Note**: You can specify other process names for logging, or use an asterisk (*) to specify the default facility to use for all agent processes. For example, you can specify logger.facility.*: auth in the configuration file to direct all agent processes send messages to the auth facility of syslog.

logger.facility.adclient.audit

This configuration parameter defines the syslog facility to use for logging adclient auditing messages. You can specify separate syslog facilities for logging general adclient messages, adclient auditing messages, and adnisd messages. This parameter's value can be any valid syslog facility. For example, you can set this parameter to log messages to auth, authpriv, daemon, security, or localn facilities.

The default facility is auth. For example:

logger.facility.adclient.audit: auth

If this parameter is not defined in the configuration file, the audit messages are logged in the facility defined for the logger.facility.adclient parameter.

logger.facility.diag

This configuration parameter defines the syslog facility to use for logging diagnostic messages. Diagnostic messages are intended to help you troubleshoot operations and trace all of the LDAP, Kerberos, NTLM and RPC messages that are generated for the following tasks:

- adjoin operations
- adleave operations
- lookup object operations
- authentication operations
- log on operations
- password change

This parameter enables you to specify a separate syslog facilities for logging diagnostic from the facility used to log general adclient messages, adclient auditing messages, and adnisd messages. This parameter's value can be any valid syslog facility. For example, you can set this parameter to log messages to auth, authpriv, daemon, security, or localn facilities.

The default facility is auth. For example:

logger.facility.diag: auth

You should note that diagnostic messages are only logged if you enable logging with the addebug command. If the parameter is not defined in the configuration file, the messages are logged in the default facility or the facility defined for the logger.facility.adclient parameter.

logger.memory.bufsize

This configuration parameter specifies the default size for the in-memory circular log buffer. The in-memory circular log buffer is only enabled if the adclient watchdog process is forced to restart the adclient process. The default parameter value is 128K. You should not manually set this parameter value in the configuration file unless you are instructed to make the setting by Centrify Support.

logger.memory.enabled

This configuration parameter specifies whether the in-memory circular log buffer is enabled. The in-memory log buffer should only be enabled automatically if the adclient watchdog process is forced to restart the adclient process. Therefore, the default value for this parameter is false. You should not manually set this parameter value in the configuration file unless you are instructed to make the setting by Delinea Support.

logger.memory.log

This configuration parameter specifies the default log level for the in-memory circular log buffer. The in-memory circular log buffer is only enabled if the adclient watchdog process is forced to restart the adclient process. The default value for this parameter is DEBUG. You should not manually set this parameter value in the configuration file unless you are instructed to make the setting by Delinea Support.

logger.queue.size

This configuration parameter controls the maximum number of messages that may be queued before they are sent to syslog. The messages in the queue are sent to syslog asynchronously. During normal operation, if the number of messages in the queue reaches the value set for this parameter, no new messages are added until the number of messages in the queue decreases below the maximum number you have specified.

Each message consumes about 100 bytes of storage in the message queue.

If the logging level is set to DEBUG, this parameter's value is automatically multiplied by a factor of 4 to allow additional messages to be logged.

The parameter value must be a positive integer. For example:

log.queue.size: 256

> **Note**: Setting this parameter to zero (0) disables the message queue, and causes all log messages to be written to the syslog facility synchronously. In most cases, disabling the message queue degrades system performance, and in extreme cases, may cause a dead lock with the syslog daemon during log rotations. Therefore, Delinea recommends that you never set this parameter value to 0.

If this parameter is not defined in the configuration file, its default value is 256 KB.

If you change this parameter, you must restart the agent, adclient, for the change take effect.

lrpc.connect.timeout

This configuration parameter specifies the number of seconds the NSS or PAM service should wait for a response from the agent during an initial connection attempt. If the initial connection to adclient takes longer than specified by this parameter, the service will time out and terminate the attempt to connect. In most cases, there's no need to modify this parameter.

The parameter value must be a positive integer. For example:

lrpc.connect.timeout: 5

If this parameter is not defined in the configuration file, its default value is 5 seconds.

lrpc.session.timeout

This configuration parameter specifies the maximum number of seconds to keep the adclient connection open to respond to contextdependent requests, such as pwgetent or lsgroup requests. Lowering this value reduces the chance of a multi-threaded program being affected by an adclient restart, but may cause slow context-dependent commands to fail to return results because the session times out before the command completes its operation. Increasing the value of this parameter reduces the overhead of re-establishing a connection for multiple requests.

For example:

ldap.session.timeout: 30

lrpc.timeout

This configuration parameter specifies the number of seconds the local client should wait for a response from the agent before ending a requested operation.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be an integer greater than zero. The following example sets the inactive client timeout to 5 minutes:

lrpc.timeout: 300

If this parameter is not defined in the configuration file, its default value is 5 minutes.

Although in some environments increasing or decreasing the value of this parameter may be beneficial to optimize agent operations and Active Directory for your network topology, you should take care in changing this setting. For example, in most cases, you should not decrease this value because of the potential problems it may cause when transferring data. If you set this value too low and have a slow connection or a large amount of data to be transferred, the local client may end the operation prematurely and prevent the data transfer from completing successfully.

secedit.system.access.lockout.allowofflinelogin

This configuration parameter specifies whether to allow users to log in when the user account is locked out and the computer is not connected to Active Directory. The default value is false (that is, users cannot log in). For example:

secedit.system.access.lockout.allowofflinelogin: false

You can also set this parameter using group policy.

queueable.random.delay.interval

This configuration parameter specifies a delay, in minutes, for activities to stagger background tasks. Once defined, scheduling of those background tasks calculates a random period of time within the interval and adds the same time to the delay of those tasks. If you change the interval setting, however, the period of time is recalculated. The default setting is 0 and no delay.

Customizing Kerberos-Related Configuration Parameters

This chapter describes the configuration parameters that affect the operation of Kerberos-related activity on the local host computer.

adclient.dc.switch.update.krb5.conf

The adclient.dc.switch.update.krb5.conf configuration parameter specifies that adclient updates the krb5.conf file immediately with the current domain controller when adclient switches the domain controller, such as in failover situations. This can be helpful in situations where third party applications use the krb5.conf file to locate the domain controllers that adclient uses.

By default, this parameter is true.

If this parameter is set to false, then adclient does not update the krb5.conf file with the updated domain controller information immediately but at the next update interval that's specified by the krb5.config.update parameter.

adclient.krb5.allow_weak_crypto

This configuration parameter specifies whether to allow weak encryption types for Kerberos authentication. When this parameter is set to false, then weak encryption types (as noted in the Encryption types section of the kdc.conf file) are filtered out of the following lists:

- default_tgs_enctypes
- default_tkt_enctypes
- permitted_enctypes.

The default value for this parameter is false, which may cause authentication failures in existing Kerberos infrastructures that do not support strong crypto. Users in affected environments should set this parameter to true until their infrastructure adopts stronger ciphers.

By default, this parameter is set to false.

adclient.krb5.allow_weak_crypto: false

adclient.krb5.autoedit

This configuration parameter specifies whether the agent should automatically update the Kerberos configuration file with new information, such as domains and IP addresses, as the agent discovers this information.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be true or false. In most cases, this parameter should be set to true to allow the agent to maintain the configuration files automatically. For example:

adclient.krb5.autoedit: true

If this parameter is not defined in the configuration file, its default value is true.

adclient.krb5.cache.renewal.service.accounts

This configuration parameter specifies which service accounts are renewed automatically.

The parameter value can be a comma-separated list of service accounts, or the name of a file that contains the list of service accounts.

For example, if you specify a file that contains the service accounts using the file: keyword and a file location:

adclient.krb5.cache.renewal.service.accounts: file:/etc/centrifydc/service_accts.lst

The default value of this parameter is file:/etc/centrifydc/service_accts.lst as shown in the example.

adclient.krb5.ccache.dir

The adclient.krb5.ccache.dir parameter specifies the directory where Kerberos ccache files are stored when krb5.cache.type is FILE.

This is useful when kerberos applications in docker containers use the kerberos cache files. This parameter, in conjunction with adclient.krb5.ccache.dir.secure.usable.check enables volume bind mapping so that kerberos cache files in the host OS are available to the docker containers.

Default is empty string.

- If adclient.krb5.ccache.dir is not configured or set to default empty string, then:

  The system default ccache directory is used. If a default_ccache_name exists in the [libdefaults] stanza of krb5.conf, it is removed.

- If adclient.krb5.ccache.dir is specified, AND adclient.krb5.ccache.dir.secure.usable.check is false, then:

  The specified directory is used for the default_ccache_name in the [libdefaults] stanza of krb5.conf.

- If adclient.krb5.ccache.dir is specified, AND adclient.krb5.ccache.dir.secure.usable.check is true, BUT the kerberos cache directory is neither secure nor usable, then:

  The system default ccache directory is used. If a default_ccache_name exists in the [libdefaults] stanza of krb5.conf, it is removed.

- If adclient.krb5.ccache.dir is specified, AND adclient.krb5.ccache.dir.secure.usable.check is true, AND the kerberos cache directory is secure and usable then:

  The specified directory is used for the default_ccache_name in the [libdefaults] stanza of krb5.conf.

  > **Note**: When the ccache type is KCM, the klist lists KCM caches and file ccaches under the system default ccache directory. If the ccache directory is changed when ccache type is FILE, the newly created file ccaches might not be listed when ccache type is switched to KCM.

adclient.krb5.ccache.dir.secure.usable.check

The adclient.krb5.ccache.dir.secure.usable.check parameter specifies whether to perform a secure and usability check on a configured Kerberos ccache directory. Only used when adclient.krb5.ccache.dir set. Options are:

- false — Default. No action taken.
- true — If adclient.krb5.ccache.dir is configured, then adclient.krb5.ccache.dir.secure.usable.check checks the specified directory.

For the kerberos cache directory to be secure and usable it must meet the following criteria:

- the directory exists
- the directory is not a symlink
- the directory is root owned
- the directory is world writable and has sticky bit set

adclient.krb5.conf.file.custom

This configuration parameter enables the merging of custom krb5.conf entries into the original krb5.conf file. To use this parameter, you specify the keyword file: and the absolute path to a syntactically valid custom krb5.conf file.

For example:

adclient.krb5.conf.file.custom: file:/etc/custom.conf

By default, this parameter is not enabled, and the default value is an empty string.

After you enable this parameter, when krb5.conf is regenerated the additional directives in the custom krb5.conf file are merged into the original krb5.conf file, and conflicting lines are discarded.

The required format of the custom krb5.conf file is as follows:

```
[libdefaults]
keyword1 = value1
keyword2 = value2
[domain_realm]
domain = realm
hostname = realm
[realms]
REALM1 =
REALM2 =
[appdefaults]
to-be-copied-as-is
[capaths]
to-be-copied-as-is
[dbdefaults]
to-be-copied-as-is
[dbmodules]
to-be-copied-as-is
[kadmin]
to-be-copied-as-is
[kdc]
to-be-copied-as-is
[kdcdefaults]
to-be-copied-as-is
[logging]
to-be-copied-as-is
[login]
to-be-copied-as-is
[otp]
to-be-copied-as-is
[password_quality]
to-be-copied-as-is
[plugins]
to-be-copied-as-is
```

When you use this parameter, the following actions take place when the krb5.conf file is regenerated:

- For the directives [libdefaults], [domain_realm], and [realms], the new keyword = value pairs from the custom krb5.conf file are added to the corresponding directive in the original krb5.conf file.
- New realms from the custom krb5.conf file are added under [realms] in the original krb5.conf file.
- If a keyword already exists in the original krb5.conf file, the keyword entry from the custom file is discarded.
- For the additional sections [appdefaults], [capaths], [dbdefaults], [dbmodules], [kaadmin], [kdc], [kdcdefaults], [logging], [login], [otp], and [plugins], the entire section from the custom file is added directly into the original krb5.conf file, and any existing entries in those sections in the original

krb5.conf file are overwritten.

- Warning messages are displayed in the log for every conflict.

  Note: The specified custom krb5.conf file must be owned by root.

  Note: To use this parameter in a Mac environment, the configuration parameter adclient.krb5.autoedit must be set to true.

adclient.krb5.conf.domain_realm.anysite

This configuration parameter specifies whether or not to search for all domain controllers in a kerberized realm or just the domain controllers within the current, preferred site.

If this parameter is set to true, then the system will list all reachable domain controllers in a kerberized realm, regardless of which site they're located in.

If this parameter is set to false, then only the domain controller in the current, preferred site is listed.

For example:

adclient.krb5.conf.domain_realm.anysite: true

If this parameter is not defined in the configuration file, its default value is false.

adclient.krb5.extra_addresses

This configuration parameter specifies 0, 1, or more IP addresses. The Delinea Agent adds these IP addresses to the host computer's own IP address when it makes a Kerberos authentication request that includes IP addresses. Multiple addresses accommodate authentication in a network that uses NAT.

The IP addresses in this parameter should be in dotted quad form, each address separated from the next by a comma. As an example:

adclient.krb5.extra_addresses: 192.68.21.189,192.68.35.2

adds two IP addresses to the host machine's own IP address.

Note that this configuration parameter sets the Kerberos configuration parameter extra_addresses in krb5.conf.

This parameter has no effect unless adclient.krb5.use.addresses is set to true.

If this parameter is not defined in the configuration file, its default value is empty, which defines no extra IP addresses.

adclient.krb5.keytab.clean.nonfips.enctypes

This configuration parameter specifies whether adclient scans the computer's keytab file and removes any non-AES encryption keys for service principal names during startup. The default is false.

Use this configuration parameter to remove the keys for encryption types that are not supported when you enable FIPS mode (see fips.mode.enable). To remove the non-AES keys, enter the following

adclient.krb5.keytab.clean.nonfips.enctypes: true

> **Note**: If you specify arcfour-hmac-md5 in the adclient.krb5.permitted.encryption.types configuration parameter, the MD4 hash of the computer password is generated and saved in the keytab file.

adclient.krb5.keytab.entries

This configuration parameter specifies the number of entries that the agent maintains in the Kerberos key table for a service principal.

This value determines the number of key versions that are kept per service principal. Its value must be a positive integer. For example:

adclient.krb5.keytab.entries: 3

If this parameter is not defined in the configuration file, its default value is 3 entries.

adclient.krb5.keytab.use.all.etypes

By default, the Delinea Agent for *NIX does not always generate krb5.keytab entries of all supported encryption types. Instead, the agent generates krb5.keytab entries of the types specified in the adclient.krb5.tkt.encryption.types and adclient.krb5.permitted.encryption.types parameters.

The adclient.krb5.keytab.use.all.etypes parameter specifies whether or not to write the krb5.keytab entries of all encryption types, regardless of the adclient.krb5.tkt.encryption.types and adclient.krb5.permitted.encryption.types setting.

By default, the adclient.krb5.keytab.use.all.etypes parameter is set to false.

If you set the adclient.krb5.keytab.use.all.etypes parameter to true, then the agent generates all types of keys in the krb5.keytab file, regardless of the adclient.krb5.tkt.encryption.types and adclient.krb5.permitted.encryption.types setting.

adclient.krb5.password.change.hook

The adclient.krb5.password.change.hook configuration parameter specifies the full path of the command that adclient runs after adclient has changed a password and updated the krb5.keytab file.

By default, this parameter is empty.

Here's an example where you would use this parameter:

You want adclient to maintain an external keytab file for the ftp service that a non-privileged user "ftp" runs. You need adclient to copy only the ftp keys from the machine keytab file to a keytab file that only the "ftp" user can read. You can create a script, for example, /var/ftp/create_keytab_for_ftp.sh to help you to do this:

#/bin/sh

/usr/sbin/adkeytab -o -P ftp -K /var/ftp/ftp.keytab -b /etc/krb5.keytab && \

chown ftp:ftp /var/ftp/ftp.keytab

And then you add the script to the adclient.krb5.password.change.hook parameter:

adclient.krb5.password.change.hook: /var/ftp/create_keytab_for_ftp.sh

adclient.krb5.password.change.interval

This configuration parameter specifies the number of days in the interval between the last Active Directory password change for the computer account and the next password change for the account. At the interval, Active Directory prompts for a new account password. The agent then automatically generates a new password for the computer account and issues the new password to Active Directory.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be an integer equal to or greater than zero. If the value is zero, then the change interval is turned off and the account is not prompted for password change. For example:

adclient.krb5.password.change.interval: 28

If this parameter is not defined in the configuration file, its default value is 28 days.

adclient.krb5.password.change.verify.interval

This configuration parameter controls how long adkeytab waits between attempts to verify password changes. For example, to set the interval between verification attempts to 600 seconds (10 minutes), enter the following:

adclient.krb5.password.change.verify.interval: 600

The default setting for this parameter is 300 seconds (5 minutes).

You can specify the number of password change verifications that adkeytab attempts by using the adclient.krb5.password.change.verify.retries configuration parameter.

adclient.krb5.password.change.verify.retries

This configuration parameter controls how many times adkeytab tries to verify password changes running in the background.

In some Active Directory environments, such as those employing a read-only domain controller (RODC), Kerberos password changes may not be verified through adclient due to a replication delay. As a result of this delay, the new password is not saved to the keytab file. When this parameter is set to a value other than 0, adclient will retry verification of the new password a corresponding number of times.

If your RODC has latency problems, you may want to address this by setting adkeytab to attempt to verify password changes multiple times. For example, to direct adkeytab to attempt a total of 4 password change verifications, you would set this parameter to 3 as follows:

adclient.krb5.password.change.verify.retries: 3

The time between verification attempts can be set using the adclient.krb5.password.change.verify.interval configuration parameter.

The default setting for this parameter is 0, meaning that adkeytab will not try to verify password changes after the initial attempt.

adclient.krb5.passwd_check_s_address

This configuration parameter specifies whether Kerberos should ignore the source address on private messages. This setting is useful when Active Directory uses NAT.

The parameter value can be true or false. The default value for this parameter is true. For example:

adclient.krb5.passwd_check_s_address: false

adclient.krb5.permitted.encryption.types

This configuration parameter specifies the types of encryption that can be used in Kerberos client credentials.

The parameter value must be one or more encryption types, separated by a space. For example:

adclient.krb5.permitted.encryption.types: arcfour-hmac-md5 des-cbc-md5

If this parameter is not defined in the configuration file, the default encryption types permitted are:

- Windows 2000 server and Windows Server 2003: arcfour-hmac-md5, des-cbc-md5, and des-cbc-crc.
- Windows Server 2008 domain functional level supports these additional types:

  aes128-cts and aes256-cts. Although you can specify these types in an environment other than 2008 domain functional level, they are not useful and may cause extra network round trips during the authentication process.

adclient.krb5.permitted.encryption.types.strict

The adclient.krb5.permitted.encryption.types.strict parameter controls whether to add to or replace the encryption types specified in the setting, permitted_enctypes, in krb5.conf with the encryption types specified in the setting, adclient.krb5.permitted.encryption.types, in centrifydc.conf.

- When adclient.krb5.permitted.encryption.types.strict is false (default), then:

  The encryption types listed in adclient.krb5.permitted.encryption.types in centrifydc.conf,are added to the list of encryption types in permitted_enctypes in krb5.conf.

  This only ensures that what is specified in centrifydc.conf is present in krb5.conf. It does not remove unknown items.

- When adclient.krb5.permitted.encryption.types.strict is set to true, then:

  The encryption types listed in adclient.krb5.permitted.encryption.types in centrifydc.conf replace the encryption types specified in the setting, permitted_enctypes, in krb5.conf.

  The permitted encryption types in krb5.conf exactly match the permitted encryption types in centrifydc.conf. Extra or unknown encryption types are removed.

Example:

adclient.krb5.permitted.encryption.types.strict: false

- false — Default is false. No change in behavior. permitted_enctypes are updated from the centrifydc.conf file.

  Items from centrifydc.conf are added, if they were not already listed. Other items that were already in permitted_enctypes are left alone and not removed.

- true — replace the targeted krb5.conf parameters so they match exactly what is specified in centrifydc.conf.

  Items from centrifydc.conf are added, if they were not already listed. Other items that were already in permitted_enctypes, and not in centrifydc.conf, are removed.

To apply changes to this parameter, either restart adclient or ensure the group policy is set as follows: **Computer Configuration > Centrify Settings > DirectControl Settings > Kerberos Settings > Control if strictly enforce the permitted_encTypes**.

adclient.krb5.principal

This configuration parameter specifies whether SAM account names or user principal names (UPNs) are used as the principal in Kerberos tickets. Supported values are sam and upn.

For example:

adclient.krb5.principal: sam

The default value is sam.

If you set this parameter to upn and no UPN is available, the sAMAccountName attribute with the format SAMAccountName@DomainName is used.

In MIT Kerberos environments, however, the UPN is used even if this parameter is set to sam.

adclient.krb5.send.netbios.name

This configuration parameter specifies whether the Delinea Agent sends the host computer's NetBIOS name (the computer's pre-Windows 2000 name) together with the host computer's IP address (or addresses) when the agent makes a Kerberos authentication request that includes IP addresses. The NetBIOS name appears in the domain controller log on the host Windows server and helps identify the computer making the request.

If this parameter is set to true, the agent sends the NetBIOS name. If set to false, the agent does not send the NetBIOS name.

This parameter has no effect unless adclient.krb5.use.addresses is set to true.

If this parameter is not defined in the configuration file, its default value is true.

adclient.krb5.service.principals

This configuration parameter specifies additional service principals for entries in the Kerberos key table. The key table is populated by default with the service principals host and ftp cifs.

This parameter's value must be one or more principal service names, separated by a space or by a comma. For example:

adclient.krb5.service.principals: ldap nfs

If this parameter is not defined in the configuration file, no additional principal names are added to the Kerberos key table.

adclient.krb5.tkt.encryption.types

This configuration parameter specifies the types of encryption that can be presented to the server in the TGT when the computer is requesting service tickets.

The parameter value must be one or more encryption types, separated by a space. For example:

adclient.krb5.tkt.encryption.types: arcfour-hmac-md5 des-cbc-md5

If this parameter is not defined in the configuration file, the default encryption types permitted are:

- Windows 2000 server and Windows Server 2003: arcfour-hmac-md5, des-cbc-md5, and des-cbc-crc.
- Windows Server 2008 domain functional level supports these additional types:

  aes128-cts and aes256-cts.
  Although you can specify these types in an environment other than 2008 domain functional level, they are not useful and may cause extra network round trips during the authentication process.

adclient.krb5.tkt.encryption.type.strict

The adclient.krb5.tkt.encryption.type.strict parameter controls whether to replace the encryption types set in default_tgs_enctypes and default_tkt_enctypes in krb5.conf with the encryption types specified in adclient.krb5.tkt.encryption.types in centrifydc.conf.

- When adclient.krb5.tkt.encryption.type.strict is false (default), then:

  The encryption types listed adclient.krb5.tkt.encryption.types in centrifydc.conf are added to the list of encryption types in default_tgs_enctypes and default_tkt_enctypes in krb5.conf.

  This only ensures that what is specified in centrifydc.conf is present in krb5.conf. It does not remove unknown items.

- When adclient.krb5.tkt.encryption.type.strict is set to true, then:

  The encryption types listed in adclient.krb5.tkt.encryption.types in centrifydc.conf replace the encryption types specified in the settings, default_tgs_enctypes and default_tkt_enctypes, in krb5.conf.

  The permitted encryption types in krb5.conf exactly match the permitted encryption types in centrifydc.conf. Extra or unknown encryption types are removed.

Example:

adclient.krb5.tkt.encryption.type.strict: false

- false — Default is false. No change in behavior. default_tgs_enctypes and default_tkt_enctypes are updated from the centrifydc.conf file.

  Items from centrifydc.conf are added, if they were not already listed. Other items that were already in default_tgs_enctypes and default_tkt_enctypes are left alone and not removed.

- true — Replace the targeted krb5.conf parameters so they match **exactly** what is specified in centrifydc.conf.

  Items from centrifydc.conf are added, if they were not already listed. Other items that were already in default_tgs_enctypes and default_tkt_enctypes, and not in centrifydc.conf, are removed.

To apply changes to this parameter, either restart adclient or ensure the group policy is set as follows: **Computer Configuration > Centrify Settings > DirectControl Settings > Kerberos Settings > Control if strictly enforce the encTypes**.

adclient.krb5.use.addresses

This configuration parameter controls whether the Delinea Agent should send the host computer's local IP address (or addresses) to the Windows domain controller as part of a Kerberos authentication request. When set to true, the agent sends the IP addresses; when set to false, the agent does not send the IP addresses.

When the agent sends the host computer's IP address with a Kerberos request, the IP address appears in the Windows event logs associated with the request.

This configuration parameter works with the parameters adclient.krb5.extra_addresses and adclient.krb5.send.netbios.name. Use the first of these two parameters to add additional IP addresses to the host computer's IP address (useful in networks using NAT). Use the second to add the host computer's NetBIOS name to the IP address (or addresses) (useful for identifying the requesting computer in event logs).

If adlcient.krb5.use.addresses is set to false, neither of these two parameters has any effect because the agent does not send addresses with an authentication request.

> **Note**: This configuration parameter sets the Kerberos configuration parameter noaddresses in krb5.conf. Setting adclient.krb5.use.addresses to true sets noaddresses to false; setting adclient.krb5.use.addresses to false sets noaddresses to true.

If adclient.krb5.use.addresses is not defined in the configuration file, its default value is false.

fips.mode.enable

This configuration parameter specifies whether Kerberos uses the algorithms in the FIPS 140-2 compliant library to sign and seal messages. See fips.mode.enable for the description.

krb5.cache.clean

This configuration parameter specifies whether Kerberos credentials in the cache should be deleted when a user logs out. By default, credentials stored in the Kerberos cache that belong to users who are not logged in are periodically deleted.

To keep the credentials available in the cache use this parameter to turn off the cache clean process entirely. Alternatively, use the krb5.cache.clean.exclusion to turn off cache cleaning for specific users.

This configuration parameter allows you to control this operation specifically for zone users or for all users.

The parameter value must be one of the following valid settings:

- off to turn off the deletion of the credentials cache for all users.
- cdc to remove all of the /tmp/krb5cc* files created by the agent (adclient) that belong to any user not found in the utmp database (that is, the user has logged out).
- all to remove all of the /tmp/krb5cc* files that belong to any user not found in the utmp database. This setting removes files created by the agent (adclient), telnet, and openssh.

For example, to remove the credentials cache for all users when they log out:

krb5.cache.clean: all

The default value for this parameter is cdc.

krb5.cache.clean.exclusion

This configuration parameter specifies a list of users whose credentials in the Kerberos cache will *not* be deleted during a periodic Kerberos cache clean-out of unlogged-in users.

Each user is specified by the user's UNIX name. Separate the names in the list using a comma.

For example, to specify that three users be excluded from periodic credential clean-up:

krb5.cache.clean.exclusion: admin,paula,jeffrey

This parameter is useful in a batch processing environment where a logged-out user may leave behind running processes that require Kerberos credentials. It allows some users' credentials to remain for processes while cleaning out all other users' credentials.

The default value for this parameter is empty.

krb5.cache.clean.force.max

This configuration parameter controls whether adclient deletes credentials from the Kerberos cache if they are the specified number of days old.

If you activate this parameter, the credentials will be cleared for all users whether or not they are logged on, have active processes running, or are specified in the following lists:

krb5.cache.clean.exclusion
krb5.cache.infinite.renewal.batch.users
krb5.cache.infinite.renewal.batch.groups

For example, to force adclient to clear the cache of credentials that were authenticated 6 days previously:

krb5.cache.clean.force.max: 6

The default value for this parameter is 0, which means that this configuration parameter will not clear the credential cache for any users.

krb5.cache.clean.interval

This configuration parameter specifies how frequently in minutes to check the Kerberos cache for credentials that belong to users who are not logged on. If the user is not logged on, the credentials are deleted.

The parameter value should be a positive integer. Setting this parameter to zero disables periodic clean-up of the cache.

For example, to set the clean-up interval to 5 minutes:

krb5.cache.clean.interval: 5

The default value for this parameter deletes the credential cache for users who have logged off every one minute.

krb5.cache.infinite.renewal

This configuration parameter specifies whether you want user credentials to be automatically reissued when they expire. The parameter value can be set to true or false. If you set this parameter to true, the agent keeps a hash of the user's password in memory indefinitely. If you set this parameter to false, a user's credentials periodically expire and the user must be re-authenticated by re-entering a valid password.

If you set this parameter to true, user credentials are automatically reissued, as needed, as long as the adclient process continues to run even if the computer is disconnected from Active Directory. If you stop or restart adclient, however, the user's password hash is removed from memory. After stopping or restarting adclient, users must be re-authenticated by logging on with a valid user name and password.

The default parameter value is false. For example:

krb5.cache.infinite.renewal: false

krb5.cache.infinite.renewal.batch.groups

This configuration parameter specifies a list of Active Directory groups whose members' Kerberos credentials require infinite renewal even after the users have logged out.

Requirements to use this parameter:

- Specified groups must be Active Directory groups.
- Groups do not need to be zone enabled.
- To have their credentials automatically renewed, users in the group must:
  - Be zone enabled (that is, mapped users are not supported).
  - Log into the desired system once using the Account Password.

You must use the following format to specify group names:

SamAccountName@domain

For example:

krb5.cache.infinite.renewal.batch.groups: test_group_sam@example.com

By default, this parameter does not list any groups.

You can also use group policy to set this parameter.

krb5.cache.infinite.renewal.batch.users

This configuration parameter specifies a list of users whose Kerberos credentials require infinite renewal even after the users have logged out.

Requirements to use this parameter:

- The users must be zone enabled (that is, mapped users are not supported).
- The users must log into the desired system once using the Account Password.

You can use any of the following formats to specify user names:

unixName
userPrincipleName
SamAccountName
SamAccountName@domain

For example:

krb5.cache.infinite.renewal.batch.users: test_user, test_user@example.com, test_user_sam, test_user_sam@example.com

By default, this parameter does not list any users.

You can also use group policy to set this parameter.

krb5.cache.renew.exclusion

This configuration parameter specifies a list of UNIX users for whom you don't want adclient to automatically renew their Kerberos credential caches. This parameter is useful in situations where you need to directly manage certain users' Kerberos caches.

Specify each user by the user's UNIX name. Separate the names in the list using a comma.

For example, to specify that adclient doesn't renew these three users' Kerberos credential caches:

krb5.cache.renew.exclusion: admin,paula,jeffrey

Alternatively, you can using the file: keyword to specify a separate file that contains UNIX user names.

For example:

krb5.cache.renew.exclusion: file:/etc/centrifydc/renew.exclude

You can put a UNIX user name in each single line, and be sure to run the adreload command after modifying the file to have the changes take effect.

The default value for this parameter is empty.

krb5.cache.renew.interval

This configuration parameter specifies, in hours, how often to renew the Kerberos credentials stored in the cache for users who have logged on successfully. Because Kerberos tickets expire after a set period of time, you can use this configuration parameter to periodically renew the existing Kerberos ticket to keep existing credentials valid.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. A value of zero disables renewal. For example, to set the renewal interval to 8 hours:

krb5.cache.renew.interval = 8

If this parameter is not defined in the configuration file, its default value is 4 hours. The default value of 4 hours allows two attempts at renewal over a typical Kerberos ticket lifespan of 10 hours. If possible, you should allow enough time for at least two renewal attempts if you reset the value to something other than the 4-hour default.

krb5.conf.plugins.ccselect.disable

This configuration parameter controls whether adclient disables the Kerberos built-in ccselect plugins.

If you set this parameter to false, the plugins will not be disabled.

For example,

krb5.conf.plugins.ccselect.disable: false

By default, this parameter is set to true, and the built-in ccselect plugins are disabled.

You can also set this parameter using group policy.

krb5.cache.type

This configuration parameter specifies the type of Kerberos credential cache that the agent (adclient) creates when an Active Directory user logs in. The parameter value can be set to FILE or KCM.

> **Note**: The use of in-memory credential caches such as KCM is not supported on Mac OS X computers. In Mac OS X environments, credential caches are file-based, and setting this parameter has no effect.

If you set this parameter to FILE, the agent creates a file-based credential cache for each Active Directory user in /tmp when the user logs in. A file-based credential cache persists until the file is deleted.

If you set this parameter to KCM, the agent creates an in-memory credential cache for each Active Directory user when the user logs in. The Centrify-KCM service, run as root, manages in-memory credential caches. When the agent, adclient, starts up, if the parameter is set to KCM, adclient starts the KCM service. If you change the parameter from FILE to KCM while adclient is running, adclient starts the KCM service the next time it is forced to reload configuration parameters, for example, if you run the adreload command or if a user opens a new session.

Setting this parameter affects new users only — not users who have already logged in. For example, if you change from a file-based, to an in-memory credential cache, the agent will continue to use the file-based credential cache for any user who was logged in at the time of the change. If a logged in user opens a new session, or a new user logs in, the agent will use an in-memory cache for them.

An in-memory credential cache ends as soon as the Centrify-KCM service is stopped.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The default parameter value is FILE, which specifies a file-based credential cache. To specify an in-memory credential cache, set the value to KCM. For example:

krb5.cache.type: KCM

krb5.conf.k5login.directory

Use this policy to specify an alternative location for user .k5login files.

If specified, this string value will be used for the k5login_directory in the [libdefaults] stanza in krb5.conf and the user's .k5login file will be named as <k5login_directory>/<unix_name>.

For security reasons the specified directory should be owned by root and writeable by root only. If the directory does not exist, adclient will create it.

krb5.conf.kcm.socket.path

The krb5.conf.kcm.socket.path parameter specifies an alternate socket path for the KCM server. It applies when krb5.cache.type is KCM.

This is useful, as it allows you to configure an alternative kcm socket path, for example, /var/centrifydc. Using an alternative socket path then allows the socket to be shared between docker hosts and docker containers. It requires adreload after a change in value.

- When the parameter is an empty string (default), the default path /var/run/.centrify-kcm-socket is used.
- When the parameter is set to an non-empty string AND krb5.conf.kcm.socket.path.secure.usable.check is false, then this socket path is used without secure and usable check.
- When the parameter is set to an non-empty string AND krb5.conf.kcm.socket.path.secure.usable.check is true, then the configured socket path is checked to see if it is valid:
    - If the socket path is valid, this configured socket path is used.
    - If the socket path is not valid, the default socket path, /var/run/.centrify-kcm-socket, is used.

To change the socket path:

1. In centrifydc.conf, set krb5.conf.kcm.socket.path to a valid path.
2. If the configured kcm socket path is not secure, but you still want to use it, ensure the parameter, krb5.conf.kcm.socket.path.secure.usable.check, is false.
3. Run adreload.

krb5.conf.kcm.socket.path.secure.usable.check

The krb5.conf.kcm.socket.path.secure.usable.check parameter specifies whether to perform a secure and usable check on the alternate socket path for the KCM server. This parameter works in conjunction with krb5_conf_kcm_socket_path. Options are:

- false — Default. No action taken.
- true — If krb5.conf.kcm.socket.path is configured, then krb5.conf.kcm.socket.path.secure.usable.check checks the specified directory.

A socket path is valid when it meets the following criteria:

- the parent directory exists
- the parent directory is not a symlink
- the parent directory is writable by root only
- the socket path does not exist, or it exists but it is not directory

krb5.config.update

This configuration parameter specifies, in hours, how frequently the agent updates the Kerberos configuration file.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If adclient.krb5.autoedit is set to false, this parameter has no effect. If adclient.krb5.autoedit is set to true, this parameter value must be a positive integer. For example, to set the update interval to 8 hours:

krb5.config.update: 8

If this parameter is not defined in the configuration file, its default value is 8 hours.

krb5.forcetcp

This configuration parameter specifies whether to allow Kerberos requests to use UDP or to force all Kerberos requests to use TCP.

If krb5.forcetcp is set to false, Kerberos requests may use UDP. If krb5.forcetcp is set to true, all Kerberos requests use TCP only.

In most cases, you set this configuration parameter using group policy.

You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If this parameter is not defined in the configuration file, its default value is true.

krb5.forwardable.user.tickets

This configuration parameter specifies whether you want the agent to create forwardable Kerberos user tickets. Creating a forwardable ticket allows a user's logon ticket to be sent to another computer and used to access to additional systems and resources. For example, if a user logs on and is authenticated on one computer, then uses a Kerberized telnet session to connect to a second computer, a forwarded ticket allows the user to access to additional Kerberized resources from that second computer without separate authentication.

In most environments, forwarding user tickets is a safe practice. However, if you do not want tickets to be forwarded, you can use this parameter to prevent the agent from creating forwardable tickets.

The parameter value should be 1 is you want to allow ticket forwarding or 0 is you want to prevent ticket forwarding. For example, if you want the agent to create forwardable user tickets:

krb5.forwardable.user.tickets: 1

If this parameter is not defined in the configuration file, its default value is 1 (yes).

krb5.pac.validation

This configuration parameter specifies whether or not to verify that the user's PAC (Privilege Authorization Certificate) information is from a trusted KDC (Key Distribution Center) so as to prevent what's referred to as a "silver ticket" attack.

When performing credential verification, a service ticket is fetched for the local system. After the credential is verified, the local system uses the PAC information in the service ticket.

This setting take effect when krb5.verify.credentials is enabled or when DirectControl is using the user's PAC from a service ticket. This setting does not apply to retrieving the PAC by way of the S4U2Self protocol.

There are 3 possible values for krb.pac.validation:

- disabled (default): NO PAC validation will be done at all.
- enabled: If PAC Validation fails, the PAC information is used and the user login is allowed.
- enforced: If PAC Validation fails, the PAC information is discarded and the user login is denied.

Setting this parameter to enabled or enforced will have significant impact on the user login and user's group fetch performance.

For example:

krb5.pac.validation: disabled

If this parameter is not defined in the configuration file, its default value is disabled.

krb5.permit.dns.spn.lookups

This configuration parameter specifies whether you want to permit the agent to look up service principal names (SPN) using DNS. In most cases, you should set this parameter to false to ensure the security of the system. You should only set this configuration parameter to true if you can safely rely on DNS for security and want to use programs that use the Delinea Kerberos libraries to access a computer using an IP address or localhost.

For example:

krb5.permit.dns.spn.lookups: false

If this parameter is not defined in the configuration file, its default value is false.

krb5.sso.block.local_user

This configuration parameter specifies whether single sign-on (SSO) is permitted for local users, or if only zone-enabled Active Directory users are allowed to log in through SSO.

By default, this parameter is set to true, and the user UNIX name is checked against the nss.ignore.user list. If the UNIX name is in the list, the user is considered a local user, and SSO is not allowed. In this situation, the user must enter the local user password to log in.

If this parameter is set to false, local users are allowed to log in through SSO.

For example:

krb5.sso.block.local_user: true

krb5.sso.ignore.k5login

This configuration parameter specifies whether the k5login module should ignore .k5login for SSO.

The default value is false.

krb5.support.alt.identities

This configuration parameter specifies whether the agent uses the Kerberos altSecurityIdentities name for user authentication (true) or not (false) instead of the Windows user name, regardless of which names are supplied.

Using altSecurityIdentities for authentication works as long as the alternate name is always used or the passwords are synchronized, and if the third-party key distribution center (KDC) is reachable. If these two conditions aren't met, you can disable the feature by setting this parameter to false. In that case, the agent uses only Windows to authenticate the user and ignores any Kerberos altSecurityIdentities.

For example:

krb5.support.alt.identities: false

If this parameter is not defined in the configuration file, its default value is true.

krb5.unique.cache.files

This configuration parameter specifies whether to generate a unique ticket cache file name for each Kerberos authentication for a given user (except the first). The unique ticket cache file name takes the following form:

krb5cc_cdc<uid>_XXXXXX

The <uid> is the users Unix ID, and the XXXXXX is a unique set of characters (i.e. krb5cc_cdc512_u0PSdt). This allows a given user to log on more than once, without subsequent logoffs interfering with other logon instances.

If this parameter is set to false, the ticket cache filename takes the following form:

krb5cc_<UID>

With this parameter set to false, old versions of the ticket cache file are overwritten. If a user logs in twice, the first logout causes the file to be deleted, leaving the other logon instance without a credential cache.

The environment variable KRB5CCNAME is populated with the generated name.

The default value is true, except on macOS where it is false.

krb5.use.kdc.timesync

This configuration parameter enables Kerberos to automatically correct for a time difference between the system clock and the clock used by the KDC. You only need to set this parameter if your system clock is drifting and the system is not using NTP and adclient SNTP settings.

In most cases, you set this configuration parameter using group policy.

You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

For example:

krb5.use.kdc.timesync: true

If this parameter is not defined in the configuration file, its default value is false.

krb5.verify.credentials

This configuration parameter specifies whether to perform a spoofing check to verify a TGT for the local system.

By default, the agent verifies a user's TGT by retrieving and verifying a service ticket for the local system. This check is done to prevent a well-known attack (the Zanarotti or screen-saver attack) whereby a rogue KDC could respond to the agent's request for the user's TGT.

However, the spoofing check can be time consuming, so you can set this parameter to false to disable the spoofing check and significantly improve authentication performance.

For example, to disable the check:

krb5.verify.credentials: false

If this parameter is not defined in the configuration file, the default value is true.

krb5.udp.preference.limit

This configuration parameter sets the maximum size packet that the Kerberos libraries will attempt to send over a UDP connection before retrying with TCP. If the packet size is larger than this value, only TCP will be tried. If the value is set to 1, TCP will always be used. The hard UDP limit is 32700. Values larger than this are ignored and the UDP hard limit is enforced.

This key only takes effect if krb5.forcetcp is set to false.

If krb5.forcetcp is true, and the agent is managing the krb5.conf file, it will set udp_preference_limit = 1, so that the Kerberos libraries will always use TCP.

In most cases, you set this configuration parameter using group policy to set a specific value.

You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If this parameter is not defined in the configuration file, the default value is 1465; for example:

krb5.udp.preference.limit:1465

Customizing PAM-Related Configuration Parameters

This section describes the configuration parameters that affect the operation of PAM related activity on the local host computer.

Configuring PAM-related parameters on IBM AIX computers

On IBM AIX computers, the PAM configuration parameters described in this chapter apply to the AIX Loadable Authentication Module (LAM) or to the PAM interface. If you have configured the AIX computer to use the PAM interface, the configuration parameters apply to the PAM settings. If the AIX computer is configured to use the LAM interface, the parameters configure LAM settings, as applicable. For more information about AIX-specific configuration parameters, see the Customizing AIX configuration parameters.

Controlling access to AIX computers

On most computers, the predefined login-all PAM access right is required to allow users who are assigned the UNIX Login role to log on and use PAM-enabled applications in the zones they have permission to access. However, if you have AIX computers that are configured to use the Loadable Authentication Module (LAM) instead of PAM in a zone, users will be able to log on even if they have not been assigned the UNIX Login role. In addition, if you define your own custom PAM access rights, those rights will not be applicable on AIX computers that use the LAM interface.

To prevent users from logging on to or using unauthorized applications on AIX computers is a zone, you can explicitly allow or deny access to specific users and groups through configuration parameters or group policies or change the configuration of your AIX computers to use the more commonly supported Pluggable Authentication Module (PAM) interface. For more information about controlling access, see Enforcing access rights on AIX computers.

Explicitly allowing and denying access

If you have AIX computers that use the Loadable Authentication Module (LAM) interface, you cannot use the predefined login-all PAM access right or custom PAM access rights to authorize who can log on and who can use specific applications. Therefore, the default UNIX Login role does not apply on AIX computers that use the LAM interface. If you are primarily concerned with who can log on to those computers, you can use the pam.allow.groups, pam.allow.users, or both parameters to explicitly specify the groups and users who can log on to AIX computers that use the LAM interface. All other groups and users—including those assigned the UNIX Login role—will be denied access. Alternatively, you can use the pam.deny.users, pam.deny.groups, or both parameters to explicitly specify the users and groups who are not allowed to log on.

Changing the configuration of AIX computers

By default, AIX computers are configured to use the Loadable Authentication Module (LAM) instead of the Pluggable Authentication Module (PAM) subsystem. If you want to be able to use the default or custom PAM access rights to authorize access to specific applications, you might want to reconfigure your AIX computers to use the PAM interface instead of the LAM interface. If you choose to reconfigure AIX computers, you should also be sure to replace the OpenSSH package for LAM with the OpenSSH for PAM and thoroughly test your applications.

pam.account.conflict.both.mesg

This configuration parameter specifies the message displayed if both user name and user ID conflicts are detected during login; that is, there are two local account conflicts. For example, a local user (user2) and the Active Directory user (user1) have the same UID (10001) but different user names, and another local account has the same user name (user1) as the Active Directory user but has a different UID value (10002):

```
user1 10001 #AD User
user1 10002 #local user
user2 10001 #local user
```

When the message is displayed, the %s token in the message string is replaced with the name of the first conflicting local account, and the %d token is replaced with the UID of the second conflicting local account. The message string you define must contain exactly one %s token and exactly one %d token, in that order, and no other string replacement (%) characters.

For example:

```
pam.account.conflict.both.mesg: \
Accounts with conflicting name (%s) and UID (%d) exist locally
```

For more information about displaying a warning when local conflicts are detected, see pam.uid.conflict.

pam.account.conflict.name.mesg

This configuration parameter specifies the message displayed if a user name conflict is detected during login; that is, if there is a local user with the same name but a different UID than the Active Directory user logging on; for example,

user1 10001 #local user
user1 10002 #AD user

When the message is displayed, the %s token in the message string is replaced with the name of the conflicting local account. The message string you define must contain exactly one %s token, and no other string replacement (%) characters.

For example:

pam.account.conflict.name.mesg: \
Accounts with conflicting name (%s) exist locally

For more information about displaying a warning when local conflicts are detected, see pam.uid.conflict.

pam.account.conflict.uid.mesg

This configuration parameter specifies the message displayed if a user identifier (UID) conflict is detected during login; that is, if there is a local user with a different user name but the same UID as the Active Directory user logging on. For example:

user1 10001 #local user
user2 10001 #AD user

When the message is displayed, the %d token is replaced with the UID of the conflicting local account. The message string you define must contain exactly one %d token, and no other string replacement (%) characters.

For example:

pam.account.conflict.uid.mesg: \
Account with conflicting UID (%d) exists locally

For more information about displaying a warning when local conflicts are detected, see pam.uid.conflict.

pam.account.disabled.mesg

This configuration parameter specifies the message displayed if a user attempting to log on is denied access because the user's account has been disabled in Access Manager or Active Directory Users and Computers.

For example:

pam.account.disabled.mesg: Account cannot be accessed at this time. Please contact your system administrator.

pam.account.expired.mesg

This configuration parameter specifies the message displayed if a user attempting to log on is denied access because the user's account has expired.

For example:

pam.account.expired.mesg:
Account cannot be accessed at this time. Please contact your system administrator.

pam.account.locked.mesg

This configuration parameter specifies the message displayed if a user account is locked because of too many failed login attempts.

For example:

pam.account.locked.mesg: Account locked

> **Note**: These messages may not be displayed depending on the login method, the daemon version, or the version of the operating system. (Ref: CS-16710c)

pam.adclient.down.mesg

This configuration parameter specifies the message displayed during password change if user is a local UNIX user that's mapped to an Active Directory account, and the Delinea Agent (adclient) is not accessible.

For example:

pam.adclient.down.mesg: (Unable to reach Active Directory - using local account)

In most cases, you set this configuration parameter by selecting **Enabled** and specifying the message to be displayed.

pam.allow.groups

This configuration parameter specifies the groups allowed to access PAM-enabled applications. When this parameter is defined, only the listed groups are allowed access. All other groups are denied access.

> **Note**: This parameter does not support cross-forest groups. (Ref: CS-18659a)

If you want to use this parameter to control which users can log in based on group membership, the groups you specify should be valid Active Directory groups, but the groups you specify do not have to be enabled for UNIX. Local group membership and invalid Active Directory group names are ignored.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you use this parameter to control access by group name, the agent checks the Active Directory group membership for every user who attempts to use PAM-enabled applications on the host computer.

When a user attempts to log on or access a PAM-enabled service, the pam_centrifydc module checks with Active Directory to see what groups the user belongs to. If the user is a member of any Active Directory group specified by this parameter, the user is accepted and authentication proceeds. If the user is not a member of any group specified by this parameter, authentication fails and the user is rejected.

The parameter's value can be one or more group names, separated by commas, or the file: keyword and a file location. For example, to allow only members of the administrators, sales, and engineering groups in Active Directory to log in:

pam.allow.groups: administrators,sales,engineering

You can use the short format of the group name or the full canonical name of the group.

To enter group names with spaces, enclose them in double quotes; for example:

pam.allow.groups: "domain admins",sales,"domain users"

To specify a file that contains a list of the groups allowed access, type the path to the file:

pam.allow.groups: file:/etc/centrifydc/groups.allow

If no group names are specified, no group filtering is performed.

If you make changes to this parameter, you should run adflush to clear the cache to ensure your changes take effect.

Specifying group names for computers joined to Auto Zone

If a computer is configured to use the Auto Zone instead of a specific zone, you should specify group names using the format defined by the auto.schema.name.format parameter. For example the auto.schema.name.format parameter can be set to the following:

- SAM (default) uses the samAccountName attribute for the group—web_qa
- SAM@domainName uses the samAccountName@domain_name format—web_qa@acme.com
- NTLM uses the NTLM format and separator defined for adclient.ntlm.separators—acme.com+web_qa

You can look in the centrifydc.conf configuration file for the value of auto.schema.name.format, or run adedit or adquery commands to see the UNIX name for any group. For example, to see the UNIX name for the Web_qa Active Directory group when the auto.schema.name.format parameter is set to SAM, you can execute a command similar to this to return the UNIX group profile name:

```
adquery group -n web_qa
webqa.us
```

pam.allow.override

This configuration parameter is used to override authentication through Active Directory to ensure the root user or another local account has permission to log on when authentication through Active Directory is not possible, when there are problems running the adclient process, or when there are network communication issues.

When you specify a user account for this parameter, authentication is passed on to a legacy authentication mechanism, such as /etc/passwd. You can use this parameter to specify an account that you want to ensure always has access, even if communication with Active Directory or the adclient process fails. For example, to ensure the local root user always has access to a system even in an environment where you have enabled root mapping, you can specify:

pam.allow.override: root

To log in locally with the override account, you must specify the local user name and password. However, because the account is mapped to an Active Directory account, you must append @localhost to the user name. For example, if you have specified root as the override account and are using root mapping, you would type root@localhost when prompted for the user name. You can then type the local password for the root account and log in without being authenticated through Active Directory.

> **Note**: If you are mapping the root user to an Active Directory account and password, you should set this parameter to root or to a local user account with root-level permissions (UID 0), so that you always have at least one local account with permission to access system files and perform privileged tasks on the computer even if there are problems with the network connection, Active Directory, or the adclient process.

>**Note**: If you are using a Solaris machine with the Name Switch Cache Daemon (NSCD) running, you will not be able to log in as an override user using \<*username*\>@localhost. (Ref: CS-29816c)

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

>**Note**: The pam.allow.override configuration parameter is not supported on AIX computers. This is because using the user name with the suffix @localhost is not supported on AIX. The LAMGetEntry call that is used to get user information and extended attribute information does not support login name changes. So, the login fails as there is no way to find the user or authenticate the user. There is no equivalent setting for AIX computers. (Ref: CS-33506a)

pam.allow.password.change

This configuration parameter specifies whether users who log in with an expired password should be allowed to change their password. You can set this parameter to true or false and use it in conjunction with the pam.allow.password.expired.access parameter to control access for users who attempt to log on with an expired password.

If both this parameter and pam.allow.password.expired.access are set to true, users logging on with an expired password are allowed to log on and are prompted to change their password.

If the pam.allow.password.expired.access parameter is set to true, but this parameter is set to false, users logging on with an expired password are allowed to log on but are not prompted to change their password and the message defined for the pam.allow.password.change.mesg parameter is displayed.

If both this parameter and pam.allow.password.expired.access are set to false, users who attempt to log on with an expired password are not allowed to log on or change their password and the message defined for the pam.allow.password.change.mesg parameter is displayed.

For example, to allow users with expired passwords to change their password:

pam.allow.password.change: true

pam.allow.password.change.mesg

This configuration parameter specifies the message displayed when users are not permitted to change their expired password because the pam.allow.password.change parameter is set to false.

For example:

pam.allow.password.change.mesg: Password change not permitted

pam.allow.password.expired.access

This configuration parameter specifies whether users who log in with an expired password should be allowed access. You can set this parameter to true or false and use it in conjunction with the pam.allow.password.change parameter to control access for users who attempt to log on with an expired password.

If this parameter is set to true, users logging on with an expired password are allowed to log on, and either prompted to change their password if the pam.allow.password.change parameter is set to true, or notified that they are not allowed to change their expired password if the pam.allow.password.change parameter is set to false.

If this parameter is set to false, users logging on with an expired password are not allowed to log on and the message defined for the pam.allow.password.expired.access.mesg parameter is displayed.

For example, to allow users with expired passwords to log on:

pam.allow.password.expired.access: true

pam.allow.password.expired.access.mesg

This configuration parameter specifies the message displayed when users are not permitted to log on with an expired password because the pam.allow.password.expired.access parameter is set to false.

For example:

pam.allow.password.expired.access.mesg: Password expired - access denied

pam.allow.users

This configuration parameter specifies the users who are allowed to access PAM-enabled applications. When this parameter is defined, only the listed users are allowed access. All other users are denied access.

If you want to use this parameter to control which users can log in, the users you specify should be valid Active Directory users that have a valid UNIX profile for the local computer's zone. If you specify local user accounts or invalid Active Directory user names, these entries are ignored.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you specify one or more users with this parameter, user filtering is performed for all PAM-enabled applications on the host computer.

When a user attempts to log on or access a PAM-enabled service, the pam_centrifydc module checks the users specified by this parameter to see if the user is listed there. If the user is included in the list, the user is accepted and authentication proceeds. If the user is not listed, the user is rejected.

The parameter value can be one or more user names, separated by commas, or the file: keyword and a file location. For example:

pam.allow.users: root,joan7,bbenton
pam.allow.groups: administrators,sales,engineering

You can use the short format of the user name or the full canonical name of the user.

To enter user names with spaces, enclose them in double quotes; for example:

pam.allow.users: "sp1 user@acme.com",joan@acme.com,"sp2 user@acme.com"

To specify a file that contains a list of the users allowed access, type the path to the file:

pam.allow.users: file:/etc/centrifydc/users.allow

If no user names are specified, then no user filtering is performed.

If you make changes to this parameter, you should run adflush to clear the cache to ensure

Specifying user names for computers joined to Auto Zone

If a computer is configured to use the Auto Zone instead of a specific zone, you should specify user names using the format defined by the auto.schema.name.format parameter. For example the auto.schema.name.format parameter can be set to the following:

- SAM (default) uses the samAccountName attribute for the user—jcool
- SAM@domainName uses the samAccountName@domain_name format—jcool@acme.com
- NTLM uses the NTLM format and separator defined for adclient.ntlm.separators

You can look in the centrifydc.conf configuration file for the value of auto.schema.name.format parameter or run adedit or adquery commands to see the UNIX name for any user. For example, to see the UNIX name for the jcool Active Directory user when the auto.schema.name.format parameter is set to SAM, you can execute a command similar to this to return the UNIX user profile name:

adquery user -n jcool

pam.auth.create.krb5.cache

This configuration parameter specifies whether PAM creates the Kerberos user credential cache. A value of true specifies that the Kerberos user credential cache is created. A value of false specifies that the Kerberos user credential cache is not created. The default value is true. For example:

pam.auth.create.krb5.cache: true

- When this parameter is set to false, the Kerberos user credential cache is not created, and any attempt to perform an SSO operation will fail.
- The Kerberos user credential cache can be file-based or it can be a KCM in-memory cache, depending on the krb5.cache.type setting (see krb5.cache.type.
- This parameter is also controlled by group policy.

pam.auth.failure.mesg

This configuration parameter specifies the message displayed during a password change if the user enters an incorrect old password.

For example:

pam.auth.failure.mesg: Password authentication failed

pam.config.program.check

This configuration parameter specifies a list of extra PAM configuration files that are in the pam.d directory and that the authentication service updates (in addition to the standard PAM configuration files, such as /pam.d/system-auth, /pam.d/common-auth and so forth).

The default list is as follows:

pam.config.program.check: ftp,pure-ftpd,vsftpd,wu-ftpd,dzdo,sasauth

pam.create.k5login

This configuration parameter specifies whether the .k5login file should be created automatically in the user's home directory. This file is used to enable Kerberos authentication and single sign-on in PAM-aware applications.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value can be true or false. If set to true, the agent will create the .k5login file in the user's home directory.

For example:

pam.create.k5login: true

pam.deny.change.shell

This configuration parameter specifies whether a user who is denied access, for example, because they are listed as a user in the pam.deny.user or are not listed in the pam.allow.user parameter, should have their shell set to the shell defined by the nss.shell.nologin parameter. The parameter value can be set to true or false.

If set to true, this parameter adds an extra level of security by ensuring that the zone user who is denied access cannot obtain any shell access, even if authenticated through Kerberos, SSH, or some other non-PAM related method. If this parameter is set to false, the denied user's shell is not changed and so may be able to access the system.

Because of the potential security issue, the default value for this parameter is true. However, since group lookups can be time-consuming for simple NSS queries, you can set this parameter to false to prevent the agent from changing the user's shell when denied access.

For example, to leave the user's shell unchanged when denied access, set this parameter to false.

pam.deny.change.shell: false

pam.deny.groups

This configuration parameter specifies the groups that should be denied access to PAM-enabled applications. When this parameter is defined, only the listed groups are denied access. All other groups are allowed access.

> **Note**: This parameter does not support cross-forest groups. (Ref: CS-18659a)

If you want to use this parameter to control which users can log in based on group membership, the groups you specify should be valid Active Directory groups, but the groups you specify do not need to be enabled for UNIX. Local group membership and invalid Active Directory group names are ignored.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

When a user attempts to log on or access a PAM-enabled service, the pam_centrifydc module checks with Active Directory to see which groups the user belongs to. If the user is a member of any Active Directory group specified by this parameter, the user is denied access and authentication fails. If the user is not a member of any group specified by this parameter, authentication succeeds and the user is logged on.

The parameter's value can be one or more group names, separated by commas or spaces, or the file: keyword and a file location. For example, to prevent all members of the vendors and azul groups in Active Directory from logging on:

pam.deny.groups: vendors,azul

You can use the short format of the group name or the full canonical name of the group.

To enter group names with spaces, enclose them in double quotes; for example:

pam.deny.groups: "domain admins",sales,"domain users"

To specify a file that contains a list of the groups that should be denied access:

pam.deny.groups: file:/etc/centrifydc/groups.deny

> **Note**: If a computer is configured to use Auto Zone without a zone, enter group names in the format specified by the auto.schema.name.format parameter:

- SAM (samAccountName — this is the default); for example: finance_admins
- samAccountName@domain_name; for example: finance_admins@acme.com
- NTLM; for example: acme.com+finance_admins

> **Note**: You can look in the centrifydc.conf configuration file for the value of auto.schema.name.format, or run adquery group -n to see the UNIX name for any group. For example, to see the UNIX name for the Finance_Admins group (and SAM, the default, is set for auto.schema.name.format), execute the following command, which returns the UNIX name as shown:

```
[root]#adquery group -n Finance_Admins
finance_admins
```

If this parameter is not defined in the configuration file, no group filtering is performed.

> **Note**: If you make changes to this parameter, you should run adflush to clear the cache to ensure your changes take effect.

pam.deny.users

This configuration parameter specifies the users that should be denied access to PAM-enabled applications. When this parameter is defined, only the listed users are denied access. All other users are allowed access.

If you want to use this parameter to control which users can log in, the users you specify should be valid Active Directory users that have been enabled for UNIX. If you specify local user accounts or invalid Active Directory user names, these entries are ignored.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

When a user attempts to log on or access a PAM-enabled service, the pam_ module checks the users specified by this parameter to see if the user is listed there. If the user is included in the list, the user is rejected and authentication fails. If the user is not listed, the user is accepted and authentication proceeds.

The parameter value can be one or more user names, separated by commas or spaces, or the file: keyword and a file location. For example, to prevent the user accounts starr and guestuser fcentrifydcrom logging on:

pam.deny.users: starr,guestuser

You can use the short format of the user name or the full canonical name of the user.

To enter user names with spaces, enclose them in double quotes; for example:

pam.deny.users: "sp1 user@acme.com",joan@acme.com,"sp2 user@acme.com"

To specify a file that contains a list of the users that should be denied access:

pam.deny.users: file:/etc/centrifydc/users.deny

> **Note**: If a computer is configured to use Auto Zone without a zone, enter user names in the format specified by the auto.schema.name.format parameter:

- SAM (samAccountName — this is the default); for example: jcool
- samAccountName@domain_name; for example: jcool@acme.com
- NTLM; for example: acme.com+jcool

> **Note**: You can look in the centrifydc.conf configuration file for the value of auto.schema.name.format, or run adquery user -n to see the UNIX name for any user. For example, to see the UNIX name for jcool (and SAM, the default, is set for auto.schema.name.format), execute the following command, which returns the UNIX name as shown:

```
[root]#adquery user -n jcool
jcool
```

If this parameter is not defined in the configuration file, no user filtering is performed.

> **Note**: If you make changes to this parameter, you should run adflush to clear the cache to ensure your changes take effect.

pam.homedir.create

This configuration parameter specifies whether a new home directory should be created automatically when a new Active Directory user logs on to a system for the first time.

For example, to specify that home directories be created automatically when new Active Directory users log on to a system for the first time:

pam.homedir.create: true

In most cases, you set this configuration parameter using group policy.

> **Note**: For computers that use NFS to mount home directories, you should set this parameter to false. If you have a Solaris environment and set this parameter to true, you should make sure the default location for creating a home directory is not /home/{$user} since this path is not allowed in a typical Solaris environment. In addition, some platforms may require you to manually create a skeleton directory that contains default initial profiles to use when creating new home directories. You can use the pam.homeskel.dir parameter to specify the location of this skeleton directory if it exists in your environment.

pam.homedir.create.hook

By default, the agent uses the mkdir() function to create the user's home directory. However, if desired, you can set this parameter so that you create the user's home directory by way of a script.

The script should be:

- root owned and only writeable by owner
- executable
- not a symlink

When you create the script, be sure that it accepts the following arguments:

- -h (home directory path)
- -u (the UID for the home directory)
- -g (the GID for the home directory)

There is a sample script /usr/share/centrifydc/samples/homedir.sh.sample; this script can create a Solaris ZFS dataset for a user's home directory.

For example:

pam.homedir.create.hook: /usr/bin/homedir.sh

When you specify the script for this parameter, be sure to also specify the absolute path to the script.

pam.homedir.create.mesg

This configuration parameter specifies the message displayed when a user's home directory is created.

For example:

pam.homedir.create.mesg: Created home directory

pam.homedir.perms

This configuration parameter specifies the permissions for a user's home directory if a new home directory is created for the user on the local computer.

For example, to give read, write, and execute permissions on the directory to the user and no other permissions:

pam.homedir.perms: 0700

In most cases, you set this configuration parameter using group policy.

pam.homedir.perms

This configuration parameter specifies the permissions for a user's home directory if a new home directory is created for the user on the local computer.

For example, to give read, write, and execute permissions on the directory to the user and no other permissions:

pam.homedir.perms: 0700

In most cases, you set this configuration parameter using group policy.

pam.homedir.update.ownership

This configuration parameter specifies whether or not to update the home directory ownership when a user logs in.

By default, this parameter is set to false.

```
pam.homedir.update.ownership: true
```

pam.homedir.perms.recursive

This configuration parameter specifies whether to use the permissions defined in the PAM skeleton directory or the permissions defined in pam.homedir.perms when a new home directory is created for a user.

This parameter can have a value of true or false. When set to true, a user's new home directory is created with the contents of the skeleton directory and the permissions defined in pam.homedir.perms. When set to false, a user's new home directory is created using the contents and permissions of the skeleton directory.

This parameter has a default value of false. For example:

pam.homedir.perms.recursive: false

pam.homeskel.dir

This configuration parameter specifies where the PAM skeleton directory is located. The skeleton directory to used to automatically create a new home directory and UNIX profile for a new user, if needed.

The parameter value must be a path name. For example:

pam.homeskel.dir: /etc/skel

If this parameter is not defined in the configuration file, no files are copied when a new user directory is created.

pam.ignore.users

This configuration parameter specifies one or more users that the agent will ignore for lookup in Active Directory. This configuration parameter ignores listed users for authentication and NSS lookups. Because this parameter allows you to intentionally skip looking up an account in Active Directory, it allows faster lookup for system accounts such as tty, root, and bin and local login accounts.

> **Note**: Starting with Delinea DB2 agent 5.2.3, the db2.implement.pam.ignore.users parameter controls whether the agent checks pam.ignore.users. The pam.ignore.users parameter is checked only if db2.implement.pam.ignore.users is set to true. If db2.implement.pam.ignore.users is set to false, pam.ignore.users is not checked, and all users are authenticated in Active Directory. See db2.implement.pam.ignore.users for more information about db2.implement.pam.ignore.users.

In most cases, you set this configuration parameter using group policy. This list is then stored in the /etc/centrifydc/user.ignore file and used to disable lookups in Active Directory for the users specified.You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be one or more user names, separated by a space, or the file: keyword and a file location. For example, to specify a list of users to authenticate locally:

pam.ignore.users: root sys tty

To specify a file that contains a list of the users to ignore:

pam.ignore.users: file:/etc/centrifydc/users.ignore

If this parameter is not defined in the configuration file, no users are specified.

Skipping Active Directory authentication for local AIX users

By default, the agent modifies the AIX Loadable Authentication Module (LAM) for the SYSTEM user attribute to look like this:

SYSTEM=CentrifyDC OR CentrifyDC[NOTFOUND] AND compat

This setting specifies that the first attempt to authenticate a user should be passed to Active Directory through the agent. In some cases, however, you may have local user accounts that you only want to authenticate locally. Although there are parameters in the access control configuration file (centrifydc.conf) that enable you to ignore Active Directory authentication for specific local users, these parameters are not completely applicable on computers running AIX. To exclude any local user account from Active Directory authentication on AIX, you can run the following command for the user:

chuser SYSTEM=compat username

Alternatively, you can edit the /etc/security/user file and change the stanza for a particular user's SYSTEM attribute to:

SYSTEM=compat

If you later decide you want to migrate the local user account to use Active Directory, you can run the following command for the user to reset the default authentication:

chuser SYSTEM= username

> **Note**: To reset the user account to be authenticated through Active Directory, there must be a space after the equal sign (=) in the command line.

pam.mapuser.username

This configuration parameter maps a local UNIX user account to an Active Directory account. Local user mapping allows you to set password policies in Active Directory even when a local UNIX account is used to log in. This parameter is most commonly used to map local system or application service accounts to an Active Directory account and password, but it can be used for any local user account. For more information about mapping local accounts to Active Directory users, see "Mapping local UNIX accounts to Active Directory in the *Administrator's Guide*.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, you should note that the local account name you want to map to Active Directory is specified as the last portion of the configuration parameter name. The parameter value is the Active Directory account name for the specified local user. For example, the following parameter maps the local UNIX account oracle to the Active Directory account oracle_storm@acme.com if the host computer's name is storm:

pam.mapuser.oracle: oracle_$HOSTNAME@acme.com

You can specify the user name in the configuration file with any of the following valid formats:

- Standard Windows format: domain\user_name
- Universal Principal Name (UPN): user_name@domain
- Alternate UPN: alt_user_name@alt_domain
- UNIX user name: user

You must include the domain name in the format if the user account is not in the local computer's current Active Directory domain.

If this parameter is not defined in the configuration file, no local UNIX user accounts are mapped to Active Directory accounts.

pam.mfa.program.ignore

This configuration parameter specifies a list of programs for which multi-factor authentication is ignored. If you have configured roles to require multi-factor authentication, users assigned to those roles will be required to provide two types of authentication to access PAM applications. However, some PAM applications do not support more than one authentication challenge.

You can use this parameter to add the program names that do not support multi-factor authentication. When users access the PAM applications you specify for this parameter, the multi-factor authentication requirement is ignored so that users can log on rather than be denied access.

For example, if you have configured a role with the login-all PAM application right and the Require multi-factor authentication system right, you can use this parameter to skip multifactor authentication for specific PAM applications—such as xscreensaver and vsftpd—where multi-factory authentication is not needed or not supported.

pam.mfa.program.ignore: xscreensaver vsftpd

You can specify multiple options separated by spaces.

By default, ftpd, proftpd, vsftpd, java, httpd, cdc_chkpwd, kdm, and unix2_chkpwd are all added to this parameter.

pam.ntlm.auth.domains

This configuration parameter specifies the list of domains that should use NTLM authentication instead of Kerberos authentication. This parameter enables you to authenticate users behind a firewall when the Kerberos ports are blocked, but a trust relationship exists between domains inside and outside the firewall. When you set this parameter, the local domain controller outside of the firewall passes its authentication requests through the transitive trust chain for authentication inside of the firewall.

The parameter value must be one or more fully-qualified Active Directory domain names. The Active Directory domain names must be mapped to NTLM domain names, either automatically if the firewall does not prevent the mapping from being discovered, or manually by modifying the contents of the /etc/centrifydc/domains.conf file if the firewall prevents the mapping from automatically being discovered.

If firewall constraints prevent the automatic discovery of Active Directory to NTLM domain mapping, you can manually configure how Active Directory domain names map to NTLM domains by editing the /etc/centrifydc/domains.conf file to consist of a list of colon-separated values in the form of:

AD_DomainName:NTLM_DomainName

For example, the domains.conf file should consist of entries similar to the following:

AJAX.ORG:AJAX

FIREFLY.COM:FIREFLY

HR1.FIREFLY.COM:HR1

You can then use the adclient.ntlm.domains parameter using the file: keyword to specify the location of this file. For example:

adclient.ntlm.domains: file:/etc/centrifydc/domains.conf

> **Note**: If you don't want to define the Active Directory to NTLM mapping in a separate file, you can set the adclient.ntlm.domains parameter to map domain names using the format AD_DomainName:NTLM_DomainName. For example:

adclient.ntlm.domains: AJAX.ORG:AJAX FIREFLY.COM:FIREFLY

After you have configured the mapping, you can list the Active Directory domain names for this parameter. For example, to specify that the Active Directory domains AJAX.ORG and FIREFLY.COM, which are outside of the firewall with a one-way trust to the forest inside the firewall, should use NTLM authentication, you could set the parameter like this:

pam.ntlm.auth.domains: AJAX.ORG, FIREFLY.COM

For more information about manually defining the mapping of Active Directory domains to NTLM domains, see adclient.ntlm.domains.

Alternatively, you can set the group policy **Computer Configuration > Centrify Settings > DirectControl Settings > Pam Settings > Specify NTLM authentication domains**.

pam.password.change.mesg

This configuration parameter specifies the text displayed by a PAM-enabled application when it requests a user to change a password.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value must be an ASCII string. UNIX special characters and environment variables are allowed. For example:

pam.password.change.mesg: Changing Active Directory password for\

If this parameter is not present, its default value is “Change password for”.

pam.password.change.required.mesg

This configuration parameter specifies the message displayed if the user enters the correct password, but the password must be changed immediately.

For example:

pam.password.change.required.mesg: \
You are required to change your password immediately

pam.password.confirm.mesg

This configuration parameter specifies the text displayed by a PAM-enabled application when it requests a user to confirm his new password by entering it again.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value must be an ASCII string. UNIX special characters and environment variables are allowed. For example:

pam.password.confirm.mesg: Confirm new Active Directory password:\

If this parameter is not present, its default value is “Confirm new password:”.

pam.password.empty.mesg

This configuration parameter specifies the message displayed if the user enters an empty password.

For example:

pam.password.empty.mesg: Empty password not allowed

pam.password.enter.mesg

This configuration parameter specifies the text displayed by a PAM-enabled application when it requests a user to enter his password.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value must be an ASCII string. UNIX special characters and environment variables are allowed. For example:

pam.password.enter.mesg: Active Directory password:\

If this parameter is not present, its default value is “Password:”.

pam.password.expiry.warn

This configuration parameter specifies how many days before a password expires the PAM-enabled applications should start issuing the pam.password.expiry.warn.mesg to the user.

The parameter value must be a positive integer. For example, to issue a password expiration warning 10 days before a password is set to expire:

pam.password.expiry.warn: 10

If this parameter is not present, the default value is 14 days.

pam.password.expiry.warn.mesg

This configuration parameter specifies the text displayed by a PAM-enabled application to warn the user that her password will expire in pam.password.expiry.warn days or less.

When the message is displayed, the '%d' token is replaced with the number of days until expiration. The message must contain exactly one '%d' token and no other '%' characters.

For example:

pam.password.expiry.warn.mesg: Password will expire in %d days

pam.password.new.mesg

This configuration parameter specifies the text displayed by a PAM-enabled application when it requests a user to enter his new password during a password change.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value must be an ASCII string. UNIX special characters and environment variables are allowed. For example:

pam.password.new.mesg: Enter new Active Directory password:\

If this parameter is not present, its default value is “Enter new password:”.

pam.password.new.mismatch.mesg

This configuration parameter specifies the message displayed during password change when the two new passwords do not match each other.

For example:

pam.password.new.mismatch.mesg: New passwords don't match

pam.password.old.mesg

This configuration parameter specifies the message displayed by a PAM-enabled application when it requests a user to enter his old password during a password change.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The parameter value must be an ASCII string. UNIX special characters and environment variables are allowed. For example:

pam.password.old.mesg: (current) Active Directory password:\

If this parameter is not present, its default value is "(current) password:".

pam.policy.violation.mesg

This configuration parameter specifies the message displayed during password change if the operation fails because of a domain password policy violation. For example, if the user attempts to enter a password that doesn't contain the minimum number of characters or doesn't meet complexity requirements, this message is displayed.

For example:

pam.policy.violation.mesg: \
The password change operation failed due to a policy restriction set by the Active Directory administrator.
This may be due to the new password length, lack of complexity or a minimum age for the current password.

pam.setcred.respect.sufficient

This configuration parameter overrides an anomaly in the operation of the PAM interface on some platforms that denies access to a user who has entered the correct password. The default setting depends upon the platform as follows:

- For HPUX and Mac OSX platforms the default is true
- For all other platforms the default is false.

  Note: Some Solaris 2.6 and Solaris 8 users have reported getting the error message PAM_AUTH_ERR after entering the correct password. If this occurs, set pam.setcred.respect.sufficient: true.

pam.setcred.support.refresh

This parameter specifies whether the PAM flag PAM_REFRESH_CRED is supported and can be used to trigger creation of the credential cache and renew Kerberos tickets. The default is false, in which case the PAM_ESTABLISH_CRED flag is used to trigger creation of the credential cache and renew Kerberos tickets. For example:

pam.setcred.support.refresh: false

pam.setcred.support.reinitialize

This parameter specifies whether the PAM flag PAM_REINITIALIZE_CRED is supported and can be used to trigger creation of the credential cache and renew Kerberos tickets. The default is false, in which case the PAM_ESTABLISH_CRED flag is used to trigger creation of the credential cache and renew Kerberos tickets.

For example:

pam.setcred.support.reinitialize: false

pam.sync.mapuser

This configuration parameter controls whether the password synchronization service keeps passwords synchronized for local users that are mapped to an Active Directory account.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you set this parameter in the configuration file, the parameter value should be a list of local user accounts that are mapped to Active Directory accounts. For example:

pam.sync.mapuser: root oracle sanchez

If you set this parameter and a mapped user changes his password, PAM updates the password hash for the corresponding local UNIX account in the local /etc/shadow file so that the passwords match. Synchronizing the passwords in this way ensures that local users can still log on even if there are problems with the network, Active Directory, or the adclient process. For example, if Active Directory is not available, the mapped user can log on as a local user by appending @localhost to the user name:

sanchez@localhost

Password synchronization requires you to do the following:

- Install either the Delinea Password Synchronization component or the Microsoft Password Synchronization Service on all domain controllers.

  If you do not have the Microsoft Password Synchronization Service installed on your domain controllers, you can install and use the Delinea Password Synchronization extension instead. You can install the Delinea Password Synchronization extension when you install other Delinea Management Services using the setup program or by running the standalone password extension installation program.

- Configure the zone properties for the computer's zone to support agentless clients and to use the proper NIS domain name and Active Directory attribute for storing the user's password hash.

- Map the specified local users to Active Directory using either the pam.mapuser.username configuration parameter or group policy.

- Verify the Active Directory user to which the local user is mapped has a profile in the zone you have configured for agentless authentication.

This parameter has no effect on Mac OS X systems.

pam.uid.conflict

This configuration parameter specifies how you want the agent to respond if a user logs on with an Active Directory account and either the Active Directory user name or Active Directory UID conflicts with a local user account. The purpose of detecting a duplicate user name or duplicate UID is to prevent an Active Directory user from signing on and receiving privileges to modify files created by a different local user.

The pam.uid.conflict configuration parameter determines what happens when this type of conflict is found. The parameter value must be set to one of the following valid options:

ignore	Do not report duplicate user names or UID conflicts. If detected, log the conflict at the info level if logging is enabled.
warn	Warn the user of the user name or UID conflict after s successful login. Log the conflict at warning level if logging is enabled. This is the default value.
error	Report UID conflict to user after user name is entered. Don't accept password. Don't allow log in. Log conflict at error level.

For example:

pam.uid.conflict: warn

> **Note**: If both the Active Directory user name and Active Directory UID are the same as a local user name and UID, the accounts do not conflict and the user can log on regardless of how you set this parameter. Although this situation is rare, you should avoid using Active Directory user names and UIDs that duplicate local user names and UIDs but apply to different individual users.

If this parameter is not present, its default value is warn.

pam.workstation.denied.mesg

This configuration parameter specifies the message displayed if a user attempting to log on is denied access because of a workstation restriction.

For example:

pam.workstation.denied.mesg: \
Your account is configured to prevent you from using this computer. Please try another computer.

microsoft.pam.privilege.escalation.enabled

The configuration parameter specifies if the Microsoft Privileged Access Management (PAM) Privilege Escalation feature is supported or not within the Delinea environment.

If microsoft.pam.privilege.escalation.enabled is true, then, when an Active Directory user logs in, the configured privilege that's granted to the user through PAMGroup takes effect until the granted period has elapsed.

The Privileged Access Management (PAM) Privilege Escalation feature can be enabled or disabled through Group Policy. Select **Computer Configuration › Centrify Settings › DirectControl Settings › Enable Active Directory PAM Privilege Escalation feature**

The Microsoft PAM Privilege Escalation feature specifies if Delinea DirectControl uses Microsoft PAM Privilege Escalation feature in the computer.

For example:

microsoft.pam.privilege.escalation.enabled: true

Default is false, the Microsoft PAM Privilege Escalation feature support is disabled. Setting it to true enables grants the Active Directory user, at log in, the same configured privilege as the user's PAMGroup. This is in effect until the grant period expires.

Customizing Group Policy Configuration Parameters

This section describes the configuration parameters that affect group policy support on the local host computer.

gp.disable.all

This configuration parameter can be used to disable both computer and user group policies on a local computer. If set to true, all group policy settings are ignored.

For example:

gp.disable.all: true

If this parameter is not defined in the configuration file, its default value is false.

gp.disable.machine

This configuration parameter can be used to disable computer-based group policies on a local computer. If set to true, all computer-based group policy settings are ignored.

For example:

gp.disable.machine: true

If this parameter is not defined in the configuration file, its default value is false.

gp.disable.user

This configuration parameter can be used to disable user-based group policies on a local computer. If set to true, all user-based group policy settings are ignored.

For example:

gp.disable.user: true

If this parameter is not defined in the configuration file, its default value is false.

gp.disk.space.check.folders

This configuration parameter specifies the folders that need the free disk space check. If the free space in any specified folder is less than the value in gp.disk.space.min, then group policy settings will not be updated.

Specify a comma-separated list of folders; for example, the default is:

gp.disk.space.check.folders: /,/etc,/var

Delinea

gp.disk.space.min

This configuration parameter specifies the minimum free disk space in kilobytes (KB) that is required for a group policy update. If the free disk space in any folder specified in gp.disk.space.check.folders is less than this value, then group policy settings will not be updated.

When updating the configuration file, the Perl mapper scripts create a temp file, print to it, and replace the original file. If the disk is full, the mapper cannot write to the temp file, so the temp file is empty, and the original file is replaced by the empty temp file. This configuration parameter and gp.disk.space.min prevent the mapper writing to a temp file when disk space is low.

The default value is 5120 KBytes. Set this parameter to 0 to not check free disk space.

gp.mappers.certgp.pl.additional.cafiles

This setting defines a list of certificate files which will be included in the certgp.pl install, if found.

It can be a list of certificates to be added. For example:

gp.mappers.certgp.pl.additional.cafiles: <ca-file> <ca-file> ...

It can also point to a file that contains a list of certificate files to be added. For example:

gp.mappers.certgp.pl.additional.cafiles: file:/etc/centrifydc/cert_included.list

The default value is empty.

gp.mappers.certgp.pl.exclude.cacerts

This setting defines a certificate list which will be excluded from the certgp.pl install, if matched.

It can be a list of fingerprints of the certificates to be excluded. For example:

gp.mappers.certgp.pl.exclude.cacerts: <fingerprint> <fingerprint> ...

It can also point to a file that contains a list of fingerprints of the certificates to be excluded. For example:

gp.mappers.certgp.pl.exclude.cacerts: file:/etc/centrifydc/cert_excluded.list

The default value is empty.

gp.mappers.directory.machine

This configuration parameter specifies the root directory that contains all of the mapping programs for computer-based group policy settings. Individual programs map entries from the virtual registry into configuration settings in the appropriate files on the local computer.

The parameter value must be a path name. For example:

gp.mappers.directory.machine: /usr/share/centrifydc/mappers/machine

If this parameter is not defined in the configuration file, its default value is /usr/share/centrifydc/mappers/machine.

gp.mappers.directory.user

This configuration parameter specifies the root directory that contains all of the mapping programs for user-based group policy settings. Individual programs map entries from the virtual registry into configuration settings in the appropriate files on the local computer.

The parameter value must be a path name. For example:

gp.mappers.directory.machine: /usr/share/centrifydc/mappers/user

If this parameter is not defined in the configuration file, its default value is /usr/share/centrifydc/mappers/user.

gp.mappers.error_file

This configuration parameter specifies the name of the file where the group policy mapper programs write error messages.

For example:

gp.mappers.error_file: mapper.errors

gp.mappers.machine

This configuration parameter specifies the list of mapping programs to run to configure computer-based policies. The mapping programs are contained in the root directory specified by gp.mappers.directory.machine (/usr/share/centrifydc/mappers/machine by default). The mapping programs are executed in the order in which they are specified. The mapping program centrifydc.conf.pl will always run even if unspecified and does not run only if you specify that it not run (described later).

In most cases you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you want to temporarily override group policy.

To specify mapping programs to run, you can list each individual program name literally, or you can use wild card characters that are a subset of regular expression wild card characters:

- An asterisk (*) specifies any set of zero or more characters. "map*", for example, specifies any program names starting with "map". "set*.pl" specifies any program names starting with "set" and ending with ".pl". And "*dc*" specifies any program names that include "dc". "*" means all programs.
- A question mark (?) specifies any single character. "map???", for example, specifies any six-character program name starting with "map".
- Square brackets ([ ]) enclosing a set of characters specifies a single character that is one of the enclosed characters. "mapprogram[123]", for example, matches the program names mapprogram1, mapprogram2, and mapprogram3.

You can specify a program name *not* to execute by preceding it with an exclamation point (!). If you specify "* !mapprogram1", for example, you specify that all mapping programs in the mapping program root directory should execute except for "mapprogram1". Note that the only way you can stop the automatically executing program centrifydc.conf.pl from executing is to specify "!centrifydc.conf.pl" in this parameter.

You can combine all of these rules to give you precise control over which mapping programs run. Some examples:

gp.mappers.machine: * specifies all mapping programs in the mapping program parent directory.

gp.mappers.machine: mapgp* !mapgp2 specifies all mapping programs in the mapping program parent directory that start with "mapgp" *except* for "mapgp2". Note that centrifydc.conf.pl will execute because it hasn't been specified not to execute and so executes automatically.

gp.mappers.runcommand.as.root.env.list

This configuration parameter specifies the list of environment variables that are exported to the environment so that a root user can run Group Policy commands. Use the forward slash "/" to specify environment variables and their values. Use a space to separate multiple name/value pairs. If an environment variable contains spaces, enclose the value in quotes or add a backslash "\" before the space.

You can also specify other environment variables as a value.

For example:

gp.mappers.runcommand.as.root.env.list: env1/value1 env2/va\ lue2 env3/"va lue3" env4/value4_$

> **Note**: If the gp.mappers.runcommand.as.user parameter is set to true, the gp.mappers.runcommand.as.root.env.list has no effect for user Group Policy commands because the service runs the user's group policy commands as the user's login shell and resets all environment variables.

gp.mappers.runcommand.as.user

This configuration parameter specifies whether to run user group policy commands as the current user. The default for this parameter is false, which means that the service runs these commands as root.

The RunCommand.pl script reads this parameter setting and if the parameter is set to true, then it runs commands as follows:

su - $args ->user() -c $command

gp.mappers.runmappers

This configuration parameter specifies the location of the runmappers program. The runmappers program is started by the agent and invokes individual mapping programs for computers, users or both.

The parameter value must be a path name. For example:

gp.mappers.runmappers: /usr/share/centrifydc/mappers/runmappers

If this parameter is not defined in the configuration file, its default value is /usr/share/centrifydc/mappers/runmappers.

gp.mappers.timeout

This configuration parameter specifies the maximum time, in seconds, to allow for a single mapping program to complete execution. If a mapping program takes longer than this period to successfully complete its execution, the process is stopped and the next mapping program is started.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer that is less than the value set for the gp.mappers.timeout.all parameter. For example, to set the timeout interval to 60 seconds:

gp.mappers.timeout: 60

The default value for this parameter on Mac is 120 seconds.

The default value for this parameter on all other platforms is 30 seconds.

gp.mappers.timeout.all

This configuration parameter specifies the maximum time, in seconds, to allow for all mapping programs to complete execution. The parameter value must be a positive integer that is less than the value set for the lrpc.timeout parameter.

The default value for this parameter on Mac is ten minutes (600 seconds). For example:

gp.mappers.timeout.all: 600

The default value for this parameter on all other platforms is four minutes (240 seconds). For example:

gp.mappers.timeout.all: 240

gp.mappers.umask

This configuration parameter specifies the default umask for mapping programs that create files. The default value for this parameter sets the following read and write permissions for mapping programs that create files:

u=rwx
g=rx
o=

The parameter value specifies these permissions using numeric mode. For example:

gp.mappers.umask: 0027

gp.mappers.user

This configuration parameter specifies the mapping programs that map user-based policy settings to run. The mapping programs are executed in the order in which they are specified.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you want to temporarily override group policy.

In defining the list of mapping programs to run, you can use an asterisk (*) as a wild card to match a set of program names. For example, you can specify a* to match all programs with names that start with the letter a. You can use square brackets ([ ]) to match any character within the brackets. For example, you can specify mapprogram[123] to match the program names of mapprogram1, mapprogram2, and mapprogram3. You can also use an exclamation point (!) with a program name to exclude a program from the list. For example, you can specify !mysample to prevent the mapping program mysample from running.

To run all of the mapping programs for user-based policy settings, you can specify:

gp.mappers.user: *

To run a subset of the mapping program, you can explicitly define the order and which programs to run. For example, to run the program mapgp1, followed by mapgp4 and mapgp3, but skipping the execution of mapgp2:

gp.mappers.user: mapgp1 !mapgp2 mapgp4 mapgp3

gp.refresh.disable

This configuration parameter specifies whether to disable the background processing of group policy updates. This configuration parameter applies to both computer- and user-based policies.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you want to temporarily override group policy. For example:

gp.refresh.disable: false

gp.reg.directory.machine

This configuration parameter specifies the root directory of the virtual registry for computer-based group policies. The parameter value must be a path name. For example:

gp.reg.directory.machine: /var/centrifydc/reg/machine

If this parameter is not defined in the configuration file, its default value is/var/centrifydc/reg/machine.

gp.reg.directory.user

This configuration parameter specifies the root directory of the virtual registry for user-based group policies.

The parameter value must be a path name. For example:

gp.reg.directory.user: /var/centrifydc/reg/users

If this parameter is not defined in the configuration file, its default value is /var/centrifydc/reg/users.

gp.use.user.credential.for.user.policy

This configuration parameter specifies whether to use the user's credentials to retrieve user group policies. By default, all group policies are retrieved using the computer account credentials, which are associated with the adclient process rather than the user who is currently logged on. In most cases, this default behavior is sufficient because most of the Delinea group policies are computer configuration policies. However, if the computer account does not have permission to access the Group Policy Object where user policies are defined, the default behavior prevents user policies from being applied.

You can set this configuration parameter to true to use the user's credentials to retrieve user group policies. For example:

gp.use.user.credential.for.user.policy: true

If this parameter is not defined in the configuration file, its default value is false.

gp.user.login.run

This configuration parameter specifies when user-based group policies should run. By default, user-based group policies are applied when a user first logs on to a computer, then at a regular interval in background to check for updates and changes while the user's session remains active. However, running group policies at every login and refresh interval for users who are already logged on can impact performance on computers where there are a large number of group policies being applied. You can use this parameter to reduce the load on those computers by customizing when group policies should be applied.

This configuration parameter enables you to specify whether the user-based group policies should be applied:

- Only once when the user first logs on and not again until the user logs off and logs back on.
- When the user first logs on and regularly at the refresh interval for as long as the user remains logged on.
- Never when the user logs on, but periodically at the refresh interval thereafter.

The valid parameter values for this configuration parameter are once, always, and never.

For example, to specify that user-based group policies should only run once when the user first logs on but not thereafter, you can set this parameter to once:

gp.user.login.run: once

If this parameter is not defined in the configuration file, its default value is always to apply the user group policies when a user first logs on and periodically refresh the policies in the background for as long the user remains logged on.

Customizing NSS-Related Configuration Parameters

This section describes the configuration parameters that affect the operation of NSS-related activity on the local host computer.

> **Note**: On AIX, the NSS configuration parameters described in this chapter may apply to interfaces in the AIX Loadable Authentication Module (LAM). For consistency across platforms, most of the parameter names are the same and retain the reference to NSS settings they configure, but NSS is not used on AIX.

nss.alias.source

This configuration parameter specifies the source to look up aliases, and you specify one of the following values:

- nismaps (default)
- mail
- proxyaddresses

To look up the alias from an Active Directory user object, use the mail or proxyAddresses value. Because proxyaddresses is a custom attribute, you need to also include it in the adclient.custom.attributes.user parameter or else the alias source reverts to nismaps.

Using the mail or proxyAddresses values don't work with users in a one-way trusted forest.

nss.gecos.attribute

This configuration parameter specifies the Active Directory user object attribute to use for the GECOS field. The default value for this parameters is the gecos attribute in the Active Directory RFC2307 schema.

The order of precedence for the GECOS field setting is:

1. The GECOS setting for the UNIX service connection point (SCP) in Active Directory.
2. The nss.gecos.attribute setting.
3. The displayName attribute of the user object.

If nss.gecos.attribute is set and GECOS is not set for the UNIX SCP, the user attribute specified by nss.gecos.attribute is used for the GECOS field in UNIX profiles and NSS lookups. If nss.gecos.attribute is not defined or the Active Directory RFC2307 schema is not used, the user object's displayName attribute is used as the GECOS field for UNIX profiles.

If you set this configuration parameter, the parameter value is case-sensitive and must exactly match the case used for the attribute name in Active Directory. For example:

nss.gecos.attribute: displayName

nss.gid.ignore

This configuration parameter specifies a set of one or more group identifiers that the Delinea NSS module will ignore for lookup in Active Directory.

In most cases, this configuration parameter's value is generated automatically by group policy.

If you select the **Specify group names to ignore** policy and click **Enabled**, you can type the list of local group names not stored in Active Directory. The list you specify for the group policy is then stored in the /etc/centrifydc/group.ignore file and used to automatically generate the /etc/centrifydc/gid.ignore file. These files are then used to disable looking up account information in Active Directory for the groups specified, which results in faster name lookup service for system group accounts such as tty and disk.

You can, however, define this parameter manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you manually set this parameter, the parameter value should be one or more group identifiers, separated by a space, or the file: keyword and a file location. For example:

nss.gid.ignore: 0 20 5861
nss.gid.ignore=file:/etc/centrifydc/gid.ignore

A default set of groups to ignore are defined in sample /etc/centrifydc/group.ignore and /etc/centrifydc/gid.ignore files. If you edit either file, be sure to run the adreload command after modifying the file to have the changes take effect.

nss.group.ignore

This configuration parameter specifies a set of one or more groups that the Delinea NSS module will ignore for lookup in Active Directory.

In most cases, this configuration parameter's value is generated automatically by group policy.

If you select the **Specify group names to ignore** policy and click **Enabled**, you can type the list of local group names not stored in Active Directory. The list you specify for the group policy is then stored in the /etc/centrifydc/group.ignore file and used to automatically generate the /etc/centrifydc/gid.ignore file. These files are then used to disable looking up account information in Active Directory for the groups specified, which results in faster name lookup service for system group accounts such as tty and disk.

You can, however, set this parameter manually in the configuration file if you aren't using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be one or more group names, separated by a space, or the file: keyword and a file location. For example:

nss.group.ignore: maintenance apps
nss.group.ignore=file:/etc/centrifydc/group.ignore

A default set of groups to ignore are defined in sample /etc/centrifydc/group.ignore and /etc/centrifydc/gid.ignore files. If you are not using group policies, you can uncomment the nss.group.ignore parameter in the /etc/centrifydc/centrifydc.conf file to ignore the default set of groups.

> **Note**: If you plan to edit the group.ignore file, be sure to run the adreload command after modifying the file to have the changes take effect.

nss.group.override

This configuration parameter allows you to override group profile entries for zone groups. Using this parameter is similar to defining override filters for local groups in the /etc/group file. By defining override filters, you can use this parameter to give you fine-grain control over the groups that can access a local computer. You can also use the override controls to modify the information for specific fields in each group entry on the local computer. For example, you can override the group ID or member list for a specific group on the local computer without modifying the group entry itself.

In most cases, you set this configuration parameter using group policy. The entries created by group policy are then stored in the /etc/centrifydc/group.ovr file and used to filter group access to a local computer.You can, however, set this parameter manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The syntax for overriding group entries is similar to the syntax used for overriding NIS. You use + and – entries to allow or deny access for specific groups on the local system. Additional fields correspond to the standard /etc/group fields separated by colons (:).

In most cases, the nss.group.override parameter is used to identify a file location of an override file that contains all of group override entries you want to use on the local computer. For example:

nss.group.override: file:/etc/centrifydc/group.ovr

Within the override file, you use the following format:

+zone_group_name:group_name:group_password:group_id:member_list
-zone_group_name:group_name:group_password:group_id:member_list

For example:

+users::::
+adminsjdoe,bsmith,frank
+ftpusers:ftp::300:
-webusers
+

> **Note**: Changes to the group password field are ignored.

For more information about overriding group entries, see the sample group override file /etc/centrifydc/group.ovr.

> **Note**: If you make changes to this parameter or the override file, you should run adflush to clear the cache to ensure your changes take effect.

nss.group.skip.members

This configuration parameter allows you to skip the retrieval of group membership information for specific groups. Retrieving group membership information from Active Directory can be a very time-consuming and memory-intensive operation for groups with a large number of users, or when using nested groups, but in many cases this information is not needed to perform common UNIX operations. Using this configuration parameter to skip the retrieval of group membership information for specific groups can greatly improve performance for groups with a large number of members.

The parameter value should be a comma-separated list of the UNIX commands for which you can skip group member expansion in the getgrent() call.

The default setting for this configuration parameter is the following for most systems:

ls,chown,find,ps,chgrp,dtaction,dtwm,pt_chmod,id,login,sshd,sshd2,getty,dtlogin,su,adsetgrps,adid

For AIX system, the default is the following:

nss.group.skip.members=ls,chown,find,ps,chgrp,dtaction,dtwm,pt_chmod,id, login,sshd,sshd2,getty,dtlogin,su,adsetgrps,adid

> **Note**: Setting this parameter does not affect the information returned when the nscd or pwgrd daemon is running on a system. The nscd or pwgrd daemons provide a cache for faster user and group lookups, but when the response comes from this cache, the agent cannot modify the response to skip the members listed with this parameter.

nss.nobody.gid

This configuration parameter specifies the group ID (GID) of the system's nobody group.

For example:

nss.nobody.gid: 99

nss.nobody.group

This configuration parameter specifies the group name of the system's nobody group.

For example:

nss.nobody.group: nobody

nss.nobody.uid

This configuration parameter specifies the user ID (UID) of the system's nobody user.

For example:

nss.nobody.uid: 99

nss.nobody.user

This configuration parameter specifies the user name of the system's nobody user.

For example:

nss.nobody.user: nobody

nss.passwd.hash

This configuration parameter specifies whether to include the UNIX password hash in response to the getpw* commands. The parameter value can be true or false. The default value for the parameter is false because the password hash is sensitive information and can make a system vulnerable to a brute force attack. However, if you have applications, such as Informix, that validate users based on the password hash retrieved from NSS, you can set this parameter to true to accommodate those applications.

If you set this parameter to true, however, you must also install a password synchronization service on all of the domain controllers in the domain. The password synchronization service can be the Delinea Password Filter, or the Password Synchronization Service provided by Microsoft in Windows Server 2003 R2 or in the Microsoft Services for UNIX (SFU) package.

nss.passwd.info.hide

This configuration parameter specifies whether to hide the following password attributes from non-root users:

- Maximum Password Age
- Password Expiration Date
- Minimum Password Age
- Change Password Needed
- Password Last Changed On

The parameter value can be true or false. When this parameter is set to true, only users with root permissions can view the password attributes shown above. When this parameter is set to false, users without root permissions can view the password attributes.

The default value for this parameter is true on all UNIX operating systems except HP-UX. On HP-UX, the default is false because HP-UX does not support hiding these attributes.

nss.passwd.override

This configuration parameter allows you to override user profile entries for zone users. Using this parameter is similar to defining override filters for local users in the /etc/passwd file. By defining override filters, you can use this parameter to give you fine-grain control over the user accounts that can access a local computer. You can also use the override controls to modify the information for specific fields in each /etc/passwd entry on the local computer. For example, you can override the user ID, primary group ID, default shell, or home directory for specific login accounts on the local computer without modifying the account entry itself.

In most cases, you set this configuration parameter usinggroup policy. The entries created by group policy are then stored in the /etc/centrifydc/passwd.ovr file and used to filter user access to a local computer.You can, however, set this parameter manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The syntax for overriding passwd entries is similar to the syntax used for overriding NIS. You use + and – entries to allow or deny access for specific users on the local system. Additional fields correspond to the standard /etc/passwd fields separated by colons (:).

In most cases, the nss.passwd.override parameter is used to identify a file location of an override file that contains all of passwd override entries you want to use on the local computer. For example:

nss.group.override: file:/etc/centrifydc/passwd.ovr

> **Note**: Although the passwd.ovr file is generated from the list of override entries you specify using group policy, you can also manually create or update the override file on any local computer, if needed. A sample illustrating the syntax is provided in the /etc/centrifydc/passwd.ovr.sample file.

Within the override file, you use the following format for entries:

+zone_username:username:password:uid:gid:GECOS:home_directory:shell

For example:

```
+mike:::::::/usr/local/ultrabash
+kris:kdavis:x:6:6:Kris Davis:/home/kdavis:/bin/bash
+janedoe@acme.test:jdoe300:300:
+@sysadmins:::::::
-ftp
+@staff:::::::
+@rejected-users:32767:32767:/bin/false
+:/sbin/nologin
+:
```

> **Note**: Overriding the password hash field is ignored. Changing this field in the override file does not affect zone user passwords. In overriding passwd entries, users accounts must be enabled for UNIX in the zone, but the groups do not need to be UNIX-enabled.

In the example above, the @ symbol denotes an Active Directory name. It may be an Active Directory group name, a zone name, or some other container name. You may also specify an Active Directory user principal name instead of the zone name.

Entries in the override file are evaluated in order from first to last with the first match taking precedence. This means the system will only use the first entry that matches a particular user. For example, if the user cruz is a member of both the staff group and the rejected-users group and you have defined the override entries as listed in the example above, the cruz user account is allowed to log on to the computer because the staff entry is evaluated and matched before the rejected-users entry. If the order were reversed in the override file, the cruz account would be flagged as a rejected-users account and denied access.

> **Note**: If you manually create the passwd.ovr file, you must include the following as the last line in the file:

+::::::::

For more information about overriding group entries, see the sample passwd override file /etc/centrifydc/passwd.ovr. For information about using the NSS Overrides group policy to generate and maintain the passwd.ovr file, see the Access Manager online help.

> **Note**: If you make changes to this parameter or the override file, you should run adflush to clear the cache to ensure your changes take effect.

nss.process_group.ignore

This configuration parameter specifies a set of one or more process groups that the Delinea NSS module will ignore for lookup in Active Directory. A *process group* is a collection of related processes which can be called at the same time.

nss.program.ignore

This configuration parameter specifies one or more programs that should not look up account information in Active Directory. The programs you specify for this parameter do not use the agent to contact Active Directory.

Setting this parameter helps to ensure that local programs that create, manage, or use local user and group information do not attempt to look up conflicting information in Active Directory. For example, you can specify programs such as adduser and addgroup to ensure those programs can still be used to create and update local accounts independent of Active Directory:

nss.program.ignore: addgroup,adduser

The specific programs you should include in the list vary by platform and the specific operating environment you are using. The default setting for this configuration parameter includes the most common program names that shouldn't make calls to Active Directory through the agent.

If you have auditing enabled, the agent's auditing service maintains a cache of user information for performance reasons. When you have auditing enabled, you can also use this parameter to circumvent the agent accessing its local cache when you use commands that manipulate local user information directly. For example, you would want the agent to skip checking its local cache when you use commands such as useradd, userdel, adduser, usermod, mkuser, rmuser, chuser, and any other programs that directly access the local /etc/passwd file.

> **Note**: Setting this parameter does not affect the information returned when the nscd or pwgrd daemon is running on a system. The nscd and pwgrd daemons provide a cache for faster user and group lookups, but when the response comes from this cache, the agent cannot modify the response to skip the programs listed with this parameter.

You can also set this configuration parameter usinggroup policy.

nss.program.ignore.check.parents

This configuration parameter specifies whether to recursively check the parent processes' names for the "nss.program.ignore" parameter. The default value is false.

You can also set this configuration parameter using group policy.

nss.shell.emergency.enabled

This configuration parameter specifies whether to use the default login shell when a user or group attempting to access the computer is not allowed to log in.

The default no-login shell and its location is typically platform-specific. For example, on machines running Red Hat Linux, the default shell for users who are denied access is:

/sbin/nologin

The default for this parameter is false, which means that the nologin shell configured in nss.shell.nologin is returned.

nss.shell.nologin

This configuration parameter specifies the default login shell to use when a user or group attempting to access the computer is not allowed to log on. The default no-login shell and its location is typically platform-specific. For example, on Red Hat Linux the default shell for users who are denied access is /sbin/nologin.

For example:

nss.shell.nologin: /sbin/nologin

> **Note**: If you make changes to this parameter, you should run adflush to clear the cache to ensure your changes take effect.

nss.split.group.membership

This configuration parameter specifies whether to split up or truncate large groups when you use the getent group UNIX command to retrieve group information.

In operating environments that do not support large groups, commands that return group information could fail or return incomplete results when a group has a membership list exceeds the maximum size allowed. Typically, the maximum size allowed for groups is 1024 bytes, which is roughly equivalent to 125 users. If your environment contains large groups that exceed the 1024-byte limit, you can set this parameter to true to have those groups automatically split into multiple groups when they reach the maximum size.

When this parameter is set to true and you issue the getent group command without specifying a group name, large groups are split into sublists, and all sublists are returned. When this parameter is set to false, large groups are truncated, and only the truncated results of the group list (typically the first 1024 bytes) are returned.

> **Note**: This policy has no effect in Mac OS X environments.
>
> **Note**: This configuration parameter takes effect only when you do not specify a group name on the getent group command line. Because of the way in which group information is queried in NSS, group lists are always truncated (and not split) when you specify a group name on the getent group command line (for example, getent group group_name).

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

The default value is true for Solaris, HPUX, and IRIX, but false for all other operating environments. For example:

nss.split.group.membership: true

nss.squash.root

This configuration parameter specifies whether you want to force root and wheel super-user accounts to be defined locally. If you set this parameter to true, Active Directory users with a UID of 0, a GID of 0, a user or group name of root, or a group name of wheel are not permitted to log on. Because the agent cannot prevent Active Directory users or groups from being assigned a UID or GID of 0, which would give those users or groups root-level access to the computers in a zone, you can use this parameter to prevent any Active Directory users with a UID or GID of 0 from logging on. Setting this parameter to true forces the privileged accounts to be defined as local accounts and not authenticated through Active Directory.

For example:

nss.squash.root: true

If you set this parameter to false, you should use other configuration parameters, such as pam.ignore.users or user.ignore to skip Active Directory authentication for system accounts so that Active Directory users cannot be granted root access on the computers in the zones they are permitted to access.

The default value for this parameter is true. It is possible, however, for an Active Directory administrator to override this setting through the use of group policy applied to a local computer, for example, by using the **Sudo rights** group policy. There is no way to effectively prevent the setting from being changed, except by disabling computer-based group policies in the local centrifydc.conf file or by strictly controlling who has permission to enable and apply group policies to computers that join an Active Directory domain. For information about disabling group policies using parameters in the local centrifydc.conf file, see gp.disable.all or gp.disable.machine in Customizing

nss.uid.ignore

This configuration parameter specifies a set of one or more user identifiers that the Delinea NSS module will ignore for lookup in Active Directory.

In most cases, this configuration parameter's value is generated automatically by group policy.

If you select the **Specify user names to ignore** group policy and click **Enabled**, you can type the list of local user names not stored in Active Directory. The list you specify for the group policy is then stored in the /etc/centrifydc/user.ignore file and used to automatically generate the /etc/centrifydc/uid.ignore file. These files are then used to disable looking up account information in Active Directory for the users specified, which results in faster name lookup service for system user accounts such as tty and disk.

You can, however, define this parameter manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you manually set this parameter, the parameter value should be one or more user identifiers, separated by a space, or the file: keyword and a file location. For example:

nss.uid.ignore: 0 20 5861
nss.uid.ignore=file:/etc/centrifydc/uid.ignore

A default set of system user accounts to ignore is defined in the sample /etc/centrifydc/user.ignore file and in the /etc/centrifydc/uid.ignore file. If you edit either file, be sure to run the adreload command after modifying the file to have the changes take effect.

nss.user.group.prefer.cache

Use this parameter to specify whether or not to always use the cached information and defer the refreshing of Active Directory information in the background.

If you have a lot of NSS queries for users or groups, you can improve adclient performance by enabling this parameter.

The default value for this parameter is false.

This parameter applies to NSS user and group queries (getpw* and getgr*).

nss.user.ignore

This configuration parameter specifies one or more users that the Delinea NSS module will ignore for lookup in Active Directory. Because this parameter allows you to intentionally skip looking up specific accounts in Active Directory, it allows faster lookup for system accounts such as tty, root, and bin.

> **Note**: This configuration parameter only ignores the listed users for NSS lookups. To ignore users for authentication and NSS lookups, use the pam.ignore.users configuration parameter.

In most cases, this configuration parameter's value is generated automatically by group policy.

If you select the **Specify user names to ignore** policy and click **Enabled**, you can type the list of local user names not stored in Active Directory. This list is then stored in the /etc/centrifydc/user.ignore file and used to automatically generate the /etc/centrifydc/uid.ignore file. These files are then used to disable looking up account information in Active Directory for the users specified, which results in faster name lookup service for system user accounts such as tty and disk.

You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value should be one or more user names, separated by a space, or the file: keyword and a file location. For example:

```
nss.user.ignore: root sys tty
nss.user.ignore=file:/etc/centrifydc/user.ignore
```

A default set of users to ignore are defined in sample /etc/centrifydc/user.ignore and /etc/centrifydc/uid.ignore files. If you are not using group policies, you can uncomment the nss.user.ignore parameter in the /etc/centrifydc/centrifydc.conf file to ignore the default set of users.

> **Note**: If you plan to edit the user.ignore file, be sure to run the adreload command after modifying the file to have the changes take effect.

nss.user.ignore.all

This configuration parameter specifies how the list of users in nss.user.ignore is applied during lookups.

The parameter value can be true or false.

When you set this parameter to true, lookups generated by NSS, ldapproxy, or JAPI ignore the Active Directory users listed in nss.user.ignore.

When you set this parameter to false, only lookups generated by NSS ignore the Active Directory users listed in nss.user.ignore.

The default value is false.

nss.watch.slow.lookup.info.threshold

This configuration parameter specifies the threshold (in milliseconds) for the time spent on a complete NSS request. When a NSS request exceeds this threshold, the NSS module writes information to a message to the INFO log file.

By default, this parameter is set to -1, which means that there is no threshold.

For example: nss.watch.slow.lookup.info.threshold:10.

nss.watch.slow.lookup.info.threshold.group

This configuration parameter specifies the threshold (in milliseconds) for the time spent on a complete NSS request categorized by group. When a NSS request exceeds this threshold for the user category, the NSS module writes to a message to the INFO log file.

The group category indicates the following NSS calls: getgrnam* getgrgid*

The nss.watch.slow.lookup.info.threshold.group setting overrides that set by the nss.watch.slow.lookup.info.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: nss.watch.slow.lookup.info.threshold.group:35.

nss.watch.slow.lookup.info.threshold.user

This configuration parameter specifies the threshold (in milliseconds) for the time spent on a complete NSS request categorized by user. When a NSS request exceeds this threshold for the user category, the NSS module writes to a message to the INFO log file.

The user category indicates the following NSS calls: getpwnam* getpwuid* getgrouplist

The nss.watch.slow.lookup.info.threshold.user setting overrides that set by the nss.watch.slow.lookup.info.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: nss.watch.slow.lookup.info.threshold.user:15.

nss.watch.slow.lookup.warn.threshold

This configuration parameter specifies the threshold (in milliseconds) for the time spent on a complete NSS request. When a NSS request exceeds this threshold, the NSS module writes information to a WARN log file.

By default, this parameter is set to -1, which means that there is no threshold.

For example: nss.watch.slow.lookup.warn.threshold:20.

nss.watch.slow.lookup.warn.threshold.group

This configuration parameter specifies the threshold (in milliseconds) for the time spent on a complete NSS request for the group category. When a NSS request exceeds this threshold, the NSS module writes information to a WARN log file.

The group category indicates the following NSS calls: getgrnam* getgrgid*

The nss.watch.slow.lookup.info.threshold.user setting overrides that set by the nss.watch.slow.lookup.warn.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: nss.watch.slow.lookup.warn.threshold.group:30.

nss.watch.slow.lookup.warn.threshold.user

This configuration parameter specifies the threshold (in milliseconds) for the time spent on a complete NSS request for the user category. When a NSS request exceeds this threshold, the NSS module writes information to a WARN log file.

The user category indicates the following NSS calls: getpwnam* getpwuid* getgrouplist

The nss.watch.slow.lookup.info.threshold.user setting overrides that set by the nss.watch.slow.lookup.warn.threshold parameter.

By default, this parameter is set to -1, which means that there is no threshold.

For example: nss.watch.slow.lookup.warn.threshold.user:25.

lam.attributes.group.ignore

This parameter points to a file containing a list of AIX group attributes that the lam module should ignore and let AIX handle it to either provide the default value or return ENOATTR. The default is file:/etc/centrifydc/attributes.group.ignore.

lam.attributes.user.ignore

This parameter points to a file containing a list of AIX user attributes that the lam module should ignore and let AIX handle it to either provide the default value or return ENOATTR. The default is file:/etc/centrifydc/attributes.user.ignore.

lam.max.group.count

This configuration parameter applies to the AIX Loadable Authentication Module (LAM) and specifies the maximum number of Active Directory groups that the lsgroup ALL command will return.

The parameter value must be an integer. The default value for this parameter is 1000 groups. If you specify 0 or a negative value (for example, -1), there is no limit on the number of groups returned. For example:

lam.max.group.count: 100

Before changing this parameter setting or using a value of 0, you should consider its impact on your environment. Increasing the value of this parameter may provide more complete information about the number of Active Directory UNIX groups, but may result in slower performance if there are more Active Directory UNIX groups in the zone than the maximum you specify. Similarly, if you do not set a limit, you may experience performance problems if you have a large number of Active Directory groups. Decreasing the value of this parameter may provide better response time if there are more Active Directory UNIX groups in the zone than the maximum you specify, but further limits how much information is returned.

If this parameter is not defined in the configuration file, its default value is 1000 groups.

lam.max.user.count

This configuration parameter applies to the AIX Loadable Authentication Module (LAM) and specifies the maximum number of Active Directory users that the lsuser ALL command will return. This value also limit the results returned by the getpwent() and nextuser() functions.

The parameter value must be an integer. The default value for this parameter is 1000 users. If you specify 0 or a negative value (for example, -1), there is no limit on the number of users returned. For example:

lam.max.user.count: 100

Before changing this parameter setting or using a value of 0, you should consider its impact on your environment. Increasing the value of this parameter may provide more complete information about the number of Active Directory UNIX users, but may result in slower performance if there are more Active Directory UNIX users in the zone than the maximum you specify. Similarly, if you do not set a limit, you may experience performance problems if you have a large number of Active Directory users. Decreasing the value of this parameter may provide better response time if there are more Active Directory UNIX users in the zone than the maximum you specify, but further limits how much information is returned.

If this parameter is not defined in the configuration file, its default value is 1000 users.

Customizing NIS Configuration Parameters

This section describes the configuration parameters that affect the operation of the Delinea Network Information Service on the local host computer. The Delinea Network Information Service—`adnisd` -— provides a mechanism for responding to NIS client requests from computers not managed by a Server Suite Agent.

log.adnisd

This configuration parameter specifies the logging level for the Delinea Network Information Service. The default logging level is the logging level set for the log configuration parameter or INFO if neither parameter is defined in the configuration file. For example, to diagnose problems with the Delinea Network Information Service without changing the logging level for other components:

log.adnisd: DEBUG

log.adnisd.netgroup

This configuration parameter specifies the logging level for netgroup processing of the Centrify Network Information Service. The default logging level is the logging level set for the log.adnisd parameter if that parameter is defined. This parameter value can be set to DEBUG to log netgroup diagnostics or to INFO to suppress messages.

For example:

log.adnisd.netgroup: INFO

You can also set lower-level logging for netgroup processing using the following parameters:

log.adnisd.netgroup.syntax	Syntax warnings and errors for netgroup processing. The default value is the value defined for the log.adnisd.netgroup parameter.
log.adnisd.netgroup.inv	Inversion processing. The default value is the value defined for the log.adnisd.netgroup parameter. This parameter value can be set to DEBUG to log netgroup diagnostics or to INFO to suppress messages.

logger.facility.adnisd

This configuration parameter specifies the syslog facility to use for logging adnisd operations. This parameter enables you to log adnisd messages using a different syslog facility than the facilities used for logging general adclient messages or adclient audit messages. This parameter's value can be any valid syslog facility. For example, you can set this parameter to log messages to auth, authpriv, daemon, security, or localn facilities. The default is the auth facility. For example:

logger.facility.adnisd: auth

nisd.domain.name

This configuration parameter specifies the NIS domain name for the adnisd process to use when communicating with NIS clients.

For example, to specify that you want to use euro-all as the NIS domain name in the zone named Europe-00-Zone, you can set this parameter as follows:

nisd.domain.name: euro-all

If this parameter is not defined in the configuration file, the zone name is used by default.

nisd.exclude.maps

This configuration parameter specifies the name of the NIS maps you want to prevent the NIS service from using in response to NIS clients. This parameter enables you to exclude specific maps rather than explicitly specifying the maps you want to make available. For example, if you have a large number of automount maps or other network information that you want to make available to NIS clients but do not want to use agentless authentication, you can use this parameter to exclude the passwd and group maps but respond to automount or netgroup requests.

To use this configuration parameter, you must add the parameter name to the /etc/centrifydc.conf configuration file, then define its value. The parameter value must be a list of valid NIS map names, separated by spaces. For example:

nisd.exclude.maps: group passwd

This parameter excludes the named map and all derived maps. For example, if you specify group, the derived maps, group.byname, and group.bygid, are excluded. If this parameter is not defined in the configuration file, all NIS maps found in Active Directory are retrieved and available for service.

This configuration parameter overrides the setting of the nisd.maps parameter. If the same map is specified for both the nisd.exclude.maps and nisd.maps parameters, the map is excluded.

nisd.largegroup.name.length

This configuration parameter specifies the maximum number of characters to use in group names when groups with a large number of members are split into multiple new groups. Because some devices that submit NIS requests have limitations on the length of group names, you can use this parameter to specify the maximum length for group names.

When the adnisd process splits the group membership for a large group into multiple smaller groups, it truncates the original group name as needed to append the suffix defined in the nisd.largegroup.suffix parameter and not exceed the number of characters specified by this parameter. For example, if you have a large group named worldwide-all-corp, and have defined the suffix string as "-all" and the maximum length for group names as 10, when the worldwide-all-corp group membership is split into multiple groups, the groups are named as follows:

world-all1
world-all2
world-all3
world-all3

For example, to set the maximum length for group names to 20 characters:

nisd.largegroup.name.length: 20

If this parameter is not defined in the configuration file, the maximum group name length is 1024 characters by default.

nisd.largegroup.suffix

This configuration parameter specifies the suffix string or character to use in group names when automatically splitting up a group with large number of members.

Because group.bygid and group.byname NIS maps can often contain membership lists that exceed the 1024 limit for how much NIS data can be served to clients, the adnisd process will automatically truncate the membership list when this limit is reached. To allow the additional membership data to be retrieved, you can configure the Delinea Network Information Service to automatically split a large group into as many new groups as needed to deliver the complete membership list.

If you specify any value for the nisd.largegroup.suffix parameter, you enable the adnisd process to automatically split a large group into multiple new groups. When a group's data size exceeds 1024 data limit, a new group is created. The new group name is formed using the original group name, followed by the string defined for the nisd.largegroup.suffix parameter and ending in a number that represents the numeric order of the new group created.

For example, if you have a large group named performix-worldwide-corp, and have defined the suffix string as "-all" and the maximum length for group names as 10, when the performix-worldwide-corp group membership is split into multiple groups, the groups are named as follows:

performix-worldwide-corp-all1
performix-worldwide-corp-all2
performix-worldwide-corp-all3
performix-worldwide-corp-all4

All of the new groups have the same group identifier (GID) as the original group. If the new group names would exceed the maximum length for group names on a platform, you can use the nisd.largegroup.name.length parameter to set the maximum length for the new groups created.

If this configuration parameter is not set, the adnisd process truncates the group membership list such that each group entry is under 1024 characters.

nisd.maps

This configuration parameter specifies the name of the NIS maps currently available for NIS service. When the adnisd daemon connects to Active Directory, it retrieves the list of NIS maps available for the local computer's zone, creates a local map data store, and updates this configuration parameter, if necessary, to indicate the maps retrieved. If any NIS client requests a map that is not in the list specified by this parameter, the daemon refuses the request.

The parameter value must be a list of NIS map names. If the parameter is included in the configuration file but no value is set, no maps are retrieved from Active Directory or available for service.

For example, to make the netgroup maps available, but no other maps, you can set this parameter as follows:

nisd.maps: netgroup,netgroup.byhost,netgroup.byuser

> **Note**: You must specify all maps, including the derived maps.

If this parameter is not defined in the configuration file, all NIS maps found in Active Directory are retrieved and available for service.

nisd.maps.max

This configuration parameter specifies the number of alternate sets of NIS maps to retain. A new set of NIS maps is normally created when adnisd switches to an alternate domain controller. Keeping these alternate sets of maps allows Centrify Network Information Service to more efficiently switch between domain controllers.

The parameter value must be an integer greater than zero. The default is 2 map sets. For example:

nisd.maps.max: 2

nisd.net_addr

This configuration parameter sets the IP address the adnisd process uses for the NIS client socket. For example, the following sets the IP address to 192.168.212.11:

nisd.net_addr: 192.168.212.11

On systems with multiple Ethernet interfaces, adnisd configures RPC to the first interface. If an NIS client is trying to communicate on a different interface, adnisd will not receive the request.

Before creating sockets, adnisd reads centrifydc.conf file to see if an IP address and TCP and UPD ports are specified. If not, it uses localhost and random port numbers assigned by the operating system.

Use the nisd.port.udp and nisd.port.tcp parameters to complete the NIS port assignment.

nisd.passwd.expired.allow

This configuration parameter specifies whether a user with an expired Active Directory password should be allowed to log on to computers authenticated through NIS requests. The parameter value can be set to true or false.

By default, when a user's Active Directory password expires the password hash field in the passwd NIS map is replaced by two exclamation marks (!!), and the user is not allowed to log on to the local NIS client computer without first logging on to a Windows computer or an agent-managed computer running adclient to update the expired password. You can use this parameter to allow the user to log on locally using the expired password.

If you set the parameter value to true, users with an existing password hash in the passwd map generated from Active Directory do not have their password hash replaced by the exclamation marks and they can continue to log on using the expired password until they update their password in Active Directory. Once they update their password in Active Directory, in the NIS map is updated with a new password hash and users can log on with the new password. If a user never updates the Active Directory password by logging on to a Windows or agent-managed computer, however, the user's expired password may be used indefinitely.

The default value for this parameter is false. For example:

nisd.passwd.expired.allow: false

nisd.port.tcp

This configuration parameter sets the TCP port number the adnisd process uses to create the socket for NIS client communications. For example, the following sets the TCP port to 2556:

nisd.port.tcp: 2556

By default, no port number is specified. If you do not specify the port number, the operating system assigns a random port number.

Use the nisd.port.udp and nisd.net_addr parameters to complete the NIS client socket configuration.

nisd.port.udp

This configuration parameter sets the UDP port number the adnisd process uses to create the socket for NIS client communications. For example, the following sets the UPD port to 2555

nisd.port.udp: 2555

By default, no port number is specified. If you do not specify the port number, the operating system assigns a random port number.

Use the nisd.port.tcp and [nisd.net_addr]nisd-net-addr.md) parameters to complete the NIS client socket configuration.

nisd.securenets

This configuration parameter specifies a list of one or more subnets from which the daemon will accept NIS requests. You use this parameter to restrict access to the Delinea Network Information Service by IP address. NIS requests that do not come from the IP addresses specified in this configuration parameters are refused by the asnisd daemon.

> **Note**: You do not need to specify the local IP address for this parameter. The Delinea Network Information Service will always accept local NIS client requests.

The parameter value must include both the specific IP address or subnet and the subnet mask, separated by a forward slash. For example:

nisd.securenets: 192.168.111.0/255.255.255.0

You can specify multiple IP addresses by separating each IP address-subnet mask pair with a comma or a space. For example:

nisd.securenets: 192.68.11.0/255.255.255.0,192.147.10.0/255.255.255.0

If this parameter is not defined in the configuration file, only local NIS client requests are accepted by the asnisd process.

nisd.server.switch.delay

This configuration parameter specifies how long, in seconds, to wait before loading maps from a backup domain controller when the connection to the primary domain controller is lost. If the Delinea Network Information Service is unable to connect to its primary Active Directory domain controller, it will respond to NIS client requests using information in the local cache until the switch to the backup domain controller is complete.

The parameter value must be an integer equal to or greater than zero. If the value is zero, then the delay is disabled. For example, to set the delay period to 2 hours:

nisd.server.switch.delay: 7200

If this parameter is not defined in the configuration file, the default delay for switching to the backup domain controller is ten minutes (600 seconds).

nisd.startup.delay

This configuration parameter specifies the maximum number of seconds that the adnisd process should wait before responding to NIS client requests.

While adnisd retrieves and generates its NIS maps, it does not respond to client requests for the maximum number of seconds specified by this parameter. At the end of the startup delay time, adnisd will respond to NIS client requests whether all maps are loaded or not. Therefore, setting this parameter enables the adnisd process to begin responding to NIS clients requests before all NIS maps are loaded or created. You should be aware, however, that if the delay time is reached before all of the NIS maps are available, NIS clients may receive partial or empty answers to their requests.

> **Note**: If all of the NIS maps are loaded or created in less time than specified by this parameter, adnisd will begin responding to NIS requests without any startup delay.

By default, the maximum startup delay is 180 seconds. If you set this configuration parameter to zero, the adnisd process will only respond to NIS client requests after all NIS maps have been loaded or created. Therefore, in most cases, the parameter value should be a positive integer. For example, to set the startup delay to two minutes, you would set the parameter value to 120:

nisd.startup.delay: 120

nisd.threads

This configuration parameter specifies the maximum number of threads to allocate for processing NIS client requests.

The parameter value must be a positive integer within the valid range of 1 to 200. If you want to increase or decrease the number of threads used, you should stop the adnisd process, modify this parameter and save the configuration file, then restart the adnisd process.

The default value for this parameter is 4 threads. For example:

nisd.threads: 4

nisd.update.interval

This configuration parameter specifies the interval, in seconds, that the adnisd daemon waits between connections to Active Directory. At each interval, the adnisd daemon connects to Active Directory, gets the latest NIS maps for the local computer's zone, and updates its local NIS map data store.

The parameter value must be an integer equal to or greater than zero. If the value is zero, then the update interval is disabled and the local NIS map data store is not updated. For example, to set the interval for getting NIS maps to 1 hour:

nisd.update.interval: 3600

If this parameter is not defined in the configuration file, the default interval is 30 minutes (1800 seconds).

Customizing AIX Configuration Parameters

This section describes the configuration parameters that affect the administration of users and groups on AIX computers.

Setting extended attributes

AIX provides extended user and group attributes that enable administrators to specify user or group characteristics, such as the ability to login remotely to a user account, use the system resource controller (SRC) to execute programs, and so on. You can define these attributes for specific users and groups or for all user and group accounts on a local computer by editing specific configuration files such as /etc/security/user, /etc/security/group, and /etc/security/limits. The specific extended attributes available depend on the version of AIX you are using. For information about the extended attributes available for users and groups, see the AIX documentation for the security configuration files.

You can centralize administration of AIX computers by setting extended attributes for individual AIX users and groups in Active Directory. You can also set configuration parameters to set default extended attribute values for all Active Directory users or groups on a particular AIX computer.

> **Note**: Certain extended attributes, such as the system privileges, or capabilities attributes, are only supported by methods in the Loadable Authentication Module (LAM) version 5.2 or later.

The agent configuration file can include AIX configuration parameters that correspond to AIX extended attributes. For example:

admin	aix.user.attr.admin
daemon	aix.user.attr.daemon
rlogin	aix.user.attr.rlogin
su	aix.user.attr.su

Each configuration parameter has a hard-coded default value. You can edit the centrifydc.conf configuration file on any computer to change its default value. You should note that changes you make in the centrifydc.conf file only affect Active Directory users and groups. The settings do not affect local users or groups. Local users and groups get their extended attributes from the settings in the AIX configuration files, such as /etc/security/user and /etc/security/limits.

Enforcing access rights on AIX computers

If you are using the AIX Loadable Authentication Module (LAM), users who do not have the PAM login-all right can still log in. For example, an Active Directory user joined to the zone with the AIX computer and assigned to a role that does NOT include the login-all right can, in fact, log in to the AIX servers using the LAM interface. This is because the LAM interface does not use the rights defined in the user's Delinea role to control access. If the same server is configured with the PAM authentication module, that user would not be able to log in.

To control user log in activity, you have two choices:

- Keep the LAM interface and use one of the following PAM configuration parameters to define who has or does not have access:
  - pam.allow.groups: This configuration parameter specifies the groups allowed to access PAM-enabled applications.
  - pam.allow.users: This configuration parameter specifies the users who are allowed to access PAM-enabled applications.
  - pam.deny.groups: This configuration parameter specifies the groups that should be denied access to PAM-enabled applications.
  - pam.deny.users: This configuration parameter specifies the users that should be denied access to PAM-enabled applications.
- Replace the LAM interface with PAM. See the IBM AIX documentation for the instructions. The conversion procedure is fairly simple, however, you should test all applications on the server to ensure that they work the same with PAM. In addition, if you are using Delinea OpenSSH there are two versions: one for LAM and one for PAM. Both a LAM and PAM versions are distributed in the package. If you convert to PAM, uninstall the LAM version and install the PAM version.

Setting extended attributes

To set an extended attribute for an individual user, you can use adedit commands.

For example, to set the value of the extended attributes aix.ttys and aix.rlogin for the user joe, you might run commands similar to the following after binding to a domain and selecting a zone:

```
select_zone_user joe@ajax.acme.test
set_zone_user_field aix.ttys r1,r2,r3
set_zone_user_field aix.rlogin true
```

To verify the value of the extended attributes you have set, you might run commands similar to the following:

```
get_zone_user_field aix.ttys
r1,r2,r3
save_zone_user
```

You can also use adedit abbreviations to set and get extended attribute values. For example:

```
slzu joe@ajax.acme.test
szuf aix.fsize 209715
szuf aix.core 2097151
szuf aix.cpu -1
szuf aix.data 262144
```

Alternatively, you can also use configuration parameters to supplement the settings in the AIX /etc/security/user file. For example, if you have not explicitly defined the aix.rlogin attribute in /etc/security/user, you can set the following parameter in the centrifydc.conf file:

```
aix.user.attr.rlogin: false
```

You can use adquery and the keyword help to view a list of the supported extended attributes. For example:

```
adquery user --extattr help
```

aix.cache.extended.attr.enable

Use this parameter to specify whether to cache extended attribute default values. Caching extended attribute default values improves performance of the lsuser command.

The default value is false.

aix.user.attr.admgroups

This configuration parameter specifies the groups that the user account administers.

For the parameter value, enter a comma-separated list of groups; for example:

aix.user.attr.admgroups: unixAdmins,dnsAdmins

This parameter corresponds to the aix.admingroups attribute in the /etc/security.user file.

The default value is the empty string (no groups).

aix.user.attr.admin

This configuration parameter specifies the administrative status of the user.

Set the parameter value to true to define the user as an administrator; for example:

aix.user.attr.adm: true

Set the value to false to specify that the user is not an administrator. This is the default value.

This parameter corresponds to the aix.admin attribute in the /etc/security.user file.

aix.user.attr.auditclasses

This configuration parameter specifies the audit classes for the user.

You may enter a list of audit classes separated by commas, or the keyword ALL or an asterisk (*) to specify all audit classes. For example:

aix.user.attr.auditclasses: general,system

Place an exclamation point in front of a class to exclude it. For example, the following setting specifies all classes except system:

aix.user.attr.auditclasses: ALL,!system

This parameter corresponds to the aix.auditclasses attribute in the /etc/security.user file.

The default value is the empty string (no audit classes).

aix.user.attr.core

This configuration parameter specifies the soft limit for the largest core file that the user can create. Use -1 to set an unlimited size.

For example, to set the value to 2097151:

aix.user.attr.core: 2097151

This parameter corresponds to the aix.core attribute in the /etc/security.limits file.

The default value is 2097151.

aix.user.attr.cpu

This configuration parameter specifies the soft limit (in seconds) for the amount of system time that a user's process can use.

Use -1 to set an unlimited size; for example, to set the limit to one hour:

aix.user.attr.cpu: 3600

This parameter corresponds to the aix.cpu attribute in the /etc/security.limits file.

The default value is -1.

aix.user.attr.data

This configuration parameter specifies the soft limit for the largest data-segment for a user's process. Use -1 to set an unlimited size.

For example, to se the value to 2097151:

aix.user.attr.data: 2097151

This parameter corresponds to the aix.data attribute in the /etc/security.limits file.

The default value is 2097151.

aix.user.attr.daemon

This configuration parameter specifies whether the user can execute programs using the system resource controller (SRC), which manages system daemons and sub systems such as adclient and NFS.

Set the parameter value to true to allow users to execute programs using the SRC. Set the value to false to prevent users from executing programs using the SRC.

This parameter corresponds to the aix.daemon attribute in the /etc/security.user file.

The default value is false, which prevents a user from executing programs using SRC.

aix.user.attr.fsize

This configuration parameter specifies the soft limit for the largest file that the user process can create. Use -1 to set an unlimited size.

For example, to set the value to 2097151:

aix.user.attr.fsize: 2097151

This parameter corresponds to the aix.fsize attribute in the /etc/security.limits file.

The default value is 2097151.

aix.user.attr.nofiles

This configuration parameter specifies the soft limit for the number of file descriptors that the user's process may have open at one time.

Use -1 to set an unlimited size.

For example, to set the limit to 2000:

aix.user.attr.nofiles: 2000

This parameter corresponds to the aix.nofiles attribute in the /etc/security.limits file.

The default value is -1.

aix.user.attr.nprocs

This configuration parameter specifies the soft limit on the number of processes a user can have running at one time.

Use -1 to specify the maximum number allowed by the system; for example:

aix.user.attr.nprocs: -1

This parameter corresponds to the aix.nprocs attribute in the /etc/security/limits file.

The default value is -1.

aix.user.attr.rlogin

This configuration parameter specifies whether remote users can access the user account through rlogin and telnet.

Set the parameter value to true to allow remote access to the user account.

Set the parameter value to false to prevent remote access to the user account.

This parameter corresponds to the aix.rlogin attribute in the /etc/security.user file.

The default value is true, which allows remote access to the user account.

aix.user.attr.rss

This configuration parameter specifies the soft limit for the largest amount of system memory that the user process can allocate. Use -1 to set an unlimited size.

For example, to set the value to 2097151:

aix.user.attr.rss: 2097151

This parameter corresponds to the aix.rss attribute in the /etc/security.limits file.

The default value is 65536.

aix.user.attr.stack

This configuration parameter specifies the soft limit for the largest stack segment for the user's process. Use -1 to set an unlimited size.

For example, to set the value to 2097151:

aix.user.attr.stack: 2097151

This parameter corresponds to the aix.stack attribute in the /etc/security.limits file.

The default value is 65536.

aix.user.attr.su

This configuration parameter specifies whether other users can use the su command to switch to this user account.

Set the parameter value to true to allow other users to switch to this user account.

Set the value to false to prevent users from switching to this user account.

This parameter corresponds to the aix.su attribute in the /etc/security.user file.

The default value is true, which allows other users to switch to this user account.

aix.user.attr.sugroups

This configuration parameter specifies the groups that can use the su command to switch to this user account.

You may enter a list of groups separated by commas, or the keyword ALL or an asterisk (*) to specify all groups. For example:

aix.user.attr.sugroups: admins,unixAdmins,dnsAdmins,enterpriseAdmins

Place an exclamation point in front of a group to exclude it. For example, the following setting specifies all groups except dnsAdmins:

aix.user.attr.sugroups: ALL,!dnsAdmins

This parameter corresponds to the aix.sugroups attribute in the /etc/security.user file.

The default value is ALL, which allows all groups to switch to the user account.

aix.user.attr.threads

This configuration parameter specifies the soft limit for the largest number of threads that a user process can create.

Use -1 to specify an unlimited number; for example:

aix.user.attr.threads: -1

This parameter corresponds to the aix.thread attribute in the /etc/security/limits file.

The default value is -1, which specifies an unlimited number of threads.

aix.user.attr.tpath

This configuration parameter specifies the status of the user's trusted path. The trusted path prevents unauthorized programs from reading data from the user terminal.

Set one of the following values for this parameter:

always	Allows the user to execute trusted processes only, which means the that the user's initial program must be in the trusted shell or another trusted process.
notsh	Prevents the user from invoking the trusted shell on a trusted path. Entering the secure attention key (SAK) causes the login session to terminate.
nosak	Disables the secure attention key (SAK) for all processes run by the user. Specify nosak if the user transfers binary that may contain the SAK. This is the default value.
on	Provides the user with normal trusted path characteristics; the user can invoke a trusted path (enter a trusted shell) with the secure attention key (SAK).

This parameter corresponds to the aix.tpath attribute in the /etc/security.user file.

The default value is nosak.

aix.user.attr.ttys

This configuration parameter specifies the terminals that can access the user account.

You may enter a list of terminals separated by commas, or the keyword ALL or an asterisk (*) to specify all terminals. For example:

aix.user.attr.ttys: /dev/pts

> **Note**: You must specify /dev/pts or ALL for network logins to work.

Place an exclamation point in front of a group to exclude it.

This parameter corresponds to the aix.ttys attribute in the /etc/security.user file. The default value is ALL, which allows all terminals to access the user account.

aix.user.attr.umask

This configuration parameter specifies the default umask to define permissions for the user. The umask value along with the permissions of the creating process determine the permissions for a new file.

This parameter corresponds to the aix.ttys attribute in the /etc/security.user file.

The parameter value can be set to a three-digit octal value. The default value is 022.

Customizing Delinea UNIX programs Configuration Parameters

This section describes the configuration parameters that affect the operation of Delinea UNIX command line programs on the local host computer.

adjoin.adclient.wait.seconds

This configuration parameter specifies the number of seconds the adjoin command should wait before exiting to ensure that the agent is available to complete the join operation.

For example, to configure the adjoin command to wait 10 seconds:

adjoin.adclient.wait.seconds: 10

adjoin.krb5.conf.file

This configuration parameter specifies the path to a customized Kerberos configuration file you want to use to join a domain.

The parameter value must be a path name. For example:

adjoin.krb5.conf.file: /etc/centrifydc/krb5_join.conf

adjoin.samaccountname.length

This configuration parameter specifies the maximum number of characters to use when the adjoin command must generate a pre-Windows 2000 computer name by truncating the host name. This parameter also determines how adjoin creates the computer account in Active Directory.

The default value is 15 characters to conform to the maximum length allowed by the NetLogon service, which is the preferred service for adclient to use for NTLM pass-through authentication. NetLogon is fast and automatically returns a user's group membership.

The maximum length allowed for the pre-Windows 2000 computer name, which is stored in the sAMAccountName attribute for the computer account in Active Directory, is 19 characters. However, if you specify more than 15 characters (up to the 19 character limit) adclient will use slower NTLM authentication methods, and will use additional LDAP searches to fetch the user's group membership.

> **Note**: This configuration parameter is ignored if you run the adjoin command with the --prewin2k option to manually specify the pre-Windows 2000 computer name.

The parameter value should be a positive integer in the valid range of 1 to 19 characters. For example:

adjoin.samaccountname.length: 15

If you specify a value greater than 19, the parameter setting is ignored and the computer name is truncated at 19 characters in the sAMAccountName attribute for the computer account.

If the computer's host name size exceeds the specified value for this parameter, adjoin will use LDAP (and require administrative privileges) to create computer accounts, instead of MS-RPC. In any case, if the computer's short host name exceeds 19 characters, then it is no longer possible to create computer accounts by using MS-RPC methods and LDAP will be used instead.

adpasswd.account.disabled.mesg

This configuration parameter specifies the message displayed by the adpasswd program when users cannot change their password because their account is locked.

For example:

adpasswd.account.disabled.mesg:
Account cannot be accessed at this time. Please contact your system administrator.

adpasswd.account.invalid.mesg

This configuration parameter specifies the message displayed by the adpasswd program when a user account is unrecognized or the password is invalid.

For example:

```
adpasswd.account.invalid.mesg: \
Invalid username or password
```

adpasswd.password.change.disabled.mesg

This configuration parameter specifies the message displayed by the adpasswd program when users are not allowed to change their password because password change for these users has been disabled in Active Directory.

For example:

adpasswd.password.change.disabled.mesg: \
Password change for this user has been disabled in Active Directory

adpasswd.password.change.perm.mesg

This configuration parameter specifies the message displayed by the adpasswd program when a user cannot change another user's password because of insufficient permissions.

For example:

adpasswd.password.change.perm.mesg:
You do not have permission to change this users password. Please contact your system administrator.

Customizing Smart Card Configuration Parameters

This section describes the configuration parameters that affect the use of Delinea access control smart cards on the local host computer.

smartcard.allow.noeku

This configuration parameter allows the use of certificates that do not have the Extended Key Usage (EKU) attribute. Normally, smart card use requires certificates with the EKU attribute. The value of this parameter can be true or false.

If you set this parameter to true, certificates without an EKU attribute can be used for SmartCard logon, and certificates with the following attributes can also be used to log on with a smart card:

- Certificates with no EKU
- Certificates with an All Purpose EKU
- Certificates with a Client Authentication EKU

If you set this parameter to false, only certificates that contain the smart card logon object identifier can be used to log on with a smart card. The default value of this parameter is false.

After changing the value of this parameter, you must re-enable smart card support by running the following sctool command as root:

[root]$ sctool -E

When you run sctool with the -E option, you must also specify the -a or -k option. You can also control this feature using group policy.

smartcard.login.force

This configuration parameter forces users to log in with a smart card.

By default, this parameter is set to `False`, which means that users are not forced to use a smart card (it's optional).

To force the use of smart cards, set this parameter to `True`:

```
smartcard.login.force: true
```

smartcard.name.mapping

This configuration parameter turns on support for multi-user smart cards.

By default, this parameter is set to False, which prevents the use of multi-user smart cards.

To allow the use of multi-user smart cards, set this parameter to True:

smartcard.name.mapping: true

smartcard.pkcs11.module

This configuration parameter specifies the path to the PKCS #11 module to be used by smart card components on the computer.

By default, smart card components use the Delinea Coolkey PKCS #11 module. However, Coolkey does not support all smart cards so you may specify a different module if necessary by specifying the absolute path to your PKCS #11 module with this parameter. For example:

rhel.smartcard.pkcs11.module /usr/$LIB/pkcs11/opensc-pkcs11.so

> **Note**: In the path specification, this parameter supports the use of the $LIB environment variable, which allows a single path specification to work for 32-bit and 64-bit systems. At run time, on 32-bit systems, $LIB resolves to lib, while on 64-bit systems it resolves to lib64.

After changing the value of this parameter, you must re-enable smart card support by running the following sctool commands as root:

```
[root]$ sctool --disable
[root]$ sctool --enable
```

Also, refresh the GNOME desktop by running the following command as root:

```
[root]$ systemctl restart gdm
```

In most cases, you set this configuration parameter using group policy.

rhel.smartcard.pkcs11.module (Deprecated)

This configuration parameter specifies the path to the PKCS #11 module to be used by smart card components on the computer.

By default, smart card components use the Delinea Coolkey PKCS #11 module. However, Coolkey does not support all smart cards so you may specify a different module if necessary by specifying the absolute path to your PKCS #11 module with this parameter. For example:

rhel.smartcard.pkcs11.module /usr/$LIB/pkcs11/opensc-pkcs11.so

> **Note**: In the path specification, this parameter supports the use of the $LIB environment variable, which allows a single path specification to work for 32-bit and 64-bit systems. At run time, on 32-bit systems, $LIB resolves to lib, while on 64-bit systems it resolves to lib64.

After changing the value of this parameter, you must re-enable smart card support by running the following sctool commands as root:

```
[root]$ sctool --disable
[root]$ sctool --enable
```

Also, refresh the GNOME desktop by running the following command as root:

```
[root]$ /usr/sbin/gdm-safe-restart
```

In most cases, you set this configuration parameter using group policy.

Customizing Authorization Configuration Parameters

This section describes the configuration parameters that affect the operation of authorization features (privilege elevation service) on the local host computer. You can configure authorization rules by defining specific command- or application-level rights, combining those rights into roles, and assigning users to those roles to control the operations they are allowed to perform on specific computers in a zone.

Delinea

adclient.azman.refresh.interval

This configuration parameter is deprecated and is replaced by the adclient.refresh.interval.dz parameter. See adclient.refresh.interval.dz for details about adclient.refresh.interval.dz.

The Server Suite upgrade utility renames this parameter if it is being used.

adclient.cache.flush.interval.dz

This configuration parameter specifies the frequency (in seconds) with which the Delinea Agent for *NIX flushes its authorization cache. You should note that this parameter only forces periodic updates to the authorization cache. It does not affect the agent's primary domain controller cache.

The default value is 0, which completely disables periodic flushing of the authorization cache.

The parameter value must be a positive integer. For example, to force the authorization cache to be cleared every 30 minutes, set the parameter as follows:

adclient.cache.flush.interval.dz: 1800

adclient.dz.refresh.hook

This parameter specifies the full path of the command that will be executed after adclient finishes the authorization cache refresh. By default, the value of this parameter is as follows:

adclient.dz.refresh.hook: /usr/share/centrifydc/etc/hooks/dz_refresh

The dz_refresh script will check for and remove any expired files in the /var/centrifydc/dz.ovr.d directory. Files in that directory have filenames in the format of yymmddHHMMSS-*.ovr, where the yymmddHHMMSS is the expiration date and time.

You can configure how often the authorization cache refreshes with the adclient.refresh.interval.dz parameter.

adclient.dzdo.clear.passwd.timestamp

This configuration parameter specifies whether users must re-authenticate with dzdo after logging out.

When a user authenticates with dzdo, a ticket is temporarily created that allows dzdo to run without re-authentication for a short period of time (set by the dzdo.timestamp_timeout parameter). If a user logs out, the ticket is reused when the user logs back in.

The parameter value can be true or false. Setting this parameter to true clears the ticket and requires users to re-authenticate to use dzdo after logging out and back in. The default parameter value is false.

For example:

adclient.dzdo.clear.passwd.timestamp: true

You can also set this parameter using group policy.

adclient.refresh.interval.dz

Note: Starting with agent version 5.1.3, this configuration parameter replaces the deprecated adclient.azman.refresh.interval parameter.

This configuration parameter specifies the maximum number of minutes to keep access control information from the authorization store cached before refreshing the data from Active Directory. Access control information consists of rights, roles, and role assignments that the Delinea Privilege Elevation Serviceuses to control access to dzdo privileged commands, dzsh restricted environments, PAM-enabled applications, and some third-party application.

Because the agent handles connecting to and retrieving information from Active Directory, this configuration parameter controls how frequently adclient checks for updates to the privilege elevation service set of information from Active Directory. If any privilege elevation service information has been modified, the cache is refreshed with the new information.

If local account management is enabled, this configuration parameter also specifies how often etc/group and etc/passwd are updated on individual computers based on the local group and local user settings that you configure in Access Manager.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

If you are manually setting this parameter, the parameter value must be a positive integer. The following example sets the cache expiration time to 30 minutes:

adclient.refresh.interval.dz: 30

If this parameter is not defined in the configuration file, its default value is 30 minutes.

adclient.sudo.clear.passwd.timestamp

This configuration parameter is used together with the tty_tickets parameter in the sudoers configuration file (/etc/sudoers) to specify whether users must re-authenticate with sudo after logging out.

When a user authenticates with sudo, a ticket is temporarily created that allows sudo to run without re-authentication for a short period of time. If a user logs out and the ticket is not cleared, the ticket is reused when the user logs back in, and the user does not need to re-authenticate. If a user logs out and the ticket is cleared, the user must re-authenticate with sudo when logging back in.

Starting with release 2015, the way that you configure whether re-authentication is required depends on the tty_tickets parameter in the sudoers configuration file (/etc/sudoers.conf). In some situations, re-authentication requirements are also controlled by this parameter. Details are as follows:

- If tty_tickets is enabled, tickets are always removed when a sudo user logs out, regardless of whether this parameter is set to true or false. That is, when tty_tickets is enabled, this parameter has no effect, and sudo users must always re-authenticate.
- If tty_tickets is disabled, the requirement for sudo users to re-authenticate is controlled by this parameter and the **Force sudo re-authentication when relogin** group policy.

Tickets are cleared, and sudo re-authentication is required, under these scenarios:

- The tty_ticket parameter in the sudoers configuration file is enabled (it is enabled by default), or
- The tty_ticket parameter in the sudoers configuration file is disabled and the adclient.sudo.clear.passwd.timestamp parameter is set to true, or
- The tty_ticket parameter in the sudoers configuration file is disabled and the **Force sudo re-authentication when relogin** group policy is enabled.

Tickets are not cleared, and sudo re-authentication is not required, under these scenarios:

- The tty_ticket parameter in the sudoers configuration file is disabled and the adclient.sudo.clear.passwd.timestamp parameter is set to false, or
- The tty_ticket parameter in the sudoers configuration file is disabled and the **Force sudo re-authentication when relogin** group policy is disabled.

The default parameter value is false.

For example:

adclient.sudo.clear.passwd.timestamp: false

You can also set this parameter using group policy.

adclient.sudo.timestampdir

This configuration parameter specifies the directory where authentication tickets reside. By default, the directory is /var/run/sudo. Some platforms use a different directory for tickets, such as /var/db/sudo/user (RHEL) or /var/lib/sudo/user (Ubuntu), which you can specify in this parameter.

The default value of this parameter is /var/run/sudo.

For example:

adclient.sudo.timestampdir: /var/run/sudo

audittrail.dz.command.with.args

This configuration parameter specifies whether to show command parameters in the audit log for dzdo and dzsh or just the command name. The default (false) is to show only the command name. For example, to keep passwords entered on the command line out of the log, leave this parameter set to false.

Set to true to show the command parameters as well as the command name.

For example:

audittrail.dz.command.with.args: true

dz.auto.anchors

This configuration parameter specifies whether you want to add anchors ($) automatically to the regular expressions you define as command rights and use in role definitions.The default setting is true to avoid matching unintended paths or commands if the regular expression pattern is not carefully set. If you set this parameter to false, you should carefully review all regular expressions used as command rights to identify all possible matches for the pattern defined.

For example:

dz.auto.anchors: true

dz.enabled

This configuration parameter is only applicable for classic zones to specify whether authorization services are enabled or disabled. In hierarchical zones, which must have agents version 5.x or later, this parameter is not applicable and is ignored. In classic zones, however, authorization is an optional feature that can be explicitly enabled or disabled.

In classic zones, users can log on as long as they have a profile in a zone. In hierarchical zones, users must be assigned to a role that grants them permission to log on. If you have agents that are joined to a classic zone, you can set this parameter to false to explicitly prevent the agent from looking up authorization information to reduce network traffic.

If you have agents from version 4.x, the default value for this parameter is true. This parameter is not defined for agents version 5.x and later.

For example:

dz.enabled: false

dz.system.path

This configuration parameter specifies the list of common System paths for locating commands in the local operating environment. The paths specified for this parameter define the program locations searched when the System match path option is selected for dzdo and dzsh commands.

This configuration parameter enables an administrator to define rights to run commands found in the user's path, the system path, or a specific location, even though the default or most commonly used paths may be different in different operating environments.

The default value for this parameter lists the most common locations for finding command line programs in the system path. For example:

dz.system.path: "/sbin:/usr/sbin:/usr/local/sbin"

dz.user.path

This configuration parameter specifies the list of common User paths for locating commands in the local operating environment. The paths specified for this parameter define the program locations searched when the User match path option is selected for dzdo and dzsh commands.

This configuration parameter enables an administrator to define rights to run commands found in the user's path, the system path, or a specific location, even though the default or most commonly used paths may be different in different operating environments.

The default value for this parameter lists the most common locations for finding command line programs in the user's path. For example:

dz.user.path: "/bin:/usr/bin:/usr/local/bin"

dzdo.always_set_home

This configuration parameter specifies whether privileged commands run with dzdo commands should set the HOME environment variable to the home directory of the target user (which is root by default). The parameter value can be true or false. Setting this parameter to true effectively implies that the -H command line option should always used. The default parameter value is false.

For example:

dzdo.always_set_home: false

This configuration parameter provides functionality equivalent to the always_set_home flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.badpass_message

This configuration parameter specifies the message that should be displayed if a user enters an incorrect password. The parameter value can be any text string enclosed by quotation marks.

For example:

dzdo.badpass_message: “The password provided is not valid.”

The default value is “Sorry, try again.”

This configuration parameter provides functionality equivalent to the badpass_message flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.command_alias

This configuration parameter specifies a mapping file containing mappings between command aliases and command files for all of the command aliases that a customer uses. If you specify a mapping file in dzdo.command_alias and then issue a dzdo command using a command alias, dzdo searches the mapping file to see if the first dzdo parameter matches any of the aliases.

If there is a match, the command path specified for the alias in the mapping file is used by dzdo to perform command matching to determine whether the command is allowed to run.

The parameter value has the following syntax:

dzdo.command_alias: *aliasfile_full_pathname*

For example, the following line in centrifydc.conf results in the default mapping file (dzdo.commandalias.map) being used:

dzdo.command_alias: /etc/centrifydc/dzdo.commandalias.map

The syntax of the content within the mapping file is:

command_alias_1: command_path [*arguments*]
command_alias_n: command_path [*arguments*]

For example, a mapping file could contain the following, which defines two command aliases—oracle_startup and centrifydc_startup:

oracle_startup: /opt/oracle/startup
centrifydc_startup: /opt/centrifydc/startup

Actual mapping files can contain any number of aliases.

dzdo.edit.checkdir

This configuration parameter prevents a user from editing files using the dzedit command in a directory that the user already has permissions to edit using their own account.

If a user who can already write to a directory with their own account uses dzedit to edit the same directory, it is possible that they may unintentionally edit arbitrary files in the directory if wild cards are used to specify the files the user intends to edit.

Set this configuration parameter to true to specify whether dzedit will check the user's directory permissions, and deny the user the ability to modify files in the directory when they run as root if they have sufficient permissions to edit the directory using their own account.

For example:

dzdo.edit.checkdir: true

The default value of this configuration parameter is true.

dzdo.edit.follow

This configuration parameter prevents users from editing a file in a directory using dzedit that is reached by following a symbolic link (symlink) if the user already has permissions to edit the directory. Edits are also prevented on all sub-directories on the file path.

In some cases, if a user that already has permissions to write to a directory but invokes dzedit to edit a file in that directory which contains a symlink, they may edit the linked file as well.

If set to false, this configuration parameter will not allow a user to edit files reached by symbolic link by using dzedit.

It is strongly recommended that you keep the specified value as false.

For example:

dzdo.edit.follow: false

The default value of this configuration parameter is false.

dzdo.env_check

This configuration parameter specifies the list of environment variables that the dzdo process should check for the special characters, % or /, in the value. If the dzdo process finds environment variable values containing the special characters, it removes those variables from the user's environment. Variables with % or / characters are removed regardless of whether you have selected the **Reset environment variables** option for the command in Access Manager.

The default list of variables to check is displayed when you run dzdo -V command as root. You can customize the list by modifying this configuration parameter in the centrifydc.conf file.

The parameter value can be a comma-separated list of environment variable names.

For example:

dzdo.env_check: COLORTERM,LANG,LANGUAGE,LC_*,LINGUAS,TERM

This configuration parameter provides functionality equivalent to the env_reset flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.env_delete

This configuration parameter specifies the default list of environment variables to be removed from the user's environment. This configuration parameter only applies if you have selected the **Remove unsafe environment variables** option for the command in the Access Manager. The variables specified with this parameter are removed in addition to the default list of variables displayed when you run the dzdo -V command as root.

The parameter value can be a comma-separated list of environment variable names.

For example:

dzdo.env_delete: IFS,CDPATH,LOCALDOMAIN,RES_OPTIONS,HOSTALIASES, \ NLSPATH,PATH_LOCALE,LD_*,*RLD**,*TERMINFO,TERMINFO_DIRS,* \ *TERMPATH,TERMCAP,ENV,BASH_ENV,PS4,GLOBIGNORE,SHELLOPTS,* \ *JAVA_TOOL_OPTIONS,PERLIO_DEBUG,PERLLIB,PERL5LIB,* \ *PERL5OPT,PERL5DB,FPATH,NULLCMD,READNULLCMD,ZDOTDIR,TMPPREFIX,* \ *PYTHONHOME,PYTHONPATH,PYTHONINSPECT,RUBYLIB,RUBYOPT,KRB5_CONFIG,* \ *KRB5_KTNAME,VAR_ACE,USR_ACE,DLC_ACE,SHLIB_PATH,LDR**, \ LIBPATH,DYLD_*

This configuration parameter provides functionality equivalent to the env_delete flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.env_keep

This configuration parameter specifies the default list of environment variables to preserve in the user's environment. This configuration parameter only applies if you have selected the **Reset environment variables** option for the command in the Access Manager. The variables specified with this parameter are preserved in addition to the default list of variables displayed when you run the dzdo -V command as root.

The parameter value can be a comma-separated list of environment variable names.

For example:

dzdo.env_keep: COLORS,DISPLAY,HOME,HOSTNAME,KRB5CCNAME, LS_COLORS,MAIL,PATH,PS1,PS2,TZ,XAUTHORITY,XAUTHORIZATION

This configuration parameter provides functionality equivalent to the env_keep flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.lecture

This configuration parameter specifies whether dzdo displays a warning message about using the program before displaying the password prompt. The valid parameter values are:

once	To display the warning message only the first time the command is run.
never	To never display a warning message.
always	To display the warning message every time the program is invoked.

The default parameter value is once. For example:

dzdo.lecture: once

This configuration parameter provides functionality equivalent to the lecture flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.lecture_file

This configuration parameter specifies the full path to a file containing the warning message you want displayed. If this parameter is not set, a default message is displayed.

For example, to use a custom message in the file dzdo_warning:

dzdo.lecture_file: /etc/custom/dzdo_warning

This configuration parameter provides functionality equivalent to the lecture_file flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.legacyzone.mfa.enabled

Enable this configuration parameter to require multi-factor authentication for users to run the dzdo command. If you enable this parameter, users will be required to authenticate with MFA if they are required to re-authenticate to run dzdo, and are listed in either adclient.legacyzone.mfa.required.users or adclient.legacyzone.mfa.required.groups.

You must enable adclient.legacyzone.mfa.enabled for this policy to take effect.

This configuration parameter does not support rescue rights; users listed in adclient.legacyzone.mfa.rescue.users will not be able to run dzdo without MFA.

To enable this policy, set this parameter to true. The default value for this parameter is false.

For example:

dzdo.legacyzone.mfa.enabled: true

dzdo.log_good

This configuration parameter specifies whether you want to log messages for successful command execution. By default, the dzdo program logs both valid and invalid command execution. To log information about only invalid command execution, set this parameter to false. The default value for this parameter is true.

For example:

dzdo.log_good: true

The dzdo program typically logs messages to the file /var/log/secure.

You can also set this parameter using group policy.

dzdo.passprompt

This configuration parameter lets you specify the password prompt displayed when running privileged commands. This parameter serves the same function as the dzdo -p command.

You can use the following escapes in the prompt:

%u	Expands to the invoking user's login name
%U	Expands to the login name of the user the command will be run as. If not specified, defaults to root
%h	Expands to the local hostname without the domain name
%H	Expands to the local hostname including the domain name
%p	Expands to the user whose password is asked for
%%	Collapses to a single % character

The default prompt is [dzdo] password for %p: where %p is root unless specified otherwise.

For example,

dzdo.passprompt: "[dzdo] Enter password for %U@%h"

You can also set this parameter using group policy.

dzdo.passwd_timeout

This configuration parameter specifies the number of minutes before the dzdo password prompt times out. The default parameter value is 5 minutes. You can set this parameter to zero (0) to have the password prompt never timeout.

For example:

dzdo.passwd_timeout: 5

This configuration parameter provides functionality equivalent to the passwd_timeout flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.path_info

This configuration parameter specifies whether the dzdo program should inform the user when it cannot find a command in the user's PATH. By default, the parameter value is true and the program will display an error statement indicating that the command could not be found in the user's PATH. You can set this configuration parameter to false if you want to prevent dzdo from indicating whether a command was not allowed or simply not found.

For example:

dzdo.path_info: true

This configuration parameter provides functionality equivalent to the path_info flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.search_path

This configuration parameter specifies the search path for the dzdo program to use to look for commands and scripts that require privileges to run. You can specify a list of directories for the dzdo program to search for commands and scripts. If you configure this parameter, the dzdo program will search in the specified directories no matter which path the command rights are configured to use in the Access Manager **System search path** option.

If commands are configured to use the path defined in the Access Manager **System search path** option and the dzdo.search_path parameter is not defined, the following actions take place:

- The current user's path is used to search for the commands.
- Only the commands located under the System path are allowed to execute.

There is no default value for this parameter.

The parameter value can be a list of directories or the name of a file that contains the list of directories. For example, you can specify a file that contains the directories to search using the file: keyword and a file location:

dzdo.search_path: file:/etc/centrifydc/customized_dzdo_directories

If you specify a file name for this parameter, you should ensure the file is owned by root and not accessible to any other users.

You can also set this parameter using group policy.

dzdo.requiretty

This configuration parameter specifies whether a user needs to be logged in to a valid tty session in order to run dzdo. If you set this parameter to true, this means that the user can run dzdo only from a login session and not from a cgi-bin or cron(8) script.

By default, this parameter is set to false so that it's not required to run a tty session in order to run dzdo.

dzdo.secure_path

This configuration parameter specifies the path for the dzdo program to use when executing commands and scripts that require privileges to run. If you specify a directory using this parameter, the dzdo program will only execute commands and scripts that are found in that directory.

Setting both the dzdo.search_path and dzdo.secure_path parameters to the same value is equivalent to setting the secure_path parameter in the sudoers configuration file.

There is no default value for this parameter.

The parameter value can be a list of directories or the name of a file that contains the list of directories. For example, you can specify a file that contains the directories to search using the file: keyword and a file location:

dzdo.secure_path: file:/etc/centrifydc/customized_dzdo_directories

Within the file, lines should contain path separated by colons. For example, a file specifying two paths might look like this:

/etc/centrifydc/reports/exec_report_cmds:/usr/sbin/ora_cmds

If you specify a file name for this parameter, you should ensure the file is owned by root and not accessible to any other users.

You can also set this parameter using group policy.

dzdo.set_home

This configuration parameter sets the HOME environment variable to the home directory of the target user when the -s command line option is used. The parameter value can be true or false. The default parameter value is false.

For example:

dzdo.set_home: false

This configuration parameter provides functionality equivalent to the set_home flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.set.runas.explicit

This configuration parameter specifies whether a user must explicitly identify the 'runas' user when executing a command with dzdo.

The parameter value can be true or false; the default value is true.

When the parameter value is true, if a user executes a command with dzdo and does not explicitly identify the user or group to run as (with the -u or -g option), adclient assumes that the command should be run as root. If the user is not authorized to run the command as root, dzdo fails to execute the command and issues an error message; for example:

```
User u1 is authorized to run adinfo as user qa1
dzdo.set.runas.explicit: true
...
[u1@rh6]$dzdo adinfo
Sorry, user u1 is not allowed to execute '/usr/bin/adinfo' as root on rh6.
```

When the parameter value is false, if a user executes a command with dzdo and does not explicitly identify the user or group to run as (with the -u or -g option), adclient attempts to resolve the user. If the command defines a single runas user, dzdo executes the specified command and sends a message to the log file; for example:

```
User u1 is authorized to run adinfo as user qa1
dzdo.set.runas.explicit: false
...
[u1@rh6]$dzdo adinfo
Local host name: rh6
Joined to domain acme.com
...
```

If the command defines multiple runas users, dzdo cannot resolve the user to run as and attempts to run the command as root. Since the user is not authorized to run the command as root, dzdo fails to execute the command and issues an error message; for example:

```
User u1 is authorized to run adinfo as users qa1 and adm
dzdo.set.runas.explicit: true
...
[u1@rh6]$dzdo adinfo
Sorry, user u1 is not allowed to execute '/usr/bin/adinfo' as root on rh6.
```

In all cases, a user can execute a command successfully with dzdo by using the -u option to explicitly identify the runas user; for example:

```
[u1@rh6]$dzdo -u qa1 adinfo
Local host name: rh6
Joined to domain acme.com
...
```

You can also set this parameter using group policy.

dzdo.timestampdir

This configuration parameter specifies the directory where dzdo stores the user's login timestamp files. The default is directory is /var/run/dzdo.

For example:

dzdo.timestampdir: /var/run/dzdo

This configuration parameter provides functionality equivalent to the timestampdir flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.timestamp_timeout

This configuration parameter specifies the maximum number of minutes allowed between operations before prompting the user to re-enter a password. The default parameter value is 5 minutes. You can set this parameter to zero (0) to always prompt for a password when users run privileged commands with dzdo. If set to a value less than 0 the user's timestamp never expires.

For example:

dzdo.timestamp_timeout: 5

This configuration parameter provides functionality equivalent to the timestamp_timeout flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.timestamp_type

The privilege elevation service uses per-user timestamp files for credential caching. You can use this configuration parameter to specify the type of timestamp record for the service to use.

By default, this parameter is set to tty.

You can set this parameter to any of the following values:

- **global**: A single time stamp record is used for all of a user's login sessions, regardless of the terminal or parent process ID.
- **ppid**: A single time stamp record is used for all processes with the same parent process ID (usually the shell). Commands run from the same shell (or other common parent process) will not require a password for dzdo.timestamp_timeout minutes (5 by default). Commands run by way of sudo with a different parent process ID, for example from a shell script, will be authenticated separately.
- **tty**: One time stamp record is used for each terminal, which means that a user's login sessions are authenticated separately. If no terminal is present, the behavior is the same as ppid. Commands run from the same terminal will not require a password for dzdo.timestamp_timeout minutes (5 by default).

For example:

```
dzdo.timestamp_type:ppid
```

You can also set this parameter using group policy.

dzdo.tty_tickets

This configuration parameter specifies whether dzdo should require authentication once per-tty rather than once per user. The parameter value can be true or false. The default parameter value is false.

For example:

dzdo.tty_tickets: false

This configuration parameter provides functionality equivalent to the tty_tickets flag for configuring the sudoers file and sudo operation.

You can also set this parameter using group policy.

dzdo.use_pty

The dzdo.use_pty configuration parameter specifies if dzdo will always run commands in pseudo-terminal, also called a pseudo-pty or pseudo-tty. If you enable this parameter, dzdo runs commands in a pseudo-terminal even if there's no input or output logging. Using this option would make it impossible for a malicious program to run under dzdo to fork a background process that retains information to the user's terminal device after the main program finishes.

By default, this parameter is false.

dzdo.use.realpath

This configuration parameter specifies whether dzdo uses command paths resolved by realpath when searching for commands. The default parameter value is false, meaning that realpath is not used.

When set to true, this parameter specifies that realpath is used to expand all symbolic links and resolve references to:

- /./
- /../
- extra / characters

You can also set this parameter using group policy.

dzdo.user.command.timeout

When set to true, this parameter specifies a timeout on the DZDO command line with a -T option. If the timeout expires before the command has exited, the command is terminated.

The default setting is false.

dzdo.validator

This configuration parameter specifies the full path to a script that is executed each time the dzdo command is run. The script is run synchronously under the user's Active Directory name.

The dzdo command always runs the /usr/share/centrifydc/sbin/dzcheck script before it executes the command specified. However, the distribution package does not include a dzcheck script.

You do not need to create a dzcheck script to use dzdo. You only need to create a script if you want to modify dzdo behavior—for example, to prompt the user to enter some information before executing the command. To incorporate your modification, you would write the script, name it dzcheck and put it in /usr/share/centrifydc/sbin.

Use the dzdo.validator command only if you need to specify a different path or file name. (If you name your script dzcheck and store it at the default location, you do not need to use dzdo.validator.) For example, if the script was named myvalidator and it was in the /etc/centrifydc directory, you would add the following command in centrifydc.conf:

dzdo.validator: /etc/centrifydc/myvalidator

The dzdo command sets three environment variables:

- DZDO_USER: the Active Directory name of the user invoking dzdo
- DZDO_COMMAND: the command
- DZDO_RUNASUSER: the user name that the command will be run as

The script should return one of the following values:

- 0 Success. dzdo will continue and run the command.
- non-zero Failure: dzdo will not run the command. In this event, dzdo does NOT show a message on the console. If you want to notify the user of the failure, include the message in the script.

When the logging level is set to DEBUG, the call to the script and the return value are logged in var/log/centrifydc.log. If DEBUG is off, the call to the script and return value are logged in /val/log/messages.

dzdo.validator.required

This configuration parameter specifies whether dzdo is required to run the validator script. The default value is false.

> **Note**: The dzdo command skips the validator script if the script is not available, is not owned by root, or is group/world writable. By default, dzdo continues to run the command even if the validator script is skipped. When this parameter is set to true, dzdo does not run the command if validator script is skipped.

dzsh.roleswitch.silent

This configuration parameter specifies whether to display role information when changing from one role to another is a restricted shell.

By default, changing from one role to another displays a message indicating that you have changed your current role. For most commands that run in a restricted shell, displaying this message has no affect on the execution of the command.

There are cases, however, where a command—such as `sftp` or git—expects a specific type of response. Because the role change message is not the expected response, the message can cause the command to fail.

You can use this parameter to address those cases where the role change message would cause a command to fail.

Set this configuration parameter to true to prevent the role switch information from being displayed when running commands in a restricted shell. The default value is false.

For example:

dzsh.roleswitch.silent: true

Customizing Auto Zone Configuration Parameters

This section describes the configuration parameters that affect the operation of a local host computer joined to Auto Zone. These parameters have no effect if the computer is not joined to Auto Zone.

auto.schema.allow.groups

This configuration parameter specifies a list of Active Directory groups that define which Active Directory users are valid users in the Auto Zone. Members of the specified groups are considered valid users in the Auto Zone.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

Adding zone users based on group membership

By default, all Active Directory users are included in the Auto Zone. If you specify one or more groups using this parameter the only users who can log in using their Active Directory account are members of the specified groups, members of nested groups, users whose primary group is set to one of the groups specified, and all users specified in auto.schema.allow.users.

For example, to specify that only the members of the sf-adms and sf-apps groups should be allowed to log on to computers in Auto Zone, you would enter the following:

auto.schema.allow.groups: sf-adms sf-apps

The groups you specify for the auto.schema.allow.groups parameter must be security groups, but can be domain local, global, or universal groups.Distribution groups are not supported.

You can separate each group by a space or a comma and you can use double quotes or escape characters to include spaces or special characters in group names. For example: in group names. For example,

auto.schema.allow.groups: server_users, "Domain Admins", Domain\ Users

You should note that this parameter does not add the Active Directory groups you specify to Auto Zone. It does not assign the groups a numeric identifier (GID) or make the groups available to use as a primary group for any of the users added to Auto Zone. This parameter simply enables UNIX profiles for the users that are members of the specified groups. You can use the auto.schema.groups parameter to specify the Active Directory groups to include an in the Auto Zone and assign it a GID. You can configure the primary group for users using the auto.schema.primary.gid parameter.

Supported group name formats

You can specify groups by name or you can list the group names in a file using any of the following formats:

- SAM account name: sAMAccountName@domain
- User Principal Name: name@domain
- NTLM: DOMAIN/sAMAccountName
- Full DN: CN=commonName,...,DC=domain_component,DC=domain_component
- Canonical Name: domain/container/cn

The adclient process writes any group name that is not recognized to the agent log file.

Specifying the parameter value in a separate file

To specify a file that contains a list of Active Directory group names, you can set the parameter value using the file: keyword and a file location. For example:

auto.schema.allow.groups: file:/etc/centrifydc/auto_user_groups.allow

In the /etc/centrifydc/auto_user_groups.allow file, you would type each group name on its own line using any of the supported name formats. For example:

server_users
"Domain Admins"
Domain Users
CN=group6,CN=Users,DC=domain,DC=com

Limitations of this parameter

Auto Zone does not support one-way trusts. If there are any users in a specified group who belong to a domain that has a one-way trust relationship to the joined domain, they will not become valid users on the computer.

If you set this parameter, you should be aware of search limit defined for the auto.schema.search.return.max parameter. The setting for that parameter will limit the number of users returned in search results and stored in the cache. For example, if the auto.schema.search.return.max parameter is set to 100, and you use this parameter to specify an Active Directory group with 200 members, a query would only return results for the first 100 users. The remaining members of the group will still be allowed to log on to computers in the Auto Zone, but the results of queries might be misleading.

If desired, you can disable the auto.schema.search.return.max parameter by setting the parameter value to 0. Disabling the search limit ensures that all of the users in the specified Active Directory groups are listed as valid zone users when you run queries whether the number of users exceeds or falls short of the number specified for the auto.schema.search.return.max parameter. If you are not concerned about whether search results accurately reflect the users in the Active Directory groups you have defined for the auto.schema.allow.groups parameter, however, you don't need to modify the auto.schema.search.return.max parameter.

auto.schema.allow.users

This configuration parameter specifies which Active Directory users to include in the Auto Zone.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

Adding specific Active Directory users to Auto Zone

By default, all Active Directory users in a forest are included in the Auto Zone. If you specify one or more users using this parameter, however, only the specified users and members of the groups specified in the auto.schema.allow.groups parameter can log in using their Active Directory account.

For example, to specify that only the users jane and sai.wu should be allowed to log on to computers in Auto Zone:

auto.schema.allow.users: jane.doe sai.wu@ajax.org

You can separate each user name by a space or comma and use double quotes or escape characters to include spaces or special characters in group names. For example,

auto.schema.allow.groups: jane.doe, "Alex Adams", jae\ chin

Supported user name formats

You can specify users by name or you can list the user names in a file in any of the following formats:

- SAM account name: sAMAccountName@domain
- User Principal Name: name@domain
- NTLM: DOMAIN/sAMAccountName
- Full DN: CN=commonName,...,DC=domain_component,DC=domain_component
- Canonical Name: domain/container/cn

The adclient process writes any user name that is not recognized to the agent log file.

Specifying the parameter value in a separate file

To specify a file that contains a list of Active Directory user names, you can set the parameter value using the file: keyword and a file location. For example:

auto.schema.allow.users: file:/etc/centrifydc/auto_user_users.allow

In the /etc/centrifydc/auto_user_users.allow file, you would type each user name on its own line using any of the supported name formats. For example:

jane.doe
sai/wu@ajax.org
CN=Alex Adams,CN=Users,DC=ajax,DC=org

auto.schema.apple_scheme

This configuration parameter specifies that you want to use the Apple algorithm to automatically generate user and group identifiers. The Apple algorithm for generating identifiers is based on the objectGuid attribute for the user or group object. The Delinea mechanism for automatically generating UIDs and GIDs is based on the security identifier for the user or group objects. Both methods ensure a globally unique and consistent identifier for the user or group.

By default, this parameter value is set to false. If you want to use the Apple algorithm, set the parameter value to true. For example:

auto.schema.apple_scheme: true

If you set this parameter to use the Apple algorithm, you must use adflush to clear the cache, then restart the adclient process to update UIDs, GIDs, and user primary GIDs. Note that the user's primary group must be available in Auto Zone. If a user's primary group is not in the zone, the user will have an incomplete profile and unable to log on. If a user is provisioned with an incomplete profile, an error is recorded in the Window Event log.

After clearing the cache and restarting the agent, run the fixhome.pl script to correct conflicts between the new user UID and the home directory ownership.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

auto.schema.domain.prefix

This configuration parameter specifies a unique prefix for a trusted domain. You must specify a whole number in the range of 0 to 511.

The Delinea algorithm for generating unique identifiers combines the prefix with the lower 22 bits of each user or group RID (relative identifier) to create unique UNIX user (UID) and group (GID) IDs for each user and group in the forest and in any two-way trusted forests.

Ordinarily, you do not need to set this parameter because the Delinea Agent automatically generates the domain prefix from the user or group security identifier (SID). However, in a forest with a large number of domains, domain prefix conflicts are possible. When you join a computer to a domain, the Centrify Agent checks for conflicting domain prefixes. If any conflicts are found, the join fails with a warning message. You can then set a unique prefix for the conflicting domains.

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

To set this parameter, append the domain name and specify a prefix in the range 0 - 511. For example:

auto.schema.domain.prefix.acme.com: 3
auto.schema.domain.prefix.finance.com: 4
auto.schema.domain.prefix.corp.com: 5

The default behavior, if you do not set this parameter, is for the agent to automatically generate the domain prefix from the user or group security identifier (SID).

auto.schema.groups

This configuration parameter specifies the Active Directory groups to include in the Auto Zone. When you specify one or more groups in this parameter, the groups specified are assigned a group ID on this computer.

The command syntax is:

auto.schema.groups: groupname [, groupname, groupname, ...]

By default all Active Directory groups are included.

> **Note**: If an Active Directory user specified in auto.schema.allow.users is a member of a group and that group is NOT specified in auto.schema.groups, that group is ignored.

Any groups listed under auto.schema.groups can be domain local, global or universal security groups. Distribution groups are not supported.

You specify each group by name or you can list the groups in a file. The group name can be specified in any of the following formats:

- SAM account name: sAMAccountName@domain

  (specify the domain if the group is not in the current domain)

- User Principal Name: name@domain
- NTLM: DOMAIN/sAMAccountName

  > **Note**: Use the adclient.ntlm.separators parameter to specify different NTLM separators.

- Full DN: CN=commonName,...,DC=domain_component,DC=domain_component
- Canonical Name: domain/container/cn

adclient writes any name that is not recognized to the agent log file.

You can also define the groups using group policy.

Examples:

auto.schema.groups: finance_users
auto.schema.groups: “Mktg Users”
auto.schema.groups: ops@domain.com

You can specify multiple groups in a single command. Separate each group by a comma and use escape characters to include, for example, spaces, backslashes, or a comma in the group specification. For example,

auto.schema.allow.groups: server_users, "Domain Admins", Domain\ Users, \ group1, group2@domain.com, domain\\group3, domain+group4, \
domain/group5, CN=group6\,CN=Users\,DC=domain\,DC=com, \
domain/Users/group7

You can also use a file instead. The syntax is file:/path. For example,

auto.schema.allow.groups: file:/etc/centrifydc/auto_user_groups.allow

In the file, enter each group line by line. However, you do not need the escape characters. For example, the following list enters the same groups as the previous example:

server_users
"Domain Admins"
Domain Users
group1
group2@domain.com
domain\group3
domain+group4
domain/group5

CN=group6,CN=Users,DC=domain,DC=com
domain/Users/group7

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

auto.schema.homedir

This configuration parameter specifies the home directory for logged in users. The default, if you do not specify this parameter, is:

- Mac OS X: /Users/%.
- Linux, HP-UX, AIX: /home/%
- Solaris: /export/home/%

The syntax % specifies the logon name of the user. For example, in the centrifydc.conf configuration file, if you add:

auto.schema.homedir:/Users/%

and jsmith logs on to a Mac OS X machine, the home directory is set to /Users/jsmith.

If the parameter auto.schema.use.adhomedir is true, the home directory is set to the value in Active Directory for the user, if one is defined. If auto.schema.use.adhomedir, is false or if a home directory is not specified for the user in Active Directory, the home directory is set to the value defined for this parameter, auto.schema.homedir.

> **Note**: The configuration parameter auto.schema.homedir.illegal_chars defines characters that are not allowed in home directory names. Any illegal characters in the specified name are removed from the home directory name on the computer.

You can also specify the home directory on all machines joined to Auto Zone by using group policy.

auto.schema.primary.gid

This configuration parameter specifies the primary GID for Auto Zone users. The auto.schema.private.group parameter must be set to false to use this parameter.

> **Note**: On Mac OS X, the default value of auto.schema.private.group is false. On Linux, HP-UX, Solaris, and AIX, the default value of auto.schema.private.group is true.

To specify the GID for an existing group, you must first find the GID for the group. To find the GID for a group, you can use the adquery command or adedit. For example, to find the GID for the group Support, open a terminal session and type:

```
>adquery group --gid Support
```

The command returns the GID for the Active Directory group Support:

```
1003
```

You can then set this parameter to the value returned. For example:

```
auto.schema.primary.gid: 1003
```

If you do not set this parameter, the value defaults to the following:

- On Mac OS X:

  ```
  auto.schema.primary.gid: 20
  ```

- On Linux, HP-UX, Solaris, and AIX:

  ```
  auto.schema.primary.gid: -1
  ```

If you are using the Apple algorithm to automatically generate user and group identifiers, including the group identifier for primary groups, set this parameter to -1 to disable it. For example:

```
auto.schema.primary.gid: -1
```

In most cases, you set this configuration parameter using group policy. You can, however, set it manually in the configuration file if you are not using group policy or want to temporarily override group policy.

auto.schema.private.group

This configuration parameter specifies whether to use dynamic private groups.

Specify true to create dynamic private groups. If you specify true, the primary GID is set to the user's UID and a group is automatically created with a single member.

Specify false to not create private groups.

On Mac OS X, the default value of this parameter is false. On Linux, HP-UX, Solaris, and AIX, the default value is true.

If you specify false, the primary GID is set to the value of auto.schema.primary.gid. On Mac OS X, the default value of auto.schema.primary.gid is 20. On Linux, HP-UX, Solaris, and AIX, the default value of auto.schema.primary.gid is -1.

auto.schema.shell

This configuration parameter specifies the default shell for the logged in user. The default value is:

- /bin/bash on Mac OS X and Linux systems
- /bin/sh on UNIX systems, including Solaris, HPUX, AIX.

You can also set the default shell on all machines joined to Auto Zone by using group policy.

auto.schema.use.adhomedir

Note: This configuration parameter applies to Mac OS X computers only.

This configuration parameter specifies whether or not to use the Active Directory value for the home directory if one is defined. Set to true to use the Active Directory value (the default), or false to not use the Active Directory value. If you set the value to false, or if you set the value to true but a home directory is not specified in Active Directory, the value for auto.schema.homedir is used.

auto.schema.name.format

This configuration parameter specifies how the Active Directory username is transformed into a UNIX name (short name in Mac OS X). The options are

- SAM (default)

  An example SAM name is joe

- SAM@domainName

  An example SAM@domainName is joe@acme.com

- NTLM

  An example NTLM name is acme.com-joe

auto.schema.separator

> **Note**: This configuration parameter has been deprecated in favor of adclient.ntlm.separators, which applies whenever NTLM format is used. The auto.schema.separator parameter only applies when the computer is connected to Auto Zone.

This configuration parameter specifies the separator to be used between the domain name and the user name if NTLM format is used. The default separator is a plus (+). For example:

auto.schema.separator:+

which results in a name such as:

acme.com+jcool

auto.schema.search.return.max

This configuration parameter specifies the number of users that will be returned for searches by utilities such as dscl and the Workgroup Manager application. Because Auto Zone enables access to all users in a domain, a search could potentially return tens of thousands of users. This parameter causes the search to truncate after the specified number of users.

The default is 1000 entries.

auto.schema.name.lower

This configuration parameter converts all usernames and home directory names to lower case in Active Directory.

Set to true to convert usernames and home directory names to lowercase.

Set to false to leave usernames and home directories in their original case, upper, lower, or mixed.

The default for a new installation is true.

auto.schema.iterate.cache

This configuration parameter specifies that user and group iteration take place only over cached users and groups.

Set the value for auto.schema.iterate.cache to true to restrict iteration to cached users and groups.

Set the value for auto.schema.iterate.cache to false to iterate over all users and groups. The default value is false.

auto.schema.uid.conflict

This configuration parameter specifies what is done if adclient discovers that an Active Directory user already exists with the same UID. There are two options:

- allow: Allow the duplicate UID; an information message is logged.
- disallow: If a duplicate UID already exists, the second user with the same UID is ignored; a warning message is logged.

Examples:

auto.schema.uid.conflict: allow
auto.schema.uid.conflict: disallow

auto.schema.homedir.illegal_chars

This configuration parameter specifies the characters in a home directory name that are not allowed in UNIX, Linux or Mac OS X home directory names. Each character in a home directory name that matches one of the specified characters is simply removed from the name; for example:

/home/user$34 /* illegal $ character
/home/user34 /* illegal character removed

The default setting in centrifydc.conf for UNIX (HP-UX, Solaris, AIX) and Linux systems is the following:

auto.schema.homedir.illegal_chars: \t\n /\\$><?*%|\"\'`[]

The default setting in centrifydc.conf for Mac OS X systems is the following (space is omitted):

auto.schema.homedir.illegal_chars: \t\n/\\$><?*%|\"\'`[]

Run the adflush command after you change the value to flush the cache.

auto.schema.thycotic.rids

Use this parameter to specify that the service generates UIDs and GIDs based on the algorithm used by Delinea Secret Server instead of the algorithm that Server Suite uses.

By default, this parameter is set to false, which means that the service generates UIDs and GIDs based on Server Suite.

The Delinea UID/GID generation algorithm is as follows:

uid/gid = RID of object * 100 + suffix

The service generates the suffix by getting a list of the Active Directory domain names that are in the Active Directory forest and then sorts that list. The suffix is the same as the index, but it starts from 1 instead of zero.

auto.schema.unix.name.disallow.chars

This configuration parameter specifies the characters in an Active Directory user or group name that are not allowed in UNIX, Linux or Mac OS X names. Each character in the name that matches the characters specified is replaced in the corresponding UNIX name by the character specified in auto.schema.substitute.chars.

> **Note**: Be sure to specify the replacement character in auto.schema.substitute.chars. Otherwise, the offending character is simply removed from the name, and you run the risk of duplicate UNIX names.

The default setting in centrifydc.conf for UNIX (HP-UX, Solaris, AIX) and Linux systems is the following:

auto.schema.unix.name.disallow.chars: \t\n /\\><?|\"\'`[],:;~!@#$%^&*()=

The default setting in centrifydc.conf for Mac OS X systems is the following (space is omitted):

auto.schema.unix.name.disallow.chars: \t\n/\\><?|\"\'`[],:;~!@#$%^&*()=

Run the adflush command after you change the value to flush the cache.

auto.schema.substitute.chars

This configuration parameter specifies the character that replaces any characters specified in auto.schema.unix.name.disallow.chars encountered in an Active Directory user or group name in the corresponding UNIX name.

The default setting in centrifydc.conf is the following:

auto.schema.substitute.chars: _ (underbar)

Run the adflush command after you change the value to flush the cache.

auto.schema.max.unix.name.length

This configuration parameter specifies the maximum length for a generated UNIX user or group name. The UNIX names are generated from the Active Directory user and group names.

The default setting in centrifydc.conf is the following:

auto.schema.max.unix.name.length: 33

Run the adflush command after you change the value to flush the cache.

Customizing Auditing Configuration Parameters

This section describes the configuration parameters that you can set on audited computers that have a Centrify Agent for *NIX installed. These parameters affect the operation of the auditing service (dad) and the UNIX shell wrapper (cdash).

The parameters are defined in a text file named centrifyda.conf in /etc/centrifyda on each audited computer.

> **Note**: For information about specifying an audit trail target in the centrifydc.conf file, see audittrail.targets.

agent.max.missed.update.tolerance

This configuration parameter specifies the number of unsuccessful attempts the Delinea auditing agent makes to join a collector before displaying a notification that the agent is not joined to a collector. Each attempt is made after an interval of 5 minutes.

For example, if you want the agent to warn you that it is not connected to a collector after 3 attempts, you would enter the following:

agent.max.missed.update.tolerance: 3

The default value for this parameter is 4.

You can use this parameter with the dad.collector.connect.timeout parameter which specifies the amount of time, in seconds, the agent waits during each connection attempt before it determines that it cannot connect to a collector.

agent.send.hostname

This configuration parameter enables audited sessions to display the host name specified by the agent on audited computers instead of the host name resolved by the collector through DNS. This configuration parameter is useful in configurations where the DNS servers used by the collectors cannot reliably resolve host names from IP addresses. The most common scenarios that might require you to use this configuration parameter are when the agents are in a virtual environment using network address translation (NAT) or in a perimeter network outside of a firewall.

You can set this parameter to true if you want the agent to determine the host name used. If you set this configuration parameter to false, the collector determines the agent's host name based on its IP address.

For example:

agent.send.hostname: true

agent.video.capture

This configuration parameter enables or disables saving the video capture for a specific agent, which overrides the video capture settings configured for the entire DirectAudit installation. If video capture is disabled, the collector does not display the video output and does not save it to the database.

The default value uses the settings that you have configured for the entire installation.

To save the captured video output to the database, you set this parameter to enabled. To not save the captured video output, set this parameter to disabled.

For example:

agent.video.capture: enabled

autofix.nss.conf

This configuration parameter enables dad to fix /etc/nsswitch.conf automatically if anything goes wrong. If set to true, the dad process configures the /etc/nsswitch.conf file automatically. If set to false, the /etc/nsswitch.conf file is left unmodified.

The default value is true.

For example, to disable changes to the /etc/nsswitch.conf file:

autofix.nss.conf: false

cache.enable

This configuration parameter controls whether the dad process caches name service query results about users and groups. If set to true, the dad process stores query results, for example, from user lookup requests, in memory for better performance. If set to false, query results are not saved and must be retrieved whenever they are needed.

If set to true, you can use the cache.max.size and cache.time.to.live parameters to control the number and duration of entries in the cache. You can also use the daflush command to clear the cache manually when you want to ensure you get updated information. For example, if you remove the UNIX Login role for an Active Directory user, some information for that user might remain in the cache and be returned when you run a command such as getent passwd. You can run daflush to ensure the user is removed completely from the local computer cache, including the auditing name service cache.

The default value for this parameter is true.

For example, to disable the name service cache on an audited computer:

cache.enable: true

cache.max.size

This configuration parameter controls the maximum number of entries that can be stored in the dad name service cache. query results about users and groups. This parameter is only applicable if the cache.enable parameter is set to true. The dad process stores query results up to the value set for this parameter in memory for better performance.

The default value for this parameter is 80,000 entries.

For example, to increase the maximum number of name service results that can be stored on an audited computer:

cache.max.size: 85000

cache.time.to.live

This configuration parameter controls the length of time entries should remain valid in the name service cache. You can specify the maximum number of seconds cached query result should be available in the cache. This parameter is only applicable if the cache.enable parameter is set to true.

The default value for this parameter is 10 minutes (600 seconds).

For example, to increase the number of seconds query results are available in the cache on an audited computer:

cache.time.to.live: 900

cagent.audit.session

This configuration parameter determines if session auditing is enabled with the Delinea Client. A value of 1 means that session auditing is enabled and a value of 0 (zero) means that session auditing is disabled. The default value is 1.

To change the setting, run dacontrol -d to disable auditing or dacontrol -e to enable auditing. Do not use cedit to edit this parameter.

dad.client.idle.timeout

This configuration parameter determines the time interval within which dad checks for disconnected dash sessions.

The default value for this parameter is 30 minutes (1800 seconds).

dad.collector.connect.timeout

This configuration parameter specifies the amount of time, in seconds, the agent waits during each connection attempt before it determines that it cannot connect to a collector.

The default value for this parameter is 60 seconds.

You can use this parameter with the agent.max.missed.update.tolerance parameter which allows you to specify the number of unsuccessful attempts that the agent can make to connect to a collector before notifying the user that it is not connected to a collector.

dad.dumpcore

This configuration parameter enables dad to do a core dump if an audited computer crashes. This parameter overrides the default ulimit setting. If set to true, the agent will generate a core dump if the computer crashes. If set to false, no core dump is generated.

The default value is **false.**

dad.gssapi.seal

This configuration parameter specifies whether the auditing service seals network communications with the collector using a secure GSSAPI connection. If set to **true**, the network connection is sealed and cannot be read. If set to **false**, the connection is not sealed and is humanreadable.

The default value is **true.**

dad.gssapi.sign

This configuration parameter specifies whether the auditing service signs network communications with the collector over a secure GSSAPI connection. If set to **true**_, the network connection is signed. If set to **false**, the connection is not signed.

The default value is **true.**

dad.process.fdlimit

This configuration parameter specifies the number of file descriptors that can be used for audited sessions.

For some UNIX platforms, such as Solaris, the default number of available file descriptors for each process is insufficient of auditing sessions, because the Delinea Agent requires two descriptors per session.

Use this parameter to increase the number of file descriptors available. For example:

dad.process.fdlimit: 2048

This configuration parameter can also be set using Group Policy.

dad.resource.cpulimit

This configuration parameter specifies the maximum percentage of CPU usage that dad can use before dad is restarted, or before the event is logged in /var/log/centrifydc.log. Whether dad is restarted when the threshold is exceeded is controlled by [dad.resource.restart]dad-resource-restart.md).

The default value of this parameter is 50, meaning that dad is restarted or the event is logged when dad CPU usage exceeds 50%. For example:

dad.resource.cpulimit: 50

The dad resource monitor automatically checks the usage of various dad resources during runtime. For each resource that is monitored, you can configure the threshold value that triggers a dad restart or a log entry.

When dad is restarted, the client is purged, and counters for resources such as CPU usage, file descriptors, and memory are reset. See dad.resource.restart for more information about the advantages of setting a threshold that is lower than the default system value.

dad.resource.cpulimit.tolerance

This configuration parameter specifies the number of times that CPU usage can exceed the threshold set in dad.resource.cpulimit before dad is restarted, or before the event is logged in /var/log/centrifydc.log. Whether dad is restarted when the value of this parameter is exceeded is controlled by dad.resource.restart.

The default value of this parameter is 5, meaning that the CPU usage set in dad.resource.cpulimit can be exceeded four times before dad is restarted on the fifth instance or the event is logged. For example:

dad.resource.cpulimit.tolerance: 5

The dad resource monitor automatically checks the usage of various dad resources during runtime. For each resource that is monitored, you can configure the threshold value that triggers a dad restart or a log entry.

When dad is restarted, the client is purged, and counters for resources such as CPU usage, file descriptors, and memory are reset. See dad.resource.restart for more information about the advantages of setting a threshold that is lower than the default system value.

dad.resource.fdlimit

This configuration parameter specifies the maximum file descriptors that dad can use before dad is restarted, or before the event is logged in /var/log/centrifydc.log. Whether dad is restarted when the threshold is exceeded is controlled by dad.resource.restart.

The default value of this parameter is 500, meaning that dad is restarted or the event is logged when dad file descriptor usage exceeds 500. For example:

dad.resource.fdlimit: 500

The dad resource monitor automatically checks the usage of various dad resources during runtime. For each resource that is monitored, you can configure the threshold value that triggers a dad restart or a log entry.

When dad is restarted, the client is purged, and counters for resources such as CPU usage, file descriptors, and memory are reset. See dad.resource.restart for more information about the advantages of setting a threshold that is lower than the default system value.

dad.resource.memlimit

This configuration parameter specifies the maximum memory usage (in bytes) that dad can use before dad is restarted, or before the event is logged in /var/log/centrifydc.log. Whether dad is restarted when the threshold is exceeded is controlled by dad.resource.restart.

The default value of this parameter is 104857600 (100 MB), meaning that dad is restarted or the event is logged when dad memory usage exceeds that value. For example:

dad.resource.memlimit: 104857600

The dad resource monitor automatically checks the usage of various dad resources during runtime. For each resource that is monitored, you can configure the threshold value that triggers a dad restart or a log entry.

When dad is restarted, the client is purged, and counters for resources such as CPU usage, file descriptors, and memory are reset. See dad.resource.restart for more information about the advantages of setting a threshold that is lower than the default system value.

dad.resource.restart

This configuration parameter specifies whether dad restarts or just logs the event when a resource threshold is exceeded. Events that are logged are recorded in /var/log/centrifydc.log.

The default value of this parameter is false, meaning that when a resource threshold is exceeded, the event is logged, but dad is not restarted. For example:

dad.resource.restart: false

The dad resource monitor automatically checks the usage of various dad resources during runtime. For each resource that is monitored, you can configure the threshold value that triggers a dad restart or a log entry.

You can set resource thresholds in these parameters:

- dad.resource.cpulimit
- dad.resource.cpulimit.tolerance
- dad.resource.fdlimit
- dad.resource.memlimit
- dad.resource.timer

When dad is restarted, the client is purged, and counters for resources such as CPU usage, file descriptors, and memory are reset.

Setting a low threshold for restarting dad and purging the client can avoid problems with resources being consumed prematurely. For example, when cdash calls another cdash recursively, dad receives a large number of client requests. Solaris has only 256 file descriptors for ulimit by default. Unless you configure a threshold lower than 256, cdash does not stop recursive calling until 257 calls, and all of dad's file descriptors could be consumed by that one operation.

dad.resource.timer

This configuration parameter specifies how often (in seconds) the dad resource monitor checks dad resource usage.

The default value of this parameter is 600 (10 minutes), meaning that the dad monitor checks dad resource usage every 10 minutes. For example:

dad.resource.timer: 600

The dad resource monitor automatically checks the usage of various dad resources during runtime. For each resource that is monitored, you can configure the threshold value that triggers a dad restart or a log entry.

When dad is restarted, the client is purged, and counters for resources such as CPU usage, file descriptors, and memory are reset. See dad.resource.restart for more information about the advantages of setting a threshold that is lower than the default system value.

dad.timer.diskspace

This configuration parameter specifies the number of seconds between checks of disk space when the disk space reserved for offline storage is less than the value specified in the spool.diskspace.min parameter.At each check, a warning message is written to the log file.

The default value is 360 seconds.

dad.timer.monitor.nss.conf

This configuration parameter controls how frequently the dad process checks the /etc/nsswitch.conf file for changes. Set this parameter to the number of seconds between checks.

The default value is 60 seconds.

dash.allinvoked

This configuration parameter was previously required to support auditing of shells invoked in scripts and command-level auditing. The parameter is no longer required and can be removed if you upgrade the agent to the latest version and enable command-level auditing through NSS. If you do not update the agent, you can use this parameter to specify whether to audit all shell invocations. If set to **true**, all login and non-login shells are audited. If set to **false**, only login shells and login sub-shells are audited. If set to false, invoked shells are not audited.

The default value is **false**.

dash.auditstdin

This configuration parameter specifies whether the agent captures standard input (stdin). If set to true, the auditing service records all session input and output, including stdin data. If set to false, the auditing service records all session activity to standard output, but does not capture stdin data.

The default value is true.

dash.auditstdin.except

This configuration parameter specifies strings that cdash should ignore when capturing stdin data. For security, typed passwords are always ignored by default. Use regular expressions and do not include quotes. Leading and trailing spaces are ignored, spaces in the middle are not affected. For example:

dash.auditstdin.except: (prompt1|prompt2)

will match strings like these:

This is prompt1:
Prompt2 asks for password:

The default value is empty to only ignore the passwords that users enter. For more information about specifying exceptions, see the comments in the centrifyda.conf file.

dash.cmd.audit.blacklist

This configuration parameter specifies whether certain privileged command patterns are skipped while auditing is enabled.

To add a command pattern to skip, list the regular expression you wish to skip to this parameter. When enabled, an audit trail is still sent by the agent, but the specified command and arguments will not be captured. For example, the following list will skip auditing of the “date” command:

dash.cmd.audit.blacklist: date

By default, no command patters are skipped while auditing.

dash.cmd.audit.show.actual.user

This configuration parameter specifies whether command-based auditing records will display the actual user account used to run a privileged command that requires auditing, as well as the run-as account.

By default, the value of this parameter is set to false, and only the run-as account used to execute privileged commands is shown in auditing records. To enable this parameter, set the value to true. For example:

dash.cmd.audit.show.actual.user: true

dash.cont.without.dad

This configuration parameter specifies whether cdash prompts the user to restart auditing when it determines that dad is not running. If set to true, cdash does not prompt the user to restart auditing and continues without the dad process. If set to false, cdash prompts the user to restart auditing to continue.

The default value is false.

dash.force.audit

This configuration parameter specifies one or more session binary files to audit. This parameter was previously required to support command-level auditing on managed computers. The parameter is no longer required and can be removed if you upgrade the agent to the latest version.

Instead of setting this parameter, you must run the following command to enable auditing for specific command-line programs:

dacontrol --enable --command cmd_path

If you do not update the agent, you can use this parameter to specify commands to be audited by appending .daudit to the file name. For example, to audit secure shell (ssh) sessions:

dash.force.audit: /usr/share/centrifydc/bin/ssh.daudit

However, you still must run the dacontrol command to enable auditing for specific commands.

You can separate entries by typing a space or a comma. You can escape spaces or commas in file names using the backslash character (\). This parameter is not included in the configuration file by default.

dash.loginrecord

This configuration parameter specifies whether the auditing service should add utmp entries for the cdash pseudo terminals (pty). The setting of this parameter affects the results of whoami and who commands.

If set to **true**, the auditing service adds utmp entries for cdash pseudo terminals processes. With this setting, whoami in an audited shell works as expected, but who commands list logged-in users twice.

If set to false, the auditing service does not create additional utmp entries. With this setting, the whoami command in an audited shell cannot determine complete user information. Workaround: on some operating systems: who --lookup works, but the who command lists users only once.

The default value is false.

dash.obfuscate.pattern

This configuration parameter enables you to hide sensitive information in the standard output (stdout) in audit results by using patterns to define the hidden information.

Beginning with release 2015.1, each pattern that you create must be embedded inside double quote characters (“). For example:

“nnnn-nnnn-nnnn-nnnn”

> **Note**: If there is a delay in the display of standard output information that you have designated to be hidden by defining a pattern, the agent may not recognize the pattern, and the information may be shown. To avoid delays, your obfuscation string should not exceed the size of the Cdash standard output buffer, which is 4KB.
>
> **Note**: In releases earlier than 2015.1, patterns could be embedded inside double quote characters (“) or slash characters (/). If slash characters were used, they are converted automatically to double quote characters when you upgrade from 2015 to 2015.1.

Each single character in a pattern corresponds to one character in actual session data.

Supported characters in a pattern are as follows:

A	Any upper case letter.
d	Any character.
D	Any letter.
n	Any decimal digit character.
s	Symbols, such as the following: ~ ` ! @ # $ % ^ & * (- _ = + [{] } | \ : ; ' < , > . ? /
-	Separator for exact matching in session data.
_	Separator for exact matching in session data.
(	Separator for exact matching in session data.
)	Separator for exact matching in session data.
,	Separator for exact matching in session data.
.	Separator for exact matching in session data.

If you define more than one pattern, separate the patterns with spaces. For example:

“nnnn-nnnn” “A-nnnn”

By default, this parameter does not contain any patterns.

dash.obfuscate.regex

This configuration parameter enables you to hide sensitive information in the standard output (stdout) in audit results by using regular expressions to define the hidden information patterns.

Beginning with release 2015.1, each regular expression that you create must be embedded inside double quote characters (“). For example:

“[A-Z][0-9]{6}\\([0-9A-Z]\\)”

If you define more than one regular expression, separate the regular expressions with spaces. For example:

“[0-9]-[0-9]” “[a-z]-[0-9]”

> **Note**: If there is a delay in the display of standard output information that you have designated to be hidden by defining a pattern, the agent may not recognize the pattern, and the information may be shown. To avoid delays, your obfuscation string should not exceed the size of the Cdash standard output buffer, which is 4KB.
>
> **Note**: In releases earlier than 2015.1, patterns could be embedded inside double quote characters (“) or slash characters (/). If slash characters were used, they are converted automatically to double quote characters when you upgrade from 2015 to 2015.1.

By default, this parameter does not contain any regular expressions.

dash.obfuscate.stdin

This configuration parameter specifies whether cdash hides (obfuscates) the STDIN. Setting this parameter to true is useful in situations where users enter sensitive data such as login credentials and so forth. The service hides the STDIN data according to the patterns specified in the dash.obfuscate.pattern and dash.obfuscate.regex parameters.

> **Note**: If the user uses line-editing keys such as left arrow, right-arrow, and so forth on the command line, the obfuscation will fail. The exception is that if a user uses the backspace key, the obfuscation will still occur.

By default, this parameter is set to false.

dash.parent.skiplist

This configuration parameter lists the names of parent processes that should not be audited. If the name of a process's parent is in this list, cdash will drop out without auditing.

You can add parent processes to the list or remove the default parent processes if you do not want to skip auditing for these processes. List entries must be separated by spaces.

For example, to skip auditing for the sapstartsrv, gdm-binary, gdm-session-wor, kdm, and sdt_shell parent processes:

dash.parent.skiplist: sapstartsrv gdm-binary gdm-session-wor kdm sdt_shell

You can also set this parameter using group policy.

dash.prompt.message.file

This parameter specifies a file that contains auditing messages that display to the user in various situations. The default location of the file is /etc/centrifda/dash.prompt.message. In that file are some key-value pairs that you can customize to your preferred wording or language.

The following situations apply if the user is set as "Audit required" but also doesn't have the "Always permit logon" right:

- dad.stopped.purposely - If an administrator intentionally stops the auditing service (also referred to as the DirectAudit daemon, or dad), the following message displays:

- dad.stopped.unexpectedly - If the auditing service stops unexpectedly, the following message displays:

- dad.diskspace.too.low- If there isn't enough disk space on the audited system, the following message displays:

fails, contact your administrator to increase the available disk space and then try again.

dash.reconnect.dad.retry.count

This configuration parameter specifies how many times cdash attempts to connect to dad after dad has started.

The default value is 3 retry attempts.

dash.reconnect.dad.wait.time

This configuration parameter specifies the number of seconds to wait after restarting dad before attempting to reconnect to dad.

The default value is 1 second.

dash.select.timeout

Use this parameter to specify the number of milliseconds that cdash waits while checking if the data is ready.

The default value is -1, which means that cdash determines the timeout dynamically.

> **Note**: If there is no data ready to be obfuscated in the timeout period, cdash flushes the buffered data to the collector immediately. Because of this, it's recommended that you specify a timeout value that is larger than the delay between keystrokes: for example, 5000 (equal to 5 seconds). Otherwise, cdash might split the data into multiple segments which would not match the patterns specified in the dash.obfuscate.pattern and dash.obfuscate.regex parameters and therefore the data obfuscation fails.

dash.shell.env.var.set

This configuration parameter specifies whether cdash should set the SHELL environment variable to the user's actual shell or the audit shell.

If set to true, the SHELL environment variable is set to the user's actual shell. If set to false, the SHELL environment variable is set to the audited shell.

The default is true.

dash.ssh.command.skiplist

This configuration parameter specifies the commands that can be executed using a secure shell (ssh) connection without being audited. You can use this parameter to prevent the auditing service from capturing unwanted session information. For example, by setting this parameter, you can avoid recording all of the binary data sent to and from the server when you execute file transfer commands such as rsync, sftp, or scp through a secure shell connection. By default, the parameter is configured to skip auditing for the rsync, sftp and scp commands, which are the most commonly used file transfer programs.

You can add programs to the list or remove the default programs if you don't want to skip auditing for these sessions. If you remove file transfer programs from the list, however, long data streams might cause problems when transferred to collector service.

For example, to skip auditing for ftp, rsync, sftp, scp, and wget commands:

dash.ssh.command.skiplist: ftp rsync sftp scp wget

dash.user.alwaysallowed.list

This configuration parameter lists the names of UNIX users who are allowed to use a session even if the computer cannot be audited due to environment setup issues.

By default, root is the only user allowed to use an unaudited session.

To use this parameter, specify a space-separated list of UNIX user names.

You can also set this parameter using group policy.

dash.user.skiplist

This configuration parameter lists the names of UNIX users and Active Directory users with a UNIX login who should not be audited. You can separate user names by typing a space or a comma. For example:

dash.user.skiplist: MaeJones kelly,dmorris,BookerJames

The default value is empty.

When you list a user in the dash.user.skiplist, this overrides the user's audit level. For example, if the user is set as "Audit Required" and also in dash.user.skiplist, the user might log in successfully but without being audited.

event.execution.monitor

Use the event.execution.monitor parameter to monitor all programs that users run in an audited session.

To use this parameter, you must have enabled the agent to perform advanced monitoring with the command dacontrol -m.

The default value for the event.execution.monitor parameter is false.

In the audit.log file, you can find these events by looking for the cda_sys_execve messages. In the cdc.log file you can find them by looking for the Emit COMMAND_HISTORY.

event.execution.monitor.user.skiplist

Use the event.execution.monitor.user.skiplist parameter to specify a list of users to exclude from advanced monitoring for program execution. For these users, the auditing service does not record any programs that they run, even when the parameter event.execution.monitor is set to true.

For users specified in this list, the auditing service checks for the user account that the program is run by, also known as the “run as” user account.

To use this parameter, you must have enabled the agent to perform advanced monitoring with the command dacontrol -m.

event.file.monitor

Use the event.file.monitor parameter to enable advanced monitoring for configuration files. To use this parameter, you must have enabled the agent to perform advanced monitoring with the command dacontrol -m.

If advanced monitoring is enabled for files, the auditing service monitors any activity in the following folders:

- /etc/
- /var/centrify/
- /var/centrifydc/
- /var/centrifyda/

The default value for the event.file.monitor parameter is true.

In the audit.log file, you can find these events by looking for the cda_file_monitor_write messages. In the cdc.log file you can find them by looking for the Emit AUDIT_TRAIL.

event.file.monitor.process.skiplist

Use the event.file.monitor.process.skiplist parameter to specify which processes to not monitor that are in an area that you've already configured to provide detailed file monitoring. To use this parameter, you must have enabled the agent to perform advanced monitoring with the command dacontrol -m.

When either adclient or dad processes or one of their sub-processes access or alter one of the files specified in the event.file.monitor list, this activity is automatically excluded from advanced monitoring.

The default value for this parameter is daspool.

event.file.monitor.user.skiplist

Use the event.file.monitor.user.skiplist parameter to specify a list of users to exclude from advanced monitoring for files. For these users, the auditing service does not record any write access to directories specified in event.file.monitor.

For users specified in this list, the auditing service checks this list against the original login user.

For example:

The event.file.monitor.user.skiplist parameter does not include the user dwirth. Dwirth uses the following command:

dzdo cp /tmp/badfile /etc/badfile

This activity generates the following audit event:

user dwirth run as root opened the file /etc/badfile using the /bin/cp command.

To use this parameter, you must have enabled the agent to perform advanced monitoring with the command dacontrol -m.

The default value for this parameter is root.

event.monitor.commands

Use the event.monitor.commands parameter to specify a list of commands to monitor. Be sure to list each command with the full path. The auditing service generates an audit trail event when a user runs any of these monitored commands, and ignores any commands listed in the event.monitor.commands.user.skiplist.

To use this parameter, you must have enabled the agent to perform advanced monitoring with the command dacontrol -m. Otherwise, you will not get any report or audit trail event results.

In the audit.log file, you can find these events by looking for the cda_cmd_exec messages. In the cdc.log file you can find them by looking for the Emit AUDIT_TRAIL and Emit COMMAND_HISTORY messages.

event.monitor.commands.user.skiplist

Use the event.monitor.commands.user.skiplist parameter to specify any users for whom you do not want to monitor the commands that they run. Any user that you specify in this parameter will not generate an audit trail event when they run any command, even if the command is listed in event.monitor.commands.

lang_setting

This configuration parameter specifies the code page that is used by DirectAudit for character encoding.

You can set this parameter to one of the following valid values:

- utf8
- iso8859-1

The default value is utf8.

You can also set this configuration parameter using group policy.

lrpc2.message.signing

Use the lrpc2.message.signing to manage message singing behavior.

You can set this parameter to one of the following values:

- Disabled (default) to not ever sign LRPC2 messages.
- Allowed does not require LRPC2 message signing but may be chosen if required.
- Required must sign LRPC2 messages.

lrpc2.timeout

This configuration parameter specifies the number of seconds cdash and dainfo waits while trying to contact the dad service before timing out.

The default value is 30 seconds.

You can also set this configuration parameter using group policy.

lrpc2.rebind.timeout

This configuration parameter specifies the number of seconds that dareload (-b) waits while trying to connect to the dad service before timing out.

The default value is 300 seconds.

You can also set this configuration parameter using **for rebinding** group policy.

nss.alt.zone.auditlevel

This configuration parameter enables you to specify a default audit level for all users who do not have an audit level explicitly defined using the nss.user.override.userlist parameter. Note that this parameter is only applicable in classic zones. You should not set this parameter if you are using hierarchical zones.

You can set this parameter to one of the following valid values:

- use_sysrights
- audit_if_possible
- no_audit
- audit_required

The default value is use_sysrights. This setting determines the audit level by communicating with the adclient process.

The effective audit level for a user is determined in the following order:

1. If the user is included in the list specified by the nss.user.override.userlist parameter and the audit level is specified for the user, the specified audit level is used.
2. If the user is included in the list specified by the nss.user.override.userlist parameter and the audit level is not specified for the user, the value specified by the nss.user.override.auditlevel parameter is used.
3. If the user is not included in the list specified by the nss.user.override.userlist parameter, the audit level specified for the nss.alt.zone.auditlevel parameter is used.

nss.nologin.shell

This configuration parameter enables you to specify one or more non-login shells for audited users. In most cases, when audited users log on, they are placed in a wrapper shell so that their activity can be captured and sent to a collector. To use a real shell instead of the wrapper shell, you can specify shells to be non-login shells for audited users to access. After you set this parameter, you should restart the auditing service (dad).

For example, to define the shells /sbin/shell_test1 and /bin/shell_test2 as a non-login shells, you would type:

nss.nologin.shell: /sbin/shell_test1 /bin/shell_test2

If this parameter is not configured, the default no-login shells /sbin/nologin and /bin/false are used.

nss.user.conflict.auditlevel

This configuration parameter enables you to override a user's audit level when the user is listed in the user.ignore list and has the use_sysrights audit level. Valid parameter values are:

audit_if_possible
no_audit
audit_required

By default, this parameter is set to audit_if_possible.

nss.user.override.auditlevel

This configuration parameter specifies the default audit level for any users specified for the nss.user.override.userlist without an audit level defined. This parameter replaces the deprecated user.ignore.audit.level parameter.

You can set this parameter to one of the following valid values:

- use_sysrights
- audit_if_possible
- no_audit
- audit_required

The default value is use_sysrights. If there are classic zone users not included in nss.user.override.userlist parameter, the default audit level is the value specified for the nss.alt.zone.auditlevel parameter.

nss.user.override.userlist

This configuration parameter enables you to specify an audit level for a list of users that will bypass Active Directory. In most cases, the auditing service connects to Active Directory to get user profile and audit level information. You can use this parameter to bypass Active Directory, for example, to specify local user accounts that do not have a corresponding user account in Active Directory, but for which you want to audit session activity. This parameter replaces the deprecated user.ignore parameter.

You can specify the parameter value by typing individual entries using the format user_name[:audit_level], separated by spaces, or by using the file: keyword and a file location.

You can set the audit_level to one of the following valid values:

- use_sysrights
- audit_if_possible
- no_audit
- audit_required

The use_sysrights setting indicates that you want to use the audit level information associated with the user's role. If you don't specify an audit level for a user with this parameter, the default audit level is to the audit level you specify for the nss.user.override.auditlevel parameter. For example, you can set the value using individual user name entries like this:

nss.user.override.userlist: maya:use_sysrights tai:no_audit carlos

Alternatively, you can using the file: keyword and a file that has one user_name[:audit_level] per line. For example:

nss.user.override.userlist: file:/etc/centrifyda/user_auditing_classiczones

Be sure to run the dareload command after modifying the configuration file to have the changes take effect.

Note that this parameter is most commonly used to specify the audit level for local user accounts. However, you can use it to specify both local and Active Directory users, if needed. To include Active Directory users in the list of users specified with this parameter, you must specify the Active Directory user's UNIX login name as a parameter value in the user list you define with this parameter.

> **Note**: For computers that have only the Delinea Client for Linux installed, there is a sample file that you can use to specify users outside of Active Directory. The sample file is /etc/centrifyda/nss.user.override.userlist.sample. To point the client to this sample file, include the following line in your centrifyda.conf file:
> nss.user.override.userlist: /etc/centrifyda/nss.user.override.userlist.sample

preferred.audit.store

If your UNIX or Linux computer has multiple IP addresses that match the criteria for multiple audit stores, use the preferred.audit.store parameter to specify the preferred audit store that the DirectAudit agent will use.

If you have this kind of installation and you don't specify the preferred audit store, the collector may or may not connect to the correct audit store.

prefer.site.over.subnet

When the audit and monitoring service is running on a system and it needs to connect to an audit store, you can use this prefer.site.over.subnet parameter to specify the search precedence.

If you set this parameter to true, then the agent looks for an audit store based on the Active Directory sites. If the search fails, then the agent looks for an audit store based on the subnet.

By default, this parameter is false, which means that audit stores are chosen first based on their subnet addresses and then based on the Active Directory sites.

For example:

prefer.site.over.subnet: true

spool.diskspace.logstate.reset.threshold

This configuration parameter specifies a threshold percentage of disk space that is added to the minimum percentage of disk space (set in the spool.diskspace.min parameter) that determines when the information/warning/error log state is reset. Message logging resumes only after the log state is reset.

When disk space drops below the minimum percentage (for example, 10%), a warning is logged. Additional warnings are not logged until disk space has risen above the minimum percentage + threshold percentage (for example, 10% + 2% = 12%), and then drops again below the minimum percentage (10%).

Setting a threshold percentage is useful to prevent unnecessary log messages when disk space hovers near the minimum percentage and would otherwise trigger a log message every time the minimum percentage is crossed.

The default value is 2 percent of disk space.

You can also set this parameter using group policy.

spool.diskspace.min

This configuration parameter specifies the minimum volume of disk space required on the partition containing the offline spool file before spooling stops.

You can set this value as a percentage of the disk space, or you can set it as an exact size. To set the value as an exact size, specify the unit value after the number value. The unit values are not case-sensitive.

For example, to set the minimum volume of disk space to 28 gigabytes, you would enter the following:

spool.diskspace.min: 28GB

You can specify the following unit values:

- B (byte)
- KB (kilobytes)
- MB (megabytes)
- GB (gigabytes)
- TB (terabyrtes)

To specify the value as a percentage, you can either use the percent (%) symbol, or enter a number with no unit value. If you specify a number, make sure that there isn't a space between the number and the unit value; for example, to specify 28 gigabytes enter "28GB" not "28 GB". Including a space, such as "28 GB", is interpreted as a percentage, such as "28%".

The default value is 10 percent of disk space.

You can also set this parameter using group policy.

spool.diskspace.softlimit

This configuration parameter specifies the volume of disk space required on the partition containing the offline spool file to avoid warnings in the log. If available disk falls below the level specified in this parameter, a warning is logged and auditing will continue until disk space falls below the level specified in spool.diskspace.min.

You can set this value as a percentage of the disk space, or you can set it as an exact size. To set the value as an exact size, specify the unit value after the number value. The unit values are not case-sensitive.

For example, to set the minimum volume of disk space to 5 kilobytes, you would enter the following:

spool.diskspace.min: 5 kb

You can specify the following unit values:

- B (byte)
- KB (kilobytes)
- MB (megabytes)
- GB (gigabytes)
- TB (terabyrtes)

To specify the value as a percentage, you can either use the percent (%) symbol, or enter a number with no unit value.

The value of this parameter must be greater than or equal to the value of spool.diskspace.min.

The default value is 12 percent of disk space.

You can also set this parameter using group policy.

spool.maxdbsize

This configuration parameter specifies maximum disk space in bytes to allocate to the offline storage database. Use 0 to designate no limit.

The default value is 0 (unlimited).

You can also set this parameter using group policy.

uid.ignore

This configuration parameter specifies one or more numeric user identifiers (UID) that you want to ignore for authentication and lookup requests in Active Directory. In most cases, you use this parameter to specify local user accounts that do not have a corresponding user account in Active Directory, but for which you want to audit session activity. You can specify the parameter value by typing individual user identifiers, separated by spaces, or by using the file: keyword and a file location. For example, you can set the value using individual UID values like this:

uid.ignore: 0 500 5861

Alternatively, you can using the file: keyword and the sample uid.ignore file that is installed with the Delinea Agent. The sample uid.ignore file ignores the most common default system accounts. For example:

uid.ignore: file:/etc/centrifydc/uid.ignore

If you edit the /etc/centrifydc/uid.ignore file, be sure to run the adreload command after modifying the file to have the changes take effect.

user.ignore

This configuration parameter specifies one or more user names that you want to ignore for authentication and lookup requests in Active Directory. In most cases, you use this parameter to specify local user accounts that do not have a corresponding user account in Active Directory, but for which you want to audit session activity. You can specify the parameter value by typing individual user names, separated by spaces, or by using the file: keyword and a file location. For example, you can set the value using individual user name values like this:

user.ignore: tai carlos games gopher

You can also specify the user's audit level by adding the value after the user names added to user.ignore. For example:

user.ignore: tai carlos:audit_if_possible

Alternatively, you can using the file: keyword and the sample user.ignore file that is installed with the Delinea Agent. The sample user.ignore file ignores the most common default system accounts. For example:

user.ignore: file:/etc/centrifydc/user.ignore

If you edit the /etc/centrifydc/user.ignore file, be sure to run the adreload command after modifying the file to have the changes take effect.

user.ignore.audit.level

This configuration parameter is no longer used except for backward compatibility. It has been replaced by the nss.user.override.auditlevel parameter. This configuration parameter specifies the audit level setting for the user that you want to ignore for authentication and lookup requests in Active Directory. In most cases, you use this parameter when you have specified local user accounts that do not have a corresponding user account in Active Directory, but for which you want to audit session activity. By default, the users you specify for the uid.ignore or user.ignore parameter are audited if auditing is enabled and the auditing service (dad) is running on the local computer (audit if possible). You can disable the auditing of user activity for the users specified by the uid.ignore or user.ignore parameter by setting this parameter value to one (1). For example, if you don't want to audit activity for the users specified in uid.ignore or user.ignore list, set the parameter as follows:

user.ignore.audit.level: 1

You cannot require auditing for the users specified in uid.ignore or user.ignore list because those users would be unable to log on if the auditing service stops running or is removed from a local computer. To prevent users from being locked out, you can only set this parameter to audit if possible (0) or no auditing (1).

Customizing LDAP Proxy Configuration Parameters

This section describes the configuration parameters that affect the use of Delinea direct access LDAP proxy handling on the local host computer.

ldapproxy.cache.credential.expire

This configuration parameter specifies how long ldapproxy holds the ldapproxy credential cache. The cache expires in the specified number of seconds. Default is 300 seconds:

ldapproxy.cache.credential.expires <seconds>

The ldapproxy credential cache retains the user login Active Directory verification.

- If a user logs in within the expiration window, ldapproxy does not require another adclient verification.
- If a user logs in and the ldapproxy credential cache is expired, ldapproxy sends a request for authentication to adclient. adclient can authenticate using its own cache or send to AD for authentication.

Restart centrify-ldapproxy to apply changes.

[root]$ /usr/share/centrifydc/bin/centrify-ldapproxy restart

ldapproxy.netgroup.use.rfc2307nisnetgroup

This configuration parameter specifies which type of netgroup object that the LDAP proxy searches. By default, this parameter is set to false and the LDAP proxy searches the NIS map netgroup objects.

ldapproxy.netgroup.use.rfc2307nisnetgroup false

If you set this ldapproxy.netgroup.use.rfc2307nisnetgroup parameter to true, then the LDAP proxy searches RFC2307 NIS netgroup objects.

Restart centrify-ldapproxy to apply changes.

[root]$ /usr/share/centrifydc/bin/centrify-ldapproxy restart

ldapproxy.performance.log.interval

This configuration parameter specifies the interval between each log dump of ldapproxy events. The interval is number of seconds. The default value, 0, disables the parameter.

ldapproxy.cache.enabled true

ldapproxy.performance.log.interval <seconds>

The ldapproxy statistics collected include:

- Search cache statistics, such as: cache hit, cache negative hit, cache miss, cache expires, cache overflow and object clone error.

  Search cache statistics require the ldapproxy.cache.enabled parameter is set to true and the ldapproxy.performance.log.interval is set to a non-zero value.

- Authentication statistics, such as: authentication requests, satisfied from cache, actual authentication to adclient, and average response time of actual authentication through adclient.

  Authentication statistics require the ldapproxy.performance.log.interval is set to a non-zero value.

Restart centrify-ldapproxy to apply changes.

[root]$ /usr/share/centrifydc/bin/centrify-ldapproxy restart

Important: We are currently migrating this content to this platform. For a complete, working version, please visit our legacy platform here.

The *Group Policy Guide* describes the Delinea group policies that are available in Server Suite for cross-platform access control and privilege management. These group policies allow you to centrally manage computer and user configuration settings through the Microsoft Group Policy Objects.

Intended Audience

This guide is intended for administrators who want to customize the operation of Delinea software by modifying group policies.

This guide is intended as a supplement to the main documentation set and assumes that you have a working knowledge of Delinea architecture and administration and Active Directory group policies.

Using this Guide

Depending on your environment and role as an administrator or user, you may want to read portions of this guide selectively. The guide provides the following information:

- Group policies in Active Directory provides an introduction to group policies, how they are enabled, and how they are applied to Active Directory objects.
- Server Suite group policy overview provides an overview of how Delinea group policies work.
- Adding Delinea settings to Group Policies Objects describes how to add Centrify group policies to a Group Policy Object and how to edit group policy settings.
- DirectControl Settings describes the group policies that control Delinea configuration parameters that are not related to auditing.
- Audit and audit trail settings describes the group policies that control Delinea auditing configuration parameters.
- Additional group policies for UNIX services describes the single-purpose group policies you can add to a Group Policy Object.
- GNOME settings describes the Gnome group policies you can add to a Group Policy Object.
- Mac OS X Settings provides an overview of the group policies available for Mac OS X users and computers.
- Defining custom group policies describes how to create custom administrative templates to implement your own group policies.

Group Policies in Active Directory

This section provides an overview of how to use group policies configuration management in an Active Directory environment. It includes an introduction to the concept of Group Policy Objects on Windows and a summary of how group policies settings are inherited through an Active Directory structure.

The following topics are covered:

Configuring Computer and User Settings

How Group Policies are Applied

Editing a Group Policy Object

Selecting Computer or User Settings

Applying Policies in Nested Organizational Units

Configuring Group Policies to be Refreshed

> **Note**: This section only provides an overview of key concepts for working with group policies and Group Policy Objects. For more complete information about creating and using group policies and working with Group Policy Objects, see your Active Directory documentation. If you are already familiar with group policies and inheritance rules for Group Policy Objects, you can skip this chapter.

Configuring Computer and User Settings

Group policies allow you to specify a variety of configuration options and apply those settings to specific groups of computers and users through Active Directory. In a standard Windows environment, these configuration options control many aspects of computer operation and the user experience, including the user's desktop environment, operations performed during startup and shutdown, local security enforcement, user- and computer-based settings in the local Windows registry, and software installation and maintenance services.

The configuration options available and the settings you make for those options are defined in a **Group Policy Object** (GPO) linked to an Active Directory object. Each Group Policy Object can consist of configuration information that applies to computers, configuration information that applies to users, or sections of policy specifically devoted to each.

Every Group Policy Object includes a default set of **Administrative Templates** and Software and Windows Settings that are created automatically as part of the Group Policy Object. Centrify provides additional templates to manage the Linux, UNIX, and Mac OS X computers. See Adding Centrify Policies from XML Files to learn how to add the Delinea templates to a group policy object.

There are two default Group Policy Objects available when you install or promote a server to be a Windows domain controller:

- Default Domain Controllers Policy
- Default Domain Policy

Your organization may have additional Group Policy Objects customized to suit your environment.

How Group Policies are Applied

Before you can configure any settings by enabling group policies, you must create or select a Group Policy Object where the policies will apply. You can link Group Policy Objects to a specific organizational unit, domain, or site in Active Directory.

To create a new Group Policy Object

1. Open the Group Policy Management console (gpmc.msc).
2. Select a domain, organizational unit, or site, right-click, then select **Create a GPO in this domain, and Link it here**.

   You must have read and write permission to access the system volume of the domain controller and the right to modify the selected site, domain, or organizational unit.
3. Type a name and, optionally, select an existing Group Policy Object to use as a model for the new Group Policy Object, then click **OK**.

Alternatively, you can select a domain, organizational unit, or site in the Group Policy Management console, right-click, then select **Link an Existing GPO** to link an existing Group Policy Object—such as the Default Domain Policy—to the selected domain, organizational unit, or site. Note that you cannot link a Group Policy Object to generic containers—such as the default Users, Computers, or Domain Controllers containers—or to containers you create.

Once you link a Group Policy Object to an organizational unit, domain, or site, the specific policies you enable are applied when computers are rebooted, when users log on, or at the next update interval if you set policies to be periodically refreshed.

Order in which Policies are Applied

You can link Group Policy Objects throughout the hierarchical structure of the Active Directory environment. When you have different policies at different levels, they are applied in the following order unless you explicitly configure them to block inheritance or behave differently:

- Local Group Policy Objects are applied first.
- Site-level Group Policy Objects are applied in priority order.
- Domain-level Group Policy Objects are applied in priority order.
- Organizational Unit-level Group Policy Objects are applied in priority order down the hierarchical structure of your organization, so that the last Group Policy Object used in the one that applies to the Organizational Unit the user or computer resides in.

As this set of rules suggests, a Group Policy Object linked to a site applies to all domains at the site. A Group Policy Object applied to a domain applies directly to all users and computers in the domain and by inheritance to all users and computers in organizational units and containers farther down the Active Directory tree.

A Group Policy Object applied to an organizational unit applies directly to all users and computers in the organizational unit and by inheritance to all users and computers in its child organizational units.

You can modify the specific users and computers the GPO is applied to by choosing a different point in the hierarchy, blocking the default inheritance, using security groups to create Access Control Lists, or defining WMI filters.

> **Note**: There are four group policies (run command, sudo, crontab entries and Linux firewall) that can merge the lines of different group policies to a resulting group policy. For the policies to merge, the policy in each group policy must be enforced. Policies with higher precedence will be placed lower in the resulting multi-line policy. (Ref: CS-21048a)

How the Resulting Policy Set is Determined

The order in which Group Policy Objects apply is significant because, by default, policy applied later overwrites policy applied earlier for each setting where the later applied policy was either Enabled or Disabled. Settings that are Not Configured don't overwrite anything — any Enabled or Disabled setting applied earlier is allowed to persist. You can modify this default behavior by forcing or preventing Group Policy Objects from affecting specific groups of users or computers, but in most cases, you should avoid doing so.

As an example, consider an organization with a single domain called arcade.com which is divided into the following top-level organizational units:

- USA
- Spain
- Korea

Each of these may be divided into lower-level organizational units, indicating major departmental or functional groupings for the top-level organizational unit.

For example, the USA organizational unit may be divided into CorporateHQ, Development, and Sales.

A computer placed in the CorporateHQ organizational unit might then have several different Group Policy Objects applied to it. For example, the arcade.com organization might have a default domain Group Policy Object that applies to all organizational units in the domain, and each organizational unit might also have its own Group Policy Object applied.

The following table illustrates the configuration settings for two computer configuration policies—Windows Update > **Configure Automatic Updates** and Windows Media Player > **Prevent Desktop Shortcut Creation**—for the Group Policy Objects applied to the example organization arcade.com.

Default Domain Policy	arcade.com	Configure Automatic Updates: Enabled with Auto download and notify for install Prevent Desktop Shortcut Creation: Enabled
USA-Specific	USA	Configure Automatic Updates: Not Configured Prevent Desktop Shortcut Creation: Enabled
All Development	CorporateHQ	Configure Automatic Updates: Not Configured Prevent Desktop Shortcut Creation: Disabled

For example, if you were managing the default domain policies used in this example, you would:

1. Start Active Directory Users and Computers.
2. Right-click the domain, arcade.com, then click **Properties**.
3. Click the **Group Policy** tab.
4. Select the **Default Domain Policy**, then click **Edit** to open the Default Domain Policy in the Group Policy Object Editor.
5. Click **Computer Configuration > Administrative Templates > Windows Components > Windows Update > Configure Automatic Updates** to **Enabled** and set the **Auto download and notify for install** update option and click **OK**.
6. Click **Computer Configuration > Administrative Templates > Windows Components > Windows Media Player > Prevent Desktop Shortcut Creation** to **Enabled** and click **OK**.

When all of the policies described in the table are applied in their default order, a computer in the CorporateHQ organizational unit would be configured with the following policy settings:

- Configure Automatic Updates: **Enabled** with **Notify for download and notify for install**
- Prevent Desktop Shortcut Creation: **Disabled**

The User Configuration policies applied in a Group Policy Object are also determined by the organizational unit in which a UNIX user is a member. For example, if you define separate User Configuration policies in a Group Policy Object linked to the USA organizational unit, you must also add the users to this organization unit for the policies to apply. For more information, see Applying Policies in Nested Organizational Units.

Editing a Group Policy Object

Any time you create a new Group Policy Object for an organizational unit, domain, or site, it includes a set of default configuration options for computers and users. Initially, all of these default configuration options are defined as “Not configured” or “Not defined” and have no effect. You can then enable the specific policies you want to use for the organizational unit, domain, or site linked to the current Group Policy Object by opening the Group Policy Object in the Group Policy Management Editor.

To edit a specific Group Policy Object

1. Open Administrative Tools, Group Policy Management (gpmc.msc).
2. Expand the Forest and Domains nodes to select a domain,
3. Expand Group Policy Objects for the domain.
4. Select an existing Group Policy Object—such as Default Domain Policy—then right-click and select **Edit**.

The default templates in Group Policy Objects do not include Centrify policies for Centrify-managed computers. For information about adding Centrify policies to Group Policy Objects, see Adding Centrify Policies from XML Files.

Selecting Computer or User Settings

Group Policy Objects consist of two types of group policy settings:

- **Computer Configuration** policies define the startup and shut down operations and other computer-specific behavior. These configuration settings apply to the computers regardless of the user account that logs on to the computer.
- **User Configuration** policies define log-on and log-off operations and other user-specific behavior. These configuration settings apply to the user account regardless of the computer the user logs on to. With these settings, users can move from computer to computer with a consistent profile.

Because the computer and user group policies contain different configuration settings, they don't affect each other directly. In planning how to implement group policies, however, you need to keep in mind which policies must be computer-based and which must be user-based. In many cases, the same group policy might be available as both a computer configuration policy and a user configuration policy. In those cases, you need to decide whether the policy is best applied to computers and all users who log on or to individual users when logging on, regardless of the computers they use.

Applying Policies in Nested Organizational Units

In many production environments, user accounts are most often defined in a parent organizational unit and computers are often placed in a child organizational unit (OU). If you have a Group Policy Object that is linked to the child organizational unit for computer policies, but the user accounts are in a parent organizational unit, the user configuration policies linked to the child organizational unit are not applied to the users when they log in to the computers in the child organizational unit. Instead, the user configuration policies linked to the child OU only apply to the users who are in that child OU.

There are two ways to apply different user configuration policies at lower levels in the organizational unit tree:

- Set the User Configuration policies at the parent level and then configure the child organizational unit to inherit the group policies from the parent.
- Enable the **User Group Policy loopback processing mode** group policy in the Group Policy Object linked to the child organizational unit to implement different user configuration policies at each level.

The **User Group Policy loopback processing mode** group policy is located under Computer Configuration, Policies, Administrative Templates, System, Group Policy. When it is enabled, Active Directory applies the Group Policy Object settings defined for the computers in the child organizational unit to all users.

Enable the Loopback Policy

1. Open Administrative Tools, Group Policy Management (gpmc.msc).
2. Select the Group Policy Object linked to the child organizational unit, right-click, then select Edit.
3. Expand Computer Configuration to view policies under Group Policy.
4. Double-click **User Group Policy loopback processing mode** group policy, the select **Enabled**.

   For Mode, select **Replace** if you defined a whole new set of policies or **Merge** if you are just modifying a subset of policies.

Delinea

Configuring Group Policies to be Refreshed

The computer portion of a Group Policy Object is normally applied any time you restart a computer that receives group policies. The user portion of a Group Policy Object is normally applied any time a user logs on to a computer. Both the computer and user portions of a Group Policy Object can also be configured to refresh automatically at a set interval.

To configure the refresh interval and the conditions for refreshing group policies, use the policies listed under **Computer Configuration > Administrative Templates > System > Group Policy** and **User Configuration > Administrative Templates > System > Group Policy** of a Group Policy Object.

If you configure your Group Policy Objects to refresh periodically, at the interval you specify, the computer contacts Active Directory to get the Group Policy Objects that apply and configures itself with the appropriate settings. If policies are refreshed at a set interval, users can change their configuration settings or their computers' configuration settings, but the changes will be overridden when the group policies are refreshed at the next interval.

If you configure the refresh policy settings for users or computers, the refresh policy applies to both Windows and agent-managed computers and users.

Server Suite Group Policy Overview

This section describes how Server Suite maps the policy settings defined in a Group Policy Object to configuration settings for Server Suite-managed computers and users.

The following topics are covered:

Mapping Settings to a Virtual Registry

In the Windows environment, most of the configuration settings defined in a Group Policy Object are implemented through entries in the local Windows registry. For Linux, UNIX, and Mac OS X computers and users, however, local configuration details are typically defined using a set of configuration files stored in the /etc directory. In addition, the Window and Linux, UNIX, and Mac OS X environments have different configuration requirements, and consequently require different settings to be available through group policy.

To address these differences, Centrify provides its own group policies that allow administrators to use Group Policy Objects to configure settings for Centrify-managed computers and users. To enable you to use Group Policy Objects to configure settings for Linux-, UNIX-, and Mac OS X-based computers and users, Centrify...

- Provides its own **administrative templates** (.xml and .admx files) that define Linux-, UNIX-, and Mac OS X-specific configuration settings.
- Uses the adclient daemon to collect configuration details from Active Directory based on the Group Policy Objects applied for the current computer or user and create a **virtual registry** of those configuration settings on the local Linux, UNIX, or Mac OS X computer.
- Runs local programs that map the configuration details in the virtual registry to the appropriate configuration file changes on the local Linux, UNIX, or Mac OS X computer.

The virtual registry is a collection of files that contain **all** of the group policy configuration settings from the group policies applied to the computer through the group policy hierarchy, including settings that apply only to Windows computers. Because the files that make up this virtual registry are not native to the Linux, UNIX, or Mac OS X environment, the Centrify software then uses a set of **mapping programs** to read the files, determine the settings that are applicable to Linux, UNIX, or Mac OS X computers and users, and make the appropriate changes in the corresponding Linux, UNIX, or Mac OS X configuration files to implement the configuration specified. The mapping programs ignore any Windows-specific settings that have been applied and only map the settings that are appropriate for the Linux, UNIX, or Mac OS X environment.

> **Note**: The virtual registry only supports the group policies that are implemented through registry settings. Group policies that are implemented in other ways, for example, by running an executable script on each computer, aren't supported.

The authentication service daemon, adclient, retrieves policy settings from the Active Directory domain controller and starts the program runmappers (/usr/share/centrifydc/mappers/runmappers). The runmappers program runs the individual mapping programs that are stored in the /usr/share/centrifydc/mappers/machine and /usr/share/centrifydc/mappers/user directories. Those individual mapping programs read settings from the virtual registry and write them as the appropriate settings in application-specific configuration files.

The individual mapping programs also keep track of local changes that conflict with group policy settings, so those changes can be restored if the computer is removed from the domain, or if the configuration setting is removed from a Group Policy Object.

Configuring Settings in Administrative Templates

Administrative templates are stored as files with the.xml or .admx extension in the system volume and are used to define a specific set of configuration options. For most of the configuration settings that apply to Linux, UNIX, or Mac OS X users or computers, you must use Centrify group policy administrative templates. To apply a group policy setting, you must add the template that defines the group policy to a Group Policy Object; see Adding Centrify Policies from XML Files.

In addition, every Group Policy Object includes a default set of Administrative Templates. The default administrative templates provide configuration options for Windows users and computers. In a few cases, however, settings you can configure in the default administrative templates do apply to Centrify-managed computers and users. For information about Windows settings that can be applied to Linux, UNIX, and Mac OS X users and computers, see Using Standard Windows Group Policies.

Mapping Computer Configuration Policies

The Centrify Agent, adclient, determines the group policies that apply to Centrifymanaged computers using the same rules for inheritance and hierarchy that apply to Windows computers. When the Linux, UNIX, or Mac OS X computer starts or when the computer policies are refreshed, adclient:

- Contacts Active Directory.
- Checks for the Group Policy Objects that are linked to each organizational unit of which the local computer is a member.
- Determines all of the configuration settings that apply to the local computer, and retrieves those settings from the System Volume (SYSVOL).
- Writes all of the configuration settings to a virtual registry on the local computer.
- Starts the runmapperS program to initiate the mapping of configuration settings using individual mapping programs for computer policies.

The mapping programs in the /usr/share/centrifydc/mappers/machine directory then read the virtual registry for the appropriate Linux-, UNIX-, or Mac OS X-specific computer configuration settings and locate the appropriate configuration files to change, then modify those files accordingly.

After the computer starts, the adclient daemon will periodically check with Active Directory to determine the current group policy settings for the computer unless you disable group policy updates.

Mapping User Configuration Policies

The adclient daemon determines the group policies that apply to Linux, UNIX, or Mac OS X users using the same rules for inheritance and hierarchy that apply to Windows users. When a user logs into an agent-managed computer, the adclient process detects the log-in and does the following:

- Contacts Active Directory.
- Checks for the Group Policy Objects that are linked to each organizational unit the user is a member of.
- Determines all of the configuration settings that apply to the user account, and retrieves those settings from the System Volume (SYSVOL).
- Writes all of the configuration settings to a virtual registry on the local computer.
- Starts the runmappers program to initiate the mapping of configuration settings using individual mapping programs for user policies.

The mapping programs in the /usr/share/centrifydc/mappers/user directory then read the virtual registry for the appropriate Linux-, UNIX-, or Mac OS X-specific user configuration settings and locate the appropriate configuration files to change, then modify those files accordingly.

After the user has logged on, the adclient daemon will periodically check with Active Directory to determine the current group policy settings for the user unless you disable group policy updates.

Editing Configuration Settings Manually

Many of the group policies are used to modify the parameter values in the authentication service configuration file /etc/centrifydc/centrifydc.conf. When you make changes to a group policy setting, the change is reflected in the /etc/centrifydc/centrifydc.conf file on each joined Linux, UNIX, or Mac OS X computer after the following events:

- The computer restarts.
- The computer configuration policies refresh at the next update interval.
- You run the adgpupdate command.

If you enable Centrify group policies, you do not need to manually edit the configuration parameters in the /etc/centrifydc/centrifydc.conf file. In some rare cases, however, you may find it useful to customize these parameters on a particular computer. For example, you can use configuration parameters to temporarily disable group policies for users, computers, or both, on a computer.

For more information about customizing behavior using the Centrify configuration files and configuration parameters instead of group policies, see the *Configuration and Tuning Reference Guide*.

Updating Configuration Policies Manually

Although there are Windows group policy settings that control whether group policies should be refreshed in the background at a set interval, Delinea also provides a UNIX command line program, adgpupdate, to manually refresh group policy settings at any time. With this command, you can specify whether you want to refresh computer configuration policies, user configuration policies, or both.

When you run adgpupdate, the adclient process does the following:

- Contacts Active Directory for computer configuration policies, user configuration policies, or both. By default, adclient collects both computer and user configuration policies.
- Determines all of the configuration settings that apply to the computer, the current user, or both, and retrieves those settings from the System Volume (SYSVOL).
- Writes all of the configuration settings to a virtual registry on the local computer.
- Starts the runmappers program to initiate the mapping of configuration settings using individual mapping programs for user and computer policies.
- Resets the clock for the next refresh interval.

For more information about using the adgpupdate command, see the adgpupdate man page.

Using Standard Windows Group Policies

Every Group Policy Object includes default administrative templates for user and computer configuration. Most of the settings in the default administrative templates only apply to Windows computers and Windows user accounts. However, there are a few of these common Windows configuration settings that can be applied to Centrify-managed computers and users. These configuration options are not duplicated in Centrify administrative templates.

You can set the following standard Windows group policy options for Centrify-managed computers and users:

Computer Configuration > Policies > Administrative Templates > System > Group Policy	* Turn off background refresh of Group Policy * Group Policy refresh interval for computers
Computer Configuration > Policies > Administrative Templates > System > Windows Time Service > Time Providers	* Global Configuration Settings - MaxPollInterval
Computer Configuration > Policies > Administrative Templates > System > Windows Time Service > Time Providers	* Enable Windows NTP Client This policy specifies that adclient poll the domain NTP server to synchronize the clock of the local computer. This policy modifies the adclient.sntp.enabled parameter in the centrifydc.conf configuration file. If you disable this policy, adclient does not attempt to synchronize the computer with the domain NTP server. The computer uses the local NTP policies, as defined in ntp.conf. Whether you enable the policy or not, no settings are changed in the ntp.conf file.
Computer Configuration > Policies > Administrative Templates > Windows Components > Smart Card > Allow certificates with no extended key usage certificate attribute	* Allow sctool to obtain Kerberos credentials even though the certificate does not have the extended key usage attribute.
Computer Configuration > Policies > Windows Settings > Security Settings > Local Policies > Security Options	Interactive logon: Message text for users attempting to log on Interactive logon: Prompt user to change password before expiration
Computer Configuration > Policies > Windows Settings > Security Settings > Account Policies > Password Policy	Enforce password history Maximum password age Minimum password age Minimum password length Password must meet complexity requirements Store passwords using reversible encryption
Computer Configuration > Policies > Windows Settings > Security Settings > Public Key Policies > Trusted Root Certification Authorities	Specifies the trusted root CA certificate to use
User Configuration > Policies > Administrative Templates > System > Group Policy	Group Policy refresh interval for users

Reporting group policy settings

On Windows computers, you can use the optional Group Policy Management Console to see the results of group policy settings for a specific computer or user, including Server Suite-managed computers and users.

You can also review the results of group policy settings for a Server Suite-managed computer or a specific user by viewing the gp.report file locally on the computer. This report is automatically updated at each group policy update interval. By default, the gp.report for computer configuration is located in the /var/centrifydc/reg/machine directory and the gp.report for user configuration is located in the /var/centrifydc/reg/users/_username_ directory.

Generating a report of Delinea group policies

Delinea includes a command-line utility on Linux and UNIX systems called adgpresult that you can use to generate a report of all the group policy settings that are in effect for the local computer, the current user, or a specified user.

If you have applied a GPO (group policy object) to a site, domain, or organizational unit that includes a Delinea-managed computer, then you can use the adgpresult command to see all the computer and user configuration policies that have been applied.

The command displays a Resultant Set of Policies similar to the Microsoft Windows gpresult program.

Example usage and options

```
adgpresult [--all] [--machine] [--user __user_name__]
```

You can use the following options with this command:

-a, --all I Option displays both the computer and user group policy settings that are in effect for the local computer and the current user account.

-m, --machine I Option displays only the computer group policy settings that are currently in effect on the local computer.

-u, --user I The --user option displays only the user group policy settings that are in effect for the currently logged on user or for the user specified by the user_name argument.

Example:

To report only the computer configuration policies and save the results to a file, you could type a command similar this:

```
adgpresult --machine \> /tmp/unix-rsop-rhel6
```

Adding Centrify Settings to Group Policy Objects

This chapter describes how to add Centrify-specific group policies to a Group Policy Object and how to set policies for Centrify-managed computers and users.

The following topics are covered:

Configuring Audit Event Logging Location by Group Policy

Audit trail group policies are located in category-specific subfolders (such as **Audit Analyzer Settings**, Audit Manager Settings, and so on). Additionally, a **Delinea Global Settings** subfolder contains group policies that you can set at a global level.

Any category-specific audit trail targets that you set (for example, **Audit Manager Settings** › **Send audit trail to log file**) override global audit trail targets (for example, Delinea Global Settings › Send audit trail to log file). Each subfolder in **Delinea Audit Trail Settings** contains the same set of group policies.

> **Note**: To send audit trail events to both the database and the local logging facility, enable both of these group policies.

Send Audit Trail to Audit Database

Enable this group policy to specify that audit events for this component **Audit Analyzer, Audit Manager**, and so on—are sent to the active audit store database.

See the **Explain** tab in the group policy for details about which parameter each group policy sets in the agent configuration file.

Send Audit Trail to Log File Enable this group policy to specify that audit events for this component— such as **Audit Analyzer, Audit Manager**, and so on—are sent to the local logging facility (syslog on UNIX systems, Windows event log on Windows systems).

See the Explain tab in the group policy for details about which parameter each group policy sets in the agent configuration file.

Set Global Audit Trail Targets

Specify the target for audit trail information.

If you set this group policy to **Not configured** or **Disabled**, the destination of audit trail information depends on which version of DirectAudit is installed. If DirectAudit 3.2 or later is installed, audit trail information is sent to the local logging facility and DirectAudit. If a DirectAudit version earlier than 3.2 is installed, audit trail information is only sent to the local logging facility.

If you set this group policy to **Enabled**, you can specify the target for audit trail information. Possible settings are:

- 0 (Audit information is not sent.)
- 1 (Audit information is sent to Delinea Audit & Monitoring Service. This capability is supported by DirectAudit version 3.2 and later.)
- 2 (Audit information is sent to the local logging facility, either syslog on UNIX systems or Windows event log on Windows systems.)
- 3 (Audit information is sent to both DirectAudit and the local logging facility.)
- This group policy modifies the audittrail.targets setting in the agent configuration file.

Adding Administrative Templates to a Group Policy Object

A Group Policy Object (GPO) consists of configuration information that applies to computers, configuration information that applies to users, or sections of policy specifically devoted to each. You can extend the configuration options provided by any Group Policy Object by adding Centrify-provided or custom administrative templates to the object. For example, you can add configuration settings for Centrifyagents to a Group Policy Object by adding the centrifydc_settings.xml administrative template. Other administrative templates can be added to control other settings, such as Mac OS X system preferences, if they apply to your environment.

Installing Centrify Group Policy Templates

When you install Access Manager using the installation wizard and you specify that all components be installed, the Centrify group policy templates are included in the installation. See "Install Access Manager and update Active Directory" in the *Administrator's Guide for Windows* for details about using the Access Manager installation wizard.

> **Note**: For details about where the Centrify group policy templates reside after they are installed, see Adding Centrify Policies from XML Files.

Because Centrify group policy templates and extensions are packaged separately from other Access Manager components, you have the following options if you prefer to install group policy templates and extensions separately from Access Manager:

- You can install Centrify group policy templates and extensions on any Windows domain computer without also installing Access Manager on the computer.
- You can install Access Manager on any Windows domain computer without also installing Centrify group policy templates and extensions on the computer.

The group policy template and extension package has its own .exe and .msi installer files, so that you can install group policy templates and extensions interactively through an installation wizard (by executing the .exe file) or silently from the command line (by executing the .msi file). Additionally, you can select or de-select the group policy template and extension component for installation when you run the Access Manager installation wizard.

For details about installing group policy templates and extensions separately from Access Manager, see "Install group policy extensions separately from Access Manager" in the *Administrator's Guide for Windows*.

Template File Formats

Centrify provides templates in both XML and ADMX format. In most cases, it is best to use the XML templates, which provide greater flexibility, such as the ability to edit settings after setting them initially, and in many cases contain validation scripts for the policies implemented in the template.

However, in certain cases, you may want to add templates by using the ADMX files. For example, if you have implemented a set of custom tools for the Windows ADMX-based policies, and want to extend those tools to work with the Centrify policies, you can implement the Centrify policies by adding the ADMX template files. You should note, however, that ADMX templates do not support extended ASCII code for locales that require double-byte characters. For these locales, you should use the XML templates.

Selecting a Group Policy Object for Centrify Settings

Depending on the requirements of your organization and how you have linked existing Group Policy Objects to sites, domains, and organizational units in your Active Directory forest, you might want to use one of the default Group Policy Objects, use a Group Policy Object you have created specifically for your organization, or create a new Group Policy Object that is specifically for Centrify settings.

If you have created an organizational structure for Centrify objects as described in the *Planning and Deployment Guide*, creating a new Group Policy Object specifically for Centrify policies gives you the most flexibility and control over the configuration settings for managed computers and the operation of Centrify software. In deciding whether to create a new Group Policy Object or use an existing Group Policy Object, you should consider where policies should be applied. You can link Group Policy Objects to sites, domains, or organizational units to control the scope of the policies you set.

If you prefer to minimize the number of Group Policy Objects you deploy, you can add Centrify settings to one of default Group Policy Objects that are installed on the Windows domain controller:

- Default Domain Controllers Policy
- Default Domain Policy

You can add Centrify settings to any Group Policy Object regardless of whether you have any settings configured or applied to Windows users and computers. Settings that apply to Centrify-managed computers only affect computers where the Centrify Agent is installed.

Linking a Group Policy Object to an Organizational Unit

You can link a Group Policy Object to an organizational unit, domain, or site using the Group Policy Management Console. To set group policies for a selected Active Directory site, domain, or organizational unit, you must have read and write permission to access the system volume of the domain controller and the right to modify the selected directory object.

If you have created an organizational structure for Centrify as described in the *Planning and Deployment Guide*, the most natural place to link a Group Policy Object is the top-level container of that organizational unit structure, for example, the Centrify container.

Create and Link a Group Policy Object for Centrify Settings

1. Click **Start > Administrative Tools > Group Policy Management**.
2. Select the Centrify organizational unit, right-click, then select **Create a GPO in this domain, and Link it here**.
3. Type a name for the new Group Policy Object, for example, Centrify Policy, then click **OK**.

If you want to apply group policies to lower levels in the organizational structure, you can do so by linking Group Policy Objects to lower level organizational units. For example, if you created a separate organizational unit for zone computers, you can link a Group Policy Object to that organizational unit. However, you cannot link Group Policy Objects to containers (CN).

Using Security Filtering for Group Policies

You can use Active Directory security groups and group policy security filtering if you want to restrict the policies applied to subsets of zone computers or users. By creating an Active Directory security group and setting security filtering for a Group Policy Object, you can achieve fine-grain control over where group policies are applied within the Centrify organizational unit structure. For example, you can create an Active Directory group called europe that has a specific set of computers in it, then restrict the application of group policies to that group.

To enable security filtering of group policies:

1. Create the Active Directory security group with the appropriate members.
2. Open the Group Policy Management Console and select the Group Policy Object for which you want to enable filtering.
3. On the Scope tab, under Security Filtering, click **Add**.
4. Be certain that 'Group' appears in **Select this object type**; if not, Click **Object Types** and select **Groups**.
5. Type all or part of the name for the group you created for filtering, click **Check Names**.

   If more than one group is returned, select the appropriate group, then click **OK**.
6. Click **OK** to link the security group to scope of the Group Policy Object.

Adding Policies from XML Files

In most cases, you should add Centrify policies from XML templates to the Group Policy Object you are using for Centrify settings. The XML-based format is the current standard for group policy templates.

To add Centrify group policies from Centrify XML templates:

1. Click **Start > Administrative Tools > Group Policy Management**.
2. Expand the appropriate site, domain, or organizational unit to select Group Policy Object you want to use for Centrify policies, right-click, then click **Edit**.

   For example, expand the top-level Centrify organizational unit to select the Centrify Policy object, right-click, then click **Edit**.
3. In the Group Policy Management Editor, expand Computer Configuration and Policies.
4. Select Centrify Settings, right-click, then click **Add/Remove Templates**.
5. In the Add/Remove Templates dialog box, click **Add**.
6. In most cases, the directory with the templates is already selected and the following Centrify templates are listed:

   - centrify_gnome_settings
   - centrify_linux_settings
   - centrify_mac_settings
   - centrify_unix_settings
   - centrifydc_fips
   - centrifydc_settings
   - centrifyds_settings

   If the templates are not listed, navigate to the group policy directory under the Access Manager installation directory. For example, if you installed files in the default location, navigate to the following directory:

   C:\Program Files\Common Files\Centrify Shared\Group Policy Management Editor Extension\policy

   If you want to add templates for auditing, navigate to the Centrify Audit & Monitoring Service installation directory. For example, if you installed files in the default location, navigate to the following directory:

   C:\Program Files\Centrify\Audit\AuditManager
7. Select the Centrify templates you want to use, then click **Open**.
8. In the Add/Remove Templates dialog box, click **OK** to add the new templates.

   Group policies for access control and privilege management are listed under **CentrifySettings**. You can expand this node and the categories below it to explore the group policies available.

   Group policies for auditing are listed under **Centrify Audit Settings**. You can expand this node and the categories below it to explore the group policies available.

   By default, all group policies are set to "Not configured."

Adding Templates after an Upgrade

To make any new policies available after you upgrade Centrify software, you must add new versions of the templates you use after you upgrade the Access Manager or the auditing console. To add new versions of the templates after an upgrade, repeat Linking a Group Policy Object to an Organizational Unit to Adding Centrify Policies from XML Files. If you see the message, The selected XML file already exists. Do you want to overwrite it?, click **Yes** to overwrite the old template file with the new template and make any new or modified group policies available. Overwriting the template does not affect any configuration settings that have been applied. Policies that you have enabled remain enabled.

Enabling Delinea Policies

By default, all group policies, including Delinea group policies are set to Not configured. You can selectively enable the specific computer and user policies you want to use. Most of the Delinea group policies set configuration parameters on managed computers. If you choose to enable any of these group policies, you should be familiar with the corresponding configuration parameters described in the *Configuration and Tuning Reference Guide*.

To enable and configure Delinea settings:

1. Open the Group Policy Management console.
2. Select the Group Policy Object to which you have added Delinea policies, right-click, then select **Edit**.
3. Expand **Computer Configuration > Policies > Centrify Settings**.
4. Select a policy name, right-click, then select **Properties**.
5. Click **Enabled**.

   Depending on the policy, you might need to select values or provide other information to complete the configuration. For more information about the policy and how to set configuration options, click the **Explain** tab. For information about limitations to the values that you specify, see Centrify Policy Limitations later in this chapter.
6. Click **Apply** after making the change.

The policies you enable are applied when computers in the site, domain, or organizational units are rebooted, users next log on, or at the next update interval.

Delinea Policy Limitations

Some Delinea group policies allow you to select values from a list when you enable the group policy. Depending on how the list is configured, in some cases you cannot select more than 999 items from the list.

For example, if you enable the **Specify AD users allowed in Auto Zone** group policy, you are prompted to specify the names of AD users. You can specify AD user names by typing them, by specifying a file containing a predefined list of user names, or by selecting them from the list of all AD users. Because of the way in which the AD user list is configured, you cannot select more than 999 users from it. If you attempt to select more than 999 users, the following message is displayed:

```
Please enter 0 to 999 entries for User
```

This limitation applies to several other group policies in addition to **Specify AD users allowed in Auto Zone**.

It is generally not advisable to select 1000 or more items from a list to define a data set in a group policy. Instead, whenever possible you should use groups or a file containing a predefined list of items to define a large data set.

DirectControl Settings

The following table summarizes the group policies listed directly under **Centrify Settings › DirectControl Settings**. The full descriptions follow the table.

Add centrifydc.conf Properties	Add configuration parameters to centrifydc.conf configuration file.
Maintain DirectControl 2.x Compatibility	Maintain access for legacy users or computers.
Merge Local Group Membership	Merge local group membership from /etc/group into the zone group membership for groups that have the same name and GID.
Prefer Authentication Credentials Source	Instruct adclient to authenticate the user using the cached credentials.
Set LDAP Fetch Count	Specify the number of objects to obtain in a single LDAP request.
Set Password Cache	Control the caching of user passwords.
Set User Mapping	Map a local user account to an Active Directory account.
Use FIPS 140-2 Compliance Algorithms	Select the algorithms used for the authentication protocols.

Additional group policies for DirectControl Settings are organized under the following subnodes:

- Account Prevalidation - Contains policies to manage prevalidation of users and groups for disconnected systems.
- Adclient Settings - Contains policies to control certain aspects of the operation of the agent on managed computers.
- Auto Zone Group Policies - Contains policies to control certain aspects of the operation of the agent on machines that are joined to Auto Zone.
- Dzdo Settings - Contains policies to control certain aspects of the operation of dzdo and sudo.
- Group Policy Settings - Contains policies to manage the execution of the Centrify group policy mapping programs.
- Kerberos Settings - Contains policies to manage the Kerberos configuration. You can use these settings to control updates to the Kerberos configuration files and credential renewal.
- Local Account Management Settings - Contains policies to control agent management of local users and groups.
- Logging Settings - Contains policies to control logging policy settings. You can use these settings to specify the syslog facility to use for logging different adclient processes and to control the amount of memory to use to queue log messages.
- Login Settings - Contains policies to control login and local account access. You can use these settings to grant or deny access to specific users and groups or to ignore Active Directory authentication for some users and groups.
- MFA Settings - Contains policies for configuring multi-factor authentication in classic zones and Auto Zones. You can use these settings to specify which users or groups require a two-step authentication procedure for login, define rescue users that can log in when multi-factor authentication is unavailable, and to specify a cloud URL to be used in multi-factor authentication.
- Network and Cache Settings - Contains policies to specify the maximum period for client connection time-outs and object expiration intervals. You can use these settings to determine how long to wait for a response when connecting to Active Directory and how long objects should be kept in the local cache.
- NIS Daemon Settings - Contains policies to control operation of the Centrify Network Information Service (adnisd) on the local host computer. The adnisd service provides a mechanism for the Centrify Agent to respond to NIS client requests from other computers not managed by Centrify software.
- NSS Overrides - Contains policies to specify the passwd or group override entries you want to use in place of the entries in the local /etc/passwd or /etc/group files. You can use these settings to provide fine-grain control of the users and groups who can use the computer and to override the user ID, group ID, default shell, or home directory for specific login accounts or groups.
- PAM Settings - Contains policies to customize the behavior of the Centrify PAM module.
- Password Prompts - Contains policies to customize the prompts displayed when Active Directory users are prompted to provide their password. You can use these settings to change the text displayed when Active Directory users log in or change their password.
- Sudo Settings - Contains policies to control certain aspects of the operation of sudo.
- User's Initial Group ID - Contains policies to control group numbers. You can use this setting to specify the default group identifier for new users.

Add centrifydc.conf properties

Use the **Add centrifydc.conf properties** group policy to add configuration parameters to the agent configuration file. Although you can set many configuration parameters and values by using the associated group policy, not all configuration parameters have an associated group policy. The **Add centrifydc.conf properties** group policy enables you to specify any configuration parameter and its value.

See the *Configuration and Tuning Reference Guide* for a list of all configuration parameters.

To use this group policy, select **Enabled**, then click **Add**. Enter a property name and property value. For example, to change the adnisd update interval to 10 minutes:

Property name: nisd.update.rate

Property value: 600

Be careful when adding parameters because there is no error checking. If you enter a nonexistent property name or invalid value, the parameter and value will be added to the configuration file as-is. An invalid parameter name will simply be ignored but an invalid value could cause configuration problems.

Enable Active Directory PAM Privilege Escalation Feature

Use the **Enable Active Directory PAM Privilege Escalation Feature** group policy to specify if the Microsoft Privileged Access Management (PAM) Privilege Escalation feature is supported or not within the Delinea environment.

If this policy is Enabled, then, when an Active Directory user logs in, the configured privilege that's granted to the user through PAMGroup takes effect until the granted period has elapsed.

The Microsoft PAM Privilege Escalation feature specifies if Delinea DirectControl uses Microsoft PAM Privilege Escalation feature in the computer.

This group policy modifies the `microsoft.pam.privilege.escalation.enabled` setting in the agent configuration file.

Maintain DirectControl 2.x compatibility

Use the **Maintain DirectControl 2.x compatibility** group policy if you have legacy users or computers who were given access using the console, version 2.x.x.

If all of your Active Directory users are enabled for Linux, UNIX, or Mac OS X access using the console, version 3.0 or later, you should leave this policy as not configured.

This group policy modifies the `adclient.version2.compatible` setting in the agent configuration file.

Merge Local Group Membership

Use the **Merge local group membership** policy to determine whether to merge local group membership from the /etc/group file into the zone group membership for groups that have the same name and GID. For example, if the agent retrieves the membership list of kwan, emily, and sam for the group profile with the group name performx1 and GID 92531 from Active Directory and there is also a local group named performx1 with the GID 92531 with users wilson and jae, the merged group would include all five members (kwan, emily, sam, wilson, jae).

This group policy modifies the adclient.local.group.merge setting in the agent configuration file. By default, the parameter associated with this policy is set to false to prevent unexpected results.

Be careful when enabling this policy, because it violates normal NSS behavior and, therefore, may have unexpected side effects. You should analyze your environment carefully, and determine that you can safely merge local and Active Directory group profiles before enabling this policy.

Prefer Authentication Credentials Source

Use the **Prefer Authentication against cached credentials** policy to authenticate the user using the cached credentials first, regardless of the current connectivity state with the Active Directory domain controller.

By default, the parameter associated with this policy is set to false. You can enable this policy to reduce traffic on slow networks. However, if the Active Directory credentials are not synchronized with the cached credentials, you run the risk of undesired side affects when the computer is online.

This group policy modifies settings in the agent configuration file. For more information about the configuration file and this configuration settings, see adclient.prefer.cache.validation.

Set LDAP Fetch Count

Use the **Set LDAP fetch count** group policy to specify the number of objects to obtain in a single LDAP request. You can use this group policy to optimize the number of objects to suit your environment.

If you select **Enabled** for this group policy, you can then set the number of objects to obtain in a single LDAP request by balancing speed and memory usage against network bandwidth and latency. As you increase the number of objects included in an LDAP request, you may improve the overall performance by decreasing the number of connections to Active Directory and reducing the overall demand on the server, but you increase the RAM used by the agent. If you decrease the number of objects included in an LDAP request, you may reduce overall performance because of the additional network traffic, but decrease the memory used by the agent.

On faster networks, you can safely retrieve a small number of objects. On slower networks or when retrieving information for large groups (for example, groups with more than 1000 users), you may want to increase the value for this parameter.

This group policy modifies the adclient.fetch.object.count setting in the agent configuration file.

Set Password Cache

Use the **Set password cache** group policy to control the handling of user passwords. By default, the Centrify Agent stores a UNIX-style MD5 hash of each user's password in the cache when the user is authenticated during login. Storing the password hash allows previously authenticated users to log on when the computer is disconnected from the network or Active Directory is unavailable.

If you select **Enabled** for this group policy, you can set the following options:

- **Allow Password storage** Allow specified users to have their password hash stored in the cache. If you set this option and specify a list of users, only those users can log on when the computer is disconnected from the network or Active Directory is unavailable. To list the specific users allowed to have their password hash stored, type the user names separated by commas or spaces, or click **List**, then **Add** to browse and select Active Directory users to add.

  This option modifies the adclient.hash.allow parameter in the agent configuration file. By default, all users have their password hash stored.

- **Deny Password storage** Prevent specified users from having their password hash stored. If you set this option and specify a list of users, only those users are prevented from logging on when the computer is disconnected from the network or Active Directory is unavailable. To list the specific users who should not have their password hash stored, type the user names separated by commas or spaces, or click **List**, then **Add** to browse and select Active Directory users to add. This setting overrides "Allow Password storage".

  This option modifies the adclient.hash.deny parameter in the centrifydc.conf agent configuration file. By default, all users have their password hash stored.

- **Cache life** Specify the number of days a password hash for any user can be stored in the cache before it expires. A value of zero (0) specifies that the password hash should never expire. When you enable this policy, a value of 7 (days) appears in the field. You can accept this value or enter a different value up to 9999.

  This option setting modifies the adclient.hash.expires parameter in the centrifydc.conf agent configuration file. The default setting for this parameter is 0, which means that by default, the cache does not expire.

For more information about the configuration file and these configuration settings, see adclient.hash.allow, adclient.hash.deny, and adclient.hash.expires in the *Configuration and Tuning Reference Guide*.

Set User Mapping

Use the **Set user mapping** group policy to map a local Linux, UNIX, or Mac OS X user account to an Active Directory account. Local user mapping allows you to set password policies in Active Directory even when a local Linux, UNIX, or Mac OS X account is used to log in. This group policy is most commonly used to map local system or application user accounts on a computer to a different Active Directory account and password, so that you can enforce password complexity rules for the account, but it can be used for any local user account.

When you select **Enabled** for the Set user mapping group policy, you can then click **Show** to add or remove user accounts.

To add mapped user accounts to the policy, click **Add**. You can then type the Linux, UNIX, or Mac OS X user account name in the first field and the Active Directory account name to which you want to map the local account in the second field, then click **OK**.

Once this policy is applied, users or services attempting to log in with the local mapped account must provide the Active Directory password for the account. For example, if you have mapped the local user caine to an Active Directory account that uses the password +shark1, the user logging in with the caine user name must provide the +shark1 password or authentication will fail.For more information about mapping local Linux, UNIX, or Mac OS X accounts to Active Directory accounts, see the *Administrator's Guide for Linux and UNIX* or the *Administrator's Guide for Mac*.

User's Initial Group ID

Use the group policy under **User's Initial Group ID** to specify the default group identifier (GID) to use for new users when you run the adupdate user add command.

Use FIPS 140-2 compliance algorithms

Use the **FIPS compliant algorithms for encryption, hashing and signing** group policy to specify the use of FIPS 140-2-compliant cryptographic algorithms for authentication protocols.

Basic requirements

Delinea supports FIPS 140-2 compliance for authentication using Kerberos and NTLM with the following requirements and caveats:

- FIPS mode is available on agent version 5.0.2 or later but only on supported operating systems. See the NIST validation entry for the Centrify FIPS mode for the current list of supported platforms.
- Domain controllers must be at Windows Server 2008 domain functional level, or later.
- The administrator must explicitly add the centrifydc_fips.xml or directly edit the administrative template to enable this policy.

  Note: Delinea recommends that you use the centrifydc_fips.xml template. When you do, the agent performs several checks before implementing the policy to confirm that your domain controller and joined computers meet the requirements.
- If multiple encryption types are specified only the AES128-CTS and AES256-CTS encryption type keys (with RSA for public key generation, DSA for digital signature generation and SHA1, SHA256, SHA384 or SHA512 for hashing) are generated and saved to the keytab file. However, if arcfour-hmac-md5 encryption is specified, the MD4Hash of the machine password will be generated and saved to the keytab file.

  Note: Which encryption types are used in each joined computer is controlled by a parameter set in each Linux, UNIX, or Mac OS X computer's configuration file. See the adclient.krb5.permitted.encryption.types description in the Notes section on Related Configuration Parameters for an explanation.
- Inter-realm keys for the AES128-CTS or AES256-CTS encryption types must be established between any trusted domains to enable Active Directory users to log on to a joined computer (see the ksetup utility to set up inter-realm keys).
- FIPS mode only allows NTLM pass-through authentication over SChannel. FIPS mode is not available for NTLM authentication over SMB or SMB2.
- In some environments, offline multi-factor authentication is not compatible with FIPS mode. See the *Multi-factor Authentication Quick Start Guide* for details about this restriction.

Enabling the Policy

To enforce FIPS 140-2 compliance, select the Computer Configuration › Policies› Centrify Settings › DirectControl Settings › **Use FIPS compliant algorithms for encryption, hashing, and signing** policy, open the properties, and select **Enabled**.

The policy takes effect after the next group policy update.

When you use the XML group policy template, the agent performs the following validation checks:

- It verifies that each joined computer is running a supported operating system.
- It verifies that each machine is joined to a domain at domain functional level 2008 or above. If the domain does not meet the domain functional level requirements, the agent issues the following warning:

  FIPS mode is supported only on domain with 2008 domain functional level or up.

  Enabling this policy with lower domain functional level may prevent adclient from working properly. Are you sure you want to enable this policy?

  Respond Yes to enable the policy regardless or No to abort. However, if the current domain functional level is inadequate or FIPS mode is not supported on the host platform, the agent does not restart when the policy is applied.

For all joined computers that pass, the agent is automatically stopped and restarted. After a successful restart, the adjoin, adleave, and adinfo commands run in FIPS mode immediately. If a joined computer is running an unsupported platform, the computer's configuration file is not updated and the agent is not restarted.

There are several restrictions and rules governing the use of FIPS mode. The following bullets summarize the policy:

- Pre-validated groups and users that use FIPS mode to log on when disconnected must have each user's Active Directory msDSSupportedEncryptionTypes

attribute set to use Kerberos AES 128- or 256-bit encryption. You can set this attribute in the users' accounts using Active Directory Users and Computers or ADSI Edit.
- The value of the corresponding Windows policy to use FIPS compliant algorithms has no effect on the Windows, Linux, UNIX, or Mac OS X computers managed through the Centrify Agent. You must use the Centrify policy to enable FIPS mode. The Centrify policy is only available when you add the centrifydc_fips.xml or centrifydc_fips.admx template (see Adding Centrify policies from XML files).

Related configuration parameters

The following centrifydc.conf configuration parameters affect FIPS operation. See the *Configuration and Tuning Reference Guide* for details about these parameters.

- fips.mode.enable: Enable FIPS mode on a per-computer basis. This group policy modifies the fips.mode.enable parameter in centrifydc.conf.
- adclient.krb5.clean.nonfips.enctypes: If FIPS mode is enabled and this configuration parameter is set to true, adclient scans the computer's keytab file and removes all non-AES encryption keys for service principal names (SPNs) during startup. The default is false.
- adclient.krb5.permitted.encryption.types: If FIPS mode is enabled, and if you include the arcfour-hmac-md5 encryption type in this configuration parameter, and if adclient.krb5.clean.nonfips.enctypes is true, adclient generates the MD4 hash for the computer password and saves it in the keytab file.

Account Prevalidation

Prevalidation enables specific users or the members of a specific group to access a Delinea-managed computer using their Active Directory credentials even if the following conditions would normally prevent them from logging on:

- The computer is disconnected from the network and unable to contact Active Directory to authenticate their identity.
- The user has not previously logged onto the computer.

Without prevalidation, only users who have previously logged on and had their password hashes stored in the local cache can be authenticated when the computer is disconnected from the network.

You can use the **Account Prevalidation** group policies to manage the users and groups who are authorized or denied access to disconnected computers.

Use the following group policies specify the users and groups that can be prevalidated:

- Specify Allowed Groups for Prevalidation
- Specify Allowed Users for Prevalidation

Use the following group policies specify the users and groups that cannot be prevalidated:

- Specify Denied Groups for Prevalidation
- Specify Denied Users for Prevalidation

Use the following group policies specify other prevalidation settings:

- Set Prevalidation Service Name
- Set Prevalidation Update Interval

Specify Allowed Groups for Prevalidation

Enable this policy and enter a comma-separated list of groups to prevalidate users in the specified groups for access Delinea-managed computers. To allow prevalidation for all users in the zone without any exceptions, you can enter all@zone in **Specify allowed groups for prevalidation**.

This group policy modifies the following setting in the agent configuration file:

adclient.prevalidate.allow.groups

Specify Allowed Users for Prevalidation

Enable this policy and enter a comma-separated list of users to prevalidate specific users for access Centrify-managed computers. This group policy modifies the following setting in the agent configuration file:

adclient.prevalidate.allow.users

Specify Denied Groups for Prevalidation

Enable this policy and enter a comma-separated list of groups that cannot be prevalidated for access Centrify-managed computers. If you allow any groups or users to be prevalidated, you can use this policy to define exceptions for any groups that should be prevented from prevalidation.

In most cases, you would use this policy to exclude a subset of users that are in a group that is a member of an allowed group. For example, you might want allow all users in the admins group to be prevalidated, except the users who are members of the nested outsource subgroup. To accomplish this, you would enable "Specify allowed groups for prevalidation" for the admins group, then use the "Specify denied groups for prevalidation" policy to deny access to users who are members of the outsource group.

This group policy modifies the following setting in the agent configuration file:

adclient.prevalidate.deny.groups

Specify Denied Users for Prevalidation

Enable this policy and enter a comma-separated list of users to prevent prevalidation of specific users for access Centrify-managed computers. If you allow any groups or users to be prevalidated, you can use this policy to define exceptions for any users who should be prevented from prevalidation. In most cases, you would use this policy to exclude a subset of users that are members of an allowed group.

This group policy modifies the following setting in the agent configuration file:

adclient.prevalidate.deny.users

Set Prevalidation Service Name

Enable this policy to specify the service name to use for prevalidated users and groups. You must use the name you specify in this parameter when you register the Service Principal Name (SPN) for a user or group with the setspn.exe utility. The default value is preval.

Setting the Service Principal Name for a User

For users or groups of users to be prevalidated, their accounts must be active accounts with permission to log on to the local computer and have a Service Principal Name (SPN) set in the form of:

```
preval/user
```

Where preval is the service name specified by the adclient.prevalidate.service parameter and username is the user logon name, which can be either of the following:

- the name part of the user's UPN, if the domain part matches the user's domain
- sAMAccountName, if the UPN is empty or the UPN's domain part is different from the user's domain

To enable prevalidation for a user, you can use the Windows setspn.exe utility to add a Service Principal Name for the user. For example, to register the Service Principal Name for the user kai@arcade.com using preval as the service name, you could type a command similar to the following in a Windows Command Prompt window:

```
setspn -A preval/kai kai
```

This setspn command registers the SPN in Active Directory for the preval service and the specified user account, for the Active Directory user kai. On the computers where this user is allowed to be prevalidated, the user can be authenticated without having logged on previously.

Setting the Service Principal Name for Group Members

If you are allowing prevalidation for an administrative group, you must register a Service Principal Name for each member of the group. For example, if you are allowing prevalidation for the admins group and this group has five members, you would use the setspn.exe utility to register a Service Principal Name for each of those members.

Set Prevalidation Update Interval

Enable this policy to specify the interval, in hours, for refreshing the credentials for prevalidated user and group accounts. The credentials for prevalidated users must be periodically refreshed to ensure they are in sync with Active Directory and that prevalidation will continue working after password changes.

The parameter value should be a positive integer. A value of 0 disables all prevalidation of users. The default is 8 hours.

This group policy modifies the adclient.prevalidate.interval setting in the agent configuration file.

Refreshing Prevalidated Credentials

Prevalidated credentials are periodically refreshed at the interval defined by the Set prevalidation update interval policy to ensure that prevalidation will continue working after password changes. In addition, the credentials for prevalidated users and groups are periodically retrieved from Active Directory whenever you do the following:

- Reboot the local computer.
- Start or restart the agent (adclient).
- Run the adflush command to clear the cache.
- Change a password from the local system.

Adclient Settings

Use the group policies under **Adclient Settings** to control the operation of the agent on managed computers.

Some of these policies are platform-specific policies that control whether the agent can automatically edit specific files on the local computer. In most cases, you should enable the policies that allow the agent to maintain configuration files automatically.

If you choose to not enable any of the platform-specific policies, you must manually edit the appropriate configuration files on individual computers. For example, if not configuring files automatically through a group policy, you must manually edit the /etc/nsswitch.conf and /etc/pam.d/system-auth or /etc/pam.d files to include adclient information or authentication through Active Directory will fail and you may disable login access entirely. For more information about updating configuration files manually, see *Customizing adclient configuration parameters* in the Configuration and Tuning Reference Guide.

> **Note**: Several Auto Zone group policies are located within the **Adclient Settings** node. For details about Auto Zone group policies, see Auto Zone Group Policies.

Add Attributes to Cached Objects

Use the following group policies to add specified Active Directory attributes to the local cache:

- Add attributes to cached user objects
- Add attributes to cached group objects
- Add attributes to cached computer objects

You can use the `adquery --dump` command to see which attributes are cached by default.

These policies modify the following parameters in the `centrifydc.conf` configuration file:

`adclient.custom.attributes.user`

`adclient.custom.attributes.group`

`adclient.custom.attributes.computer`

Auto Zone Group Policies

Use the **Auto Zone** group policies under **Adclient Settings** to set configuration parameters for all managed computers in the Auto Zone at once rather than configuring parameters for computers individually.

The Auto Zone group policies are defined in the centrifydc_settings.xml template file. These group policies and parameters have no effect on computers not joined to Auto Zone.

Auto Zone Default Shell

Set the default shell when joined to Auto Zone. The default value is:

- /bin/bash on Mac OS X and Linux computers
- /bin/sh on UNIX systems, including Solaris, HPUX, and AIX

This group policy modifies the auto.schema.shell parameter in the centrifydc.conf configuration file.

Delinea

Auto Zone Domain Prefix Overrides

Specify a unique prefix for a trusted domain. The Auto Zone algorithm combines the prefix with the lower 22 bits of each user or group relative identifier (RID) to create unique Linux, UNIX, or Mac OS X numeric user (UID) and group (GID) identifiers for each user and group in the forest and in any two-way trusted forests.

Ordinarily, you do not need to set this parameter because Delinea automatically generates the domain prefix from the user or group security identifier (SID). However, in a forest with a large number of domains, domain prefix conflicts are possible. When you join a computer to a domain, if Delinea detects any conflicting domain prefixes, the join fails with a warning message. You can then set a unique prefix for the conflicting domains.

To set this parameter, select **Enabled**, then click **Add**. Type a domain name and type a prefix or use the arrows to set a prefix number. The prefix must be in the range 0 - 511. Click **OK** to enter the prefix and domain. Add as many prefixes as you need, then click **OK** to close the group policy property page.

This group policy modifies the `auto.schema.domain.prefix` parameter in the agent configuration file.

Auto Zone Home Directory

Specify the default home directory. If you do not enable this policy, the default home directory will be based on the platform as follows:

- Mac OS X: /Users/%{user}
- Linux, HP-UX, and AIX: /home/%{user}
- Solaris: /export/home/%{user}

The variable %{user} specifies the logon name of the user. For example, if you specify /Users/%{user} and jsmith logs on to the Mac OS X computer, the home directory is set to /Users/jsmith.

This group policy modifies the auto.schema.homedir parameter in the agent configuration file.

Auto Zone Remote File Service (Mac OS X)

Specify the type of remote file service to use for the network home directory. The options are: SMB (default) and AFP. This group policy only applies to Mac OS X computers. When you type a path for the network home directory in Active Directory, it requires the format /server/share/path, but on Mac OS X computers, the format for mounting a network directory requires the remote file service type as part of the path/type/server/share/path. By identifying the remote file-service type, you can type the network path in the format required by Active Directory, and convert the path into the format required by Mac OS X computers.

This group policy modifies the auto.schema.remote.file.service parameter in the agent configuration file.

Generate New UID/GID using Apple Scheme In Auto Zone

Use the Apple algorithm to automatically generate user and group identifiers. The Apple algorithm for generating identifiers is based on the objectGuid attribute for the user or group object. The Centrify mechanism for automatically generating UIDs and GIDs is based on the security identifier for user or group objects. Both methods ensure a globally unique and consistent identifier for the user or group.

This group policy modifies the auto.schema.apple_scheme parameter in the agent configuration file.

Set User's Primary GID in Auto Zone

Specifies the group identifier (GID) to use as the default primary group for all users. If this policy is not configured, the primary GID for users in Auto Zone is set to one of the following platform-specific values:

- Mac: 20
- Linux, Solaris, HPUX, AIX: -1

If you enable this group policy, you must specify an integer from -1 to 2147483647. You cannot leave the GID field blank if you enable this group policy.

If you set this group policy to -1, the primary GID is generated according to the selected scheme:

- Apple scheme
- Relative identifier (RID)
- Active Directory value

This group policy modifies the `auto.schema.primary.gid` parameter in the agent configuration file.

Delinea

Specify AD Groups Allowed In Auto Zone

Specify the Active Directory groups that are included in the Auto Zone. By default, all Active Directory groups are included in the Auto Zone. When you enable this policy, only the specified groups are included in the Auto Zone and assigned a GID on the computer.

You can manually enter each group name separated by a comma, or click **List**, then **Add**, to browse for groups to add. If you manually add groups, use one of the following formats:

- SAM account name
- NTLM: DOMAIN\\sAMAccountName (also DOMAIN/sAMAccountName)
- UPN or sAMAccountName@domain
- Full DN: CN=commonName, …,DC=domain_component, DC=domain_component,…
- Canonical Name : domain.com/container1/cn

You can also specify the groups in a file.

Any groups listed may be domain local, global, or universal security groups. Distribution groups are not supported. If an Active Directory user specified in "Specify AD users allowed in Auto Zone" is a member of a group that is *not* specified in the current group policy, that group is ignored.

This group policy modifies the auto.schema.groups parameter in the agent configuration file.

Specify AD Users Allowed in Auto Zone

Specify the Active Directory users that are included in the Auto Zone and able to log in using their Active Directory account.

By default, all Active Directory users are included in the Auto Zone. When you enable this policy, only the specified users and members of the groups specified with the Specify Groups of AD Users Allowed in Auto Zone policy are included in the Auto Zone and able to log in using their Active Directory account.

You can manually enter each user name separated by a comma, or click **List**, then **Add**, to browse for users to add. If you manually add users, use one of the following formats:

- SAM account name
- NTLM: DOMAIN\\sAMAccountName (also DOMAIN/sAMAccountName)
- UPN or sAMAccountName@domain
- Full DN: CN=commonName, …,DC=domain_component, DC=domain_component,…
- Canonical Name : domain.com/container1/cn

You can also specify the users in a file.

This group policy modifies the auto.schema.allow.users parameter in the agent configuration file.

Delinea

Specify Groups of AD Users Allowed in Auto Zone

Specify the Active Directory users that are included in the Auto Zone by specifying the groups whose members should be included. By default, all Active Directory users are included in the Auto Zone. When you enable this policy, only the users listed for the Specify AD Users Allowed in Auto Zone policy and members of the listed groups (including members of nested groups under these groups and users' whose primary group are set to these groups) are included in the Auto Zone.

You can manually enter each group name separated by a comma, or click **List**, then **Add**, to browse for groups to add. If you manually add groups, use one of the following formats:

- SAM account name
- NTLM: DOMAIN\\sAMAccountName (also DOMAIN/sAMAccountName)
- UPN or sAMAccountName@domain
- Full DN: CN=commonName, ...,DC=domain_component, DC=domain_component,...
- Canonical Name : domain.com/container1/cn

You can also specify the groups in a file.

Any groups listed may be domain local, global, or universal security groups. Distribution groups are not supported.

This policy does not include the group in Active Directory Auto Zone, just the users in that group. This means that the group is *not* automatically assigned a GID. Use the Specify AD Groups Allowed in Auto Zone group policy to include a group in the Auto Zone and assign it a GID.

Auto Zone does not support one-way trusts. Therefore, any users in the group who belong to a domain that has a one-way trust relationship to the joined domain do not become valid users on the computer.

This group policy modifies the auto.schema.allow.groups parameter in the agent configuration file.

Configure /etc/nsswitch.conf (Solaris, HPUX, Linux)

Allow automatic editing of the Name Service Switch configuration (nsswitch.conf) file on **HP-UX**, **Solaris**, and **Linux** computers. This policy modifies the adclient.autoedit.nss setting in the agent configuration file.

Configure /etc/{pam.conf,pam.d} (AIX, Solaris, HPUX, Linux, Mac OS X)

Allow automatic editing of the PAM configuration (pam.conf file or pam.d directory) on **AIX, HP-UX**, **Solaris**, **Linux, and Mac OS X** computers. This policy modifies the adclient.autoedit.pam setting in the agent configuration file.

Configure /etc/security/user (AIX)

Allow automatic editing of the LAM user configuration files on **AIX** computers. This policy modifies the adclient.autoedit.user setting in the agent configuration file.

Configure /usr/lib/security/methods.cfg (AIX)

Allow automatic editing of the LAM methods.cfg files on **AIX** computers. This policy modifies the adclient.autoedit.methods setting in the agent configuration file.

Configure Directory Services (Apple OS/X)

Allow automatic editing of the Directory Service configuration on **Mac OS X** computers This policy modifies the adclient.autoedit.dsconfig setting in the agent configuration file.

Configure Dump Core Setting

Specify whether the agent should be allowed to dump core. The value you set for this group policy overrides the default `ulimit` setting. When you enable this group policy, select one of the following options from the drop down menu:

- never to specify that the agent never dump core.
- once to specify that the agent should dump core only when there is no existing core dump file. Note that this setting is not valid on Mac OS X computers. On Mac OS X, once behaves the same as always, which dumps core on every crash.
- always to specify that the agent dump core on every crash.

This policy modifies the `adclient.dumpcore` setting in the agent configuration file.

Disable Multi-Factor Authentication (MFA) on Delinea-Managed Computers

Enabling this policy disables multi-factor authentication on Delinea-managed computers. By default, this policy is “Not configured” which allows multi-factor authentication to be used if roles or rights are configured to require it.

This policy modifies the adclient.mfa.enabled setting in the agent configuration file.

Disable nscd Group and passwd Caching (Solaris, Linux)

Do not allow editing of the name service cache daemon configuration (nscd.conf) on **Solaris** and **Linux** computers. Note that selecting this policy disables rather than enables automatic editing of the file. This policy modifies the adclient.autoedit.nscd setting in the agent configuration file.

Disable pwgrd (HPUX)

Do not allow automatic editing of the password and group hashing and caching daemon (pwgrd) on **HP-UX** computers. Note that selecting this policy disables rather than enables automatic editing of the file. This policy modifies the adclient.autoedit.pwgrd setting in the agent configuration file.

Enable Core Dump Cleanup

Specify whether to delete old core dumps generated by the agent. By default, this policy is not configured, and core dumps generated by the agent will never be deleted. If you enable this group policy, agentgenerated core dumps are kept for the number of days that you specify. The default value is 30 days, but you can specify any number of days.

On Mac OS X, the default core dump location is /cores/. On most UNIX systems, the core dump location is the working directory of the current process. However, the core dump location can be customized on some platforms, including RHEL, Solaris, and AIX.

If the core dump location is inside /var/centrifydc and you enable this policy, all old core dumps are deleted without checking the process name first. If the core dump location is somewhere other than /var/centrifydc and you enable this policy, only the core dumps generated by the agent processes (for example, adclient, cdcwatch, and kcm) are deleted.

This policy does not modify the agent configuration file.

Enable Logon Hours Local Enforcement

Specify whether you want both Active Directory and the Centrify Agent to check for user logon hour restrictions, or just Active Directory. If you disable this policy, only Active Directory will check the user logon hour restrictions. By default, the configuration parameter set by this policy is set to `true`.

You might want to set this parameter to false if the user and Centrify Agent are in different time zones, and one time zone recognizes Daylight Savings Time, while the other does not. Otherwise, the user might not be able to log on at certain times.

This group policy modifies the `adclient.logonhours.local.enforcement` setting in the agent configuration file.

Encrypt adclient Cache Data

Specify to encrypt the local cache of Active Directory data. If you enable this policy, all of the Active Directory data stored in the cache is encrypted and the cache is flushed each time the agent starts up. If you disable or do not configure this policy, the cache is not encrypted and is not flushed when the agent starts up.

This group policy modifies the `adclient.cache.encrypt` setting in the agent configuration file.

Force Domains and Forests to be One-Way Trusted

Use the Force domains and forests to be one-way trusted group policy to specify a list of two-way trusted domains that need to be treated as one-way trusted domains. This is useful when two-way trusted domains are not accessible from UNIX machines, for example, they are behind a firewall. Configuring this parameter allows x-forest users to authenticate onto the trusting machines.

To set this group policy, select **Computer Configuration > Centrify Settings > DirectControl Settings > Adclient Settings > Force domains and forests to be one-way trusted**.

The default is an empty list.

Provide the following information for the group policy:

- A list of forests or domains to be treated as one-way trusted.

  Specify a list of two-way trusted forests, and domains that have two-way external trust relationship with the local domain, to be treated by DirectControl Agent as one-way trusted forests or domains.

This parameter is likely to be used together with the configuration parameters, **Specify NTLM authentication domains** and **Specify AD to NTLM domain mappings**, if these forests and domains are not accessible from UNIX machines.

- Use the group policy, **Specify NTLM authentication domains**, to specify the list of domains that use NTLM authentication instead of Kerberos authentication.
- Use the group policy, **Specify AD to NTLM domain mappings**, to map AD domains to NTLM domains.

Alternative to using this group policy, **Force domains and forests to be one-way trusted**, you can use the configuration parameter, adclient.one-way.x-forest.trust.force.

Force Password Salt Lookup from KDC

Force the Centrify Agent to look up the complete principal name, including the Kerberos realm used as the key salt, from the KDC. Enabling this policy is only required if you remove arcfour-hmac-md5 from the list of encryption types specified for the adclient.krb5.tkt.encryption.types parameter in agent configuration file and if you change a userPrincipalName attribute in Active Directory without changing the user's password.

Enabling this policy may cause "pre-auth required" warning messages to appear in the Active Directory event log.

This group policy modifies the adclient.force.salt.lookup setting in the agent configuration file.

Map /home to /User (Mac OS X)

Although this group policy is defined in the centrifydc_settings.xml file, not in the mac_settings.xml file, it applies to Mac OS X computers only. See the *Administrator's Guide for Mac* for a description of this policy.

Run adclient on all Processors

Specify whether to use all processors on a multi-processor system. By default, adclient uses all processors.

This policy modifies the adclient.use.all.cpus setting in the agent configuration file. This parameter is set to true by default. Disable this policy to set the parameter to false if adlcient becomes unstable.

Set Cache Cleanup Interval

Specify how often the agent should clean up the local cache. At each cleanup interval, the agent checks the cache for objects to be removed or expired, and at every 10th interval, the agent rebuilds local indexes. The value should be less than the values specified for the following parameters in the Centrify Agent configuration file:

adclient.cache.negative.lifetime adclient.cache.flush.interval adclient.cache.object.lifetime

The default cleanup interval is 10 minutes.

This group policy modifies the adclient.cache.cleanup.interval setting in the agent configuration file.

Set the Connector Refresh Interval

This policy controls how frequently connections to Centrify Connectors are refreshed. The refresh task is a background process that searches for and selects the nearest available connector to use for connectivity between the Active Directory forest and the identity platform service.

By default, the process runs every 8 hours. You can use this group policy to modify that interval. If the interval is set to 0, the refresh task will be suspended.

This group policy modifies the adclient.cloud.connector.refresh.interval parameter setting in the agent configuration file.

) [tags]: # (heartbeat,NIX) [priority]: # (46)

Set the Heartbeat Interval (

Use this policy to specify how often (in minutes) adclient will send an INFO message to the UNIX syslog.

By default, this policy is set to zero (0), which means that this task is disabled.

Set Maximum Number of Threads

Specify the maximum number of threads the agent will allocate for processing client requests. The value should be greater than or equal to the number of pre-allocated threads specified by the Set minimum number of threads policy. If you do not enable the policy, the default value is 20 threads.

This group policy modifies the adclient.clients.threads.max setting in the agent configuration file.

Set the Maximum Simultaneous Authentication Requests Allowed

This policy specifies the maximum number of identity platform authentication requests that can be processed simultaneously. The default is 10 simultaneous requests.

If you change this setting, you must restart the adclient process.

This group policy modifies the adclient.cloud.auth.token.max setting in the agent configuration file.

Set Minimum Number of Threads

Specify the number of threads the agent pre-allocates for processing client requests. The value must be an integer, zero or greater. If you set the value to zero, the agent processes requests sequentially. If you do not enable this policy, the default value is 4 threads.

This group policy modifies the adclient.clients.threads setting in the agent configuration file.

Specify Low Disk Space Interval

Specify how frequently the agent should check the disk space available for the local cache. The default interval checks the available disk space every 5 minutes. If the disk space available at any interval is less than the value you set for the Specify low disk space warning level policy, the agent will stop saving data in the local cache and will discard any new data until you free up enough disk space for it to resume saving data in the local cache.

The value must be an integer zero or greater. A value of zero disables checking for available disk space.

Keep in mind that the value you set for this policy can affect the recovery of a system after the agent stops writing data to the local cache. If you set the value to 0, the agent will not check for available disk space so it will not return to normal operation when disk space is freed up. In addition, setting value to 0 or to a long interval may cause the agent to consume too much of the disk for its local cache and make the computer unstable or unusable. Therefore, you should keep the interval for checking the available disk space relatively short. Keeping the interval short will also help to ensure that the agent resumes normal operation and saving data to its cache at the earliest opportunity.

This group policy modifies the adclient.disk.check.interval setting in the agent configuration file.

Specify Low Disk Space Warning Level

Generate a warning message when the disk space available for the local cache reaches a critical level. If you enable this policy, you also need to specify the threshold for available disk space that should trigger the warning message. By default, the warning is triggered if the free disk space reaches 51200 KB. Setting the Minimum Free Disk Space to 0 KB disables the display of a warning message.

If you enable the Specify low disk space interval policy, the agent will check the availability of free disk space at the interval specified. If the disk space available at any interval is less than the KB you set for the warning level, the agent stops saving data in the local cache. At the next interval when the available disk space exceeds the KB you set for this policy, the agent resumes normal operation and saving data to its cache.

Keep in mind that the value you set for this policy can affect the recovery of a system. The agent will only resume writing data to its local cache if there is more disk space available than what you have specified to generate the warning.

This group policy modifies the adclient.disk.check.free setting in the agent configuration file.

Specify a Per Machine (Random) Delay for Cache Refreshed Background Tasks

This group policy allows you to specify a per machine (random) delay, in minutes, for cache refreshed background tasks.

When there are more than one machines joined to the same domain and a number of those machines schedule background tasks to frequently access AD at the same time, the convergence of these activities causes a delay in AD. If you stagger these activities, you can avoid the convergence.

Once defined, scheduling background tasks calculates a random period of time within the interval and adds the same time to the delay of the tasks. If you change the interval setting, the period of time is recalculated. This only applies to newly scheduled background tasks.

The default setting is 0 and no delay. This policy modifies the queueable.random.delay.interval setting in the Centrify DirectControl configuration file.

Use the Legal Kerberos Type for Cache Encryption

Specify the type of encryption to use when encrypting the local cache. The encryption type you specify must be a type supported in the Kerberos environment. For example, Windows Server 2003 Kerberos supports the following cryptographic algorithms: RC4-HMAC, DES-CBC-CRC and DES-CBC-MD5.

This group policy is only used if the Encrypt adclient cache data policy is enabled. If Encrypt adclient cache data is not enabled, this policy is ignored.

This group policy modifies the adclient.cache.encryption.type setting in the agent configuration file.

addns Settings Group Policies

Use the group policies under **Addns Settings** to configure domain name service settings in the agent configuration file.

Enable addns Invoked by adclient

Enable whether adclient automatically launches the addns command. The addns command dynamically updates the DNS records on an Active Directory-based DNS server in environments where the DHCP server cannot update DNS records automatically.

In most cases, you do not need to use the addns command if a host's IP address is managed by a Windows-based DNS server and the host obtains its IP address from a Windows-based DHCP server because the DHCP server updates the DNS record for the host automatically.

If you are not using a Windows-based DNS server, you should use nsupdate or a similar command appropriate to the operating environment of the DNS server to update DNS records.

You can set the parameters of the addns command by specifying them in the Set Command Line Options Used by adclient group policy.

The default value for Mac OS X computers is True. The default value for all other platforms is False.

This group policy modifies the adclient.dynamic.dns.enabled parameter in the agent configuration file.

Set Command Line Options Used by adclient

Specify the parameters to use for the addns command if it is enabled by the Enable addns Invoked by adclient group policy. For example, the default setting is:

```
/usr/sbin/addns -U -m
```

The -U option creates or updates the IP address and domain name pointer (PTR) records in the DNS server for the local computer.

The -m option uses the local computer account's Active Directory credentials to establish a security context with the DNS server.

Note that computers that act as a gateway between networks may require you to specify the network adapter IP address in the addns command line. To ensure that you register the correct network address with the Active Directory DNS server, set adclient.dynamic.dns.command with a command line that uses the correct IP address for the network interface you want to use.

This group policy modifies the adclient.dynamic.dns.command parameter in the agent configuration file.

Set DNS Records Update Interval

Specify whether or not dynamic DNS records are periodically updated for this host and, if there are updates, the interval between updates. This interval value is defined in seconds and takes an integer of 0 or greater. If you set the value to 0, the DNS update feature will be disabled. Set the value to 1 or greater to specify the number of seconds between DNS update attempts.

The default for the is parameter is 0.

This group policy modifies the adclient.dynamic.dns.refresh.interval parameter in the agent configuration file.

Set Wait Response Interval for Update Requests

Specify the amount of time, in seconds, that the addns process waits for responses to its request for updates. The parameter value takes an integer of 0 or greater. The default value for this policy is 7 seconds.

This group policy modifies the addns.tcp.timeout parameter in the agent configuration file.

dzdo Settings

Use the group policies under **Dzdo Settings** to control the operation of dzdo.

Always Add Anchors to Regex in dzdo and dzcmds

Specifies whether you wan to add anchors automatically to the regular expressions you define as command rights and use in role definitions. This group policy helps to prevent matching unintended paths or commands if the regular expression pattern is not carefully set.

If you set this group policy to **Disabled**, you should carefully review all regular expressions used as command rights to identify all possible matches for the pattern defined.

This group policy modifies the dzdo.auto.anchors setting in the agent configuration file.

Enable Logging of Valid Command Execution in dzdo

Specify whether messages resulting from successful command execution are logged. Messages are written to the syslog auth facility or authpriv facility, typically located in /var/log/secure.

If you set this group policy to **Not configured** or **Enabled**, the dzdo program logs both valid and invalid command execution.

If you set this group policy to **Disabled**, information about only invalid command execution is logged.

This group policy modifies the dzdo.log_good setting in the agent configuration file.

Enable User Command Timeout

This group policy modifies the `dzdo.user.command.timeout` setting in the Centrify DirectControl configuration file. When this group policy is set to **Enabled**, the user may specify a timeout on the `dzdo` command line with a `-T` option. If the timeout expires before the command has exited, the command will be terminated. The default setting is disabled.

Force dzdo Re-Authentication when Relogin

Specify whether users must authenticate again with dzdo after logging out.

When a user authenticates with dzdo, a ticket is temporarily created that allows dzdo to run without re-authentication for a short period of time. If a user logs out, the ticket is reused when the user logs back in.

Enable this policy to remove the tickets when a user logs out. The user will be required to re-authenticate again when logging back in.

The default, when the policy is not set, is to not clear the tickets when users log out.

This group policy modifies the adclient.dzdo.clear.passwd.timestamp setting in the agent configuration file.

Force dzdo to Set HOME Environment Variable

Specify whether privileged commands run with dzdo commands should set the HOME environment variable to the home directory of the target user (which is root by default).

If you set this group policy to **Not configured** or **Disabled**, the dzdo program does not set the HOME environment variable.

If you set this group policy to **Enabled**, the dzdo program sets the HOME environment variable. Enabling this group policy effectively implies that the -H command line option should always used.

This group policy provides functionality equivalent to setting the always_set_home flag for configuring sudo operation.

This group policy modifies the dzdo.always_set_home setting in the agent configuration file.

Force dzdo to Set HOME Environment Variable when Runs with '-s' Option

Specify whether privileged commands run with dzdo using the -s command line option should set the HOME environment variable to the home directory of the target user (which is root by default).

If you set this group policy to **Not configured** or **Disabled**, the dzdo program does not set the HOME environment variable.

If you set this group policy to **Enabled**, the dzdo program sets the *HOME* environment variable.

This group policy provides functionality equivalent to setting the set_home flag for configuring sudo operation.

This group policy modifies the dzdo.set_home setting in the agent configuration file.

Force per tty Authentication in dzdo

Specify whether dzdo requires authentication once per tty rather than once per user.

If you set this group policy to **Not configured** or **Disabled**, authentication is required once per user. If you set this group policy to **Enabled**, authentication is required once per tty.

This group policy provides functionality equivalent to setting the tty_tickets flag for configuring sudo operation.

This group policy modifies the dzdo.tty_tickets setting in the agent configuration file.

Prompt Error Message if Command not Found by dzdo

Specify whether the dzdo program informs the user when it cannot find a command in the user's PATH.

If you set this group policy to **Not configured** or **Enabled**, the dzdo program displays an error statement indicating that the command could not be found in the user's PATH.

If you set this group policy to **Disabled**, dzdo is prevented from indicating whether a command was not allowed or simply not found.

This group policy provides functionality equivalent to setting the path_info flag for configuring the sudo operation.

This group policy modifies the dzdo.path_info setting in the agent configuration file.

Replace sudo by dzdo

Specify whether to replace sudo with dzdo.

Enable this policy to redirect sudo commands to dzdo. This policy creates a symbolic link between sudo and dzdo. When a user executes a sudo command, dzdo is executed instead. Role assignment settings for the user determine whether the user is allowed to execute the commands specified with sudo.

Be certain to set /usr/share/centrifydc/bin as the first search directory for the PATH variable if you enable this group policy.

This policy is only applicable if you are using zones. It is not applicable for computers that join Auto Zone.

Require dzdo Command Validation Check

Specify whether to enforce the validation check for dzdo privileged commands.

If you set this group policy to **Enabled**, privileged commands will run only after being validated by the dzdo validator. If a command fails validation, or if the dzdo validator does not exist, is not available, or is not trusted—for example because it is not owned by root or is group or world writeable—the command will not run.

If you set this group policy to **Not configured** or **Disabled**, no attempt is made to validate privileged commands, and the commands will run without validation.

This group policy modifies the dzdo.validator.required setting in the agent configuration file.

The dzdo validator is located and configured as described in Set dzdo Validator later in this section.

Require runas User for dzdo

Specify whether a user must explicitly identify the 'runas' user when executing a command with dzdo.

If you set this group policy to **Not configured** or **Enabled**, and a user executes a command with dzdo and does not explicitly identify the user or group to run as with the -u or -g option, adclient assumes that the command should be run as root. If the user is not authorized to run the command as root, dzdo fails to execute the command and issues an error message.

If you set this group policy to **Disabled** and a user executes a command with dzdo that does not explicitly identify the user or group to run as, adclient attempts to resolve the user. If the command defines a single runas user, dzdo executes the specified command and sends a message to the log file.

If the command defines multiple runas users, dzdo cannot resolve the user to run as and attempts to run the command as root. Because the user is not authorized to run the command as root, dzdo fails to execute the command and issues an error message.

In all cases, a user can execute a command successfully with dzdo by using the \-u option to explicitly identify the runas user. For example:

```
[u1@rh6]\$dzdo -u qa1 adinfo
```

This group policy modifies the dzdo.set.runas.explicit setting in the agent configuration file.

Require User is Logged in to a Real tty to Run dzdo

This group policy ensures a user is logged in to a valid tty to run dzdo. This policy modifies the dzdo.requiretty setting in the Centrify DirectControl configuration file. By default, this group policy is not configured, and you do not require a tty to run dzdo.

Set Directory to Store User Timestamp by dzdo

Specify the directory where dzdo stores the user's login timestamp files.

If you set this group policy to **Not configured** or **Disabled**, the default directory /var/run/dzdo is used.

If you set this group policy to **Enabled**, you can specify a directory of your choice.

This group policy provides functionality equivalent to setting the timestampdir flag for configuring sudo operation.

This group policy modifies the dzdo.timestampdir setting in the agent configuration file.

Set dzdo Authentication Timeout Interval

Specify the maximum number of minutes allowed between operations before prompting the user to re-enter a password.

If you set this group policy to **Not configured** or **Disabled**, the default timeout interval of five minutes is used. If you set this group policy to **Enabled**, you can specify a timeout interval of your choice.

You can set this parameter to zero (0) to always prompt for a password when users run privileged commands with dzdo. If you specify a value less than 0, the user's timestamp never expires.

This group policy provides functionality equivalent to setting the timestamp_timeout flag for configuring sudo operation.

This group policy modifies the dzdo.timestamp_timeout setting in the agent configuration file.

Set dzdo Password Prompt Timeout Interval

Specify the number of minutes before the dzdo password prompt times out.

If you set this group policy to **Not configured** or **Disabled**, the default timeout value of five minutes is used. If you set this group policy to **Enabled**, you can specify a timeout value of your choice.

You can set this parameter to zero (0) to have the password prompt never timeout.

This group policy provides functionality equivalent to setting the passwd_timeout flag for configuring sudo operation.

This group policy modifies the dzdo.passwd_timeout setting in the agent configuration file.

Set dzdo Validator

Specify the full path of the dzdo validator. The settings in this group policy are used only when the Require dzdo Command Validation Check group policy is enabled.

The dzdo validator is a script that runs synchronously under the user's Active Directory name. If the Require dzdo Command Validation Check group policy is enabled, the dzdo validator runs when users attempt to execute dzdo commands. Command attempts that pass validation are allowed to run. Command attempts that fail validation are not allowed to run.

The default location of the dzdo validator is /usr/share/centrifydc/sbin/dzcheck. If you set this group policy to **Not configured** or **Disabled**, the validator located in this default location is used.

If you set this group policy to **Enabled**, the dzdo validator that you specify is used.

Note that the Server Suite distribution package does not include a dzcheck script. Instead, a sample validator, /usr/share/centrifydc/sbin/dzcheck.sample, is provided for reference. To configure and enable the dzdo validator, modify the sample script or create a new script, then place that script in the default location (/usr/share/centrifydc/sbin/dzcheck) or use a location and script name of your choice that you specify in this group policy.

You do not need to create a dzcheck script to use dzdo. You only need to create a script if you want to modify dzdo behavior so that validation occurs when dzdo commands attempt to run.

This group policy modifies the dzdo.validator setting in the agent configuration file. For more information about configuring the dzdo validator, see the "dzdo.validator" section in the *Configuration and Tuning Reference Guide*.

Set Environment Variables to be Preserved by dzdo

Specify the default list of environment variables to preserve in the user's environment. This group policy applies only if you have selected the **Reset environment variables** option for the command in Access Manager.

If you set this group policy to **Not configured** or **Disabled**, the default list of variables displayed when you run the `dzdo -V` command as root is preserved.

If you set this group policy to **Enabled**, you can specify variables to preserve in addition to the default list of variables. Variables that you specify must be formatted as a comma-separated list. For example:

```
COLORS,DISPLAY,HOME,HOSTNAME,KRB5CCNAME, LS_COLORS,MAIL,PATH,PS1,PS2,TZ,XAUTHORITY,XAUTHORIZATION
```

This group policy provides functionality equivalent to setting the `env_keep` flag for configuring `sudo` operation.

This group policy modifies the `dzdo.env_keep` setting in the agent configuration file.

Set Environment Variables to be Removed by dzdo

Specify the default list of environment variables to be removed from the user's environment. This group policy applies only if you have selected the **Remove unsafe environment variables** option for the command in Access Manager.

If you set this group policy to **Not configured** or **Disabled**, the default list of variables displayed when you run the `dzdo -V` command as root is removed.

If you set this group policy to **Enabled**, you can specify variables to remove in addition to the default list of variables. Variables that you specify must be formatted as a comma-separated list. For example:

```
IFS,CDPATH,LOCALDOMAIN,RES_OPTIONS,HOSTALIASES, NLSPATH,PATH_LOCALE,LD_\*
```

This group policy provides functionality equivalent to setting the `env_delete` flag for configuring `sudo` operation.

This group policy modifies the `dzdo.env_delete` setting in the agent configuration file.

Set Environment Variables to be Removed by dzdo with Characters % or /

Specify the list of environment variables that should be checked for percent (%) or slash (/) special characters If there are environment variable values containing the special characters, dzdo removes those variables from the user's environment. Variables with % or / characters are removed regardless of whether you have selected the **Reset environment variables** option for the command in Access Manager.

If you set this group policy to **Not configured** or **Disabled**, the default list of variables displayed when you run the `dzdo -V` command as root is checked for special characters.

If you set this group policy to **Enabled**, you can specify variables to check for special characters in addition to the default list of variables. Variables that you specify must be formatted as a comma-separated list. For example:

```
COLORTERM,LANG,LANGUAGE,LC_\*,LINGUAS,TERM
```

This group policy provides functionality equivalent to setting the `env_reset` flag for configuring `sudo` operation.

This group policy modifies the `dzdo.env_check setting` in the agent configuration file.

Set Error Message when Failed to Authenticate in dzdo

Specify the message that is displayed if a user enters an incorrect password.

If you set this group policy to **Not configured** or **Disabled**, the default message "Sorry, try again" is used. If you set this group policy to **Enabled**, you can specify a message of your choice. The message can be any text string enclosed by quotation marks. For example:

"The password provided is not valid."

This group policy provides functionality equivalent to setting the badpass_message flag for configuring sudo operation.

This group policy modifies the dzdo.badpass_message setting in the agent configuration file.

Set Lecture Shown by dzdo Before Password Prompt

Specify the full path to a file containing the warning message that is displayed about using dzdo before displaying the password prompt.

If you set this group policy to **Not configured** or **Disabled**, a default message is used. If you set this group policy to **Enabled**, you can specify a file containing a message of your choice. You must specify the full path to the file. For example, to use a custom message located in the file dzdo_warning:

```
/etc/custom/dzdo_warning
```

This group policy provides functionality equivalent to setting the lecture_file flag for configuring sudo operation.

This group policy modifies the dzdo.lecture_file setting in the agent configuration file.

Set Password Prompt for Target User Password in dzdo

Specify the password prompt displayed when running privileged commands. This group policy serves the same function as the `dzdo -p` command.

If you set this group policy to **Not configured** or **Disabled**, the default prompt `[dzdo] password for *%p*:` where `*%p*` is *root* unless specified otherwise.

If you set this group policy to **Enabled**, you can specify a prompt of your choice. You can use the following escapes in the prompt:

%u —Expands to the invoking user's login name.

%U—Expands to the login name of the user the command will be run as. If not specified, defaults to root.

%h—Expands to the local hostname without the domain name.

%H—Expands to the local hostname including the domain name.

%p—Expands to the user whose password is asked for.

%%—Collapses to a single % character.

This group policy modifies the `dzdo.passprompt` setting in the agent configuration file.

Set Paths for Command Searching in dzdo

Specify the search path for the dzdo program to use to look for commands and scripts that require privileges to run.

If you set this group policy to **Not Configured** or **Disabled**, no search path is set (that is, there is no default value). If you set this group policy to **Enabled**, you can specify a list of directories for the dzdo program to search for commands and scripts. The dzdo program will search in the specified directories no matter which path the command rights are configured to use in the Access Manager **System search path** option.

If command paths are configured in Access Manager using the **System search path** option and this group policy is **Disabled** or **Not Configured**, the following actions take place:

- The current user's path is used to search for the commands.
- Only the commands located under the System path are allowed to execute.

The search path that you specify can be a list of directories or the name of a file that contains the list of directories. For example, you can specify a file that contains the directories to search using the file: keyword and a file location:

```
file:/etc/centrifydc/customized_dzdo_directories
```

If you specify a file name, you should ensure that the file is owned by root and is not accessible to any other users.

This group policy modifies the dzdo.search_path setting in the agent configuration file.

Set Secure Paths for Command Execution in dzdo

Specify the path for the dzdo program to use when executing commands and scripts that require privileges to run.

If you set this group policy to **Not Configured** or **Disabled**, no specific path is set (that is, there is no default value). If you set this group policy to **Enabled**, you can specify the directory that dzdo uses. The dzdo program will execute only the commands and scripts that are located in the directory that you specify.

The path that you specify can be a list of directories or the name of a file that contains the list of directories. For example, you can specify a file that contains the directories to search using the file: keyword and a file location:

```
file:/etc/centrifydc/customized_dzdo_directories
```

Within the file, lines should contain paths separated by colons. For example, a file specifying two paths might look this this:

```
/etc/centrifydc/reports/exec_report_cmds:/usr/sbin/ora_cmds
```

If you specify a file name, you should ensure the file is owned by root and not accessible to any other users.

Setting this group policy and the Set paths for Command Searching in dzdo group policy to the same path is equivalent to setting the secure_path parameter in the sudoers configuration file.

This group policy modifies the dzdo.secure_path setting in the agent configuration file.

Show Lecture by dzdo Before Password Prompt

Specify whether dzdo displays a warning message about using dzdo before displaying the password prompt.

If you set this group policy to **Not configured** or **Disabled**, the message defined in the Set Lecture Shown by dzdo Before Password Prompt group policy (or in dzdo.lecture_file) is displayed one time.

If you set this group policy to **Enabled**, you can specify whether and how often the message is displayed. The values that you can specify are:

- once—Display the warning message only the first time the command is run.
- never—Never display a warning message.
- always—Display the warning message every time the program is invoked.

This group policy provides functionality equivalent to setting the lecture flag for configuring sudo operation.

This group policy modifies the dzdo.lecture setting in the agent configuration file.

Use realpath to canonicalize Command Paths in dzdo

Specify whether dzdo uses command paths resolved by realpath when searching for commands.

If you set this group policy to **Not configured** or **Disabled**, realpath is not used to resolve command paths. If you set this group policy to **Enabled**, realpath is used to expand all symbolic links and resolve references to:

/./

/../

extra **/** characters

This group policy modifies the dzdo.use.realpath setting in the agent configuration file.

Set the Type of Time Stamp Record

The privilege elevation service uses per-user timestamp files for credential caching. You can use this group policy to specify the type of timestamp record for the service to use.

If you set this group policy to **Not configured** or **Disabled**, the service uses the `tty` time stamp record type.

If you set this group policy to **Enabled**, you can set this group policy to any of the following values:

__global__: A single time stamp record is used for all of a user's login sessions, regardless of the terminal or parent process ID.

__ppid__: A single time stamp record is used for all processes with the same parent process ID (usually the shell). Commands run from the same shell (or other common parent process) will not require a password for dzdo.timestamp_timeout minutes (5 by default). Commands run by way of sudo with a different parent process ID, for example from a shell script, will be authenticated separately.

__tty__: One time stamp record is used for each terminal, which means that a user's login sessions are authenticated separately. If no terminal is present, the behavior is the same as ppid. Commands run from the same terminal will not require a password for dzdo.timestamp_timeout minutes (5 by default).

This group policy modifies the `dzdo.timestamp_type` setting in the agent configuration file.

Group Policy Settings

Use the group policies under **Group Policy Settings** to manage the Centrify group policy mapping programs.

Enable User Group Policy

Specify whether to enable user-based group policies. If you enable this policy, user-based group policies are enabled. If you explicitly disable this group policy, user-based policies are disabled.

If you do not set this policy, the default is to enable user-based policies on Mac OS X machines and disable user-based policies on all other Linux and UNIX based computers.

When this policy is **Disabled**, all user configuration Software Settings and user configuration Windows Settings group policies set for computers in Centrify zones are not applied. You must enable this policy if you want to use any Software Settings, Windows Settings, or Centrify Settings group policies on computers in a Centrify zone.

User configuration group policies enabled in a child organizational unit do NOT apply to users logging in to computers in the child organizational unit who are not in that organizational unit (for example, they are in the parent organizational unit only). See Applying Policies in Nested Organizational Units if you need to have different user configuration policies at different levels in the organizational unit hierarchy.

This group policy modifies the `gp.disable.user` setting in the agent configuration file.

Group Policy Commands Environment Variable List Running as Root

This policy specifies the list of environment variables that are exported to the environment so that a root user can run Group Policy commands. Use the forward slash "/" to specify environment variables and their values. Use a space to separate multiple name/value pairs. If an environment variable contains spaces, enclose the value in quotes or add a backslash "\" before the space.

You can also specify other environment variables as a value.

Set Group Policy Mapper Execution Timeout

Specify the maximum amount of time, in seconds, to allow for a group policy mapper program to run before the process is stopped.

This group policy modifies the gp.mappers.timeout setting in the agent configuration file.

Set Machine Group Policy Mapper List

Specify the list of mapper programs to run for computer-based policies.

You can use an asterisk (*) as a wild card to match a set of program names. For example, you can specify `a*` to match all programs with names that start with the letter `a`.

You can use an exclamation point (!) with a program name to exclude a program from the list. For example, you can specify `!mysample` to prevent the mapping program `mysample` from running.

This group policy modifies the `gp.mappers.machine` setting in the agent configuration file.

Set User Group Policy Mapper List

Specify the list of mapper programs to run for user policies.

You can use an asterisk (*) as a wild card to match a set of program names. For example, you can specify `a*` to match all programs with names that start with the letter `a`.

You can use an exclamation point (!) with a program name to exclude a program from the list. For example, you can specify `!mysample` to prevent the mapping program `mysample` from running.

This group policy modifies the `gp.mappers.user` setting in the agent configuration file.

Set Total Group Policy Mappers Execution Timeout

Specify the maximum amount of time, in seconds, to allow for all group policy mapper programs to run before stopping all mapper processes.

This group policy modifies the gp.mappers.timeout.all setting in the agent configuration file.

User Group Policy Commands Run as User

This policy specifies whether to run user group policy commands as the current user. The default for this parameter is false, which means that the service runs these commands as administrator/root.

The RunCommand.pl script reads this policy setting and if the policy s set to true, then it runs commands as follows:

```
su - \$args -\>user() -c \$command
```

Use User Credential to Retrieve User Policy

Use this group policy to distinguish whether to use user credentials instead of machine credentials to retrieve user policy. By default, machine credentials are used to retrieve user policy. However, if a computer object does not have permission to access user group policy objects, user policy will not be applied.

If you enable this group policy, user credentials are used to retrieve user policy.

This group policy modifies the gp.use.user.credential.for.user.policy setting in the agent configuration file.

Kerberos Settings

Use the group policies under **Kerberos Settings** to manage the Kerberos configuration.

Allow PAM to Create User Kerberos Credential Cache

Use this policy to specify whether PAM creates the Kerberos user credential cache.

If this group policy is **Enabled** or **Not Configured**, a Kerberos user credential cache is created. The Kerberos user credential cache can be file-based or it can be a KCM in-memory cache, depending on the krb5.cache.type setting in /etc/centrifydc/centrifydc.conf.

If this group policy is disabled, the Kerberos user credential cache is not created, and any attempt to perform an SSO operation will fail.

This group policy modifies the pam.auth.create.krb5.cache setting in the agent configuration file.

Allow Weak Encryption Types for Kerberos Authentication

Use this group policy to specify whether to allow weak encryption types for Kerberos authentication.

By default (not configured), this policy allows the weak encryption types specified in the configuration parameters adclient.krb5.permitted.encryption.types and adclient.krb5.tkt.encryption.types.

These encryption types include:

- des-cdc-crc
- des-cbc-md4
- dec-cbc-md5
- dec-cbc-raw
- des3-cbc-raw
- des-hmac-sha1
- arcfour-hmac-exp
- rc4-hmac-exp
- arcfour-hmac-md5-exp

If you disable this policy, the above encryption types will not be supported. Note that setting this policy to disabled may cause authentication failures in existing Kerberos environments that do not support strong cryptography. Users in these environments should leave this policy set to **Not Configured** or **Enabled** until their environment adopts stronger cyphers.

This policy modifies the adclient.krb5.allow_weak_crypto parameter in the agent configuration file.

Alternative Location for Credential Cache Directory

Use this policy to control the adclient.krb5.ccache.dir configuration parameter. For details, see *Configuration and Tuning Reference Guide*.

The adclient.krb5.ccache.dir parameter specifies the directory where Kerberos ccache files are stored when krb5.cache.type is FILE.

This is useful when Kerberos applications in Docker containers use the Kerberos cache files. This parameter, in conjunction with adclient.krb5.ccache.dir.secure.usable.check enables volume bind mapping so that Kerberos cache files in the host OS are available to the Docker containers.

Alternative Location for User .k5login Files

Use this policy to specify an alternative location for user .k5login files.

If specified, this string value will be used for the k5login_directory in the [libdefaults] stanza in krb5.conf and the user's .k5login file will be named as \<k5login_directory\>/\<unix_name\>.

For security reasons the specified directory should be owned by root and writeable by root only. If the directory does not exist, adclient will create it.

This group policy modifies the krb5.conf.k5login.directory setting in the agent configuration file.

Disable Kerberos Built-in ccselect Plugins

Use this policy to specify whether adclient should disable the Kerberos built-in ccselect plugins.

If this group policy is **Enabled** or **Not Configured**, adclient will disable all ccselect built-in plugins in the **plugins** section of the krb5.conf file when the group policy, Manage Kerberos Configuration, is enabled.

If this group policy is set to **Disabled**, the ccselect plugins will **not** be disabled.

This group policy modifies the krb5.conf.plugins.ccselect.disable configuration parameter in the agent configuration file.

Enable Kerberos Clients to Correct Time Difference

Enable Kerberos to automatically correct for a time difference between the system clock and the clock used by the KDC. You only need to enable this group policy if your system clock is drifting and the system is not using NTP and adclient SNTP settings.

This group policy modifies the krb5.use.kdc.timesync setting in the agent configuration file.

Force Kerberos to Only use TCP

Force all Kerberos requests to use TCP rather than UDP.

This group policy modifies the krb5.forcetcp setting in the agent configuration file.

Generate the Forwardable Tickets

Specify whether you want the Centrify Agent to create forwardable Kerberos user tickets. Creating a forwardable ticket allows a user's logon ticket to be sent to another computer and used to access to additional systems and resources.

If you select **Enabled** for this group policy, service tickets can be forwarded from one service or resource to another. If you do not want tickets to be forwarded, you can uncheck this option to prevent the agent from creating forwardable tickets.

This group policy modifies the krb5.forwardable.user.tickets setting in the agent configuration file.

Generate Kerberos Version Numbers for Windows 2000

Kerberos Version Numbers (kvno), allow tickets issued with a computer's previous key to be decrypted even when the ticket was issued before the computer changed it's password, but presented afterwords.

Windows 2000 does not support these kvnos, but you can enable this policy to generate version numbers that work with Windows 2000.

However, this feature requires Centrify's Kerberos libraries so older Kerberos applications may fail to understand the generated Kerberos version numbers. You can disable this policy to support older applications with the knowledge that the race condition just described may cause authentication failures.

This group policy modifies the krb5.generate.kvno setting in the agent configuration file.

Manage Kerberos Configuration

Indicate whether you want the Centrify Agent to automatically manage the Kerberos configuration files.

This group policy modifies the `adclient.krb5.autoedit` setting in the agent configuration file.

Renew Credentials Automatically

Specify whether to automatically reissue user credentials when they expire. If you enable this group policy, the Centrify Agent keeps a hash of the user's password in memory indefinitely. If you do not enable this policy, or if you explicitly disable it, a user's credentials periodically expire and the user must be reauthenticated by re-entering a valid password.

If you enable this policy, user credentials are automatically reissued, as needed, as long as the `adclient` process continues to run even if the computer is disconnected from Active Directory. If you stop or restart `adclient`, however, the user's password hash is removed from memory. After stopping or restarting `adclient`, users must be re-authenticated by logging on with a valid user name and password.

The default value is `false`.

This group policy modifies the `krb5.cache.infinite.renewal` setting in the agent configuration file.

Set Configuration Update Interval

Specify how frequently, in hours, the Centrify Agent should update the Kerberos configuration files.

This group policy modifies the `krb5.config.update` setting in the agent configuration file.

Set Kerberos UDP Preference Limit

Specify the maximum size packet that the Kerberos libraries will attempt to send over a UDP connection before retrying with TCP. If the packet size is larger than this value, only TCP will be tried. If the value is set to 1, TCP will always be used. The hard UDP limit is 32700. If you enter a value larger than this, the value is reset to 32700 when you apply the policy.

This policy only takes effect if the policy Force Kerberos to only use TCP is not configured or is disabled (the configuration parameter krb5.forcetcp is set to false).

If Force Kerberos to only use TCP is enabled and the agent is managing the krb5.conf file, it will set udp_preference_limit = 1, so that the Kerberos libraries will always use TCP.

If you do not enable this group policy, the default value is 1465.

This group policy modifies the krb5.udp.preference.limit setting in the agent configuration file.

Set Credential Renewal Interval

Specify how frequently, in hours, Kerberos credentials are renewed. A value of 0 disables renewal completely.

This group policy modifies the krb5.cache.renew.interval setting in the agent configuration file.

Set Password Change Interval

Specify how frequently, in days, the Centrify Agent should change the computer account password in Active Directory.

This group policy modifies the adclient.krb5.password.change.interval setting in the agent configuration file.

Set Password Change Verification Interval

Specify the interval, in seconds, that adkeytab waits between computer password change verification attempts.

This group policy modifies the adclient.krb5.password.change.verify.interval setting in the agent configuration file.

The default setting is 300 seconds (5 minutes).

Set Password Change Verification Attempts

Specify the number of times that adkeytab attempts to verify password changes after an initial, failed attempt.

Some environments, such as those using a read-only domain controller (RODC), can experience replication delays that may prevent Kerberos password changes to be verified through adclient. As a result of this delay, the new password may not be saved to the keytab file.

Increasing the number of verification attempts can address replication delays that may result from having a read-only domain controller.

This group policy modifies the adclient.krb5.password.change.verify.retries setting in the agent configuration file.

The default setting is 0, which means that adkeytab does not attempt additional password verification attempts after the initial failure.

Specify Credential Cache Type for AD Users

Specify the type of Kerberos credential cache that adclient will create when an Active Directory user logs in. You can specify a file-based or in-memory-based credential cache.

> **Note**: The use of in-memory credential caches is not supported on Mac OS X computers, therefore applying this group policy setting to a Mac OS X computer has no effect.

To specify the type of cache to create, click **Enabled**, then select the type of cache from **Kerberos credential cache type**.

If you select **File-based credential cache**, the Centrify Agent creates a file-based credential cache for each Active Directory user in /tmp when the user logs in. A file-based credential cache persists until the file is deleted.

If you select **In-memory credential cache provided by Centrify-KCM service**, the Centrify Agent creates an in-memory credential cache for each Active Directory user when the user logs in. The Centrify-KCM service, run as root, manages in-memory credential caches. When the adclient process starts up, if the policy is configured for an in-memory credential cache, adclient starts the KCM service. If you change the setting from file-based to in-memory while adclient is running, adclient starts the KCM service the next time it is forced to reload configuration parameters, for example, if you run the adgpupdate command to update group policy settings, or if a user opens a new session.

Setting this parameter affects new users only — not users who have already logged in. For example, if you change from a file-based, to an in-memory credential cache, Direct Control will continue to use the file-based credential cache for any user who was logged in at the time of the change. If a logged in user opens a new session, or a new user logs in, the agent will use an in-memory cache for them.

An in-memory credential cache ends as soon as the Centrify-KCM service is stopped.

This group policy modifies the krb5.cache.type setting in the agent configuration file.

Specify Groups to Infinitely Renew Kerberos Credentials

Specify a list of Active Directory groups whose members' Kerberos credentials require infinite renewal even after the users have logged out. Groups that you specify must be Active Directory groups, but do not need to be zone enabled. However, only zone enabled users in a group will have their credentials automatically renewed.

If this group policy is **Enabled**, group member's credentials are renewed automatically. You must use the following format to specify groups when you enable this group policy:

sAMAccountName@domain

For example:

test_group_sam@example.com

By default, this group policy is disabled.

This group policy modifies the krb5.cache.infinite.renewal.batch.groups setting in the agent configuration file.

Specify Maximum Kerberos Credential Cache Lifetime

Specify whether adclient deletes credentials from the Kerberos cache if they are the specified number of days old.

If this group policy is **Enabled**, the credentials will be cleared for all users whether or not they are logged on, have active processes running, or are specified in the following group policy lists:

- Specify Groups to Infinitely Renew Kerberos Credentials
- Specify Users to Infinitely Renew Kerberos Credentials

You can configure this group policy by enabling it and setting the value to the age of the credential cache to be cleared, in days.

The default value for the group policy is 0 days, which means that this group policy does not clear any credential caches.

This group policy modifies the krb5.cache.clean.force.max setting in the agent configuration file.

Specify Users to Infinitely Renew Kerberos Credentials

Specify a list of users whose Kerberos credentials require infinite renewal even after the users have logged out. Users that you specify must be zone enabled (that is, mapped users are not supported). If this group policy is enabled, user credentials are renewed automatically.

You can use any of the following formats to specify user names:

unixName

userPrincipleName

sAMAccountName

sAMAccountName@domain

For example:

test_user

test_user@example.com

test_user_sam

test_user_sam@example.com

By default, this group policy is disabled.

This group policy modifies the krb5.cache.infinite.renewal.batch.users setting in the agent configuration file.

Specify Whether CDC k5login Module Should Ignore .k5login for SSO

Specify whether the k5login module should ignore .k5login for SSO.

The default value is false.

This group policy modifies the krb5.sso.ignore.k5login setting in the agent configuration file.

Specify Whether Kerberos PAC Checksum Validation Should be Done

This group policy specifies whether or not to verify that the user's PAC (Privilege Authorization Certificate) information is from a trusted KDC (Key Distribution Center) so as to prevent what's referred to as a "silver ticket" attack.

When performing credential verification, a service ticket is fetched for the local system. After the credential is verified, the local system uses the PAC information in the service ticket.

This group policy takes effect when the policy is enabled or when DirectControl is using the user's PAC from a service ticket. This setting does not apply to retrieving the PAC by way of the S4U2Self protocol.

There are 3 possible values for this policy:

- disabled (default): NO PAC validation will be done at all.
- enabled: If PAC Validation fails, the PAC information is used and the user login is allowed.
- enforced: If PAC Validation fails, the PAC information is discarded and the user login is denied.

Setting this group policy to enabled or enforced will have significant impact on the user login and user's group fetch performance.

Strictly Enforce Default Encryption Types

This parameter specifies if DirectControl should add or replace the default encryption types listed in the settings, default_tgs_enctypes and default_tkt_enctypes in krb5.conf with the types specified in the setting adclient.krb5.tkt.encryption.types in centrifydc.conf.

- When this group policy is not set (default) — No change in behavior. It means DirectControl adds any additional encryption types.

  Default encryption types from centrifydc.conf are added, if they were not already listed. Other items that were already in default_tgs_enctypes and default_tkt_enctypes are left alone and not removed.

- When this group policy is set — DirectControl replaces the encryption types listed in the settings, default_tgs_enctypes and default_tkt_enctypes in krb5.conf to match exactly with the encryption types listed in the setting, adclient.krb5.tkt.encryption.types in centrifydc.conf.

  Default encryption types from centrifydc.conf are added, if they were not already listed. Other items that were already in default_tgs_enctypes and default_tkt_enctypes, and not in centrifydc.conf, are removed.

This group policy is set as follows: **Computer Configuration > Centrify Settings > DirectControl Settings > Kerberos Settings > Control if strictly enforce the encTypes**.

Strictly Enforce Permitted Encryption Types

This parameter specifies if DirectControl should add or replace the permitted encryption types listed in the setting, permitted_enctypes in krb5.conf with the types specified in the setting, adclient.krb5.permitted.encryption.types in centrifydc.conf.

- When this group policy is not set (default) — No change in behavior. it means DirectControl adds any additional encryption types.

  Permitted encryption types from centrifydc.conf are added, if they were not already listed. Other items that were already in permitted_enctypes are left alone and not removed.

- When this group policy is set — DirectControl replaces the setting, permitted_enctypes in krb5.conf to match exactly with encryption types listed in the setting, adclient.krb5.permitted.encryption.types in centrifydc.conf.

  Permitted encryption types from centrifydc.conf are added, if they were not already listed. Other items that were already in permitted_enctypes, and not in centrifydc.conf, are removed.

This group policy is set as follows: **Computer Configuration > Centrify Settings > DirectControl Settings > Kerberos Settings > Control if strictly enforce the permitted_encTypes**.

Use DNS to Lookup KDC

Allow the agent to use DNS to locate the Kerberos Key Distribution Center (KDC).

This group policy modifies the krb5.use.dns.lookup.kdc setting in the agent configuration file.

Use DNS to Lookup Realms

Allow the agent to use DNS to locate Kerberos realms.

This group policy modifies the krb5.use.dns.lookup.realm setting in the agent configuration file.

Local Account Management Settings

Use the group policies under **Local Account Management** to control whether local accounts are managed by the agent, and other aspects of local account management by the agent.

Enable Local Account Management Feature

Specify whether the agent manages local users and groups on the computer where the agent is installed.

When this group policy is **Enabled**:

- The agent gets the local user and local group profiles from the zone, and updates the local password and local group files using the information defined in the zone.
- You can view and manage local users and groups in Access Manager as described in the *Administrator's Guide for Linux and UNIX*.

By default, this group policy is disabled (unless you upgraded from a Server Suite release in which it was enabled), and the agent does not manage local users and groups.

This group policy modifies the adclient.local.account.manage setting in the agent configuration file.

Notification Command Line

Define a command to process changes to local account profiles after the agent synchronizes local user and group profiles with profiles defined in a zone.

For example, if new local users are added, removed, or have their enabled/disabled status changed locally, the command that you define in this policy is executed. Typical activities that this command might perform include setting the password for new or updated local accounts, or notifying password vault about changes to local accounts and defining actions to take regarding those accounts.

When this policy is **Enabled**, the agent invokes the defined command in another process and passes a comma separated UNIX name list to the command for further processing.

By default, this policy is not configured (that is, no command is defined).

This group policy modifies the adclient.local.account.notification.cli setting in the agent configuration file.

This policy takes effect only when local account management is enabled through the **Enable local account management feature** group policy, or through the adclient.local.account.manage configuration parameter.

Logging Settings

Use the group policies under **Logging Settings** to control the following aspects of a computer's logging facilities:

- Set Adclient Audit Logging Facility
- Set General Audit Logging Facility
- Set Log Message Queue Size
- Set NIS Audit Logging Facility

Set adclient Audit Logging Facility

Specify the syslog facility to use for logging adclient auditing messages. You can separately enable syslog facilities for logging general adclient messages, adclient auditing messages, and adnisd messages.

Select a value for this group policy from the list box, which contains a list of valid syslog facilities, for example, auth, authpriv, daemon, security, user, local *n*, and so on. The available facilities may vary depending on the operating system. The default value is auth.

If this group policy is not enabled, the audit messages are logged in the facility defined for the Set general audit logging facility policy.

This group policy modifies the logger.facility.adclient setting in the agent configuration file.

Rather than using the policy to set the facility, you can edit the agent configuration file to set the logger.facility.adclient parameter to any valid syslog facility. For example, you can set this parameter to log messages to one of auth, authpriv, daemon, security, local *n* facilities, and so on.

Set General Audit Logging Facility

Specify the syslog facility to use for logging general adclient activity. You can separately enable syslog facilities for logging general adclient messages, adclient auditing messages, and adnisd messages.

Select a value for this group policy from the list box, which contains a list of valid syslog facilities, for example, auth, authpriv, daemon, security, user, local *n*, and so on. The available facilities may vary depending on the operating system. The default value is auth.

This group policy modifies the logger.facility.* setting in the agent configuration file.

Rather than using the policy to set the facility, you can edit the agent configuration file to set the logger.facility parameter to any valid syslog facility. For example, you can set this parameter to log messages to one of auth, authpriv, daemon, security, local *n* facilities and so on.

You may also edit he agent configuration file to specify other process names for logging, or use an asterisk (*) to specify the default facility to use for all agent processes. For example, you can specify logger.facility.*: auth in the configuration file to direct all agent processes send messages to the auth facility of syslog.

Set Log Message Queue Size

This policy controls the maximum size in KB to use for queued log messages. The messages in the queue are sent to syslog asynchronously. During normal operation, if the size of the message queue reaches the value set for this parameter, no new messages are added until the size of the queue decreases below the maximum size you have specified. If the logging level is set to DEBUG, however, this policy's value is automatically multiplied by a factor of 4 to allow additional messages to be logged.

The value must be a positive integer. For example: 256

Setting this parameter to zero (0) disables the message queue, and causes all log messages to be written to the syslog facility synchronously. In most cases, disabling the message queue degrades system performance, and in extreme cases, may cause a dead lock with the syslog daemon during log rotations. Therefore, Delinea recommends that you never set this parameter value to 0.

This group policy modifies the log.queue.size setting in the agent configuration file. If this parameter is not defined in the configuration file, its default value is 256 KB.

Set NIS Audit Logging Facility

Specify the syslog facility to use for logging adnisd operations.

You can separately enable syslog facilities for logging general adclient messages, adclient auditing messages, and adnisd messages.

Select a value for this group policy from the list box, which contains a list of valid syslog facilities, for example, auth, authpriv, daemon, security, user, local *n*, and so on. The available facilities may vary depending on the operating system. The default value is auth.

If this group policy is not enabled, the audit messages are logged in the facility defined for the Set general audit logging facility policy.

This group policy modifies the logger.facility.adnisd setting in the agent configuration file.

Rather than using the policy to set the facility, you can edit the agent configuration file to set the logger.facility.adnisd parameter to any valid syslog facility. For example, you can set this parameter to log messages to one of auth, authpriv, daemon, security, local *n* facilities, and so on.

Login Settings

Use the group policies under **Login Settings** to control the following login and local account configuration options:

- Allow Localhost Users
- Allow Offline Login when User Account is Locked Out
- Enabled nss Emergency Shell
- Manage Login Filters
- Set Minimum Group ID (Lookup)
- Set Minimum User ID (Lookup)
- Set Sync Mapped Users
- Specify Group Names to Ignore
- Specify the Certificate Files to Add (Lookup)
- Specify the Fingerprints of Certificate Files to Ignore (Lookup)
- Specify User Names to Ignore
- Split Large Group Membership

Allow Localhost Users

Specify user names that should be allowed to authenticate locally when logging in.

This group policy is used to ensure that an account mapped to an Active Directory user can still access a system locally if there are problems with the network, the Active Directory server, or the agent.

If you select **Enabled** for this group policy, the users you specify can log in locally by appending @localhost to the user name. For example, if you specify the root user, you would log in as root@localhost.

This group policy modifies the pam.allow.override setting in the agent configuration file.

> **Note**: This group policy and the pam.allow.override configuration parameter are not supported on AIX computers. There is no equivalent policy or parameter for controlling local access on AIX computers.
>
> **Note**: If you are using a Solaris machine with the Name Switch Cache Daemon (NSCD) running, you will not be able to log in as an override user using <*username*>@localhost.

Allow Offline Login when User Account is Locked Out

Use this group policy to specify whether to allow a user to log in to a machine that is in disconnected mode if their account is locked.

If this policy is set to **Disabled**, or **Not configured**, by default, users with locked accounts cannot access a disconnected machine.

This group policy modifies the secedit.system.access.lockout.allowofflinelogin parameter in the agent configuration file.

Enabled nss Emergency Shell

Use this group policy to specify whether to use the default login shell when a user or group attempting to access the computer is not allowed to log on.

The default no-login shell and its location is typically platform-specific. For example, on Red Hat Linux the default shell for users who are denied access is:

/sbin/nologin

If this policy is **Disabled** or **Not configured**, by default, the nologin shell specified in the agent configuration file by the configuration parameter, nss.shell.nologin, is returned.

This group policy modifies the nss.shell.emergency.enabled parameter in the agent configuration file.

Manage Login Filters

Specify the users and groups allowed to log in to the system. With this policy, you can explicitly list either:

- Users and groups who are allowed to log in (all other users and groups are denied)
- Users and groups who should be denied access (all others are allowed)

When you enable this policy, you can select either the **allow** or **deny** option, then specify a list of user names, a list of group names, or both.

You can specify a list of users or groups in either of these ways:

- Enter a comma-separated list of users, groups, or both in the appropriate text boxes.
- Click the **List** button, then **Add**, to browse for and select users or groups to allow or deny.

Depending on your selections when you configure this group policy setting, the policy can modify any of the following configuration parameters in the agent configuration file:

pam.allow.groups

pam.allow.users

pam.deny.groups

pam.deny.users

> **Note**: This group policy does not support one-way, cross-forest groups.

Set Minimum Group ID (Lookup)

Specify the lowest group ID that is looked up in Active Directory.

> **Note**: This group policy does not apply to agent versions 4.1 or later. If you are using 4.1 or later, use the Specify Group Names to Ignore group policy to explicitly identify user groups that are always treated as local.

This group policy modifies the nss.mingid setting in the agent configuration file.

Set Minimum User ID (Lookup)

Specify the lowest user ID that is looked up in Active Directory.

> **Note**: This group policy does not apply to agent versions 4.1 or later. If you are using 4.1 or later, use the Specify User Names to Ignore group policy to explicitly identify user names that are always treated as local.

This group policy modifies the nss.minuid setting in the agent configuration file.

Set Sync Mapped Users

Synchronize the Active Directory password for local mapped users. When you enable this policy for a mapped user, if the user changes their Linux, UNIX, or Mac OS X password with the passwd command, or with a similar command, PAM changes the password to match in the local Linux, UNIX, or Mac OS X account. In this way, if there are problems with the network, Active Directory, or adclient, local users can still log into the machine.

> **Note**: This policy has no effect on Mac OS X computers.

To log in as a local user, append @localhost to the username. For example, log on as:

```
root@localhost
```

After enabling this policy, click **Browse** to search for users to add.

For this policy to work:

- The specified user must be a mapped user configured in centrifydc.conf with the pam.mapuser parameter.
- Either the Centrify or Microsoft password synchronization service must be installed on all domain controllers.
- The zone to which the machine belongs must be configured to support agentless clients.
- The Active Directory user to whom the local user is mapped must have a profile in the zone configured for agentless authentication.

This group policy modifies the pam.sync.mapuser setting in the agent configuration file.

Specify Group Names to Ignore

You can enter the list of local group names that aren't stored in Active Directory and separate each name with a space. The service will then use this list to disable looking up Active Directory account information for the specified groups. Ignoring this list of groups results in faster name lookups for system user accounts, such as tty and disk.

You can also specify a file that lists the usernames by entering the file: keyword and a file location. For example:

```
file:/etc/centrifydc/group.ignore
```

When you enable this policy, you can select the location where the group name list is populated. The default setting is "Populate group names to centrifydc.conf".

If you select "Populate group names to centrifydc.conf", this group policy modifies the nss.group.ignore setting in the DirectControl configuration (centrifydc.conf).

If you select "Populate group names to group.ignore", this group policy modifies the nss.group.ignore setting in centrifydc.conf as "file:/etc/centrifydc/group.ignore", and populates all configured group names to the group.ignore file. If you enter the file: keyword and a file location instead of the list of group names, this policy restores the ignore file /etc/centrifydc/group.ignore with the local list.

> **Note**: The selection of the populating location was added after DirectControl Agent version 5.6. If you're using version 5.5 or earlier, the agent ignores the population location setting and populates the user names to centrifydc.conf.

Specify the Certificate Files to Add (Lookup)

Define a list of certificate files which will be included in the certgp.pl install, if found.

It can be a list of certificates to be added. For example:

gp.mappers.certgp.pl.additional.cafiles: <ca-file> <ca-file> ...

It can also point to a file that contains a list of certificate files to be added. For example:

gp.mappers.certgp.pl.additional.cafiles: file:/etc/centrifydc/cert_included.list

The default value is empty.

This group policy modifies the gp.mappers.certgp.pl.additional.cafiles setting in the agent configuration file.

Specify the Fingerprints of Certificate Files to Ignore (Lookup)

Define a certificate list which will be excluded from the certgp.pl install, if matched.

It can be a list of fingerprints of the certificates to be excluded. For example:

gp.mappers.certgp.pl.exclude.cacerts: \<fingerprint\> \<fingerprint\> ...

It can also point to a file that contains a list of fingerprints of the certificates to be excluded. For example:

gp.mappers.certgp.pl.exclude.cacerts: file:/etc/centrifydc/cert_excluded.list

The default value is empty.

Specify User Names to Ignore

You can enter the list of local user names that aren't stored in Active Directory and separate each name with a space. The service will then use this list to disable looking up Active Directory account information for the specified users. Ignoring this list of users results in faster name lookups for system user accounts, such as tty and disk.

You can also specify a file that lists the usernames by entering the file: keyword and a file location. For example:

```
file:/etc/centrifydc/user.ignore
```

When you enable this policy, you can select the location where the user name list is populated. The default setting is "Populate user names to centrifydc.conf".

If you select "Populate user names to centrifydc.conf", this group policy modifies the nss.user.ignore and pam.ignore.users settings in the DirectControl configuration file (centrifydc.conf).

If you select "Populate user names to user.ignore", this group policy modifies the nss.user.ignore and pam.ignore.users settings in centrifydc.conf as "file:/etc/centrifydc/user.ignore", and populates all configured user names to the user.ignore file. If you enter the file: keyword and a file location instead of the list of user names, this group policy restores the ignore file /etc/centrifydc/user.ignore with the local list.

> **Note**: The selection of the populating location was added after DirectControl Agent version 5.6. If you're using version 5.5 or earlier, the agent ignores the population location setting and populates the user names to centrifydc.conf.

Split Large Group Membership

Specify whether you want to split up or truncate large groups. In operating environments that don't support large groups, commands that return group information may fail or return incomplete results when a group has a membership list that exceeds the maximum size allowed. Typically, the maximum size allowed for groups is 1024 bytes, which is roughly equivalent to 125 users. If you have large groups that exceed the 1024-byte limit, you can set this parameter to true to have those groups automatically split into multiple groups when they reach the maximum size.

The default value is true for Solaris, HPUX, and IRIX but false for all other operating environments.

> **Note**: This policy has no effect in Mac OS X environments.

This group policy modifies the nss.split.group.membership setting in the agent configuration file.

MFA Settings

Use the group policies under **MFA Settings** to control the following multi-factor authentication configuration options.

Enable Multi-Factor Authentication for Auto Zone and Classic Zone

Specify whether multi-factor authentication is **Enabled** for a classic zone or an Auto Zone. If you enable this policy, you can specify which Active Directory users and groups require multi-factor authentication to log on to their computers or to use privileged commands using the following group policies:

- Specify AD Users that Require Multi-Factor Authentication
- Specify AD Groups that Require Multi-Factor Authentication

This policy does not affect multi-factor authentication settings in hierarchical zones.

Before enabling this policy, you should be aware that multi-factor authentication relies on the infrastructure provided by the Delinea Platform.

Muti-factor authentication is disabled by default.

This group policy modifies the adclient.legacyzone.mfa.enabled configuration parameter in the agent configuration file.

Note that on computers running Centrify Express agents, you must set this policy using the configuration parameter. Group policies are not supported for Express agents.

Set Background Fetch Interval for Groups that Require Multi-Factor Authentication

Use this group policy to specify how often the Centrify Agent updates the cache with the list of users and groups in classic zones and Auto Zones that require multi-factor authentication, as well as the list of rescue users.

This is a background process that updates the cache periodically according to the interval specified (in minutes).

To disable this process, set the interval value to 0.

The default policy value is 30 minutes.

> **Note**: On computers running Centrify Express agents, you must set this policy using the configuration parameter. Group policies are not supported for Express agents.

This group policy modifies the adclient.legacyzone.mfa.background.fetch.interval configuration parameter in the agent configuration file.

Specify Centrify Identity Platform Tenant ID for Multi-Factor Authentication

Use this policy to specify the Delinea Platform tenant ID for multi-factor authentication.

This policy applies to Auto Zones and classic zones only.

You can get the Delinea Platform tenant ID from your service registration.

This policy modifies the adclient.legacyzone.mfa.tenantid setting in the agent configuration file.

Specify AD Users that can Login when Multi-Factor Authentication is Unavailable

Use this policy to specify rescue users who can log on to computers in a classic zone or an Auto Zone when multi-factor authentication is required, but the agent cannot connect to the Delinea cloud service.

You should specify at least one user account for this policy to ensure that someone can access the computers in the event that multi-factor authentication is unavailable.

If you enable this policy, you can specify users by name in the following formats:

- SAM account name: sAMAccountName
- SAM account name of a user in a different domain: sAMAccountName@domain
- User Principal Name: name@domain
- Canonical Name: domain/container/cn
- Full DN: CN=commonName,...,DC_domain_component,
- DCdomain_component
- An asterisk (*), which includes all Active Directory users

By default, this policy does not specify any rescue users.

This group policy modifies the adclient.legacyzone.mfa.rescue.users configuration parameter in the agent configuration file.

Specify AD Groups that Require Multi-Factor Authentication

Specify the Active Directory groups in classic zones or Auto Zones that are required to use multi-factor authentication to log on or use privileged commands.

For example, if you want to require all members of the Qualtrak Admin group to use multi-factor authentication when they log on to computers that host sensitive information, you can specify that group in this policy. Groups specified in this parameter must be security groups. Distribution groups are not supported.

If you enable this policy, you can specify groups by name in the following formats:

- sAMAccountName
- sAMAccountName@domain
- domain/container/cn

By default, no groups are required to authenticate using multi-factor authentication.

> **Note**: On computers running Centrify Express agents, you must set this policy using the configuration parameter. Group policies are not supported for Centrify Express agents. This group policy modifies the adclient.legacyzone.mfa.required.groups configuration parameter in the agent configuration file.

Specify AD Users that Require Multi-Factor Authentication

Specify the Active Directory users in classic zones or Auto Zones that require multi-factor authentication to log on or use privileged commands.

If you enable this policy, you can specify users by name in the following formats:

- sAMAccountName
- sAMAccountName@domain
- userPrincipalName@domain
- domain/container/cn
- CN=commonName,...,DC=domain_component,DC=domain_component
- An asterisk (*), which includes all Active Directory users

By default, no users are required to authenticate using multi-factor authentication.

> **Note**: On computers running Centrify Express agents, you must set this policy using the configuration parameter. Group policies are not supported for Express agents.

This group policy modifies the adclient.legacyzone.mfa.required.users configuration parameter in the agent configuration file.

Specify Delinea Identity Platform URL for Multi-Factor Authentication

Specify which Delinea Platform instance URL the agent will access in order to implement multi-factor authentication for users in classic zones and Auto Zones.

Enable this policy if you have access to more than one instance URL. If you have multiple instance URLs and do not specify which one the agent should use for multi-factor authentication, MFA will fail.

If you only have a single platform instance URL for all of the connectors in your Active Directory forest, the agent will use this URL for multi-factor authentication by default, and you do not need to enable this policy.

When specifying a cloud URL, the URL should be in the following format:

```
https://tenantid.domainfqdn:port/
```

For example:

```
https://abc0123.mydomain.com:443/
```

Note that on computers running Centrify Express agents, you must set this policy using the configuration parameter. Group policies are not supported for Express agents.

This group policy modifies the `adclient.legacyzone.mfa.cloudurl` configuration parameter in the agent configuration file.

Network and Cache Settings

Use the group policies under **Network and Cache Settings** to control connection timeout and object expiration intervals.

Blacklist DNS DC Hostnames

Specify a list of domain controllers to filter out when resolving the domain controller for the agent to contact through DNS. Set this policy to prevent the agent from attempting to contact a domain controller that you know is inaccessible, for example, because it resides behind a firewall, or from contacting a domain controller that is inappropriate because of its physical location, or because it is no longer a valid domain controller for the site.

To specify a domain controller, select **Enabled**, then click **Add** and enter the fully qualified name of a domain controller. For example:

wink2-admin13@ajax.com

You may enter only one controller at a time. To remove a controller from the list, select it and click **Remove**.

This group policy modifies the dns.block setting in the agent configuration file.

Enable LDAP Cross-Forest Search

Specify whether to allow the Centrify Agent to query trusted domains and forests for transitive trust information. If you enable this policy by selecting the **LDAP Cross-Forest Search** box, the agent generates a krb5.conf that includes information from all trusted forests and can be used to authenticate cross-forest users to Kerberos applications. If you disable this policy, the agent does not query external trusted domains or forests for information.

By default, the configuration parameter set by this policy is **Enabled**.

Querying external trusted forests can take a significant amount of time if the other forests are blocked by firewalls. You may want to set this parameter to false if your trust relationships, network topology, or firewalls are not configured properly for access.

This group policy modifies the adclient.ldap.trust.enabled setting in the agent configuration file.

Enable User Lookup and Login by CN

Specify whether you want to allow users to be found by their common name (cn) attribute.

By default, Centrify allows users to login using their Linux, UNIX, or Mac OS X profile name. In addition, Linux and Unix users can use their Active Directory displayName or Active Directory cn attribute (default value is disabled for Mac OS X users). Allowing users to log on using these additional attributes can require the agent to perform multiple searches to locate a user account in Active Directory. In environments with domain controllers under heavy load or with large user populations, searching Active Directory multiple times may negatively impact performance.

If you want to prevent the Centrify Agent from attempting to access to user information by the common name, you can disable this policy.

This group policy modifies the adclient.user.lookup.cn setting in the agent configuration file.

Enable User Lookup and Login by displayName

Specify whether you want to allow users to be found by their display name (displayName) attribute.

By default, Centrify allows users to login using their Linux, UNIX, or Mac OS X profile name. In addition, Linux and Unix users can use their Active Directory displayName or Active Directory cn attribute (default value is disabled for Mac OS X users). Allowing users to log on using these additional attributes can require the agent to perform multiple searches to locate a user account in Active Directory. In environments with domain controllers under heavy load or with large user populations, searching Active Directory multiple times may negatively impact performance.

If you want to prevent the Centrify Agent from attempting to access to user information by the display name, you can disable this policy.

This group policy modifies the adclient.user.lookup.display setting in the agent configuration file.

Force DNS to Use TCP

Force all DNS requests to use TCP rather than UDP. The initial size of the buffer is determined by the Set DNS UDP buffer size group policy (if you have enabled it), but the size will be increased, if necessary, for a specific response.

This group policy modifies the `dns.forcetcp` setting in the agent configuration file.

Force DNS to Rotate

Force all DNS queries to rotate through the list of servers in the /etc/resolv.conf file.

This group policy modifies the dns.rotate setting in the agent configuration file.

Force Switching to Different Domain Controller in the Preferred Site Periodically

This group policy specifies whether to force LDAP binding to be refreshed even if the current binding is to a local (preferred) Active Directory site. Under some conditions, binding to a different site can help facilitate load balancing between servers.

If you set this policy to **Enabled**, the agent will attempt to connect to another local domain controller when the period specified in the configuration parameter, adclient.binding.refresh.interval expires.

If this policy is set to **Disabled** or **Not configured**, by default, the agent will not attempt to connect to another domain controller if it is already connected to a preferred Active Directory site.

This group policy modifies the adclient.binding.refresh.force parameter in the agent configuration file.

Set Cache Negative Life Time

Specify the maximum time, in minutes, a negative object should remain in the cache. A negative object is returned when an object is not found in a search result. This policy determines how long that negative result should remain in the cache, regardless of the object type or object expiration time. By storing this negative result in the cache, the agent does not need to connect to Active Directory to look for an object that was previously not found.

The default period of time for keeping negative results is 5 minutes. Setting the policy value to 0 keeps negative objects in the cache indefinitely.

This group policy modifies the adclient.cache.negative.lifetime setting in the agent configuration file.

Set DNS Cache Size

Use this group policy with agent versions earlier than 4.5. This feature was deprecated starting with agent version 4.5.

Specify the unique number of DNS requests that can be cached by adclient. Set this value to approximately 10 times the number of unique domains in the forest.

This group policy modifies the adclient.dns.cache.size setting in the agent configuration file.

Set DNS Cache Timeout

Use this group policy with agent versions 4.5 and later. With agent versions earlier than 4.5, use the **Set DNS cache timeout (deprecated)** group policy.

Specify the maximum time, in seconds, before a cached DNS response expires. The default value is 300 seconds.

This group policy modifies the dns.cache.timeout setting in the agent configuration file.

Set DNS Cache Timeout (Deprecated)

Use this group policy with agent versions earlier than 4.5. This feature was deprecated starting with agent version 4.5. With agent versions 4.5 and later, use the **Set DNS cache timeout** group policy.

Specify the maximum time, in seconds, before a cached DNS response expires. The default value is 300 seconds.

This group policy modifies the adclient.dns.cache.timeout setting in the agent configuration file.

Set DNS UDP Buffer Size

Specify the maximum size of a UDP request in bytes. If the response is larger than this size, switch to TCP. If you have set the Force DNS to use TCP policy (dns.forcetcp parameter), the value you set here for the UDP buffer is the initial size of the TCP request buffer; the size will automatically be increased, if necessary, for a specific response.

The default value is 4096; the minimum is 512.

This group policy modifies the dns.max.udp.packet setting in the agent configuration file.

Set Domain DNS Refresh Interval

Use this group policy with agent versions earlier than 4.5. This feature was deprecated starting with agent version 4.5.

Specify the number of minutes between DNS updates. Specify a positive integer. The default value is 15 minutes.

This group policy modifies the `adclient.dns.update.interval` setting in the agent configuration file.

Set GC Expiration

Specify the maximum time, in seconds, that Distinguished Names are kept in the global catalog cache.

This group policy modifies the adclient.cache.expires.gc setting in the centrifydc.conf configuration file. By default, this parameter is set to 3600 seconds (1 hour).

Set Group Object Expiration

Specify the maximum time, in seconds, that a group object is kept in the local cache.

This group policy modifies the adclient.cache.expires.group setting in the agent configuration file. By default, this parameter is not defined in the configuration file, in which case, the value is determined by the Set Object Expiration group policy. If Set object expiration is not enabled, the default value is 3600 seconds (1 hour).

Set Idle Client Timeout

Specify the maximum time, in seconds, to wait before the agent closes a connection to an inactive client.

> **Note**: You must restart adclient for this policy to take effect.

This group policy modifies the adclient.client.idle.timeout setting in the agent configuration file.

Set LDAP Connection Timeout

Specify the maximum time, in seconds, for the agent to wait for a connection to an LDAP server to be established.

This group policy modifies the adclient.ldap.socket.timeout setting in the agent configuration file.

Set LDAP Response Timeout

Specify the maximum time, in seconds, for the agent to wait for a response from an LDAP server.

This group policy modifies the adclient.ldap.timeout setting in the agent configuration file.

Set LDAP Search Timeout

Specify the maximum time, in seconds, that the Active Directory Client Service will wait for a search response from an LDAP server.

This group policy modifies the adclient.ldap.timeout.search setting in the agent configuration file.

Set LDAP Trust Timeout

Specify the maximum number of seconds to wait for responses from external forests and trusted domains when attempting to determine trust relationships. If your trusted domains and forests are widely distributed, have slow or unreliable network connections, or are protected by firewalls, you may want to increase the value for this parameter to allow time for the agent to collect information from external domains and forests. The default value, if you do not set this policy, is 5 seconds.

This group policy modifies the adclient.ldap.trust.timeout setting in the agent configuration file.

Set LRPC Response Timeout

Specify the maximum time, in seconds, for an LRPC client to wait for a response.

This group policy modifies the `lrpc.timeout` setting in the agent configuration file.

Set LRPC2 Receive Timeout

Specify the maximum time, in seconds, for the agent to wait to receive data coming from a client request.

The default value is 30 seconds.

This group policy modifies the adclient.lrpc2.receive.timeout setting in the agent configuration file.

Set LRPC2 Send Timeout

Specify the maximum time, in seconds, for the agent to wait for reply data to be sent in response to a client request.

This group policy modifies the `adclient.lrpc2.send.timeout` setting in the agent configuration file.

Set Maximum Server Connection Attempts

Specify the maximum number of servers per domain the agent should attempt to connect to before going into disconnected mode. This policy is used if the agent is unable to connect to it's primary domain controller to enable it to query DNS for a list of other domain controllers and try each server in the list up to the maximum number of servers you specify. For example, if you have a large number of replica domain controllers for a given domain, you may want to use this policy to limit the number of servers for the agent to try in order to limit network traffic and improve performance.

The value should be a positive integer or 0. Setting the value to 0 means that the agent attempts to connect to every server in the list until successful.

The default value is 0.

This policy is ignored if you have defined a master domain controller for the zone to which the computer belongs because the computer only connects to that domain controller.

This group policy modifies the adclient.server.try.max setting in the agent configuration file.

This setting is deprecated for versions of adclient from 4.4.3 to 5.0.x. It is available in version 5.1.0 and later.

Set Object Expiration

Specify the maximum time, in seconds, before an object in the local cache expires. This expiration period applies to any object for which you have not set an object-specific expiration time, except Set GC Expiration, which has its own default value.

This group policy modifies the adclient.cache.expires setting in the agent configuration file. The default is 3600 seconds (1 hour).

Set Refresh Interval for Access Control Cache

Specify the maximum number of minutes to keep information from the authorization store cached before it expires.

The authorization store is an Active Directory object that stores the rights, roles, and role assignments that the privilege elevation service uses to control access to dzdo privileged commands, dzsh restricted environments, and PAM-enabled applications. Because the agent handles connecting to and retrieving information from Active Directory, this configuration parameter controls how frequently adclient retrieves the privilege elevation service set of information from Active Directory if any such data has been modified in Active Directory.

If local account management is enabled, this group policy also specifies how often etc/group and etc/passwd are updated on UNIX and Linux computers, based on the local group and local user settings that you configure in Access Manager.

If this policy is not **Enabled**, the default is 30 minutes.

Starting with agent version 5.1.3, this group policy modifies the adclient.refresh.interval.dz setting in the agent configuration file.

> **Note**: Prior to agent version 5.1.3, this group policy modified the adclient.azman.refresh.interval setting. That setting was deprecated in version 5.1.3.

Set UDP Timeout

Specify the maximum number of seconds to allow to complete UDP binding. The agent will attempt to bind twice. If the first bind request is not complete within the period specified by this policy, the agent sends a second request with a timeout period that is double the setting of this policy. If both bind requests fail to complete within the allotted time, the agent sets its status to disconnected.

For example, if you set this policy to 10 seconds and the bind request is not complete within 10 seconds, the agent sends a second bind request and waits a maximum of 20 seconds for the bind to complete before assuming the computer is disconnected from the network or Active Directory is unavailable.

The default value for this policy is 15 seconds.

This group policy modifies the `adclient.udp.timeout` setting in the agent configuration file.

Set User Object Expiration

Specify the maximum time, in seconds, that a user object is kept in the local cache.

This group policy modifies the adclient.cache.expires.user setting in the agent configuration file. By default, this parameter is not defined in the configuration file, in which case, the value is determined by the Set Object Expiration group policy. If Set object expiration is not enabled, the default value is 3600 seconds (1 hour).

Specify AD to NTLM Domain Mappings

Use the Specify AD to NTLM domain mappings group policy to manually map Active Directory domain names to NTLM domains. This parameter is useful when you need to use NTLM authentication and:

- firewalls prevent Kerberos authentication
- firewall constraints prevent the automatic discovery of Active Directory to NTLM domain mapping

To set this group policy, select **Computer Configuration > Centrify Settings > DirectControl Settings > Network and Cache Settings > Specify AD to NTLM domain mappings**.

Provide the following information for the group policy:

- One or more pairs with ActiveDirectory domain name and NTLM domain name.
- Optionally, provide a file with a list of AD to NTLM domain name pairs. Include the file location. Use separate lines for each pair in the file. For example:

```
AJAX.ORG:AJAX FIREFLY.COM:FIREFLY
HR1.FIREFLY.COM:HR1
```

After you defined the mapping of Active Directory domains to NTLM domains, you can specify the list of domains that use NTLM authentication instead of Kerberos authentication. Use either the group policy, **Specify NTLM authentication domains** or the configuration parameter, pam.ntlm.auth.domains.

Alternative to using this group policy, **Specify AD to NTLM domain mappings**, you can use the adclient.ntlm.domains configuration parameter.

Specify DNS DC Hostnames

Specify the domain controller host names if your DNS is not configured to use Active Directory. In most cases, you should not use this group policy in a production environment because Active Directory automatically updates DNS with fail-over and replica servers optimized for the Active Directory site configuration. This group policy is used primarily for configuring an evaluation environment when the DNS server is on a Linux, UNIX, or Mac OS X computer and can't provide the _ldap service records.

The domain controller name must be resolvable using either DNS or in the local /etc/hosts file. Therefore, you must add entries to the local /etc/hosts for each domain controller you want to use if you are not using DNS or if the DNS server cannot locate your domain controllers.

To specify DC host names:

After enabling this group policy, click **Add**, then enter the following information:

Domain: The domain name, for example, acme.com.

DC hostnames separated by space: One or more hostnames in the domain, for example, qa1-winxp, admin-winxp

Click **OK** to add the specified hostnames.

You can click **Add** again to add hosts from a different domain.

When you are done, click **OK**.

Once you've added one or more hostnames, you can select an existing domain and click **Edit** or **Remove** to edit or remove the specified hosts.

This group policy modifies the dns.dc.*domain_name* setting in the agent configuration file.

Specify DNS GC Hostnames

Specify the domain controller used as the global catalog if your DNS is not configured to use Active Directory. In most cases, you should not use this group policy in a production environment because Active Directory automatically updates DNS with fail-over and replica servers optimized for the Active Directory site configuration. This group policy is used primarily for configuring an evaluation environment when the DNS server is on a Linux, UNIX, or Mac OS X computer and can't provide the _gc service records.

The domain controller name must be resolvable using either DNS or in the local /etc/hosts file. Therefore, you must add entries to the local /etc/hosts for each domain controller you want to use if you are not using DNS or if the DNS server cannot locate your domain controllers.

To specify GC hostnames:

After enabling this group policy, click **Add**, then enter the following information:

Domain: The domain name, for example, acme.com.

GC hostnames separated by space: One or more hostnames in the domain, for example, qa1-winxp, admin-winxp

Click **OK** to add the specified hostnames.

You can click **Add** again to add hosts from a different domain.

When you are done, click **OK**.

Once you've added one or more hostnames, you can select an existing domain and click **Edit** or **Remove** to edit or remove the specified hosts.

This group policy modifies the dns.gc.*domain_name* setting in the agent configuration file.

Specify IP Port Range that adclient Should Use

You can use this policy to specify the low and high ends of the range of IP ports for adclient and adnisd to use. These parameters control the outbound connection port for both TCP and UDP connections.

By specifying an IP port range, you can then configure your firewall to allow traffic through that port range only.

The typical port number is between 1024 and 65535. Setting this parameter does require a restart of adclient.

NIS Daemon Settings

Use the group policies under **NIS daemon** to control the operation of the Delinea Network Information Service (adnisd) on the local host computer. The Delinea Network Information Service provides a mechanism for the agent to respond to NIS client requests from computers not managed by Centrify Agents.

Set Thread Number for NIS Daemon

Specify the number of threads that may run simultaneously for the Centrify Network Information Service (adnis) on the local computer.

After enabling the policy, type a number or use the arrow keys to select a value. You must specify an integer between 1 - 200 inclusive. If you type a value outside this range, it is automatically reset to a valid number when you click **OK** or **Apply**.

The default value is 4 threads.

This group policy modifies the nisd.threads setting in the agent configuration file.

Specify NIS Daemon Update Interval

Specify the interval, in seconds, that the adnisd daemon waits between connections to Active Directory. At each interval, the adnisd daemon connects to Active Directory, gets the latest NIS maps for the local computer's zone, and updates its local NIS map data store.

The value must be an integer equal to or greater than zero. If the value is zero, then the update interval is disabled and the local NIS map data store is not updated. For example, to set the interval for getting NIS maps to 1 hour:

3600

If this group policy is not enabled, the default interval is 30 minutes (1800 seconds).

This group policy modifies the nisd.update.interval setting in the agent configuration file.

Specify Allowed NIS Mapping Files for NIS Daemon

Specify the name of the NIS maps currently available for NIS service. When the adnisd daemon connects to Active Directory, it retrieves the list of NIS maps available for the local computer's zone, creates a local map data store, and updates this configuration parameter, if necessary, to indicate the maps retrieved. If any NIS client requests a map that is not in the list specified by this group policy, the daemon refuses the request.

Enter a list of valid NIS map names, separated by spaces. You must explicitly specify the base maps and the derived maps. For example, to make the netgroup maps available but no other maps, enable this group policy and specify the following maps:

netgroup netgroup.byhost netgroup.byuser

If this group policy is not defined, all NIS maps found in Active Directory are retrieved and available for service.

This group policy modifies the nisd.maps setting in the agent configuration file.

Specify Disallowed NIS Mapping Files for NIS Daemon

Specify the name of the NIS maps you want to prevent the NIS service from using in response to NIS clients. This group policy enables you to exclude specific maps rather than explicitly specifying the maps you want to make available. For example, if you have a large number of automount maps or other network information that you want to make available to NIS clients but do not want to use agentless authentication, you can use this parameter to exclude the passwd and group maps but respond to automount or netgroup requests.

Enter a list of valid NIS map names, separated by spaces. Note that this policy excludes the named map and all derived maps; for example:

```
group passwd
```

If you do not enable this group policy, all NIS maps found in Active Directory are retrieved and available for service. This group policy overrides the setting of the Specify allowed NIS mapping files for NIS daemon.

This group policy modifies the nisd.exclude.maps setting in the agent configuration file.

Specify Allowed Client Machines for NIS Daemon

Specify a list of one or more subnets from which the daemon will accept NIS requests. You enable this group policy to restrict access to the Centrify Network Information Service by IP address. NIS requests that do not come from the IP addresses specified in this group policy are refused by the adnisd daemon.

You do not need to specify the local IP address for this group policy. The Centrify Network Information Service will always accept local NIS client requests.

The value must include both the specific IP address or subnet and the subnet mask, separated by a forward slash. For example:

192.168.111.0/255.255.255.0

You can specify multiple IP addresses by separating each IP address-subnet mask pair with a comma or a space. For example:

192.68.11.0/255.255.255.0,192.147.10.0/255.255.255.0

If this group policy or the parameter it modifies is not defined in the configuration file, only local NIS client requests are accepted by the adnisd process. When you enable this group policy, the default value is 0/0 to allow all machines.

This group policy modifies the nisd.securenets setting in the agent configuration file.

Set Switch Delay Time for NIS Daemon

Specify how long, in seconds, to wait before loading maps from a backup domain controller when the connection to the primary domain controller is lost. If the Centrify Network Information Service is unable to connect to its primary Active Directory domain controller, it will respond to NIS client requests using information in the local cache until the switch to the backup domain controller is complete.

The value must be an integer equal to or greater than zero. If the value is zero, then the delay is disabled. For example, to set the delay period to 2 hours, enter:

7200

If group policy is not enabled, the default delay for switching to the backup domain controller is ten minutes (600 seconds).

This group policy modifies the nisd.server.switch.delay setting in the agent configuration file.

Set Maximum Number of Mapping Files Allowed for NIS Daemon

Specify the number of alternate sets of NIS maps to retain. A new set of NIS maps is normally created when adnisd switches to an alternate domain controller. Keeping these alternate sets of maps allows Centrify Network Information Service to more efficiently switch between domain controllers.

You must specify an integer value greater than zero. The default is 2 map sets.

This group policy modifies the nisd.maps.max setting in the agent configuration file.

Set Large Group Suffix for NIS Daemon

Specify the suffix string or character to use in group names when automatically splitting up a group with a large number of members.

Because group.bygid and group.byname NIS maps often contain membership lists that exceed the 1024 limit of NIS data that can be served to clients, the adnisd process automatically truncates the membership list when this limit is reached. When you enable this group policy, the Centrify Network Information Service automatically splits a large group into as many new groups as needed to deliver the complete membership list.

When a group's data size exceeds the 1024 data limit, a new group is created. The new group name is formed using the original group name, followed by the string defined for this policy, and ending in a number that represents the numeric order of the new group created.

For example, for a large group named performix-worldwide-corp, a suffix string defined as -all, and the maximum length for group names as 10, the performix-worldwide-corp group membership is split into these multiple groups:

performix-worldwide-corp-all1 performix-worldwide-corp-all2 performix-worldwide-corp-all3 performix-worldwide-corp-all4

All of the new groups have the same group identifier (GID) as the original group. If the new group names would exceed the maximum length for group names on a platform, you can use the Set large group name length for NIS daemon group policy to set the maximum length for the new groups created.

If this policy is not enabled, the adnisd process truncates the group membership list such that each group entry is under 1024 characters.

This group policy modifies the nisd.largegroup.suffix setting in the agent configuration file.

Set Large Group Name Length for NIS Daemon

Specify the maximum number of characters to use in group names when groups with a large number of members are split into multiple new groups. Because some devices that submit NIS requests have limitations on the length of group names, you can use this parameter to specify the maximum length for group names.

When the adnisd process splits the group membership for a large group into multiple smaller groups, it truncates the original group name as needed to append the suffix defined in the Set large group suffix for NIS daemon group policy and not exceed the number of characters specified by this group policy. For example, if you have a large group named worldwide-all-corp, and have defined the suffix string as -all and the maximum length for group names as 10, when the worldwide-all-corp group membership is split into multiple groups, the groups are named as follows:

world-all1 world-all2 world-all3 world-all3

If this group policy is not enabled, the maximum group name length is 1024 characters by default.

This group policy modifies the nisd.largegroup.name.length setting in the agent configuration file.

Set Domain Name for NIS Daemon

Specify the NIS domain name for the adnisd process to use when communicating with NIS clients.

If you do not enable this group policy, the zone name is used by default.

This group policy modifies the nisd.domain.name setting in the agent configuration file.

Set Startup Delay Time for NIS Daemon

Specify the maximum time (in seconds) that adnisd will wait before answering NIS requests. If this policy is not enabled, adnisd begins answering requests only after all maps have been loaded or created, or when the default value, 180 seconds is reached, whichever comes first. If you set this policy, adnisd will begin answering NIS requests no later than the specified delay, as follows:

Before the delay time is reached, if all maps have not been loaded or created, requests are blocked waiting for the specified delay.

Once the delay time is reached, requests are answered whether all maps are loaded or not. Be aware that clients may receive partial or empty answers to their requests.

If all maps are loaded or created before the delay time is reached, adnisd will immediately begin answering requests.

Specify a value between 0 and 100000. If you enable the policy and do not change the value, the default is 180 seconds.

This group policy modifies the nisd.startup.delay setting in the agent configuration file.

NSS Overrides

Use the group policies under **NSS Overrides** to override entries in the local /etc/passwd or /etc/group files. These group policies provide additional access control and account configuration options on the computers where the policies are applied.

Specify NSS Group Overrides

Specify the group override entries you want to use in place of the entries in the local /etc/group file. You can use these settings to provide fine-grain control of the groups that can use the computer and to override the group ID for specific group accounts.

This group policy modifies the nss.group.override setting in the agent configuration file.

This group policy allows define filters to control the groups that can access a local computer. You can also use the override controls to modify the information for specific fields in each group entry on the local computer. For example, you can override the group ID or member list for a specific group on the local computer without modifying the group entry itself.

The syntax for overriding group entries is similar to the syntax used for overriding NIS. You use + and – entries to allow or deny access for specific groups on the local computer. Additional fields correspond to the standard /etc/group fields separated by colons (:).

> **Note**: If you don't specify override information for a field, the information from the local /etc/group file is used. You cannot specify override information for the password hash field, however. Any changes to this field in the override file are ignored and do not affect Centrify user passwords.

If you select **Enabled** for the **Specify NSS group overrides** group policy, you can type a comma-separated list of the override entries you want inserted into the override file, group.ovr, using the following format for each entry:

```
+zone_group_name:group_name:group_password:group_id:member_list

-zone_group_name:group_name:group_password:group_id:member_list
```

For example, you can specify entries similar to the following:

```
+users::::

+admins::::jdoe,bsmith,frank

+ftpusers:ftp::300:

-webusers

+::::
```

For more information about overriding group entries, see the sample group override file /etc/centrifydc/group.ovr.

Specify NSS Password Overrides

Specify the passwd override entries you want to use in place of the entries in the local /etc/passwd file. You can use these settings to provide fine-grain control of the users and groups who can use the computer and to override the user ID, group ID, default shell, or home directory for specific login accounts.

This group policy modifies the nss.passwd.override setting in the agent configuration file.

This group policy allows you to define filters to control access to a local computer. You can also use override controls to modify the information for specific fields in each /etc/passwd entry on the local computer. For example, you can override the user ID, primary group ID, default shell, or home directory for specific login accounts on the local computer without modifying the account entry itself.

The syntax for overriding passwd entries is similar to the syntax used for overriding NIS. You use + and – entries to allow or deny access for specific users on the local system. Additional fields correspond to the standard /etc/passwd fields separated by colons (:).

> **Note**: If you don't specify override information for a field, the information from the local /etc/passwd file is used. You cannot specify override information for the password hash field, however. Any changes to this field in the override file are ignored and do not affect Centrify user passwords.

If you select **Enabled** for the **Specify NSS password overrides** group policy, you can type a comma-separated list of the override entries you want inserted into the override file, passwd.ovr, using the following format for each entry:

```
+zone_username:username:password:uid:gid:GECOS:home_directory:shell

-zone_username:username:password:uid:gid:GECOS:home_directory:shell
```

For example, you can specify entries similar to the following:

```
+mike:::::::/usr/local/ultrabash

+jane@arcade.org:jdoe::300:300:::

+@sysadmins:::::::

-ftp

+@staff:::::::

+@rejected-users:::767:767:::/sbin/nologin
```

In the example above, the @ symbol denotes an Active Directory name. The name can be an Active Directory group name, a Centrify zone name, or some other container name. You can also specify an Active Directory user principal name (UPN) instead of the zone name.

Entries in the override file are evaluated in order from first to last with the first match taking precedence. This means the system will only use the first entry that matches a particular user. For example, if the user cruz is a member of both the staff group and the rejected-users group and you have defined the override entries as listed in the example above, the cruz user account is allowed to log on to the computer because the staff entry is evaluated and matched before the rejected-users entry. If the order were reversed in the override file, the cruz`` account would be flagged as a rejected-users account and denied access.

It is important, therefore, to consider the order in which you list the override entries in the group policy configuration. The order you use to specify the entries in the group policy is the order used when the entries are inserted into the override file.

Changes to the NSS password override entries only affect the entries inserted through the group policy. You can also manually create or update override entries in the override file on any local computer, if needed. Changes made to manually inserted or edited entries do not affect the entries maintained through the NSS Overrides group policies.

For more information about overriding passwd entries, see the sample password override file /etc/centrifydc/passwd.ovr.

PAM Settings

Use the group policies under **Pam Settings** to control a computer's PAM configuration.

Create Home Directory

Control whether a home directory should be created automatically when a new user logs on to a system for the first time.

This group policy should not be applied to computers that use NFS to mount home directories. By default, if this group policy is not configured, home directories are automatically created when new Active Directory users log on to a system for the first time except on Solaris computers.

If you do not want the Centrify Agent to automatically create user home directories, select **Disabled**. This group policy modifies the pam.homedir.create setting in the agent configuration file.

Create k5login

Create a .k5login file automatically in a user's home directory the first time the user logs on.

The .k5login file is used to enable Kerberos authentication and single sign-on in PAM-aware applications.

If you want Centrify Agent to automatically create the .k5login file in the user's home directory, select **Enabled**. This group policy modifies the pam.create.k5login setting in the agent configuration file.

Set Home Directory Permissions

Set the default read, write, and execute permissions on new home directories.

This group policy specifies the default permissions to assign a user's home directory if a new home directory is created for the user on the local computer.

If you want to set the permissions on the user's home directory, select **Enabled** then specify an octal value. For example, to give read, write, and execute permissions on the home directory to the user and no other permissions, type:

```
0700
```

This group policy modifies the `pam.homedir.perms` setting in the agent configuration file. The default value is `0755` on Mac OS X computers and `0700` on all other platforms.

Set Multi-Factor Authentication to Use an External PAM Module

This policy specifies the PAM application you want to use for multi-factor authentication if you are not using the Centrify PAM module and Privileged Access Service.

By default, the Centrify PAM module and Privileged Access Service are used to provide multi-factor authentication. This group policy allows you to specify the name of another PAM module if you would prefer to use a different multi-factor authentication provider.

This group policy modifies the pam.mfa.moduile.name setting in the agent configuration file.

Set Options for Multi-Factor Authentication by an External PAM Module

Specify the options to use if multi-factor authentication is done by an external PAM application.

> **Note**: Parameters must be separated by a space.

This group policy modifies the pam.mfa.module.options setting in the agent configuration file.

Set UID Conflict Message

Specify the message displayed if a user identifier (UID) conflict is detected during login. This message is displayed if there is a local user with the same UID but a different user name than the Active Directory user logging on.

When the message is displayed, the `%d` token in the message string is replaced with the UID of the conflicting local account. The message string you define must contain exactly one `%d` token, and no other string replacement (%) characters.

For example:

```
Account with conflicting UID (%d) exists locally
```

This group policy modifies the `pam.account.conflict.uid.mesg` setting in the agent configuration file.

For information about what to do when local conflicts are detected, see Set UID Conflict Resolution.

Set UID Conflict Resolution

Control how the Centrify Agent responds if a user logs on with an Active Directory account and either the Active Directory user name or Active Directory UID conflicts with a local user account.

The purpose of detecting a duplicate user name or duplicate UID is to prevent an Active Directory user from signing on and receiving privileges to modify files created by a different local user.

If you select **Enabled** for this group policy, you can choose one of the following options:

- ignore — Do not report duplicate user names or UID conflicts. If detected, log the conflict at the info level if logging is enabled.
- warn — Warn the user of the user name or UID conflict after a successful login. Log the conflict at warning level if logging is enabled. This is the default value.
- error — Report UID conflict to user after user name is entered. Don't accept password. Don't allow log in. Log conflict at error level.

This group policy modifies the pam.uid.conflict setting in the agent configuration file.

Set User Name and UID Conflict Message

Specify the message displayed if there are both user name and user ID conflicts detected during login. This message is displayed if there are two local account conflicts. For example, this message is displayed if there is a local user and the Active Directory user that have the same UID but different user names, and there is also another local account with the same user name as the Active Directory user but the two accounts have different UID values.

When the message is displayed, the `%s` token in the message string is replaced with the name of the first conflicting local account, and the `%d` token is replaced with the UID of the second conflicting local account. The message string you define must contain exactly one `%s` token and exactly one `%d` token, in that order, and no other string replacement (%) characters.

For example:

```
Accounts with conflicting name (%s) and UID (%d) exist locally
```

This group policy modifies the `pam.account.conflict.both.mesg` setting in the agent configuration file.

For information about what to do when local conflicts are detected, see Set UID Conflict Resolution.

Update Home Directory Ownership

Use this policy to specify whether or not to update the home directory ownership when the user logs in.

The default value is false.

> **Note**: You must set the pam.homedir.create parameter to true (the default value) for this policy to work.

Set User Name Conflict Message

Specify the message displayed if a user name conflict is detected during login. This message is displayed if there is a local user with the same user name but a different UID than the Active Directory user logging on.

When the message is displayed, the `%s` token in the message string is replaced with the name of the conflicting local account. The message string you define must contain exactly one `%s` token, and no other string replacement (%) characters.

For example:

```
Account with conflicting name (%s) exists locally
```

This group policy modifies the `pam.account.conflict.name.mesg` setting in the agent configuration file.

For information about what to do when local conflicts are detected, see Set UID Conflict Resolution.

Specify Message for Creating Home Directory

Specify the message to display when a user's home directory is created.

For example:

```
Creating home directory ...
```

This group policy modifies the pam.homedir.create.mesg setting in the agent configuration file.

Specify NTLM Authentication Domains

Use the Specify NTLM authentication domains group policy to specify the list of domains that use NTLM authentication instead of Kerberos authentication.

This group policy enables you to authenticate users behind a firewall when the Kerberos ports are blocked, but a trust relationship exists between domains inside and outside the firewall.

For example, use this group policy to specify that the Active Directory domains AJAX.ORG and FIREFLY.COM, which are outside of the firewall with a one-way trust to the forest inside the firewall, use NTLM authentication.

To set this group policy, select **Computer Configuration > Centrify Settings > DirectControl Settings > Pam Settings > Specify NTLM authentication domains**.

Provide the following information for the group policy:

- One or more fully-qualified Active Directory domain names.
- The Active Directory domain names that are mapped to NTLM domain names.

  These can be mapped automatically or manually:

  * automatically, if the firewall does not prevent the mapping from being discovered.
  * manually, if the firewall prevents the mapping from automatically being discovered, by modifying the contents of the `/etc/centrifydc/domains.conf` file.

  To manually configure the mapping use either the group policy, **Specify AD to NTLM domain mappings**, or the configuration parameter, adclient.ntlm.domains.

Alternative to using this group policy, **Specify NTLM authentication domains**, you can use the configuration parameter, pam.ntlm.auth.domains.

Specify Programs for which Multi-Factor Authentication is Ignored

Specify which PAM applications are exempt from multi-factor authentication.

For example, if you have a role with the login-all PAM application right and have selected the “Multi-factor authentication required” system right, you can use this group policy to bypass multi-factor authentication for programs that don't support it. You can also add program names to this list to skip multi-factor authentication when you wan to make specific exceptions to the MFA requirement.

By default, programs which are known to be unable to support multi-factor authentication are included in the list. For example, multi-factor authentication is ignored by default for the xscreensaver and vsftpd programs.

> **Note**: Program names must be separated by a space.

This group policy modifies the pam.mfa.program.ignore setting in the agent configuration file.

Password Prompts

Use the group policies under **Password Prompts** to customize the prompts displayed when Active Directory users are prompted to provide their password.

Set Account Disabled Error Message

Customize the text displayed during login if a user is denied access because the user's account is disabled. This group policy modifies the pam.account.disabled.mesg setting in the agent configuration file.

Set Account Expired Error Message

Customize the text displayed during login if a user is denied access because the user's account has expired.

This group policy modifies the pam.account.expired.mesg setting in the agent configuration file.

Set Account Locked Message for adpasswd

Customize the text displayed by the adpasswd program when users cannot change their password because their account is locked. This group policy modifies the adpasswd.account.disabled.mesg setting in the agent configuration file.

Set adclient Inaccessible Message

Customize the message displayed during password change, for a local Linux, UNIX, or Mac OS X user who is mapped to an Active Directory account, when the agent (adclient) is not accessible. This group policy modifies the pam.adclient.down.mesg setting in the agent configuration file.

Set Password Change Disallowed Message for adpasswd

Customize the text displayed by the adpasswd program when users are not allowed to change their password because password change for these users has been disabled in Active Directory. This group policy modifies the adpasswd.password.change.disabled.mesg setting in the agent configuration file.

Set Invalid User or Password Message for adpasswd

Customize the text displayed by the adpasswd program when a user enters an account name that is not recognized or an invalid password. This group policy modifies the adpasswd.account.invalid.mesg setting in the agent configuration file.

Set Permission Denied Message for adpasswd

Customize the text displayed by the adpasswd program when a user cannot change another user's password because of insufficient permissions. This group policy modifies the adpasswd.password.change.perm.mesg setting in the agent configuration file.

Set Lockout Error Message

Customize the text displayed when a user account is locked out. This group policy modifies the pam.account.locked.mesg setting in the agent configuration file.

Set Error Message for Empty Password Entered

Customize the text displayed when a user enters an empty password. Empty passwords are not allowed. This group policy modifies the pam.password.empty.mesg setting in the agent configuration file.

Set New Password's Mismatch Error Message for Password Change

Customize the text displayed during password change when the new passwords entered do not match. This group policy modifies the pam.password.new.mismatch.mesg setting in the agent configuration file.

Set Notification Text for Password Change

Customize the text displayed when Active Directory users attempt to change their password. This group policy modifies the pam.password.change.mesg setting in the agent configuration file.

Set Old Password Incorrect Error Message for Password Change

Customize the text displayed during password change when the old password entered is incorrect. This group policy modifies the pam.auth.failure.mesg setting in the agent configuration file.

Set Violation Error Message for Password Change

Customize the text displayed during password change if the operation fails because of a domain password policy violation. For example, if the user attempts to enter a password that doesn't contain the minimum number of characters or doesn't meet complexity requirements, this message is displayed. This group policy modifies the pam.policy.violation.mesg setting in the agent configuration file.

Set Password Prompt for Confirming New Password Change

Customize the text displayed when Active Directory users are prompted to confirm their new password. This group policy modifies the pam.password.confirm.mesg setting in the agent configuration file.

Set Password Prompt for New Password Change

Customize the text displayed when Active Directory users are prompted to provide their new password. This group policy modifies the pam.password.new.mesg setting in the agent configuration file.

Set Password Prompt for Old Password Change

Customize the text displayed when Active Directory users are prompted to provide their old password. This group policy modifies the pam.password.old.mesg setting in the agent configuration file.

Set Message Text for Password Change

Customize the text displayed when Active Directory users enter the correct password but must change the password immediately. This group policy modifies the pam.password.change.required.mesg setting in the agent configuration file.

Set Login Password Prompt

Customize the text displayed when Active Directory users attempts to log in. This group policy modifies the pam.password.enter.mesg setting in the agent configuration file.

Set Password Expiry Approaching Text

Customize the text displayed when the account password is approaching the expiration date. The message is displayed when the expiration date is within the limit defined by the pam.password.expiry.warn parameter. In the message, use the %d token for the number of days until expiration.

This group policy modifies the pam.password.expiry.warn.mesg setting in the agent configuration file.

Set Workstation Denied Error Message

Customize the text displayed during login if a user is denied access because of a workstation restriction. This group policy modifies the pam.workstation.denied.mesg setting in the agent configuration file.

Sudo Settings

Use the group policies under **Sudo Settings** to specify whether users must re-authenticate with sudo after logging out.

Force sudo Re-Authentication when Relogin

Specify whether users must authenticate again with sudo after logging out.

When a user authenticates with sudo, a ticket is temporarily created that allows sudo to run without re-authentication for a short period of time. If a user logs out and the ticket is not cleared, the ticket is reused when the user logs back in, and the user does not need to re-authenticate. If a user logs out and the ticket is cleared, the user must re-authenticate with sudo when logging back in.

Starting with release 2015, the way that you configure whether re-authentication is required depends on the tty_tickets parameter in the sudoers configuration file (/etc/sudoers.conf). In some situations, re-authentication requirements are also controlled by this policy. Details are as follows:

- If tty_tickets is enabled, tickets are always removed when a sudo user logs out, regardless of whether this policy is enabled or disabled. That is, when tty_tickets is enabled, this policy has no effect, and sudo users must always re-authenticate.
- If tty_tickets is disabled, the requirement for sudo users to reauthenticate is controlled by this policy and the adclient.sudo.clear.passwd.timestamp setting in the agent configuration file.

Tickets are cleared and sudo re-authentication is required in the following scenarios:

- The tty_ticket parameter in the sudoers configuration file is enabled (it is enabled by default)
- The tty_ticket parameter in the sudoers configuration file is disabled and this group policy is enabled
- The tty_ticket parameter in the sudoers configuration file is disabled and the adclient.sudo.clear.passwd.timestamp parameter is set to true

Tickets are not cleared and sudo re-authentication is not required in the following scenarios:

- The tty_ticket parameter in the sudoers configuration file is disabled and this group policy is disabled
- The tty_ticket parameter in the sudoers configuration file is disabled and the adclient.sudo.clear.passwd.timestamp parameter is set to false

By default, this policy clears tickets in the /var/run/sudo directory. To clear tickets in a different directory, use the adclient.sudo.timestampdir parameter in the agent configuration file as described in the *Configuration and Tuning Reference Guide*. This group policy modifies the adclient.sudo.clear.passwd.timestamp setting in the agent configuration file.

Window Settings

Use the group policies under **Centrify Settings > Windows Settings > Common Settings*** to control the configuration of Centrify Agents on Windows computers.

The following topics are covered:

Common Settings

Local Account Management

MFA Settings

Remote Authentication Dial-In User Service (RADIUS) Service Settings

Common Settings

Use the group policies under **Centrify Settings > Windows Settings > Common Settings** to control Centrify-managed Windows computers.

Configure Heartbeat Message for Centrify Analytics and SIEM (Windows)

Use this policy to specify how often (in minutes) Centrify Agent for Windows will send an information message to the Windows application log.

The Centrify Agent for Windows checks this setting every 5 minutes.

By default, this policy is set to zero (0), which means that this task is disabled.

Configure Windows Authentication Grace Period for Run with Alternate Account

You use this group policy to specify that there is a grace period for users running an alternate account before they must re-authenticate. By default, this policy is not enabled. If you enable this policy, you specify the time period in minutes. This policy works in conjunction with Require re-authentication to run application with alternate account.

You set up alternate accounts in Privileged Access Service. Alternate accounts are a way that you can allow a user to access a privileged account.

There are two settings for this group policy:

- By default, when this policy is **Disabled** or **Not Configured**, there is no grace period for re-authentication for users running an application with an alternate account.
- When this policy is **Enabled**, you specify the grace period by the number of minutes. This grace period is how long the user can run an application using an alternate account before having to re-authenticate.

If you have not also enabled the Require re-authentication to run application with alternate account policy, this policy has no effect.

Configure Windows Authentication User Privilege Elevation Grace Period

You can use this group policy to configure the Windows authentication grace period (in minutes) for user privilege elevation, such as run as role, run with privilege, new desktop, and switch desktop.

This per-session grace period starts when the user performs a successful privilege escalation in the session and the grace period is restarted. If the group policy is set to:

- **Enabled**: the grace period for privilege elevation is configured in the group policy.
- **Disabled**: the grace period for privilege elevation is disabled.
- **Not Configured**: the grace period for privilege elevation is not enabled and a local policy can override the setting.

Custom Message for Locked User Accounts

Use the Custom message for locked user accounts policy to customize the message that will be shown to the user when the user tries to log into a locked user account.

- If this policy is set to **Enabled**, an administrator can specify the message that will be shown to the user when the user tries to log into a locked user account. The credential provider shows the message if the message is specified (not empty).
- If this policy is set to **Disabled** or **Not Configured**, you will see the same message as the windows credential provider.

The group policy "Custom message for locked user accounts" only changes the message for the console logon or remote logon without Network Level Authentication (NLA). If you log on remotely with NLA, Remote Desktop Client will block logon with its message.

Disable the Centrify Notification Icon

Disable the Centrify icon in the notification area of the Windows task bar for users that are not assigned any roles, or for machines that are not joined to a domain.

Enable Run with Alternate Account

You can use this group policy to enable the ability for users to run an application with an alternate account.

You set up alternate accounts in Privileged Access Service. Alternate accounts are a way that you can allow a user to access a privileged account.

There are two settings for this group policy:

- By default, when this policy is **Disabled** or **Not Configured**, the user can run an application with only their user role if Centrify Privilege Elevation Service is also enabled.
  If only Centrify Identity Platform is enabled, then in order for a user to use an alternate account, they must log in to Privileged Access Service and check out the password directly.
- When this policy is **Enabled**, the user can run an application using an alternate account by right-clicking the application icon and selecting Run with Alternate Account.

Enable Setup Centrify Offline MFA Profile

Use this group policy to enable setup of Centrify offline MFA profile.

There are two settings for this group policy:

- When this policy is **Enabled** or **Not Configured**, you can set up the passcode for multi-factor authentication. A passcode can be used to fulfill multi-factor authentication in the event the computer cannot connect to the Centrify Identity Platform.
- When this policy is **Disabled**, you cannot setup an offline MFA profile.

Enable Use of Alternate User's Role to Run an Application

You can use this group policy to use an alternate user's role to run an application. The alternate user's credential is required when you use an alternate user's role. This policy does not apply to the `runasrole` command-line interface.

There are two settings for this group policy:

- By default, when this policy is **Disabled** or **Not Configured**, the user can run an application with only their user role.
- When this policy is **Enabled**, the user can use another user's role to run an application.

Hide Command Line Arguments in Analytics

You can use this group policy to hide command line arguments from Analytics Data (RunWithPrivilege Events).

There are two settings for this group policy:

- By default, when this policy is **Enabled** or **Not Configured**, the Analytics Data does not show the command line arguments.
- If this policy is set to **Disabled**, the Analytics Data shows the command line arguments.

Prevent Local Administrators from Being Able to Log On in Rescue Mode (When There are No Explicit Rescue Users Defined)

Use this policy to prevent local administrators that are not defined rescue users from logging in to a machine that is running in rescue mode or Windows Safe Mode.

If you set this policy to **Enabled**, you should add users and groups to the rescue user list by issuing them the rescue user role, or a custom role with the rescue user system right selected.

If you are not joined to a zone (because your computers are not managed by Server Suite), you can enable the group policy, Specify a list of rescue users (when the agent is not joined to a zone), and add users to the rescue user list.

By default, if this policy is set to **Disabled** or **Not Configured**, all local administrators are able to log in without multi-factor authentication when the machine is running in rescue or safe mode.

Re-Authentication: Require Smart Card

Enable this policy to require Windows users to re-authenticate using a smart card.

By default, this setting is disabled.

Require Justification on Privilege Elevation

You can use this group policy to require any user to provide a reason when they operate with elevated privileges, such as run with privilege, run as role, and new desktop.

This group policy works in conjunction with the Specify a privilege elevation validator policy. If you only set one of these policies, any affected user is prompted to provide a reason for privilege escalation.

There are two settings for this group policy:

- By default, when this policy is **Disabled** or **Not Configured**, users can run with elevated privileges as normal.
- When this policy is **Enabled**, the agent prompts the user with a justification dialog box, where the user can provide a reason category and a text string for the reason.

  Also, if you've configured your system to work with a ticketing system such as ServiceNow, you can use the Specify a privilege elevation validator group policy to validate the ticket number that the user enters.

  You can view the reason information that users enter in the audit trail event.

You can use this group policy with loopback mode, so that you can apply the policy based on the computer that a user logs into. For more details about loopback mode, see the Microsoft documentation, such as the following page:

https://support.microsoft.com/en-us/help/231287/loopback-processing-of-group-policy

Require Re-Authentication to Run Application with Alternate Account

You use this group policy to specify that users running an alternate account must re-authenticate. By default, this policy is false.

You set up alternate accounts in Privileged Access Service. Alternate accounts are a way that you can allow a user to access a privileged account.

There are two settings for this group policy:

- By default, when this policy is **Disabled** or **Not Configured**, after the user selects the option to run an application with an alternate account, they will not be prompted to re-authenticate.
- When this policy is **Enabled**, the user who runs an application using an alternate account will need to re-authenticate. To specify how long before the user is prompted for re-authentication, you define that grace period in the Configure Windows authentication grace period for run with alternate account policy.

Specify a List of Blacklisted Domains

Enable this group policy to specify a list of domains that will be ignored by the Centrify Agent.

After enabling this policy, enter one or more domain names, separated by a comma, in the following format:

```
domain1.com,domain2.com,...,domainN.com
```

If the root domain of a trusted forest is specified in this list, all of its leaf domains will also be ignored.

By default, if this policy is set to **Not configured**, no domains are blacklisted.

Specify a List of Rescue Users (When the Agent is not Joined to a Zone)

If the agent is not joined to a zone (because your computers are not managed by Server Suite), use this policy to specify a list of users who can log in without using multi-factor authentication if the machine is running in rescue mode or Windows Safe Mode.

The user name can be specified in any of the following formats:

- sAMAccountName
- sAMAccountName@domain (if the account is not in the current domain).
- UserPrincipalName@domain
- An asterisk (*), which includes all Active Directory users.

You can enter the list of users separated by a comma, for example:

joe, janedoe, user1, user2@domain.com.

By default, if this policy is set to **Disabled** or **Not configured**, only local administrators can log on in rescue mode or safe mode. However, if you enable Prevent local administrators from being able to log on in rescue mode (when there are no explicit rescue users defined), and do not enable this policy, no one will be able to log in if the computer is running in these modes.

Specify a List of Whitelisted Domains

Enable this group policy to specify a list of domains that will be trusted and processed by the Centrify Agent. If you enable this policy, **only** these domains will be trusted.

After enabling this policy, enter one or more domain names, separated by a comma, in the following format:

```
domain1.com,domain2.com,...,domainN.com
```

You must specify the root domain on this list if you specify any of its leaf domains.

By default, if this policy is set to **Not configured**, all domains are trusted and processed by the Centrify Agent.

Specify Offline MFA Profile Desktop Notification Message

Use this group policy to specify conditions for the offline MFA profile desktop notification message.

There are two settings for this group policy:

- **Enabled** or **Not Configured**: The user-specified offline MFA profile desktop notification message appears.
- **Disabled**: The offline MFA profile desktop notification message does not appear.

Specify a Privilege Elevation Validator

You can use this computer configuration group policy to validate ticket information that a user enters when she provides a ticket number along with a privilege elevation reason. You can validate ticket information using a customized PowerShell script against a ticketing system, such as ServiceNow.

If you enable this policy, here are some important things to know:

- Centrify provides a sample script that you can use as a starting point for your own script. At the minimum, you need to enter your ServiceNow URL for the $url parameter.
- You can get the sample script from github: in the centrify-agent-windows repo, go to Samples > ITSM validation > servicenow.
- If the ticket ID is not validated successfully, the user's request for elevated privilege is rejected.
- The custom PowerShell script must be available and accessible on each Windows computer where the validation occurs. If you're not running the PowerShell script on a local computer, be sure to allow remote PowerShell access for the script.
- This group policy works in conjunction with the Require justification on privilege elevation policy. If you only set one of these policies, any affected user is prompted to provide a reason for privilege escalation.
- If the script cannot validate the ticket entry within the specified timeout duration, then the validation fails. By default, the timeout value is 2 minutes.

Please consult the group policy explain text for more details.

There are two settings for this group policy:

- By default, when this policy is **Disabled** or **Not Configured**, users can run with elevated privileges as normal.
- When this policy is **Enabled**, you specify the PowerShell script filename and users entries are validated against the third-party ticketing system before granting privileged access.

You can view the reason information that users enter in the audit trail event.

Specify Whether to Keep the Desktop Notification Permanently Visible

Use this group policy to specify whether to keep the desktop notification message visible at all times.

The desktop notification message shows what roles are currently being used by the user and may be helpful to remind those using privileged desktops which elevated privileges they are authorized to use for that desktop. Select **Enabled** to keep the message visible.

If this policy is **Disabled**, or **Not configured**, by default, the notification message will fade a few seconds after clicking the Centrify icon in the system notification tray.

Local Account Management

Use the group policies under **Centrify Settings > Windows Settings > Local Account Management** to control local Windows users and groups on Centrify-managed Windows computers.

Enable Local Account Management Feature

Use this policy to specify that Windows local account management is enabled for the Centrify Agent for Windows.

By default this policy is set to Not Configured, which in this case means that Windows local account management is not enabled.

Enforce Local Account Management Feature

Use this policy to specify that Windows local account management is enforced for the Centrify Agent for Windows. By enforcing local account management, if you remove a user from a zone or computer in Access Manager, the user is removed from all affected computers.

By default this policy is set to Not Configured, which in this case means that Windows local account management is not enforced.

Synchronization Interval

Use this policy to specify how often (in seconds) the service synchronizes local users and groups information with affected computers.

By default this policy is set to 3600 seconds, which is the equivalent to 1 hour.

Notification Command Line

Use this policy to specify the command line script that the Centrify Agent for Windows runs after provisioning local users and groups. This policy only applies if the Windows local account management feature is enabled.

MFA Settings

Use the group policies under **Centrify Settings > Windows Settings > Centrify MFA Settings** to control multi-factor authentication on Centrify-managed Windows computers.

Configure Multi-Factor Authentication for Logon when the Agent Cannot Connect to the Platform

You can use this group policy to configure offline multi-factor authentication for users that are required to use multi-factor authentication to log on to their computers in the event that the agent cannot connect to the Centrify Identity Platform.

There are three configuration possibilities:

- If an offline MFA profile is setup, prompt for offline MFA. Otherwise don't allow to proceed.
- If an offline MFA profile is set up, prompt for offline MFA. Otherwise, allow to proceed and remind user to set up the offline MFA profile.
- Allow to proceed. Don't prompt for offline MFA.

If this policy is set to **Disabled** or **Not Configured**, the default is the second option.

Configure Multi-Factor Authentication for Privilege Elevation when the Agent Cannot Connect to the Platform

You can use this group policy to configure offline multi-factor authentication for users that are required to use multi-factor authentication to use elevated roles in the event that the agent cannot connect to the Centrify Platform.

There are three configuration possibilities:

- Only users who have set up an offline MFA profile will be prompted for offline multi-factor authentication for privilege elevation. Users who have not set up an offine passcode will not be able to proceed.
- If an offline MFA profile is set up, prompt for offline MFA. Otherwise, allow the user to proceed and remind them to set up the offline MFA profile.
- Users can use elevated rights or roles when their machine is offline without multi-factor authentication.

If this policy is set to **Disabled** or **Not Configured**, the default is the first option.

Connect to the Centrify Platform Directly

Connect to the Centrify identity platform directly without using a web proxy or a connector as a web proxy. If you enable this policy, you must configure the client to be able to connect to the identity service.

Continue with MFA Challenges after Failed Windows Authentication in Logon Screen

Configuring this policy setting allows you to continue with MFA challenges, even with a failed Windows authentication.

> **Note**: The following is recommended for PCI DSS or NIST 800-53 guidelines for multi-factor or multi-step authentication.

If this policy is set to **Enabled**, authentication on the Windows logon screen continues with MFA challenges with the wrong password or use of expired/locked out/disabled accounts.

> **Note**: Specify the multi-factor authentication grace period is disabled when this policy is enabled.

If this policy is set to **Disabled** or **Not Configured**, authentication on Windows logon screen fails immediately when you enter the wrong password and the MFA challenges are not triggered. To continue to the second MFA challenge when previous challenge response failed, use the policy "Continue with additional challenges after failed challenge" in the Admin Portal.

Disable Multi-Factor Authentication for Screen Unlock

Use this policy to disable multi-factor authentication for the Windows lock screen. When multi-factor authentication is required to log on to a Windows machine, by default, users must also use multi-factor authentication to unlock the Windows lock screen. If this policy is set to **Enabled**, users that require multi-factor authentication to log on will not have to use multi-factor authentication to unlock the Windows lock screen.

If this policy is set to **Disabled** or **Not configured**, the default is to require users to use multi-factor authentication to unlock the Windows lock screen.

Disable Self-Service Password Reset

You can use this group policy to allow the administrator to force disabling of the password reset feature. There are two settings for this group policy:

- **Enabled**: If this policy is set to **Enabled**, the self-service password reset feature on the machine is disabled, including the cloud-enabled self-service password reset.
- If this policy is set to **Disabled** or **Not Configured**, the self-service password reset feature on the machine follows the cloud policy setting (cloud policy settings can be found at: **Policy Settings > User Security Policies > Self Service > Password Reset**). The cloud policy settings are accessed through the Admin Portal.

  Note: The admin portal is available after you log in to a Centrify Platform instance.

Enable Multi-Factor Authentication for Windows Login (when the Agent is not Joined to a Zone)

Use this policy to enable multi-factor authentication for Windows login when the agent is not joined to a zone.

If this policy is set to **Disabled** or **Not configured**, the default is that no user is required to use multi-factor authentication to log in.

Force to Enter Explicit UPN

Configure this policy setting to force all users that require MFA to log in to the machine using the UPN format of: user@domain.com. There are two settings for this group policy:

- If this policy is set to **Enabled**, all users that require MFA must log in using the UPN format, otherwise an error message appears "Invalid User. Please use format user@domain.com and try again."

  Note: All users that do not require MFA can log in using either the UPN format or NT account format.

- If this policy is set to **Disabled** or **Not Configured**, all users can log in using either the UPN format or NT account format.

Send UUID for MFA Challenges

Configure this group policy to enable the DirectAuthorize Agent to send user UUID with the user UPN for the MFA challenges.

- If this policy is set to **Enabled**, DirectAuthorize Agent sends the user UUID as addition field with the user UPN for the MFA challenges.
- If this policy is **Disabled** or **Not Configured**, DirectAuthorize Agent sends only the UPN for the MFA Challenges.

Skip Client Certificate Authentication

Use this group policy to skip client certificate authentication to the Centrify Platform if client certificate authentication is disabled or blocked by enterprise policies or proxy settings.

If you enable this policy, you must configure the client to be able to connect directly to the Centrify Connector for multi-factor authentication.

If this policy is set to **Disabled** or **Not configured**, client certificate authentication is required for multi-factor authentication.

Specify a Web Proxy URL

Specify a web proxy to use to connect to the Centrify identity platform. If you have enabled the client to connect to the cloud service directly, without using a connector or web proxy, enabling this policy has no effect.

Specify Active Directory Users that Require Multi-Factor Authentication on Windows Login (when the Agent is not Joined to a Zone)

Use this policy to specify the Active Directory users that are required to use multi-factor authentication to log on to Windows computers. If you enable this policy, you can specify users by name in the following formats:

- sAMAccountName
- sAMAccountName@domain
- userPrincipalName@domain
- An asterisk (*), which includes all Active Directory users

Use quotes for names containing spaces, for example, “Krusty T. Clown”.

By default, no users are required to authenticate using multi-factor authentication.

Specify How Frequently to Check for Responses to Multi-Factor Authentication Challenges

Set the polling interval in seconds for checking whether a user has responded to a multi-factor authentication challenge. Some authentication challenges require the client to wait for the user to respond to the challenge.

This value defines how frequently the client checks with the cloud service for a user's challenge response. The lower the value, the faster the client responds.

The minimum value you can specify is 1 second and the maximum value is 300 seconds. If you enable this policy, the default value is 3 seconds.

Specify the Multi-Factor Authentication Grace Period

You can use the following two group policies under **Windows Settings > MFA Settings** to control the multi-factor authentication grace period:

- Configure multi-factor authentication lock screen grace period
- Configure multi-factor authentication user privilege elevation grace period

The *Configure multi-factor authentication lock screen grace period* group policy allows the administrator to configure the multi-factor authentication grace period (in minutes) for the lock screen. If the group policy is set to:

- **Enabled**: the grace period for lock screen is enabled and it is configured in the group policy. If this value is configured to 0, it means no grace period for MFA in the lock screen.
- **Disabled**: the grace period for lock screen is disabled.
- **Not Configured**: the grace period for lock screen is not enabled and a local policy can override the setting.

The *Configure multi-factor authentication user privilege elevation grace period* group policy allows the administrator to configure the multi-factor authentication grace period for user privilege elevation, such as run with privilege and add new desktop. This per-session grace period starts when the user performs a successful MFA challenge in the session and the grace period is restarted. If the group policy is set to:

- **Enabled**: the grace period for privilege elevation is configured in the group policy.
- **Disabled**: the grace period for privilege elevation is disabled.
- **Not Configured**: the grace period for privilege elevation is not enabled and a local policy can override the setting.

Applying the MFA Lock Screen Grace Period to Remote Sessions

By default, the *Configure multi-factor authentication lock screen grace period* group policy applies only to console sessions and not to remote sessions. However, you can configure a registry key to apply the grace period to remote sessions too. You can deploy this registry key as an additional policy.

To enable the MFA lock screen grace period for remote sessions

- Add the following registry entry on each computer where you have installed the Centrify Agent for Windows:

  HKEY_LOCAL_MACHINE\SOFTWARE\Centrify\DirectAuthorize\Agent\ApplyLockScreenGracePeriodToRDPSessions = 1 (REG_DWORD)

Specify the Authentication Source for Privilege Elevation

Use this policy to specify the authentication source for privilege elevation. You can choose either multi-factor or RADIUS authentication.

If this policy is set to Enabled, agents will use the configured source for privilege elevation multi-factor authentication.

If this policy is set to Disabled, you cannot use another authentication source for privilege elevation multi-factor authentication.

If this policy is set to Not Configured, you can configure another authentication source locally on the agent.

Specify the Centrify Connector URL to Use

Specify the connector to use.

You should specify the URL with a fully-qualified domain name and port number. For example, if using a secure HTTP (HTTPS) connection, type an entry similar to the following:

```
https://acme.example.com:8080/
```

If you enable and apply this policy, you must also enable and apply the policies to specify the cloud instance URL and, if applicable, the web proxy URL.

If you don't configure this policy, the cloud instance URL will automatically locate an available connector to use by default.

Specify the Connection Timeout for Multi-Factor Authentication Requests

Use this group policy to set the connection timeout for multi-factor authentication requests. This policy defines the number of seconds to wait before the request times out.

If you enable this policy, the minimum value you can specify is 1 second, and the maximum value is 100 seconds.

If this setting is set to **Not Configured**, the default value is 15 seconds.

Specify Credential Providers to Exclude from the Logon Screen

Use this group policy to list specified credential providers to exclude from the login options on the Windows login screen when users access the machine remotely.

You must list the Class IDentifiers (CLSID) for the providers you would like to exclude. For example, to exclude the Windows Password Provider and the Smartcard Credential Provider on machines running Windows 8 or later and Windows Server 2012 or later, you would enter the following:

{60b78e88-ead8-445c-9cfd-0b87f74ea6cd},{8FD7E19C-3BF7-489B-A72C-846AB3678C96}

To find the CLISDs for installed credential providers, navigate to the following location in the HKEY_LOCAL_MACHINE registry:

SOFTWARE\Microsoft\Windows\CurrentVersion\Authentication\Credential Providers

If this policy is set to **Disabled** or **Not configured**, only the Windows Password credential provider will be disabled by default.

Specify the Platform Instance Id to Use (when the Agent is Not Joined to a Zone)

Use this policy to specify the Centrify Identity Platform instance Id also called a tenant ID) to use when the agent is not joined to a zone.

In most cases, this policy is only required if you have access to multiple platform Ids and want to explicitly specify which platform instance to connect. For example: AAH0305

You can get the Centrify Identity Platform tenant ID from your service registration.

If you're using a version of Access Manager prior to 19.6 and you upgrade your connectors to a version of 19.5 or later, please make sure you manually update the tenant URL to use the .net domain extension after the connector upgrade. Otherwise, MFA will not work and the Centrify Identity Services Platform won't be listed in the agent configuration.

If you're already using a version of Access Manager of 19.6 or later, you can set the tenant ID on the zone. Then when you upgrade your connectors, the agent gets the new tenant URL automatically.

Specify the Platform Instance URL to Use

Specify the Centrify Identity Service instance URL to use. In most cases, this policy is only required if you have access to multiple cloud instances and want to explicitly specify which instance to connect to.

You should specify the URL using the customer-specific identifier for the cloud instance and a fully-qualified domain name and port number.

For example, if using a secure HTTP (HTTPS) connection, type an entry similar to the following:

https:/ABC1234.my.centrify.net:443/

Specify the Platform Instance URL to Use (when the Agent is Not Joined to a Zone)

Use this group policy to specify which platform instance URL the agent will access for users of computers that are not joined to a zone.

Enable this policy if you have access to more than one instance URL.

If you only have a single authentication server URL for all of the connectors in your Active Directory forest, the agent will use this URL by default, and you do not need to enable this policy.

When specifying a URL, the URL should be in the following format:

https:/customerid.domainfqdn:port/

For example:

https:/abc0123.my.centrify.net:443/

Specify the Timeout on Skipping Previously Disconnected Centrify Connectors

Specify the length of time, in seconds, for the agent to ignore previously disconnected connectors while attempting to connect to the cloud for an authentication request.

You can avoid connection delays by specifying a longer timeout period for previously disconnected connectors. The agent will not attempt to connect with these connectors until the timeout period ends. The minimum value you can specify is 0 seconds and the maximum value is 86400 seconds. The default value is 1800 seconds.

Specify the timeout on Using the Last Successfully Connected Centrify Connector First

Specify the length of time, in seconds, for the agent to attempt to connect to the cloud using the last successful connector.

The lower you set this value, the faster the agent will try other connectors during the next authentication request. The minimum value you can specify is 0 seconds and the maximum value is 86400 seconds. The default value is 600 seconds.

Remote Authentication Dial-In User Service (RADIUS) Settings

Use the group policies under **Centrify Settings > Windows Settings > MFA Settings > Remote Authentication Dial-In Service (RADIUS) Settings** to control Radius multi-factor authentication on Centrify-managed Windows computers.

Enable Remote Authentication Dial-In User Service (RADIUS)

Use this policy to enable Remote Authentication Dial-In User Service (RADIUS) for privilege elevation.

If this policy is set to Enabled, you can use RADIUS for privilege elevation multi-factor authentication.

If this policy is set to Disabled, you cannot use RADIUS for privilege elevation authentication.

If this policy is set to Not Configured, you can enable RADIUS locally on the agent.

Specify the RADIUS Connection Timeout

Use this policy to specify the connection timeout in seconds for the RADIUS server.

If this policy is set to Enabled, agents will use the configured timeout for authentication.

If this policy is set to Disabled or Not Configured, you can configure the connection timeout locally on the agent.

Specify the RADIUS Server IP Address

Use this policy to specify the RADIUS server IP address.

If this policy is set to Enabled, agents will use the configured RADIUS server for authentication.

If this policy is set to Disabled or Not Configured, you can configure the RADIUS server IP address locally on the agent.

Specify the RADIUS Server Port Number

Use this policy to specify the RADIUS server port number.

If this policy is set to Enabled, the agent will use the configured port for authentication.

If this policy is set to Disabled or Not Configured, you can configure the RADIUS server port number locally on the agent.

Audit and Audit Trail Settings

This chapter describes the audit-related group policies that are located under **Centrify Audit Trail Settings** and **Centrify Audit Settings**.

Group policies located under **Centrify Audit Trail Settings** allow you to specify both category-specific and global audit trail targets. These group policies are located in subfolders under **Centrify Audit Trail Settings**. See Audit Trail Settings for details about these group policies.

Group policies located under **Centrify Audit Settings** allow you to configure the auditing agent installation, and platform-specific auditing features. These group policies are located in subfolders under **Centrify Audit Settings**. See Centrify Audit Settings for details about these group policies.

The following topics are covered:

Alternate Location for Policies Installed with an ADMX Template

If Audit Trail group policies are installed using an ADMX template instead of the plugin that the Auditing installer uses, the group policies are installed in this location in GPOE:

Computer Configuration > Policies > Administrative Templates Policy definitions (ADMX files) > Centrify Audit Trail Settings

All of the Audit Trail group policies are located in this folder, including the **Set global audit trail targets** policy.

Audit Trail Settings

There are two locations of audit trail settings:

- Some group policies are located under **Computer Configuration > Centrify Audit Trail Settings**. These policies are provided by the Centrify snap-in extension.
- Additional group policies are located under **Computer Configuration > Administrative Templates > Centrify Audit Trail Settings**. They are in an ADMX template.

Delinea

Audit Trail Snap-In Policies

For the policies located in Computer Configuration > Centrify Audit Trail Settings:

- There is a subfolder for each category of items that generate an audit trail. For example, Audit Analyzer Settings, Audit Manager Settings, and so forth.
- For global settings, the Centrify Global Settings subfolder co
- Within each subfolder, there are 2 group policies:
    - Send audit trail to Audit database
    - Send audit trail to log file

  You can configure each of these group policies to "Not configured", "Enabled", or "Disabled".

Audit Trail ADMX Template Policies

For the policies located in Computer Configuration > Administrative Templates > Centrify Audit Trail Settings:

- There is one group policy for each category of items that generate an audit trail. For example, "Set audit trail targets for category "Audit Analyzer."
- For global settings, use the "Set global audit trail targets" policy.
- You can configure each of these group policies to to "Not configured", "Enabled", or "Disabled".
- If you enable one of these policies, you also need to specify the value for Audit trail targets and Audit trail targets override. The audit trail targets and targets override is set within each of the policies (they're not separate policies).

Send Audit Trail to Audit Database

Enable this group policy to specify that audit events for this component —**Audit Analyzer**, **Audit Manager**, and so on—are sent to the active audit store database.

See the **Explain** tab in the group policy for details about which parameter each group policy sets in the agent configuration file.

Send Audit Trail to Log File

Enable this group policy to specify that audit events for this component— such as **Audit Analyzer**, **Audit Manager**, and so on—are sent to the local logging facility (syslog on UNIX systems, Windows event log on Windows systems).

See the **Explain** tab in the group policy for details about which parameter each group policy sets in the agent configuration file.

Audit Trail Overrides

This setting specifies whether to override the global audit trail targets. If this parameter is set, the system uses the targets value in the current component; otherwise, the system uses the global configured value.

There are two target settings that can be overridden:

- Whether the system sends the audit trail information to DirectAudit or not
- Whether the system sends the audit trail information to the local logging system or not. On UNIX systems, the local logging system is syslog and on Windows systems it's the Windows event log.

For this setting, you specify a single numeric value to represent where the system will send the audit trail information. (Setting one value to signify two settings is called a bit mask.) The possible settings are as follows:

0	No	No	There is no override to the audit trail target of the current component. The system uses the global audit trail target value.
1	Yes	No	The system overrides just the audit trail target for DirectAudit. This capability is supported by DirectAuditversion 3.2 and later.
2	No	Yes	The system overrides just the audit trail target for the local logging system. If you're using a DirectAuditversion prior to version 3.2, this is the default setting.
3	Yes	Yes	The system overrides both the audit trail targets for DirectAuditand the local logging system. If you're using DirectAuditversion 3.2 or later, this is the default setting.

This group policy modifies the audittrail.<product\>.<component\>.overrides settings in the agent configuration file. Each category has its own setting in that file.

Audit Trail Targets

This setting specifies how to calculate where the system sends the audit trail information for a particular component if you have also set the corresponding Audit Trail Overrides setting.

There are two kinds of audit trail targets that can be specified:

- Whether to enable the DirectAudit audit trail target for the component or not.
- Whether to enable the local logging system audit trail target or not. On UNIX systems, the local logging system is syslog and on Windows systems it's the Windows event log.

For this setting, you specify a single numeric value to represent which audit trail targets are enabled for the component. (Setting one value to signify two settings is called a bit mask.) The possible settings are as follows:

0	No	No	Neither the DirectAudit nor the local logging target are enabled for the component. This is the default setting for the group policy
1	Yes	No	Enable only the DirectAudit audit trail target for the component. This capability is supported by DirectAudit version 3.2 and later.
2	No	Yes	Enable only the local logging audit trail target for the component.
3	Yes	Yes	Enable the audit trail targets for both DirectAudit and the local logging system.

The system calculates the final audit trail targets for a component based on the following information:

- If the Audit Trail Targets Override is not specified, the system uses the global audit trail target value
- If Audit Trail Targets Override is specified, for each target (DirectAudit and local logging), whether the audit trail information will be sent to this target is determined by the following:
  - If the setting is not overridden in with Audit Trail Targets Override, the system uses the global audit trail target value
  - If the target is overridden by Audit Trail Targets Override and enabled by Audit Trail Targets, the system sends the audit trail information to this target

This group policy modifies the audittrail.<product\>.<component\>.targets settings in the agent configuration file. Each category has its own setting in that file.

Centrify Audit Settings

Centrify Auditing and Monitoring Service group policies are located in the following subfolders:

- Common Settings—Contains policies pertaining to the audit installation. See Common Settings for details about the policies in this node.
- Collector Settings—Contains policies pertaining to the collector service. See Collector Settings for details about the policies in this node.
- DirectAudit advanced monitoring—Contains policies pertaining to advanced monitoring configuration. See DirectAudit advanced monitoring for policy details.
- UNIX Agent Settings—Contains sub-nodes for policies pertaining to the Centrify Agent for *NIX. See UNIX Agent Settings for details about the policies in these sub-nodes.
- Windows Agent Settings—Contains policies pertaining to user lists used by the Centrify Agent for Windows. See Windows Agent Settings for details about the policies in this node.

Use the group policies under **Common Settings** to configure basic operations for the auditing service.

Installation

Use the Installation group policy to specify which installation agents and collectors are part of. By enabling the Installation group policy, you can prevent local administrators from configuring a computer to be part of an unauthorized installation.

> **Note**: After applying the settings through the "Centrify Auditing and Monitoring Service Settings" group policy, you must restart the target agent machine(s) for the policy to take effect.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab of the dialog box, select **Enabled**.
3. Click **Browse** to select the installation you want to secure, then click **OK**.

See the *Auditing Administrator's Guide* for more information about installing and managing installations of the auditing infrastructure.

Set the Match Order of Audit Store

When the audit and monitoring service is running on a system and it needs to connect to an audit store, you can use this policy to specify the search precedence.

If you set this policy to Enabled, then the agent looks for an audit store based on the Active Directory sites. If the search fails, then the agent looks for an audit store based on the subnet.

By default, this policy is not enabled, which means that audit stores are chosen first based on their subnet addresses and then based on the Active Directory sites.

Set Maximum Missed Status Update Tolerance

Use the Set maximum missed status update tolerance group policy to specify how many times the auditing agent will fail to connect to a collector before sending a notification that the agent is not joined to a collector. The interval between attempts is 5 minutes.

This group policy modifies the agent.max.missed.update.tolerance setting in the agent configuration file.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. Click **Edit**.
3. Select **Enabled**.
4. Enter the value. For example, enter 3 if you would like the agent to notify you after 3 failed attempts to join a collector.
5. Click **OK**.

If this group policy is Disabled or Not Configured the default value is 4.

This group policy can be used with the DirectAudit Daemon Settings group policy which allows you to specify the amount of time, in seconds, that the agent waits during each connection attempt before it determines that it cannot connect to a collector.

Set the Preferred Audit Store

Use this group policy to specify the preferred audit store that auditing will use in the event that your UNIX or Linux computer has IP addresses that match the criteria for multiple audit stores.

If you have this type of installation and you do not enable this policy and specify the preferred audit store, the collector may not connect to the correct audit store.

This group policy modifies the parameter preferred.audit.store in the agent configuration file.

Set Video Capture Auditing of User Activity

Use the Set video capture auditing of user activity group policy to specify any agents for which you want to change the video capture settings. This setting can be useful in cases where the user output should not be recorded because of security audit rules. For example, if you have enabled video capture auditing for your entire auditing installation, you can disable video capture for one or more specific agents.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab of the Properties dialog box, select **Enabled**.
3. In the Set video capture auditing section, select one of the following options:
    - **Enable Video Audit**: Select this option to turn on video capture. This setting overrides your installation-wide video capture setting.
    - **Disable Video Audit**: Select this option to turn off video capture. This setting overrides your installation-wide video capture setting.
    - **Use Installation-Wide Setting**: Select this option to make sure that this agent uses the same setting as what you have set for the entire auditing installation.
4. Click **OK** to save the change.

Use the Host Name Specified by the Agent

Enable this group policy to display the real host name of audited computers in the Audited Systems node in Audit Manager instead of the host name resolved by the collector through DNS.

This configuration parameter is useful in configurations where the DNS servers used by the collectors cannot reliably resolve host names from IP addresses. The most common scenarios that might require you to use this configuration parameter are when the agents are in a virtual environment using network address translation (NAT) or in a perimeter network outside of a firewall.

If this group policy is enabled, the host name for the agent is determined by the agent. If this group policy is not enabled, the collector determines the agent's host name based on its IP address. If this group policy is not configured, this setting will be disabled by default.

This group policy modifies the agent.send.hostname setting in the auditing configuration file.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. Click the Edit policy setting link above the policy's Description.
3. Select **Enabled**.
4. Click **OK**.

Collector Settings

Use the group policies under Collector Settings to configure the collector service.

Do Not Audit Output of Specified UNIX Commands

Use this group policy to specify one or more UNIX commands whose output you do not want to save to in the audit store database.

You can use this group policy to prevent the output from specific UNIX command that you do not want to capture or review from being saved. For example, common UNIX commands, such as the "top" and "tail" commands, might display output that you do not want to capture and store for auditing purposes. To prevent auditing the output for these types of commands, enable this group policy, click Add, then type the command.

The command string you specify must be an exact match. For example, to prevent auditing output of "cat filename", you must specify "cat filename" as the command string in this group policy.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **Add**, type the exact command you want to skip for auditing purposes, then click **OK**.
4. Repeat Step 3 for each command to skip when auditing session activity until you are finished adding commands, then click **OK**.

DirectAudit Advanced Monitoring

Use the following group policies to generate advanced monitoring for program and process execution on audited machines.

Enabling these group policies will allow you to generate reports that monitor programs and process that are run individually, as part of a script, or within other commands.

You can also configure a file monitor report which details user interaction with sensitive files.

> **Note**: You must first enable the group policy, Enable advanced monitoring to enable any of the other Advanced Monitoring policies.

Delinea

Enable Advanced Monitoring

Use this group policy to enable Advanced Monitoring.

If this policy is **Not configured**, by default, Advanced Monitoring is not enabled.

Set Monitor of Program Execution for Audit Sessions

Use this group policy to enable recording for all programs executed in an audited session. You can export these monitoring events when reviewing a session and they are also recorded in the Detailed Execution reports.

If this policy is **Not configured**, by default, this feature is not enabled.

This group policy modifies the event.execution.monitor parameter in the agent configuration file.

Delinea

Set Monitored Programs List

Use this group policy to specify a list of programs that will generate an audit trail event when executed by users.

If you enable this policy, all users executing the listed programs will generate an audit trail event, whether they are audited or not, unless the user is specified in Set skip users for monitored program executions.

Note that all commands must be specified with full paths.

If this policy is set to **Disabled** or **Not Configured**, by default, no executed programs will generate an audit trail event for any user.

This policy modifies the event.monitor.commands parameter in the agent configuration file.

Set Monitoring of System Configuration Files

Use this group policy to enable monitoring of changes made to the system configuration files in the following directory trees:

- /etc
- /var/centrify
- /var/centrifyda
- /var/centrifydc

By default, if this policy is set to **Not configured**, or if you enable this policy, all changes made to these system configuration files **will** be monitored.

Set Processes that are Skipped for System Configuration File Monitoring

Use this group policy to specify programs that modify configuration files which you do not want to be monitored when Set monitoring of system configuration files is enabled.

When you enable this policy, you can specify a list of trusted programs that can modify any system configuration files or directories without causing an audit trail event.

If this policy is **Not configured**, /usr/sbin/daspool is skipped by default, along with all adclient and dad processes and subprocesses.

Set Skip Users for Monitored Program Executions

Use this group policy to specify a list of users who can run programs and commands without generating an audit trail event.

Users listed in this policy can run commands without generating an audit trail, even if those commands are listed in Set monitored programs list.

If this policy is **Disabled** or **Not configured**, by default, all users will generate an audit trail event when executing monitored commands.

This policy modifies the event.monitor.commands.user.skiplist parameter in the agent configuration file.

Set Users that will be Skipped for Program Execution Monitoring

Use this group policy to specify a list of audited users that will not generate an audit trail event record, for use in Detailed Execution reports, when they execute programs listed in Set monitored programs list when it is enabled.

If this policy is **Not configured**, by default, no users are added to this list.

Set Users Who will be Skipped for System Configuration File Monitoring

Use this group policy to specify a list of users who can modify any system configuration file and directory without generating an audit trail event when Set monitoring of system configuration files is enabled.

If this policy is set to **Not configured**, by default, only root is added to this list.

This policy modifies the event.file.monitor.user.skiplist parameter in the agent configuration file.

UNIX Agent Settings

Use the group policy under **UNIX Agent Settings** to set auditing configuration options.

Add centrifyda.conf Properties

Use this group policy to specify any configuration parameters you want to add to the centrifyda.conf configuration file. You can specify any configuration parameter name and its value by using this group policy.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **Add**, type a property name and a property value, then click **OK**.

   For example, to change the configuration parameter autofix.nss.conf from the default value of true to false, you would type the following:

   - Property name: autofix.nss.conf
   - Property value: false
4. Repeat Collector Settings for each configuration parameter you want to set until you are finished adding property values, then click **OK**.

In typing property names and values, you should note that the agent does not perform any validation or error checking. If you specify an invalid property name or value, the parameter and value are added to the configuration file as entered. In most cases, invalid parameter names are simply be ignored. However, an invalid parameters value might cause unexpected problems when the auditing service runs.

Additional group policies for UNIX Agent Settings are organized under the following subnodes:

- **DirectAudit Daemon Settings**—Contains policies that pertain to the auditing service dad process. See DirectAudit Daemon Settings for details about the policies in this sub-node.
- **DirectAudit NSS Settings**—Contains policies that pertain to authentication requests that are processed or ignored by the Centrify name service switching (NSS) module. See DirectAudit NSS Settings for details about the policies in this sub-node.
- **DirectAudit Shell Settings**—Contains policies that pertain to the audited shell (cdash). See DirectAudit Shell Settings for details about the policies in this sub-node.
- **LRPC2 Client Settings**—Contains policies that pertain to LRPC2. See LRPC2 Client Settings for details about the policies in this sub-node.
- **Spool Disk Space Settings**—Contains policies that pertain to offline database settings. See Spool Disk Space Settings for details about the policies in this sub-node.

Delinea

Enable DirectAudit Session Auditing Properties

Use this group policy to enable and disable DirectAudit session auditing.

DirectAudit Daemon Settings

Use the group policies under DirectAudit Daemon Settings to control operations for the auditing service.

Set Allow to Dump Core

Use this group policy to specify whether the dad process is allowed to dump core. If this group policy is enabled, the dad process is allowed to dump core. If this group policy is disabled or not configured, the dad process is not allowed to dump core.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab of the Properties dialog box, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the dad.dumpcore setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Audit Level of Ignored User

Use this group policy to specify the audit level of users who are on the ignored user list. Values that you can set in this policy are:

- 0 — Audit if possible.
- 1 — Do not audit.

If this group policy is disabled or not configured, a default value of 0 is used, meaning that the audit level is "audit if possible." If you enable this group policy is enabled, you can specify a value of 0 or 1.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Set the ignored user audit level to 0 or 1.
4. Click **OK** to save settings in this policy.

This group policy modifies the `user.ignore.audit.level` setting in the `/etc/centrifyda/centrifyda.conf` configuration file.

Set Cache Live Time

Use this group policy to specify the length of time entries should remain valid in the name service cache. You can specify the maximum number of seconds cached query result should be available in the cache. This policy is applicable only if the Set cache the query results policy is enabled.

If this group policy is disabled or not configured, a default value of 600 seconds is used. If this group policy is enabled, you can specify the number of seconds.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds that cached information remains valid.
4. Click **OK** to save settings in this policy.

For example, to increase the number of seconds that query results are available in the cache on an audited computer, enable this policy and specify a value of your choice that is greater than 600 seconds.

This group policy modifies the cache.time.to.live setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Cache the Query Results

Use this group policy to specify whether the dad process caches name service query results about users and groups.

- If this group policy is disabled, query results are not saved and must be retrieved whenever they are needed.
- If this group policy is enabled or not configured, the dad process stores query results—for example, from user lookup requests—in memory for better performance.
- If this group policy is enabled, you can use the Set max cache size and Set cache live time policies to control the number and duration of entries in the cache.
- If this group policy is enabled, you can also use the daflush command to clear the cache manually when you want to ensure you get updated information. For example, if you remove the UNIX Login role for an Active Directory user, some information for that user might remain in the cache and be returned when you run a command such as getent passwd. You can run daflush to ensure that the user is removed completely from the local computer cache, including the auditing name service cache.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the cache.enable setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Check NSS Configuration File Timeout

Use this group policy to specify how frequently (in seconds) the dad process checks the /etc/nsswitch.conf file for changes.

If this group policy is disabled or not configured, a default value of 60 seconds between checks is used. If this group policy is enabled, you can specify the number of seconds between checks.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds between checks.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.timer.monitor.nss.conf setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Client Idle Timeout

Use this group policy to specify how long (in seconds) the dad client can be idle before timing out. If this group policy is disabled or not configured, a default value of 1800 seconds is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds that the dad client can be idle before timing out.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.client.idle.timeout setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Codepage of Audit Client

Use this group policy to specify the code page used for character encoding by the auditing service. Supported values are UTF8 and ISO8859-1.

If this group policy is disabled, not configured, or set to a value that is not supported, a default code page of UTF8 is used. If this group policy is enabled, you can specify a supported code page.

This group policy modifies the lang_setting setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Connect to Collector Timeout

Use this group policy to specify the amount of time, in seconds, the agent waits during each connection attempt before it determines that it cannot connect to a collector.

If this group policy is disabled or not configured, the default value is 60 seconds. This group policy modifies the dad.connect.collector.timeout configuration parameter.

You can use this parameter with the Common Settings group policy which allows you to specify the number of unsuccessful attempts that the agent can make to connect to a collector before notifying the user that it is not connected to a collector.

Set Fix NSS Configuration File Automatically

Use this group policy to specify whether to enable the dad process to fix /etc/nsswitch.conf automatically if anything goes wrong.

If this group policy is disabled, /etc/nsswitch.conf is not updated. If this group policy is enabled or not configured, /etc/nsswitch.conf is updated automatically by the dad process.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the autofix.nss.conf setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Max Cache Size

Use this group policy to specify the maximum number of entries that can be stored in the name service cache. Entries store query results about users and groups. This group policy is applicable only if the Set cache the query results group policy is enabled.

If this group policy is enabled, the query results are stored in memory up to the value that you specify, resulting in better performance. If this group policy is disabled or not configured, a default value of 80,000 entries is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the maximum number of entries to cache.
4. Click **OK** to save settings in this policy.

This group policy modifies the `cache.max.size` setting in the configuration file `/etc/centrifyda/centrifyda.conf`.

Set Resource Monitor Check Interval

Use this group policy to specify how often (in seconds) the resource monitor checks dad resource usage.

If this group policy is disabled or not configured, a default value of 600 seconds is used. If this group policy is enabled and set to 0 seconds, monitoring is disabled.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds for the interval.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.resource.timer setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Resource Monitor CPU Limit

Use this group policy to specify the maximum percentage of CPU cycles that dad can consume.

If this group policy is disabled or not configured, a default value of 50 percent is used. If this group policy is enabled and set to 0 percent, dad CPU usage is unlimited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the maximum CPU usage percentage.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.resource.cpulimit setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Resource Monitor CPU Limit Tolerance

Use this group policy to specify (in seconds) how long the maximum percentage of dad CPU cycles can be exceeded before dad is restarted. If this group policy is disabled or not configured, a default value of 5 seconds is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds that the maximum percentage of dad CPU cycles can be exceeded.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.resource.cpulimit.tolerance setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Resource Monitor File Descriptor Limit

Use this group policy to specify the maximum number of file descriptors that dad can open.

If this group policy is disabled or not configured, a default value of 1024 is used. If this group policy is enabled and set to 0, the number of file descriptors is unlimited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the maximum number of file descriptors.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.resource.fdlimit setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Resource Monitor Memory Limit

Use this group policy to specify the maximum number of bytes that can be allocated to dad.

If this group policy is disabled or not configured, a default value of 104857600 bytes (100 MB) is used. If this group policy is enabled and set to 0, dad memory allocation is unlimited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the maximum number of bytes that can be allocated to dad.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.resource.memlimit setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Resource Monitor Should Restart dad

Use this group policy to specify whether the resource monitor should restart dad if resource usage exceeds the limits set in other group policies or configuration parameters.

If this group policy is enabled, dad is restarted if resource usage exceeds specified limits. If this group policy is disabled or not configured, dad is not restarted if resource usage exceeds specified limits.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the dad.resource.restart setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Seal Over a Secure GSSAPI Connection Collector

Use this group policy to specify whether the auditing service seals network communications with the collector using a secure GSSAPI connection.

If this group policy is enabled or not configured, the network connection is sealed and cannot be read. If this group policy is disabled, the connection is not sealed and is human-readable.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the dad.gssapi.seal setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Sign Over a Secure GSSAPI Connection with Collector

Use this group policy to specify whether the auditing service signs network communications with the collector over a secure GSSAPI connection.

If this group policy is enabled or not configured, the network connection is signed. If this group policy is disabled, the network connection is not signed.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the dad.gssapi.sign setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Soft Limit of Open Files

Use this group policy to specify the number of file descriptors that can be used for audited sessions.

For some UNIX platforms, such as Solaris, the default number of available file descriptors for each process is insufficient of auditing sessions, because the Centrify Agent requires two descriptors per session.

Use this policy to increase the number of file descriptors available.

This policy modifies the dad.process.fdlimit parameter in the agent configuration file.

Set Update Agent Status Timeout

Use this group policy to specify how often (in seconds) the agent status in the audit store database is updated.

If this group policy is disabled or not configured, a default value of 300 seconds is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds between agent status updates.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.timer.update.agent.status setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Verification of Spool Disk Space Timeout

Use this group policy to specify the number of seconds between checks of disk space when the disk space reserved for offline storage is less than the percentage specified in the Set minimum percentage of disk space group policy. At each check, a warning message is written to the log file.

If this group policy is enabled, disk space is checked at the interval that you specify. If this group policy is disabled or not configured, a default value of 360 seconds is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds between disk space checks.
4. Click **OK** to save settings in this policy.

This group policy modifies the dad.timer.diskspace setting in the configuration file /etc/centrifyda/centrifyda.conf.

Direct Audit NSS Settings

Use the group policies under **DirectAudit NSS Settings** operations for the name switching service.

Override Audit Level for a List of Users

Use this group policy to specify individual user names and audit levels or a file that contains the list of user names for which you want to override the default audit level. For more information about the how this group policy affects user auditing in classic and hierarchical zones, see the discussion of the nss.user.override.userlist parameter in the *Configuration and Tuning Reference Guide*.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Type each user name and audit level using the following format:

   user_name[:*audit_level*]

   Alternatively, you can type the name of a file that contains a list of user names and audit levels.
4. Click **OK** to save your settings.

Set Audit Level for Conflict User

Use this group policy to specify the audit level to use if there is a conflict caused by a user being included in the ignores users list and having a use_sysrights audit level defined.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Select the audit level to use when there is a conflicting audit level defined for a user.
4. Click **OK** to save your settings.

Set Audit Level for Users Listed in uid.ignore

Use this group policy to specify the audit level for users who are listed in the user.ignore or uid.ignore file. For more information about the how this group policy affects user auditing in classic and hierarchical zones, see the discussion of the nss.user.override.auditlevel parameter in the *Configuration and Tuning Reference Guide*.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Select the audit level to use for users listed in the ignored user list.
4. Click **OK** to save your settings.

Set Ignored Programs

Use this group policy to list the programs that should not look up account information in Active Directory. If this group policy is not enabled or not configured, the following programs that are used for local account management are ignored by default:

useradd

userdel

adduser

usermod

mkuser

rmuser

chuser

If you enable this group policy, you must specify the list of programs to be ignored separated by spaces.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Type program names separated by spaces.
4. Click **OK** to save your settings.

Set No-Login Shells

Use this group policy to specify the shells that are treated as no-login shells.

If this group policy is disabled or not configured, the shells /sbin/nologin and /bin/false are treated as no-login shells. If this group policy is enabled, specify one or more shells in a space-separated list.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Type one or more shell names, separated by spaces, in the **No-login shells** field.
4. Click **OK** to save your settings.

This group policy modifies the nss.nolgin.shell setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Override Audit Level for Non-Hierarchical Zone Users

Use this group policy to specify the default audit level to use if a specific audit level is not defined for users in a classic zone. For more information about the how this group policy affects user auditing in classic zones, see the discussion of the nss.alt.zone.auditlevel parameter in the *Configuration and Tuning Reference Guide*.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Select the default audit level to use in classic zones.
4. Click **OK** to save your settings.

DirectAudit Shell Settings

Use the group policies under **DirectAudit Shell Settings** to configure shell operations for an audited shell.

Delinea

Defining Information Pattern in Custom Format to Obfuscate Sensitive Information

Use this group policy to specify information that is not displayed in auditing results. You specify the information to omit from display by defining a pattern in the group policy. Information that matches the pattern is not displayed in auditing results.

If this group policy is not configured or disabled, all information is displayed in auditing results. By default, this group policy is not configured.

If you enable this group policy, you must define a pattern as follows for information that is not displayed.

- Type the pattern that will not be displayed in auditing results. For example:

  nnnn-nnnn-nnnn-nnnn

- Each single character in a pattern corresponds to one character in actual session data.
- If you define more than one pattern, separate the patterns with spaces. For example:

  nnnn-nnnn A-nnnn

Supported characters in a pattern are as follows:

A	Any upper case letter.
d	Any character.
D	Any letter.
n	Any decimal digit character. e following: ~ ` ! @ # (space) $ % ^ & * (- _ = + [{] } | \ : ; ' < , > . ? /
-	Separator for exact matching in session data.
_	Separator for exact matching in session data.
(	Separator for exact matching in session data.
)	Separator for exact matching in session data.
,	Separator for exact matching in session data.
.	Separator for exact matching in session data.

This group policy modifies the dash.obfuscate.pattern setting in the centrifyda.conf configuration file.

Defining Information Pattern in Regex Format to Obfuscate Sensitive Information

Use this group policy to specify information that is not displayed in auditing results. You specify the information to omit from display by defining a regular expression in the group policy. Information that matches the regular expression is not displayed in auditing results.

If this group policy is not configured or disabled, all information is displayed in auditing results. By default, this group policy is not configured.

If you enable this group policy, you must define a regular expression as follows for information that is not displayed.

- Type a regular expression to define the information that will not be displayed in auditing results. For example:

  `[A-Z][0-9]{6}\\\\([0-9A-Z]\\\\)`

- If you define more than one regular expression, separate the regular expressions with spaces. For example:

  `[0-9]-[0-9] [a-z]-[0-9]`

This group policy modifies the `dash.obfuscate.regex` setting in the `centrifyda.conf` configuration file.

Delinea

Set Always Allowed Unix User Name List

Use this group policy to specify UNIX users who are allowed to use a session even if the computer cannot be audited due to environment setup issues.

If this group policy is disabled or not configured, root is the only user allowed to use an unaudited session. If you enable this group policy, you must specify a space-separated list of UNIX user names.

This group policy modifies the dash.user.alwaysallowed.list setting in the centrifyda.conf configuration file.

Set Audit All Invocations

Use this group policy to specify whether to audit all shell invocations.

If this group policy is **Enabled**, all login and non-login shells are audited.

If this group policy is **Disabled** or **Not Configured**:

- Only login shells and login sub-shells are audited.
- Invoked shells are not audited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the `dash.allinvoked` setting in the configuration file `/etc/centrifyda/centrifyda.conf`.

Set Audit Commands

Use this group policy to specify commands to audit.

If this group policy is enabled, you can create a command list and specify whether each command in the list is audited. Commands in the command list that have an action of **Enable** are audited by the auditing agent. Commands in the command list that have an action of **Disable** are not audited by the auditing agent.

If this group policy is disabled or not configured, commands to be audited must be configured manually on each UNIX computer.

When you add a command to the list, you must specify the full path to the command. You cannot add a link, shell, or wrapper script to the command list.

To use this group policy:

1. Double-click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **Show** to add or remove a command to the Audit Commands list.

   The Show Contents dialog box opens.
4. In the **Value Name** field, enter the full UNIX path name of the command.
5. In the **Value** field, enter "Enable" or "Disable" to specify whether to enable or disable auditing for the command.

   Click **OK** to save the changes and exit the Show Contents dialog box.
6. Click **Apply** in the Set audit commands dialog box to save settings in this policy, and then click **OK** to close the dialog box.

Set Audit STDIN Data

Use this group policy to specify whether the auditing agent captures standard input (stdin).

If this group policy is enabled or not configured, the auditing service records all session input and output, including standard input (stdin).

If this group policy is disabled, the auditing service records all session activity to standard output, but does not capture standard input data.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the dash.auditstdin setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Continue Working Without dad

Use this group policy to specify whether the audited shell (cdash) continues to run if the dad process is not running.

If this group policy is enabled or not configured, the audited shell continues to run when the dad process is not running. If this group policy is disabled, the audited shell stops running when the dad process stops running, and the user is prompted to restart the dad process.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the dash.cont.without.dad setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Except Auditing Password Strings

Use this group policy to specify strings that the auditing agent should ignore when capturing standard input data. For security, typed passwords are always ignored by default.

If this group policy is enabled, specify strings to ignore using regular expressions that do not include quotes. Leading and trailing spaces are ignored, spaces in the middle are not affected. For example:

```
dash.auditstdin.except: (prompt1\|prompt2)
```

will match strings like these:

```
This is prompt1:

Prompt2 asks for password:
```

If this group policy is disabled or not configured, this mandatory string pattern is applied:

```
(password[[:alnum:][:blank:][:punct:]]\*:[[:space:]]\*\$)\|(verify[[:alnum:] [:blank:][:punct:]]\*:[[:space:]]\*\$)
```

The default value is empty to ignore only the passwords that users enter.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Type a regular expression that defines the string to ignore.
4. Click **OK** to save settings in this policy.

This group policy modifies the dash.auditstdin.except setting in the configuration file /etc/centrifyda/centrifyda.conf. For more information about specifying exceptions, see the comments in the centrifyda.conf file.

Set Force Audit List

Use this group policy to specify one or more session binary files to audit.

If this group policy is enabled, the binary files that you specify are audited. You can separate entries in the list of binary files by typing a space or a comma. You can escape spaces or commas in file names using the backslash character (\).

If the group policy is disabled or not configured, no binary files are audited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Type one or more binary file names in the list.
4. Click **OK** to save settings in this policy.

This group policy modifies the dash.force.audit setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Not Audited ssh Command List

Use this group policy to specify a space-separated list of ssh commands that are not audited.

If the group policy is disabled or not configured, the commands scp, rsync, and sftp-server are not audited. If this group policy is enabled, the commands that you specify are not audited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Type one or more commands in the list, separated by spaces.
4. Click **OK** to save settings in this policy.

This group policy modifies the dash.ssh.command.skiplist setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Parent Process Skip List

Use this group policy to specify a list of parent processes that are not audited. If the name of a process's parent is in this list, the audited shell (cdash) will drop out without auditing.

If this group policy is disabled or not configured, the following processes are not audited by default:

sapstartsrv

gdm-binary

gdm-session-wor

kdm

sdt_shell

If you enable this group policy, you must specify a space-separated list of process names.

This group policy modifies the dash.parent.skiplist setting in the centrifyda.conf configuration file.

Set Reconnect to dad Timeout

Use this group policy to specify the number of seconds to wait after restarting the dad process before cdash attempts to reconnect to the auditing service.

If this group policy is enabled, the timeout that you specify is used. If this group policy is disabled or not configured, a default value of 1 second is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds to wait.
4. Click **OK** to save settings in this policy.

This group policy modifies the dash.reconnect.dad.wait.time setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Reconnect to dad Times

Use this group policy to specify how many times cdash attempts to connect to the auditing service after the dad process has started.

If this group policy is enabled, the number of attempts that you specify is used. If this group policy is disabled or not configured, a default value of 3 attempts is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of attempts.
4. Click **OK** to save settings in this policy.

This group policy modifies the dash.reconnect.dad.retry.count setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set Record Login Entry

Use this group policy to specify whether the auditing service should add utmp entries for the cdash pseudo terminals (pty). The setting of this group policy affects the results of whoami and who commands.

If this group policy is enabled, the auditing service adds utmp entries for cdash pty processes. Under this scenario, the whoami command in an audited shell works as expected, but the who command lists logged-in users twice.

If this group policy is disabled or not configured, the auditing service does not create additional utmp entries. Under this scenario, the whoami command in an audited shell cannot determine complete user information.

Workaround: on some operating systems, the who --lookup command works, but the who command lists users only once.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **OK** to save settings in this policy.

This group policy modifies the dash.loginrecord setting in the configuration file /etc/centrifyda/centrifyda.conf.

Set SHELL to Actual User Shell

Use this group policy to specify whether cdash sets the SHELL environment variable to the user's actual shell or to the audit shell.

If this group policy is enabled or not configured, the default value is true, and the SHELL environment variable is set to user's actual shell. If you disable this group policy, the SHELL environment variable is set to the DirectAudit audit shell.

This group policy modifies the dash.shell.env.var.set setting in the centrifyda.conf configuration file.

Set Skip Auditing Userlist

Use this group policy to specify the names of UNIX users and Active Directory users with a UNIX login who should not be audited. You can separate user names by typing a space or a comma. For example:

```
dash.user.skiplist: Mae kelly,dmorris,Booker
```

If this group policy is enabled, the users on the list are not audited. If this group policy is disabled or not configured, all users are audited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Create a list of users to audit.
4. Click **OK** to save settings in this policy.

This group policy modifies the `dash.user.skiplist` setting in the configuration file `/etc/centrifyda/centrifyda.conf`.

Show Actual User Running an Audited Command

Use this group policy to specify whether command-based auditing records will display the actual user account that executed the audited command, rather than just the run-as user account. Enable this policy to show both the run-as user account and the actual user account in command-based auditing records.

By default, this policy is not enabled, and only the run-as account used to run the privileged command is shown in auditing records. To enable this policy, set the parameter to `true`.

This group policy modifies the `dash.cmd.audit.show.actual.user` setting in the agent configuration file.

LPRC2 Client Settings

Use the group policies under **LRPC2 Client Settings** to control timeout and reconnect settings for the auditing service.

Set Contact with dad Timeout

Use this group policy to specify the number of seconds that cdash and dainfo wait before timing out while trying to contact the dad process.

If this group policy is enabled, the timeout that you specify is used. If this group policy is disabled or not configured, a default value of 30 seconds is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify the number of seconds to wait.
4. Click **OK** to save settings in this policy.

This group policy modifies the `lrpc2.timeout` setting in the configuration file `/etc/centrifyda/centrifyda.conf`.

Set Contact with dad Timeout for Rebinding Collector

Use this group policy to specify the number of seconds that dareload (-b) waits before timing out while trying to contact the dad process.

If this group policy is enabled, the timeout that you specify is used. If this group policy is disabled or not configured, a default value of 300 seconds is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. Select **Enabled**.
3. Specify the number of seconds to wait.
4. Click **OK** to save settings in this policy.

This group policy modifies the lrpc2.rebind.timeout setting in the configuration file /etc/centrifyda/centrifyda.conf.

Spool Disk Space Settings

Use the group policies under **Spool Disk Space Settings** to configure spool disk limits.

Set Maximum Disk Space for DB File Size

Use this group policy to specify maximum disk space (in bytes) to allocate to the offline storage database.

If this group policy is enabled, the file size that you specify is used. If this group policy is disabled or not configured, a default value of 0 bytes is used. A value of 0 bytes specifies unlimited file size.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify a file size.
4. Click **OK** to save settings in this policy.

This group policy modifies the `spool.maxdbsize` setting in the configuration file `/etc/centrifyda/centrifyda.conf`.

Set Minimum Percentage of Disk Space

Use this group policy to specify the minimum volume of disk space required on the partition containing the offline spool file before spooling stops.

You can set this value as a percentage of the disk space, or you can set it as an exact size. To set the value as an exact size, specify the unit value after the number value. The unit values are not case-sensitive.

You can specify the following unit values:

- B (byte)
- KB (kilobyte)
- MB (megabyte)
- GB (gigabyte)
- TB (terabyte)

The default value for this group policy is 10 percent of disk space.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify a value.
4. Click **OK** to save settings in this policy.

This group policy modifies the spool.diskspace.min parameter in the agent configuration file.

Delinea

Set Soft Limit Percentage of Disk Space

Use this group policy to specify the minimum volume of disk space that should be available for the offline storage file before warnings are posted to the log file. If available disk falls below the level specified in this group policy, a warning is logged and auditing will continue until disk space falls below the level specified in the Set minimum percentage of disk space group policy.

You can set this value as a percentage of the disk space, or you can set it as an exact size. To set the value as an exact size, specify the unit value after the number value. The unit values are not case-sensitive.

You can specify the following unit values:

- B (byte)
- KB (kilobyte)
- MB (megabyte)
- GB (gigabyte)
- TB (terabyte)

If this group policy is enabled, the volume that you specify is used. The default value is 12 percent.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify a value.
4. Click **OK** to save settings in this policy.

This group policy modifies the spool.diskspace.softlimit parameter in the agent configuration file.

Set Threshold Percentage of Disk Space to Reset Log State

Use this policy to specify a threshold percentage of disk space that is added to the minimum percentage of disk space (set in the Set minimum percentage of disk space group policy) that determines when the information/warning/error log state is reset. Message logging resumes only after the log state is reset.

When disk space drops below the minimum percentage (for example, 10%), a warning is logged. Additional warnings are not logged until disk space has risen above the minimum percentage + threshold percentage (for example, 10% + 2% = 12%), and then drops again to below the minimum percentage (10%).

Setting a threshold percentage is useful to prevent unnecessary log messages when disk space hovers near the minimum percentage and would otherwise trigger a log message every time the minimum percentage is crossed.

If this group policy is enabled, the percentage that you specify is used.

If this group policy is disabled or not configured, a default value of 2 percent is used.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Specify a percentage.
4. Click **OK** to save settings in this policy.

This group policy modifies the spool.diskspace.logstate.reset.threshold setting in the configuration file /etc/centrifyda/centrifyda.conf.

Windows Agent Settings

Use the group policies under **Windows Settings** to configure settings for agents on audited Windows computers.

Allow Selected Administrative Users to Stop the Auditing Service

Use this group policy to specify which users and groups can stop the auditing service on a local Windows computer using the DirectAudit Agent Control Panel.

If this policy is disabled or not configured, no users or groups can stop the auditing service through the control panel.

To use this group policy:

1. Double click the group policy in the right pane of the Group Policy Management Editor.
2. On the **Policy** tab, select **Enabled**.
3. Click **Add**.
4. In the Select Users or Groups dialog, specify the users or groups who will be able to stop the auditing service using the DirectAudit Agent Control Panel.
5. Click **OK** in the Select Users or Groups dialog.
6. Click **OK** in the group policy **Policy** tab to save your changes.

Audited User List

Use this group policy to specify which users and groups are audited. When you enable this group policy, only the users and groups you specify in the policy are audited. Be aware that this group policy takes precedence over the audit level set for a role.

If this policy is not configured, all users and groups are audited.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **Add** and identify specific users and groups to audit.
4. Click **OK** to save the list of users and groups.

See the *Auditing Administrator's Guide* for more information about the effect of choosing to enable this policy, the Windows Agent Settings policy, or a combination of both policies.

Non-Audited User List

Use this group policy to specify which users and groups are not audited. When you enable this group policy, only the users and groups you specify in the policy are not audited. If this policy is not configured, all users and groups are audited. If you enable both the Audited User List and the Windows Agent Settings policies, the users you include in the Non-audited user list take precedence over the Audited user list. Be aware that this group policy takes precedence over the audit level set for a role.

To use this group policy:

1. Double click the policy in the right pane of the Group Policy Management Editor.
2. On the Policy tab, select **Enabled**.
3. Click **Add** and identify specific users and groups to exclude from auditing.
4. Click **OK** to save the list of users and groups.

See the *Auditing Administrator's Guide* for more information about the effect of choosing to enable the Audited User List policy, the Windows Agent Settings policy, or a combination of both policies.

Set Maximum Recorded Color Quality

You can use this group policy to set the maximum color quality of recorded sessions. If this group policy is disabled or not configured, a default value of Low (8bit) is used.

To use this group policy:

1. Double click the group policy in the right pane of the Group Policy Management Editor.
2. Select **Enabled**.
3. Select one of the following options:
    - Native color
    - Low (8bit)
    - Medium (16bit)
    - Highest (32bit)
4. Click **OK** to save settings in this policy.

Set Maximum Size of the Offline Data File

You can use this group policy to specify the maximum percentage of disk space that the offline data file uses. If this group policy is disabled or not configured, the default is 10%.

To use this group policy:

1. Double click the group policy in the right pane of the Group Policy Management Editor.
2. Select **Enabled**.
3. Specify the maximum disk space percentage.
4. Click **OK** to save settings in this policy.

Set Update Agent Status Timeout

Use this group policy to specify how often (in seconds) the agent status in the audit store database is updated. If this group policy is disabled or not configured, a default value of 300 seconds is used.

To use this group policy:

1. Double click the group policy in the right pane of the Group Policy Management Editor.
2. Select **Enabled**.
3. Specify the number of seconds between agent status updates.
4. Click **OK** to save settings in this policy.

Additional Group Policies for UNIX Services

Server Suite provides additional group policies that control the configuration of specific Linux, UNIX, and Mac OS X services. This chapter describes these additional group policies.

The following topics are covered:

Common UNIX Settings

Some of the **Common UNIX Settings** group policies—such as Copy Files, Sudo Rights, and Copy Files from SYSVOL—are implemented with a dynamic link library (.dll) rather than an administrative template. Policies that are implemented with .dll plugins are always available on computers where the Server Suite Group Policy Management Extension is installed.

Other Common UNIX Settings policies—such as Set crontab Entries and Specify Commands to Run—are available only after you add the centrify_unix_settings.xml or centrify_unix_settings.admx template to the Group Policy Management Extension. You can add or remove the group policies from the centrify_unix_settings administrative template independent of the policies implemented in .dll plug-ins.

> **Note**: The Centrify Agent no longer supports the ADM administrative template in versions 2016 and later. All administrative templates must be formatted in either XML or ADMX.

Copy Files

Use this group policy to automatically copy a set of one or more files from the domain controller to each Linux, UNIX, and Mac OS X computer that joins the domain.

> **Note**: For the **Origin** domain in the **Source** file, you can only list out trusted domains in the current forest.

To enable and configure Copy files:

1. Create the files to copy in either of two locations:
   - sysvol on the domain controller.
   - A shared folder

     The sysvol location is assumed to be: \\domainController\sysvol\domainName\gpdata

     If the gpdata directory does not exist, create it first. Files to copy can be text or binary.
2. Select the Group Policy Object and click Edit to open the Group Policy Object Editor.
3. Select **Computer Configuration > Centrify Settings > Common Unix Settings**, then double-click **Copy files**.
4. In **Copy file policy setting**, select **Enabled**.
5. Click **Add**, then provide the following information:
   - Select a trusted domain or type a server name. For example, select acme.com or type a name admin1.acme.com.
   - Type the name of a file to copy or click **Browse** to browse to a directory and select a file. You can only add one file name at a time. To add multiple files, you must click **Add** for each one.
   - Type the name of a directory on the Centrify-managed computer, such as, /etc.
   - Select **Use destination file ownership and permissions** to apply permissions to the file based on the directory to which it is copied or select **Specify permissions and ownership** to manually apply permissions. When you select this button, you must enter permission data in the next three fields.
   - Enter file permissions using octal notation. Use man chmod for information.
   - Enter the UID for the file owner or click **Browse** to browse Active Directory for a user. The UID of the user you select is entered in this field.
   - Enter the GID for the user's group, or click **Browse** to browse Active Directory for a group. The GID of the group you select is entered in this field.
   - Select **Copy as binary file** to copy the file as binary. By default, files are copied as text files.
6. Click **OK** to add the specified file to the list.
7. Click **Add** to add another file to be copied.
8. When you are finished adding files, click **OK** to apply the policy with the files you have selected.
9. At any time, to remove a file, select it and click **Remove**. You may also select a file and click **Edit** to make changes to the information for the file, such as where to copy it or file permissions.

   > **Note**: If you change the policy from *enabled* to *not configured*, all files are removed from the list. However, files are not removed if you change from *enabled* to *disabled*.

Copy Files from SYSVOL

Use this group policy to automatically copy a set of one or more files from the domain controller to each Centrify-managed computer that joins the domain.

> **Note**: This group policy is still supported but has been deprecated in favor of Copy Files.

The steps to enable and configure the Copy Files from SYSVOL group policy are the same as Copy Files except that the files must be located in sysvol directory on the domain controller.

The sysvol location is assumed to be:

_domainController_\sysvol_domainName_\gpdata

You can create the gpdata directory if it does not exist, then put the files you want to copy in the directory. For more information, see Copy Files.

If you change the policy from *enabled* to *not configured*, all files are removed from the list. However, files are not removed if you change from *enabled* to *disabled*.

Sudo Rights

Use this group policy to centrally control which users can run commands as another user and the specific commands that can be run as that user. This policy configures the sudoers file with the appropriate lines when a user who has this policy applied logs on. When the user logs off, the lines applied for the user are removed and the sudoers file is restored to its previous state.

> **Note**: In order to work properly, the Sudo Rights group policy requires that the sudo package, including visudo and the sudoers file, is installed on the Delinea-managed computer.

When you select **Enabled** or **Disabled** for the Sudo Rights group policy, you can then add or remove user names and commands.

You add items to the text box just as you would to the sudoers file; that is, you type entries as you want them to appear in the sudoers file.

> **Note**: It is important to use the proper syntax for entries in the sudoers file. If the syntax isn't valid, the sudo command interprets the sudoers file as corrupt and no users are allowed to run commands using sudo rights. Therefore, in addition to the **Explain** tab, which describes the sudoers grammar in Extended Backus-Nauer Format (EBNF), this policy provides several other ways to help you enter and verify the correct syntax for your entries:

- The **Sample** tab shows sample sudoers file entries.
- A right click menu provides templates for inserting alias entries, as well as the ability to browse for users.
- Validation code verifies that there are no syntax errors in your entries before writing the entries to the sudoers file.

For example, the following procedure shows you how to create a command alias (for the rm command) and how to permit a user to simulate running as root to run the /usr/sbin/backup command:

1. In the Group Policy Editor, open the Sudo Rights policy properties and select **Enabled** or **Disabled**. Right-click and select **Insert Alias > Cmnd**. The following text is inserted in the box:

   ```
   Cmnd_Alias <alias>=<command>
   ```

2. Replace <alias> with DEL and <command> with the full path to the rm command:

   ```
   Cmnd_Alias DEL=/bin/rm
   ```

3. Click **Apply** to enter the command alias and verify that the syntax is correct.

4. On the next line, enter the following:

   ```
   jsmith ALL = /usr/bin/backup
   ```

   This entry gives jsmith all privilege on the Linux, UNIX, or Mac OS X computer to run the backup command. The user, jsmith, still needs to enter a password to run this command. You can use the context menu to change the entry and remove the password requirement.

5. After the '=' sign, insert a space, then right-click and select **Insert Value > Cmnd > NOPASSWD:** and NOPASSWD: is added to the entry.

   The entry now should now look like this:

   ```
   jsmith ALL = NOPASSWD /usr/bin/backup
   ```

6. Click **Apply** or **OK** to save the entry.

When a user to whom this policy applies logs in, the appropriate lines are added to the sudoers file. For example, when the user jsmith logs on to the computer machine1, the following is added to the sudoers file:

```
jsmith ALL = NOPASSWD /usr/bin/backup

Cmnd_Alias DEL=/bin/rm
```

If any of your entries have improper syntax, you will see an error message. Click **Details** to get information about the syntax error, then click **Cancel** and make corrections.

> **Note**: The right-click context menu also allows you to browse for user names. Right-click and select **Insert Value > Browse**, then enter search criteria. Select a name and click **OK**, and that name is added to the entry. In addition, as you add aliases, they are added to the context menu. For example, if you right-click and select **Insert Value > Cmnd**, you should see the **DEL** alias that you created in the previous procedure.

For more information about using sudo and the syntax to use in the sudoers file, see the man pages for sudo and sudoers appropriate to your operating

environment.

Set crontab Entries

Use the **Set crontab entries** group policy to manage crontab entries for individual users or for an entire computer. The management of computer-level crontab entries is performed as the root user. User-specific crontab entries run under the user's account.

Select the **Computer Configuration > Centrify Settings > Common UNIX Settings > Set crontab entries** group policy to configure computer-based policies for the root user.

Select the **User Configuration > Centrify Settings > Common UNIX Settings > Set crontab entries** group policy to configure user-based policies for individual users.

Both Set crontab entries group policies are defined in the centrify_unix_settings.xml administrative template.

If you select **Enabled** for either group policy, you can then click **Show** to add or remove entries in the /etc/crontab file.

To add crontab entries to the policy, click **Add**. You can then type the entry to be added to the file using the appropriate format for the local computer's operating environment, then click **OK**.

The standard format for entries in this file is:

```
Minute Hour DayOfMonth Month DayOfWeek User Command
```

For the Minute field, the valid values are 0 through 59. For the Hour field, the valid values are 0 through 23. For the Day of the Month field, the valid values are 1 through 31. For the Month of the Year field, the valid values are 1 through 12. For the Day of the Week field, the valid values are 0 through 6, with 0 representing Sunday. An asterisk (*) can be used in any of these fields to indicate all valid values.

For the Command field, you should type the entire command line to be executed at the specified times.

For example, to remove core files every weekday morning at 3:15 am, you could type an entry similar to this:

```
15 3 \* \* 1-5 find \$HOME -name core 2\>/dev/null \| xargs rm -f
```

Specify Commands to Run

Use the **Specify commands to run** group policy to configure one or more commands to run any time a computer is rebooted and at the computer group policy refresh interval when applied to a computer, or when a user logs on and at the user group policy refresh interval when applied to user accounts.

Select the **Computer Configuration > Centrify Settings > Common UNIX Settings > Specify commands to run** group policy to configure computer-based policies that run when a computer restarts and at the computer group policy refresh interval.

Select the **User Configuration > Centrify Settings > Common UNIX Settings > Specify commands to run** group policy to configure user-based policies that run when users log on.

Both **Specify commands to run** group policies are defined in the centrify_unix_settings.xml administrative template.

If you select **Enabled** for either group policy, you can then click **Show** to add or remove commands.

To add commands to the policy, click **Add**. You can then type the commands to be added to the file using the appropriate format for the local computer's operating environment, then click **OK**.

For computers, the commands you specify should be general computer commands.

For user accounts, the commands you specify should be user-specific. The user account that is used to run the command is recorded in the $ENV variable in the RunCommand.pl script. An entry in /var/log/centrifydc.log identifies the user. For example:

The commands are invoked for user: wtest2

Linux Settings

Use the group policies under **Linux Settings** to configure the following basic settings:

- Enforce Screen Locking
- Specify Basic Firewall Settings
- Specify Network Login Message Settings

Use the policies under **Linux Settings** › Security to configure the following computer configuration settings:

- Certificate validation method
- Enable Smart Card Support
- Lock Smart Card Screen for RHEL
- Require Smart Card Login

Use the policies under **Linux Settings** › Security to configure the following user configuration settings:

- Specify applications to import system NSSDB

Enforce Screen Locking

Use the **Enforce screen locking** group policy to control the screen lock enforcement and the timee out value for all users logging on to a computer or for individual users. Select the **Computer Configuration > Centrify Settings > Linux Settings > Enforce screen locking** group policy to configure computer-based screen locking. Select the **User Configuration > Centrify Settings > Linux Settings > Enforce screen locking** group policy to configure user-based screen locking.

Both Enforce screen locking group policies are defined in the centrify_unix_settings.xml administrative template. The mechanism used to control screen locking is specific to Linux-based computers, however, so the policies are listed under the Linux Settings category.

The most common way to handle screen locking on Linux computers is through the xscreensaver program. Although the xscreensaver program has a default configuration file, this centralized configuration file is automatically overridden if users have a local .xscreensaver file in their home directory. To enforce a centralized screen locking policy, this group policy creates a directory in the user's home directory that is owned by root and places a file that is also owned by root in this directory, so that the file cannot be removed by the user. When the xscreensaver program tests to see if there is a regular file in the user's home directory and does not find it, it uses the system configuration file.

> **Note**: If the user home directory is NFS-mounted, with the root-squash option set, this policy will not work as intended because the group policy (running as root) cannot create the un-deletable $HOME/.xscreensaver directory. As a workaround, the user may manually create the .xscreensaver directory with a umask of 0700 in the user home directory on the NFS server to prevent the user from changing .xscreensaver.

If you select **Enabled** for this group policy as a computer configuration policy, you can make the policy the default screen locking behavior for all users of the computer and set the default number of minutes to wait before locking the screen, but users are free to override the default.

To enforce this policy for individual users, you should enable the screen locking policy as a user configuration policy. However, enabling the user configuration screen locking group policy prevents users from changing their screen locking parameters.

Specify Basic Firewall Settings

Use the **Specify basic firewall settings** group policy to set up a simple exclusionary firewall on targeted computers using iptables. If you select **Enabled** for this group policy, the firewall will allow all outgoing traffic but block any inbound traffic, except ssh and ping, by default. To customize the firewall settings, select **Enabled**, then click **Show** to add or remove entries.

The Specify basic firewall settings group policy is defined in the centrify_linux_settings.xml administrative template.

To modify the default behavior of the policy, click **Add**. You can then type the appropriate entries to set up the iptables using the following format:

```
Name:Type:Protocol:Port:Action
```

where

- Name is an identifying string.
- Type is either INPUT or OUTPUT (caps are mandatory). Use INPUT to block incoming requests on the specified port and OUTPUT to block the computer from sending on that port.
- Protocol should be one of tcp, udp, icmp, or all.
- Port is the port number.
- Action is either ACCEPT or DROP.

For example, to allow connections to the computer that acts as a web server:

```
HTTP:INPUT:tcp:80:ACCEPT
```

The following example would prevent the computer from sending mail:

```
SMTP:OUTPUT:tcp:25:DROP
```

When you are finished setting up the iptables, click **OK**.

This group policy does not incorporate any Linux distribution or release-specific configurations to enable broad use of the policy.

Any existing tables are purged and new tables are built from the data pushed to the computer through the group policy.

Specify Network Login Message Settings

Enable the **Specify network login message settings** group policy to display the same welcome messages for both remote and local users. This group policy creates a symbolic link between the files /etc/issue.net and /etc/issue. If you disable the policy, the symbolic link is removed and /etc/issue.net is restored, if it existed originally.

The Specify network login message settings group policy is defined in the centrify_linux_settings.xml administrative template.

Security

Use the group policies under **Security** to configure the following computer settings:

- Certificate Validation Method
- Enable Smart Card Support
- Lock Smart Card Screen for RHEL
- Require Smart Card Login

These computer configuration policies are only applicable for Red Hat Enterprise Linux and Mac OS X. See the release notes for information about the smart card manufacturers and models supported. If you are setting group policies for Mac OS X, see the *Administrator's Guide for Mac* for additional group policies available only for this platform.

Use the group policy under **Security** to configure the following user settings:

- Specify Applications to Import System NSSDB

Delinea

Certificate Validation Method

Use this group policy to configure the certificate validation method.

For **Certificate Revocation List**, select one of the following settings:

- **Off**: No revocation checking is performed.
- **Best attempt**: The certificate passes unless the server returns an indication of a bad certificate. This setting is recommended for most environments.
- **Require if cert indicates**: If the URL to the revocation server is provided in the certificate, this setting requires a successful connection to a revocation server as well as no indication of a bad certificate. Specify this option only in a tightly controlled environment that guarantees the presence of a CRL server. If a CRL server is not available, SSL and S/MIME evaluations could hang or fail.
- **Require for all certs**: This setting requires successful validation of all certificates. Use only in a tightly controlled environment that guarantees the presence of a CRL server. If a CRL server responder is not available, SSL and S/MIME evaluations could hang or fail.

Enable Smart Card Support

Use this group policy to enable users to log in with smart cards. Enabling this policy automatically enables the Group Policy Settings Enable user group policy policy.

To remove smart card support after it has been enabled, you need to set this policy to Disabled. Changing the policy to Not configured after being Enabled does not remove the smart card requirement.

Specifying the PKCS #11 Module

Optionally, after enabling this policy, you can specify the PKCS #11 module to be used by smart card components. By default, smart card components use the Centrify Coolkey PKCS #11 module. However, Coolkey does not support all smart cards so you can specify a different module if necessary by specifying the absolute path to your PKCS #11 module in **PKCS #11 Module**. For example:

```
PKCS #11 Module /usr/\$LIB/pkcs11/opensc-pkcs11.so
```

This field supports the use of the $LIB environment variable in the path, which allows a single group policy to work for 32-bit and 64-bit systems. At run time on 32-bit systems $LIB resolves to lib, while on 64-bit systems it resolves to lib64. When you specify a PKCS #11 module, the group policy sets the following parameter in the Centrify configuration file to the specified path:

```
rhel.smartcard.pkcs11.module
```

After you enable this policy, it does not go into effect until you join the computer to the domain (if not already joined) and run the adgpupdate command.

Lock Smart Card Screen for RHEL

Use this group policy to lock the computer screen when the smart card is removed from the reader. Note that the Enable smart card support policy must be enabled in order for this policy to take effect.

To remove lock screen support after it has been enabled, you need to set this policy to Disabled. Changing the policy to Not configured does not remove this feature.

After you enable this policy, it does not go into effect until you join the computer to the domain (if not already joined) and reboot the computer.

Require Smart Card Login

Use this group policy to require all users to log in with a smart card. When this policy is enabled, no users can log in to the machine simply with a user name and password.

The Enable smart card support policy must be enabled in order for this policy to take effect. After you enable this policy, it does not go into effect until you join the computer to the domain (if not already joined) and reboot the computer.

If you don't want to require smart card login for all users, you can use the Active Directory account option to require smart card login for a specific user. For example:

- In Active Directory Users and Computers select the user's account and open the Properties.
- Click the Account tab, scroll down the list of Account options and select the **Smart card is required for interactive logon** option.

Specify Applications to Import System NSSDB

Use this group policy to specify one or more locations to import the NSS database that resides in /etc/pki/nssdb. This policy synchronizes the individual NSS application databases with the system NSS database. Enabling this policy gives these applications access to the most current certificates and CRLs. Many applications, including Firefox and Thunderbird have their own NSSDB for the user. This feature enables a mapper that parses the profiles.ini file at the location you specify and imports the certificates and CRLs to the location specified in the profile.

If you are using Firefox, you must run Firefox at least once before enabling this policy. Firefox creates the user-specific preference folder on first usage.

Enable this policy and click the **Add** button to specify the application directory in which to import the system NSS database. For each application, enter the location of its profiles.ini file. The entry must be in relation to the home directory of the user; that is, the path should start with ~/. For example, the entry for the default location of the Firefox profiles.ini file would be ~/.mozilla/firefox.

To discontinue using this policy after it has been enabled, you need to set it to Disabled. Changing the policy to Not configured does not discontinue the import.

Once enabled, this group policy takes effect dynamically at the next group policy refresh interval.

SSH (Secure Shell) Settings

Use the group policies **SSH Settings** to manage different aspects of secure shell (ssh) authentication. The SSH Settings group policies are defined in the centrify_unix_settings.xml administrative template.

When you set SSH Settings group policies, parameters are set in the secure shell configuration file, /etc/centrifydc/ssh/sshd_config, not in the regular configuration file. You might have other ssh configuration files stored in other default locations, depending on the operating system. The service first checks the /etc/centrifydc/ssh directory for configuration files, then looks for the configuration file in the /usr/local/etc directory on AIX computers, and /etc/ssh on AIX, SunOS, IRIX/IRIX64, and Linux computers.

Add sshd_config Properties

Use this group policy to configure secure shell properties defined in the sshd_config file by group policy.

There are two settings for this group policy:

- If the group policy is **Enabled**, you can click **Add** to add new properties as name/value pairs or edit and/or remove secure shell properties defined in the sshd_config file.
- If it is **Disabled**, or **Not Configured**, you can not add new properties as name/value pairs or edit and/or remove secure shell properties defined in the sshd_config file.

Allow Challenge-Response Authentication

Use this group policy to specify whether challenge and response authentication is allowed. Enabling this group policy sets the ChallengeResponseAuthentication option in the /etc/centrifydc/ssh/sshd_config file to yes. This setting is required to use multi-factor authentication for secure shell sessions. For more information about preparing to use multi-factor authentication, see the *Multi-factor Authentication Quick Start Guide*.

Allow Groups

Use this group policy to specify a list of groups whose members are allowed to log on through sshd. You can use wildcards (* and ?) to identify the groups to allow. Separate multiple names by spaces. Users whose primary or supplementary group membership matches any of the specified groups will be allowed to log on using a secure shell `sshd` session.

You cannot use numeric group identifiers (GID) to identify groups. By default, log in is allowed for all groups.

This group policy modifies the `AllowGroups` setting in the `/etc/centrifydc/ssh/sshd_config` file.

Allow GSSAPI Authentication

Use this group policy to allow authentication based on GSSAPI, either as the result of a successful key exchange, or through GSSAPI user authentication.

Be certain that you are using a version of OpenSSH that supports GSSAPI authentication. Otherwise, setting this policy will render the OpenSSH server unable to start.

This group policy modifies the `GSSAPIKeyExchange` setting in the `/etc/centrifydc/ssh/sshd_config` file.

Allow GSSAPI Key Exchange

Use this group policy to allow key exchanged based on GSSAPI. Note that GSSAPI key exchange does not rely on ssh keys to verify host identity.

This policy applies to protocol version 2 only.

This group policy modifies the `GSSAPIAuthentication` setting in the `/etc/centrifydc/ssh/sshd_config` file.

Allow Users

Use this group policy to specify a list of users who are allowed to log on through sshd. You may use wildcards (* and ?) to identify the users to allow. Separate multiple names by spaces.

You may also specify a host name to allow a user or users only from particular hosts. For example, mbradley@oak.com.

You may not use numerical group IDs to identify users.

This group policy modifies the Allowusers setting in the /etc/centrifydc/ssh/sshd_config file.

Deny Groups

Use this group policy to specify a list of groups whose members are not allowed to log on through sshd. You may use wildcards (* and ?) identify the groups to disallow. Separate multiple names by spaces. Log on through sshd is not allowed for users whose primary or supplementary group list matches any of the specified groups.

You may not use numerical group IDs to identify groups.

By default, log in is allowed for all groups.

This group policy modifies the DenyGroups setting in the /etc/centrifydc/ssh/sshd_config file.

Deny Users

Use this group policy to specify a list of users who are not allowed to log on through sshd. You may use wildcards (* and ?) to identify the users to disallow. Separate multiple names by spaces.

You may also specify a hostname to disallow a user or users only from particular hosts. For example, mbradley@oak.com.

You may not use numerical group IDs to identify users.

By default, log in is allowed for all users.

This group policy modifies the DenyUsers setting in the /etc/centrifydc/ssh/sshd_config file.

Enable Application Rights

Use this group policy to enable SSH application rights. Depending upon the user's role settings, this allows applications to grant rights such as password log in and allow normal shell. You configure and assign rights in zone manager.

This feature is supported in Centrify OpenSSH 4.5.4 or later. Setting this property on an unsupported version renders OpenSSH unable to start.

This group policy adds the following ServiceAuthLocation parameter to the /etc/centrifydc/ssh/sshd_config file for all computers to which the group policy object applies. It sets the path to the dzsshchk command which verifies the rights for users when they log in with SSH:

```
ServiceAuthLocation /usr/share/centrifydc/libexec/dzsshchk
```

This policy is disabled by default.

Enable PAM Authentication

Use this group policy to enable PAM authentication, account processing, and session processing. When you enable this policy, PAM authentication is implemented through the ChallengeResponseAuthentication mechanism.

Depending on your PAM configuration, enabling this policy may bypass the sshd settings of PasswordAuthentication, PermitEmptyPasswords, and PermitRootLogin without-password.

If you just want the PAM account and session checks to run without PAM authentication, then enable this policy but disable the ChallengeResponseAuthentication mechanism in sshd.

Be certain that you are using a version of OpenSSH that supports PAM authentication. Otherwise, setting this policy will render the OpenSSH server unable to start.

This group policy modifies the UsePAM setting in the /etc/centrifydc/ssh/sshd_config file.

Enable SSO MFA Properties

Use this group policy to enable multi-factor authentication for users after they authenticate through single sign-on using Centrify OpenSSH.

This group policy is only supported by OpenSSH versions 5.3.1 and later. If you attempt to enable this policy while running an earlier version of OpenSSH, the OpenSSH server will not start.

By default, this group policy is not enabled.

This group policy modifies the SSOMFA setting in the /etc/centrifydc/ssh/sshd_config file.

Match Block

You can use the Match Block group policy to add or edit match criteria so that you can match users using a variety of sub-directives.

For example, you can use this group policy if you want to set different kinds of combinations of key/value pairs to match conditions, such as the following general examples to set:

- A key/value to match a condition (key/value)
- Multiple keys/values to match a condition (key/value)
- The same keys/values to match multiple conditions (keys/values)
- Multiple keys/values to match multiple conditions (keys/values)
- Multiple conditions (keys/values) (This has the same effect as setting the policies (keys/values) individually)

For example, you could use the Match Block group policy to fulfill the following use case:

"Any user with an account login ending with *-adm will not be able to use PubkeyAuthentication"

For this example, you would set "Match User *-adm" in the match directives and set "PubkeyAuthentication no" in it's sub-directives.

The arguments to Match are one or more criteria-pattern pairs or the single token All which matches all criteria. The available criteria are User, Group, Host, LocalAddress, LocalPort, and Address.

The match patterns may consist of single entries or comma-separated lists and may use the wildcard and negation operators.

The patterns in an Address criteria may additionally contain addresses to match in CIDR address/masklen format, such as "192.0.2.0/24" or "3ffe:ffff::/32". Note that the mask length provided must be consistent with the address - it is an error to specify a mask length that is too long for the address or one with bits set in this host portion of the address. For example, “192.0.2.0/33” and “192.0.2.0/8” respectively.

Check the group policy explain text for details on which keywords can be used.

Permit Root Login

Use this group policy to specify whether and how root can log in using ssh. When you enable the policy, select one of the following options from the drop-down list:

- yes — Allow root to log in using ssh.
- without password — Disable password authentication for root. It is still possible for root to log in using another form of password authentication, such as keyboard-interactive PAM.
- forced commands only — Allow root log in with public-key authentication, but only if the command option has been enabled. All other authentication methods are disabled for root.
- no — Do not allow root to log in through ssh.

This group policy modifies the PermitRootLogin setting in the /etc/centrifydc/ssh/sshd_config file.

Set Banner Path

Use this group policy to identify a file on the Linux, UNIX, or Mac OS X computer to be sent to a remote user requesting authentication. Typically, the file contains a warning about authentication to provide legal protection to the company.

This group policy modifies the Banner setting in the /etc/centrifydc/ssh/sshd_config file.

Enable Rlogin Control SFTP

Use the Enable Rlogin Control Sftp group policy to allow remote sftp login to AIX machines when rlogin=false for the non-root users in /etc/security/user file.

This group policy overrides the rlogin=false setting in the /etc/security/user file.

Set RloginControlSftp in /etc/centrifydc/ssh/sshd_config. Default is yes. The setting term yes or no applies to whether to respect the rlogin setting or not.

- RloginControlSftp=yes, respects the rlogin=false setting, and denies the remote login. This is the default.
- RloginCongrolSftp=no, overrides the rlogin=false setting for the user, and allows remote sftp login.

Enable Rlogin Control SSH

Use the Enable Rlogin Control SSH group policy to allow remote ssh login to AIX machines when rlogin=false for the non-root users in /etc/security/user file.

This group policy overrides the rlogin=false setting in the /etc/security/user file.

Set RloginControlSsh in /etc/centrifydc/ssh/sshd_config. Default is yes. The setting term yes or no applies to whether to respect the rlogin setting or not.

- RloginControlSsh=yes, respects the rlogin=false setting, and denies the remote login. This is the default.
- RloginCongrolSsh=no, overrides the rlogin=false setting for the user, and allows remote ssh login.

Specify Authorized Key File

Use this group policy to specify the file that contains the public keys that can be used for user authentication.

If you enable this policy, specify the file in the authorized keys file box. The file specification is interpreted as an absolute path or a path relative to the user's home directory. To specify multiple files, separate each entry with a space.

The default file specification is .ssh/authorized_keys. In addition, if there are backward compatibility issues, .ssh/authorized_keys2 is checked.

Specify Ciphers Allowed for Protocol Version 2

Use this group policy to specify the ciphers allowed for SSH protocol version 2. If you enable this policy, you can add or delete ciphers to increase the speed of SSO.

Multiple ciphers must be separated by commas. If you want to add a cipher to the list, use the '+' character at the beginning of the name. If you enter the name only, you will replace the existing ciphers with the new cipher.

The order of the cipher list will determine the order that sshd uses the ciphers. For example, if you want to increase the speed of SSO, you can place the cipher, aes128-ctr, at the beginning of the list.

When this policy is disabled, the default cipher list, which is the most secure grouping, is used, but may cause delays in SSO.

To enable this group policy, you must be running Centrify OpenSSH 5.3.0 or later.

This group policy modifies the Ciphers setting in the following file: /etc/centrifydc/ssh/sshd_config.

Specify Client Alive Interval

Use this group policy to specify a timeout interval, in seconds, for requesting a response to client alive messages. If sshd does not receive a response from the client to client alive messages within the timeout interval, it sends a message through the encrypted channel requesting a response.

The default is 0, indicating that these messages are not sent to the client.

This group policy modifies the ClientAliveInterval setting in the following file: /etc/centrifydc/ssh/sshd_config.

Specify Log Level

Use this group policy to specify the log level for messages from sshd. When you enable the policy, you can select the level from a drop-down list.

The default level is INFO. DEBUG and DEBUG1 are equivalent. Logging with any of the DEBUG levels violates users privacy and is not recommended for general use.

This group policy modifies the LogLevel setting in the /etc/centrifydc/ssh/sshd_config file.

Specify Login Grace Period

Use this group policy to specify the time, in seconds, after which the server disconnects if a user has failed to log in. The default is 120 seconds.

Use 0 to specify no time limit.

This group policy modifies the LoginGraceTime setting in the /etc/centrifydc/ssh/sshd_config file.

Specify Maximum Client Alive Count

Use this group policy to specify the maximum number of client alive messages that may be sent by the secure shell daemon (sshd) without receiving a response from the client.

When the policy is enabled, the default setting is three messages.

If the threshold is reached while sshd is sending a client alive message, sshd disconnects the client, terminating the session.

This group policy modifies the ClientAliveCountMax setting in the /etc/centrifydc/ssh/sshd_config file.

Mac OS X Settings

Centrify group policies allow administrators to extend the configuration management capabilities of Windows Group Policy Objects to managed Mac OS X computers and to users who log on to Mac OS X computers. This chapter provides a high-level overview to using the group policies that can be applied to Mac OS X computers and users. For details on individual policies, see the *Administrator's Guide for Mac*.

The following topics are covered:

Group Policies and System Preferences

Windows administrators who have Mac OS X computers in their organization often want to manage settings for all of their computers and users using a standard set of tools. In a Windows environment, the standard method for managing computer and user configuration settings is through group policies applied to the appropriate site, domain, or organizational unit (OU) for computer and user accounts.

The Centrify administrative template for Mac OS X (centrify_mac_settings.xml or centrify_mac_settings.admx) provides group policies that can be applied to control the behavior of Mac OS X computers running supported versions of the Mac OS X operating system, and the configuration settings for the users who log on to those computers. By adding the administrative template for Mac OS X to a Group Policy Object, Windows administrators can access and set native Mac OS X system preferences.

This chapter provides an overview of the group policies you can enable under **Mac OS X Settings** if you add the administrative template. These group policies control the following types of Mac OS X system preferences:

- Accounts
- Appearance
- Desktop & Screen Saver
- Dock
- Saver
- Security
- Sharing
- Software Update

When you Enable a group policy in a Windows Group Policy Object, you effectively set a corresponding system preference on the local Mac OS X computer where the group policy is applied.

For example, if you enable the group policy **Computer Configuration > Policies > Centrify Settings > Mac OS X Settings > Security & Privacy > Require password to unlock each secure system preference**, it is the same as opening the Security & Privacy system preference on a local Mac OS X computer, clicking **Advanced**, and setting the **Require an administrator password to access locked preferences** option.

On the local Mac OS X computer, the corresponding option is checked:

> **Note**: Not all group policies apply to all versions of the Mac OS X operating environment or all Mac computer models. If a particular system preference doesn't exist, isn't applicable, or is implemented differently on some computers, the group policy setting may be ignored or overridden by a local setting. Use the information in this chapter as a general guideline to group policies for Mac OS X. Refer to *Administrator's Guide for Mac* for detailed group-policy information for all Mac OS X versions.

Once the administrative template for setting Mac OS X group policies is installed as described below, the Windows administrator can use Group Policy Management and Group Policy Management Editor to define, link, and enforce these policies on Mac OS X computers that are joined to an Active Directory domain.

For more information about using Active Directory Users and Computers or Group Policy Management to create and link Group Policy Objects to sites, domains, or OUs, see Adding Centrify Settings to Group Policies Objects You can also refer to that section for more information about how to add administrative templates to a Group Policy Object.

Adding Mac OS X Group Policies

Centrify group policies for Mac OS X consist of two components:

- An administrative template (.xml or .admx file) that describes the policy to the Group Policy Object Editor which runs on Windows.
- A system executable and its associated configuration files that reside on the Mac and determine the policy for the local computer or for the user who is logged into the local computer and implement the policy.

Installing the Administrative Template

By default, the .xml file for Mac OS X group policies (centrify_mac_settings.xml) is installed in the C:\Program Files\Centrify\Access Manager\group policy\policy directory when you select **Group Policy Editor Extension** in the setup program. To use any of the policies, you must add centrify_mac_settings.xml to a group policy object.

Centrify provides templates in both XML and ADMX format. In most cases, it is best to use the XML template. The ADMX template file, centrify_mac_settings.admx, resides in a different directory than the .xml file.

To install the administrative template for Mac OS X group policies:

1. Create or edit an existing Group Policy Object linked to a site, domain, or OU that includes Mac OS X computers.

   For more information about creating and linking a Group Policy Object, see the Active Directory documentation or Adding Centrify settings to Group Policies Objects.

2. In the Group Policy Object Editor, expand Computer cnfiguration, then right-click Centrify Settings and select **Add/Remove Templates**.

3. Click **Add**, then navigate to the directory that contains the Centrify centrify_mac_settings.xml administrative template. By default, administrative templates are located in the local C:\Program Files\Centrify\Access Manager\group policy\policy directory.

4. Select the centrify_mac_settings.xml file, click **Open** to add this template to the list of Current Policy Templates, then click **Close**.

You should now see the administrative template for the Mac OS X group policies listed as **Mac OS X Settings** under **Centrify Settings** in the Group Policy Object Editor.

Installing the Agent and System Files

To install the Centrify Agent and the configuration files for group policy on a Mac OS X computer, run the package installer for Mac OS X and follow the instructions displayed. For more information about installing the agent or joining the domain on a Mac OS X computer, see the *Administrator's Guide for Mac*.

Enabling and Disabling Mac OS X Group Policies

Like other group policies, policies for Mac OS X users and computers are organized into categories within the Windows Group Policy Object Editor under **Computer Configuration > Centrify Settings** or **User Configuration > Centrify Settings**. These categories typically map to Mac OS X system preferences and individual policy settings map to specific system preferences settings.

Once enabled, policies get applied at the next group policy refresh interval, after the user logs out and logs back in, or after the computer has been rebooted. The description of each group policy indicates whether the policy can be applied "dynamically" at the next refresh interval or requires a re-login or a reboot.

> **Note**: The system preference updated on an individual computer must be closed, then reopened for the group policy setting to be visible.

In most cases, group policies can be Enabled to activate the policy or Disabled to deactivate a previously enabled policy. Changing a policy to Not Configured has no effect for any Mac OS X group policies. Once a group policy is set on a local computer, it remains in effect even if the computer leaves the Active Directory domain. The administrator or users with an administrative account can change settings manually at the local computer, but any manual change are overwritten when the group policy is applied.

Setting Mac OS X Computer Policies

The following table lists the categories of group policies you can set for Mac OS X computers. These group policies are in the Mac OS X administrative template (centrify_mac_settings.xml) and accessed from **Computer Configuration > Centrify Settings > Mac OS X Settings**.

802.1X Settings	Create computer profiles for wireless network authentication. The profiles you specify with these group policies are created in the Network system preferences pane.
Accounts	Control the look and operation of the login window on Mac OS X computers. These group policies correspond to Login Options in the Accounts system preference.
App Store Settings (Deprecated)	This policy was intended to control access to the App Store, however, it has been deprecated and no longer has any effect when enabled. It is provided to allow an administrator to disable the policy if it was set in an earlier version of the authentication service or the agent.
Custom Settings	Specify whether to use the Custom payload to specify preference settings for applications that use the standard **plist** format for their preference files. You can use this group policy to add keys and values to an existing preferences **plist** file.
Energy Saver	Control sleep and wake-up options on Mac OS X computers. These group policies correspond to settings in the Hardware: Energy Saver system preference.
Firewall	Control the firewall configuration on Mac OS X computers. These group policies correspond to settings in the Firewall pane of the Sharing system preference.
Internet Sharing	Manage Internet connections on Mac OS X computers. These group policies correspond to settings in the Internet pane of the Sharing system preference.
Network	Control DNS searching and proxy settings. These group policies correspond to settings in the TCP/IP and Proxies panes of the **Network** system preference.
Remote Management	Control Apple Remote Desktop access for zone users. These group policies correspond to the **Manage > Change Client Settings** options in Apple Remote Desktop.
Scripts	Deploy login scripts when an Active Directory user or local user logs on to a Mac OS X computer. You create the scripts and store them in the Active Directory domain's system volume (sysvol). They are transferred to the Mac OS X computer when the group policies are applied and executed when a user logs on.
Security & Privacy	Control security settings on Mac OS X computers. These group policies correspond to settings in the Personal: Security & Privacy system preferences.
Services	Control access to various services on Mac OS X computers. These group policies correspond to settings in the Services pane of the Sharing system preference.
Software Update Settings	Control the options for automatic software updates on Mac OS X computers. These group policies correspond to settings in the **Software Update** system preference.

For details on the individual group policies in each category and how to configure specific policies, see the *Administrator's Guide for Mac*.

Setting Mac OS X User Policies

The following table lists the categories of group policies you can set for Mac OS X users. These group policies are in the Mac OS X administrative template (centrify_mac_settings.xml) and accessed from **User Configuration > Centrify Settings > Mac OS X Settings**.

802.1X Settings	Create user profiles for wireless network authentication. The profiles you specify with these group policies are created in the Network system preferences pane.
Automount Settings	Automatically mount network share's and the Windows home directory when a user logs in.
Application Access Settings	Control the specific applications users are either permitted to use or prohibited from using. These group policies correspond to **Applications** preferences set in the Workgroup Manager.
Desktop Settings	Control the desktop and screen saver options for users on Mac OS X computers. These group policies correspond to settings in the **Desktop & Screen Saver** system preference.
Dock Settings	Control the look and operation of the Dock displayed on the user's desktop. These group policies correspond to **Dock** preferences set in the Workgroup Manager.
Finder Settings	Configure Finder commands, preferences and views.
Folder Redirection	Redirect specified folders from a network home directory to the local machine.
Import Settings	Import plist files to customize your preferences.
Login Settings	Specify frequently used items, such as applications, folders, or server connections to automatically open when a user logs in.
Media Access Settings	Control the specific media types users are either permitted to use or prohibited from using. These group policies correspond to **Media Access** preferences set in the Workgroup Manager.
Mobility Settings	Control the synchronization rules applied for users access services from mobile devices. These group policies correspond to **Mobility** preferences set in the Workgroup Manager.
Printing Settings	Specify a list of printers for a user.
Scripts (Login/Logout)	Specify login and logout scripts that run when Active Directory users log on or log out.
Security Settings	Control the secure login options for users on Mac OS X computers. These group policies correspond to settings in the **Security** system preference.
System Preference Settings	Control the specific system preferences displayed for users. These group policies correspond to **System Preferences** set in the Workgroup Manager.

For details on the individual group policies in each category and how to configure specific policies, see the *Administrator's Guide for Mac*.

GNOME Settings

The authentication and privilege elevation provide a set of GNOME group policies that control the configuration of GNOME user preferences on Linux computers. This section provides a high-level overview to using the group policies that can be applied to user preferences for the GNOME desktop environment.

This section covers the following topics:

Delinea

GNOME Desktop Preferences

GNOME is a commonly used desktop environment for Linux computers. GNOME provides a configuration system, GConf or GSettings, to store and manage GNOME user preferences. Many settings are pre-configured and stored as user preferences in the file system. The tools you use to get and set desktop preferences depend on the version of GNOME you are using. The Centrify GNOME group policies enable you to set preferences from a central location and a single interface instead of using the native tools for configuring settings. For information about setting GNOME preferences using native tools, see the documentation provided on the GNOME website.

Adding GNOME Group Policy Templates

Server Suite provides a set of GNOME group policies that implement a majority of the GNOME desktop user preferences. When enabled, these group policies use the gconftool-2 or dconf/gsettings to get and set configuration settings on Centrifymanaged Linux computers.

The Centrify GNOME group policies are defined in the centrify_gnome_settings.xml and centrify_gnome3_settings.xml template files or in centrify_gnome_settings.admx and centrify_gnome3_settings.admx template files. Group policy template files are installed automatically on the local computer if you run the setup program on a domain controller. To apply any GNOME group policy settings, you must first add one or both templates to a Group Policy Object. See Adding Centrify Policies from XML Files.

Setting GNOME Policies

Setting GNOME policies

After you add template files to a Group Policy Object, you can enable and apply the policies to computer as described in the following procedure.

To apply GNOME group policies:

1. Open the Group Policy Management Editor.
2. Open **User Configuration > Policies > Centrify Settings > GNOME Settings**.

   The right pane displays a list of folders for GNOME setting categories that correspond to the GConf settings folders on a Linux computer, and one policy, Enable GNOME group policies. By default, all group policies are set to 'Not configured'.
3. Open category folders to find the policies you want to set.

   You may need to open several layers of sub-folders. For example, to enable the policy to show hidden files in the GNOME desktop, open **desktop > gnome > file_views** to locate the **Whether to show hidden files** policy.

   You can click the **Explain** tab in any policy to review a brief explanation of the policy and its default value.
4. Double-click the policy, select **Enabled**, then click **OK** to set the policy.

   Note: In most cases, you should set all of the GNOME policies you want to deploy before performing the next step.
5. Enable the top-level Enable GNOME group policies.

   No changes to individual GNOME policies take effect until you enable this policy. This policy allows you to set GNOME user preferences exactly as you want, then implement them all at one time, rather than implement them one at a time as you set them. See Using the Enable GNOME Group Policy for more information about this policy.
6. Expand **Computer Configuration > Policies > DirectControl Settings > Group Policy Settings**.
7. Double-click **Enable user group policy**, then select **Enabled** and click **OK**.

   By default, on Linux and computers, user-based group policies are ignored until you explicitly enable them with this policy.

Verifying GNOME Policy Settings

After setting GNOME policies, you can verify the settings on any managed Linux machine by using the gconftool-2 or dconf/gsettings command.

To verify GNOME policy settings on Linux computers:

1. Set one or more GNOME group policies.
2. Enable the "Enable GNOME group policies" master policy.
3. On a managed Linux computer, run adgpupdate to apply group policies with the updates you have made.

   The agent updates group policies at a regularly specified interval. Running adgpupdate applies the new policies immediately.
4. Run gconftool-2 or use dconf/gsettings and pipe it to grep to view specific settings; for example, to see the local GNOME setting for hidden files:

   ```
   [user1@qa1 \~]\$gconftool-2 -R /desktop \lgrep -i hidden
   show_hidden_files = true
   ```

   If you are using GNOME 2, you can run gconftool-2 -R to see all of your GNOME desktop settings. For example:

   ```
   [user1@qa1 \~]\$gconftool-2 -R /desktop /desktop/gnome:
   /desktop/gnome/file_views:
   tabs_enable = true
   tabs_open_position = end
   show_hidden_files = true
   icon_theme = crux_teal
   show_backup_files = false /desktop/gnome/applications:
   /desktop/gnome/applications/component_viewer: exec = nautilus %s
   /desktop/gnome/applications/help_viewer:
   needs_term = false
   accepts_urls = true
   exec = nautilus
   ```

   To see all system settings, you can run:

   ```
   gconftool-2 -R /system
   ```

   or all desktop gnome application settings:

   ```
   gconftool-2 -R /desktop/gnome/applications
   ```

Troubleshooting GNOME Policy Settings

Troubleshooting GNOME policy settings

The GNOME group policies handle GConf settings for common applications that are installed on most Linux platforms. If one of these common applications is not installed on a user's computer, it won't be possible to set the group policies for that application. If group policy debug is enabled in the centrifydc.conf configuration file, you will see a message such as:

```
Can not get schema: user [***] gconf_key [***]
```

If none of the GNOME policies are taking effect, you should enable debug tracing and check the log file, for example, by executing the addebug command:

```
addebug set TRACE
```

In order to enable GNOME settings, sudo must be able to run without a TTY. If you see a message such as the following:

```
sudo: sorry, you must have a tty to run sudo
```

you need to edit the sudoers file on the Linux computer to allow sudo execution without a TTY.

To allow sudo execution without a TTY to allow enabling GNOME settings

1. Log in as root on the Linux computer.
2. Edit the sudoers file; for example:

   ```
   visudo
   ```
3. Find the text requiretty; for example:

   ```
   Defaults requiretty
   ```
4. Disable requiretty for all users or a specific user by using the ! symbol, as follows:

   ```
   Defaults !requiretty
   ```

   ```
   Defaults: _userName_ !requiretty
   ```
5. Save and close the file.

Using the Enable GNOME Group Policy

Because GNOME group policies affect users' desktops, it is best to apply all the policies you set at once, rather than one at a time. To support this, you can use Enable GNOME group policies as a master policy. No changes to other GNOME policies take effect until you set the master policy to Enabled. After you enable the set of policies you want to deploy, you set this policy to have all of the policies deployed at the same time.

Similarly, you can disable all previously-enabled policies at once by disabling the master policy. For example, if you want to change some existing settings, you can temporarily disable all policies, then re-enable Enable GNOME group policies when you have made all your changes.

When you disable the master Enable GNOME group policies policy, the settings on each Linux machine revert to the local GNOME settings that were in effect before you deployed group policies. The Centrify GP mapper first saves the current GNOME settings as local values on the Linux client and before it applies the Centrify GNOME settings. If you disable GNOME group policies, the Centrify GP mapper restores the local GNOME settings that were previously saved.

Creating custom GNOME Settings Through Group Policy

If you need to use group policy to configure GNOME settings that are not controlled by the default set of GNOME 3 group policies, you can use the **Custom Gnome 3 settings** group policy to do so.

If you enable the **Custom Gnome 3 settings** group policy, you specify a GNOME schema, key, and data that are implemented by the group policy. You specify the information in the group policy as follows:

- **Gnome schema:key** field: _schema id_:_keyname_

  For example:

  org.gnome.desktop.sound:theme-name

- **Data** field: _datastring_

  For example:

  freedesktop

  > **Note**: If you define custom settings in this group policy that are already defined in a default GNOME 3 group policy, the settings in the default group policy take precedence, and the settings in this group policy are not implemented.

Defining Custom Group Policies

This chapter describes how to create custom group policies and administrative templates for your Server Suite-managed systems.

The following topics are covered:

For more detailed information about creating custom group policies and administrative templates for Windows computers, see the Microsoft Web site or your Windows documentation.

Implementing Custom Group Policies

You can define your own custom group policies for Delinea-managed computers and users and add these custom group policies to existing or new Group Policy Objects. Custom group policies consist of:

- A custom administrative template (.xml) file that describes how to set the policy within the Group Policy Object Editor. For example, the Administrative Template describes the user interface presented to the administrator on Windows computer.
- A program or script that makes the appropriate settings for the computer or the user logging on. For example, you can create a Perl script that reads the group policy settings and modifies the appropriate UNIX configuration ile to reflect those settings.

Creating a Custom Administrative Template

The administrative template enables you to specify the following for a group policy:

- The policy settings, including registry settings, type of configuration (computer or user), category, and help text for the policy.
- The user interface to set the policy.
- Validation code for user-interface fields.

> **Note**: The custom Administrative Template is not strictly required if you do not need to make the settings visible and available to the Active Directory or Windows administrator, but in most cases, you should create one using a standard text editor.

Once you create your custom .xml file, you should copy the file to the C:\Program Files\Centrify\Access Manager\group policy\policy directory on a computer that has the Group Policy Object Editor (normally a domain controller) or any other accessible directory. You can then add the custom .xml file to a new or existing Group Policy Object in the same way you add any other administrative template.

Defining a Policy

Extensible Markup Language (XML) files, like a custom administrative template file, are structured documents that contain a set of supported elements enclosed in opening and closing angle (< >) brackets. The elements can be required or optional depending on the requirements of the application.

For each group policy, an administrative template provides elements to do the following:

- Place the policy in the computer configuration, in the user configuration, or in both
- Place the policy in a category
- Define the registry key entries and values to be set
- Provide explanatory text for the policy-setting page

The following example illustrates the basic file format:

```
<class type="Machine">

  <category title="DirectControl Settings"
  keynameid="CentrifyDCPolicyRegistrySettings">

     <category title="Pam Settings"
     keynameid="CentrifyDCPolicyRegistryPam">

        <policy title="Set UID conflict resolution"
        valuename="pam.uid.conflict.enabled">

        </page>

        <!--
            UI Definition
        -->
       .
       .
       .

    </page\>

     <explainpage textid="CentrifyDCPamUidConflict_Explain" />

    </policy>

    <policy title="Create k5login" valuename="pam.create.k5login">

        <valueon value="true" />

        <valueoff value="false" />

      <explainpage textid="CentrifyDCPamCreateK5Login_Explain" />

    </policy>

   </category>

  </category>

       .

       .

       .

</class>
```

Use the following keywords to define the policy:

class	Specifies the node in which to place the policy. Use one of the following with the type keyword: Machine: Computer Configuration node User: User Configuration node Both: Computer and User Configuration nodes
category	Specifies the folder for the policy. You can place a set of related policies in a single category. You can also nest categories by placing subfolders within a folder. Use title or titleid to name a category folder.

keyname keynameid	Specifies the registry setting. You can define the registry key at different levels, including category, policy, policy page or UI control, and it applies to all child levels. You can also override the setting at any child level. You should determine whether to use an existing registry key or create a new, custom key. See Defining the User Interface for a Policy for a discussion of when to use keynameid instead of keyname.
policy	Defines the policy. Use title or titleid for the display name, keyname or keynameid to specify the registry key, and page to define the property page user interface.
explainpage	Provides a page on which you can provide an explanation or instructions for the policy. The best practice is to provide a textid string for the page, and define the content (the explanatory text) of this and other strings in a separate section of the file. See Defining the User Interface for a Policy for more information.
page	Defines the property page for the policy. Use title or titleid for the page title. See Defining the User Interface for a Policy for a description of the tags you can use within page tags to define the property page.

Defining the User Interface for a Policy

You define the user interface for a group policy property page using the page tag. The template provides a number of tags that enable you to define a variety of controls, buttons, and dialogs for finding and entering Active Directory information to set group policies. Place any of the following tags within the page /page tags to define the user interface:

> **Note**: This chapter is not intended as a complete reference to the xml schema for an administrative template file, but rather shows how tags are commonly used to define a policy. For example, the current section shows how to construct the user interface to a group policy property page; specifically, it shows the tags used to create the user interface of the group policy property page. A complete reference would also show all the elements that could go into creating a dialog box, but this is not generally relevant to creating a property page and hence is not covered in this chapter.

For this type	You can specify
text	Defines a text label control. Use text or textid to define the text to be displayed in the text label.
groupbox	Groups a set of UI controls on a policy page. Use text or textid to provide a name for the box. Use keyname or keynameid to specify the registry setting. Setting the registry key at this level overrides any setting at a higher level, for example, at the category level.
edittext	Creates a box in which a user can enter text. It requires the valuename keyword and value. The value should be the name used in the registry, if applicable. You can also use the following with edittext:

* text or textid to display a name for the box.
* default to display a default value when the policy is first enabled.
* keyname or keynameid to specify the registry setting. Setting the registry key at this level overrides any setting at a higher level, for example, at the category level.
* maxlength *value* maximum length of the string
* charcasing to specify whether to leave the case of characters in the box as is or convert them to lowercase or uppercase. The default is to leave them as is (Normal).
* required to require a value be set.
* readonly to specify whether the value can be changed. The default is to allow the value to be changed (false).
* button to define a button to be displayed after the text control box.
* validation to define validation for user input.

numeric	Creates a numeric text box control that allows a user to adjust a numeric value up or down. It requires the valuename keyword and value. The value should be the name used in the registry, if applicable. You can also use the following with numeric:

* text or textid to display a name for the box.
* keyname or keynameid to specify the registry setting. Setting the registry key at this level overrides any setting at a higher level, for example, at the category level.
* valuetype to display the type of the value in the registry setting.
* default to display a default value when the policy is first enabled.
* min *value* to set the minimum value allowed.
* max *value* to set the maximum value allowed.
* spin to define the amount to increment or decrement on each button click. The default increment is 1.
* decimalplaces to specify the number of decimal places for the value to be filled in. The default is 0.
* required to specify that the user must enter a value. The default is false, that is, the field is not required.
* validation to define validation for user input.

listbox	Provides a list view in which a user may add, remove, or edit setting values. Use dialog to associate a dialog box that enables a user to add a new entry or edit an existing entry in the list box. Specify the type of the listbox (listboxtype) to specify the kind of values the listbox generates:

* Single The box contains one column and generates a single value that is a concatenation of values from all rows separated by the separator attribute.
* Prefix The box contains one column and generates a list of registry values. The registry value name is defined by the prefix attribute and with a row number appended to the prefix name.
* Explicit The box contains two columns and generates a list of registry values. The first column contains the registry value name while the second column contains the registry value.

You can also use the following with listbox:

* text or textid to display a name for the box.
* keyname or keynameid to specify the registry setting. Setting the registry key at this level overrides any setting at a higher level, for example, at the category level.
* prefix to define the prefix of the value name of the registry setting. Use this attribute with a listtype of Prefix.
* separator to separate values when the listtype is Single.
* min to set the minimum number of rows allowed.

* max to set the maximum number of rows allowed.
* sort to specify whether sorting is enabled in the list box. | | checkbox | Boolean values. This keyword requires the valuename keyword and *value*, and the valuetype. The *value* should be the name used in the registry, if applicable. You can also use the following with this checkbox:

* text or textid to display a name for the box.
* keyname or keynameid to specify the registry setting. Setting the registry key at this level overrides any setting at a higher level, for example, at the category level.
* checked to set the check box to checked when the policy is first enabled. Without this keyword, the check box is not checked by default.
* valueon to define the registry setting when the check box is checked.
* valueoff to define the registry setting when the check box is not checked. | | radiogroup | Defines a set of two or more radio buttons (radiobutton) from which a user must make a single choice. This keyword requires the valuename keyword and value, and the valuetype. The value should be the name used in the registry, if applicable.

You can also use the following with radiogroup:

* text or textid to display a name for the box.
* keyname or keynameid to specify the registry setting. Setting the registry key at this level overrides any setting at a higher level, for example, at the category level.
* radiobutton to define radio buttons for the control. Use checked=true to specify the default radio button. | | radiobutton | A list of suggestions to allow the user to select or type a value. It requires the valuename keyword and value. The value should be the name used in the registry, if applicable. You can also use the following with combobox:

* textortextidto display a name for the box.
*checkedto define the default state for the radio button. The default isfalse(not checked).
*valueonto specify a value to be written to the registry when the radio button is checked. | | dropdownlist | A list of suggestions to allow the user to select a value. It requires thevaluenamekeyword andvalue. The value should be the name used in the registry, if applicable. You can also use the following attributes with dropdownlist:

* valuetypeto define the type of value in the registry setting.
*textortextidto display a name for the box.
*keynameorkeynameidto specify the registry setting. Setting the registry key at this level overrides any setting at a higher level, for example, at the category level.
*editableto specify whether the value in the dropdown list may be edited. The default isfalse(cannot be edited).
*requiredto require a value be set.
*sortto specify whether sorting is enabled in the dropdown list box.

You can use the following tags withindropdownlist:

* listitemto define an item in the drop-down list.
*validationto define validation for user input. | | button | Creates a button for a text field defined byedittext.

Use the dialog or adbrowse tags with button to define a dialog box to be shown when a user clicks the button.

You can also use the following attributes with button:

* textortextidto display a name for the box.
*valueidto identify the value returned from the dialog box that is launched by clicking the button. | | dialog | Provides a dialog box. You associate a dialog box to a button or to alistbox. Use titleortitleidto specify the title for the dialog.

You can use the following child tags to define a dialog box:

*groupboxto define a group box control in the dialog.
*textto define a text control in the dialog.
*edittextto define a text edit box control in the dialog.
*numericto define a numeric up down control in the dialog.
*listboxto define a list box control in the dialog.
*checkboxto define a check box control in the dialog.
*radiogroupto define a group of radio button controls in the dialog.
*dropdownlistto define a drop down list control in the dialog.
*validationto define the validation on the user inputs in the dialog. | | adbrowse | Provides a dialog box for browsing. You associate an adbrowse dialog box to a button or to alistbox. Use textortextidto specify the title for the dialog.

To browse Active Directory, useadbrowsetype to identify the type of browsing:

*FindADUser
*FindADGroup
*FindUnixUser
*FindUnixGroup
*FindComputer

Usemultiselectto define whether a user can select multiple search results in the Active Directory browse dialog.

Useseparatorto specify the separator for multiple results.

You can use the following child tags to define anadbrowsedialog box:

*groupboxto define a group box control in the dialog.
*textto define a text control in the dialog.
*edittextto define a text edit box control in the dialog.
*numericto define a numeric up down control in the dialog.
*listboxto define a list box control in the dialog.
*checkboxto define a check box control in the dialog.
*radiogroupto define a group of radio button controls in the dialog.
*dropdownlist` to define a drop down list control in the dialog. |

Using String IDs

When entering strings, such as text, keynames, and titles, you have the choice of using strings or string IDs. String IDs offer several advantages, such as a cleaner, more modular design, and the ability to customize the text if you plan to port to different languages.

The best practice is to put the string IDs in a 'Strings' section of the template file, which makes them easy to locate and modify in case of porting to other languages.

For example, the following segment from a template file shows how the explainpage tag specifies a string ID to attach explanatory text for a policy to the policy dialog box, while the actual text is defined in a 'Strings' section at a different place in the template:

```
- <!--

        Set login password prompt

  -->

- <policy title="Set login password prompt"
            valuename="pam.password.enter.enabled">

- <page\>

  - <edittext text="Set login password prompt"
              valuename="pam.password.enter.mesg"
      maxlength="1024" default="Password:">

    </edittext>

  </page>

__<explainpage textid="CentrifyDCPasswordPrompt_Explain" />__

  </policy>

- <!--

.

.

.

- <!--

============================================================

Strings

============================================================

__<string id="CentrifyDCPasswordPrompt_Explain">__The prompt that is displayed when an Active Directory user attempts to log in. Environment variables may be used in the form
\$VARNAME if a '\$' character is desired, escape it: \$</string>`

<string id="CentrifyDCPasswordChangeNotify_Explain">The message that is
displayed to an Active Directory user when they attempt to change their
password. Environment variables may be used in the form $VARNAME if a '$'
character is desired, escape it: \$</string>

.

.

.
```

Validation Settings

You can write validation scripts to check individual settings. The validation scripts are run after a user enters settings but before the settings are saved.

You can use any of the following languages to write validation scripts:

- VBScript
- JScript
- C#
- VB.net

Use the validation tag to apply a validation script to a setting. Use method to define the validation method name. Use param to define a parameter value to pass to the method or paramval to pass a registry setting value to the method. The validation result is returned by the method's return value. Use either dotnetscript to define a .net script (C# or VB.net), or script to define a script (VBScript or JScript) to do the validation.

The following segment from an administrative template file illustrates how to call a validation method:

```
- <validation>
    <method name="Validation.CheckUser" />
  - <dotnetscript language="C#">
    - <code>
      - <![CDATA[
public class Validation
                    {
                      public static string[] CheckUser(string value)
                      {
                        return Utility.CheckUnixNames(value, new
                       char[] { }, "Unix user name");
                      }
                    }
    ]]>
  </code>
 </dotnetscript>
</validation>
```

You place the code to call the method within a CDATA tag. Likewise, place the validation code itself within a CDATA tag, as in the following example:

```
- <dotnetscript language="C#">
   - <code>
    - <!--
       Validation Utility
      -->
    - <![CDATA[
        using System;
        using System.Text;
        public class Utility
        {
          .
          .

Adding a Mapper Program to the Agent

To implement group policies for UNIX computers and users, you need to create the custom scripts or programs that modify the appropriate UNIX configuration files or settings. You can create the programs or scripts using the programming or scripting language of your choice. Most of the Centrify policies use Perl scripts and you can use those scripts for models if you choose to use Perl.

Once you create a program or script to implement a group policy, you need to:

- Place the program or script in the /usr/share/centrifydc/mappers/machine directory if it is a computer configuration group policy, or in the /usr/share/centrifydc/mappers/user/*user_name* directory if it is a user configuration group policy.
- Make the program or script an executable file.
- Use the runmappers command to test that the program or script works as expected and updates the appropriate configuration file.

By default, when you use the runmappers command, it executes all of the programs in both the /usr/share/centrifydc/mappers/machine and the /usr/share/centrifydc/mappers/user/*user_name* directories. Optionally, you can run the command to only execute your custom program. For example, if you have created an executable script called setport.pl as a UNIX computer configuration policy and placed the file in the /usr/share/centrifydc/mappers/machine directory, you could use a command similar to the following to execute the script along with the other computer configuration mapper programs and test its behavior:

```
runmappers machine map
```

> **Note**: To run the mapping programs for a user, you must specify the user's UNIX login name to identify which user's group policies should be mapped or unmapped. For example, to run the mapping programs for the UNIX user account jgarcia in the /usr/share/centrifydc/mappers/user/jgarcia directory, you could use a command similar to the following:

```
runmappers user jgarcia map
```

This section provides a brief overview of Network Information Services (NIS), including the basic advantages and limitations of using NIS to publish information. It also describes the Centrify solution for using NIS to respond to client authentication and lookup requests.

You should use this section to help you determine whether the Centrify Network Information Service (adnisd) is an appropriate solution for your organization's needs.

Introduction to the Basics of NIS

In some environments, a Network Information Server (NIS) provides centralized storage and distribution of information that needs to be known throughout the network. In a typical NIS environment, one or more NIS servers are used to centrally manage a set of database **maps** that correspond to the system configuration files that are commonly found on UNIX systems. For example, there are NIS maps that correspond to the /etc/passwd, /etc/group, /etc/hosts, and /etc/services files. The maps provide the centralized information to a given set of computers that make up a **NIS domain**.

Each **NIS map** corresponds to a specific configuration file, such as the /etc/passwd or /etc/hosts file, and consists of a set of keys and values, and a version number for the data. When computers on the network require information stored in NIS maps, they send a **NIS client request** to the NIS listening port to query the **NIS server** for the information.

When a computer needs the information stored in a NIS map, it runs the ypbind process to identify and connect to the NIS server best suited to respond to its requests. When the NIS server receives a request, it replies with the appropriate information from its set of NIS maps.

Limitations of using NIS

Although NIS can be very efficient in responding to queries for network information, it is not a secure mechanism for providing authentication and authorization services. For example:

- If NIS clients use the broadcast service to locate NIS servers on the network, intruders can easily introduce their own NIS server with their own privileged accounts. Once a client binds to the rogue NIS server, the intruder can gain access to that client and perform unauthorized operations.
- The NIS server's only security policy is the securenets setting. The securenets setting identifies which NIS clients to accept queries from. If an intruder impersonates a client that the securenets setting allows the NIS server to accept, he can download all of the NIS data. Even if an intruder fails the securenets test, he could potentially inspect all of the NIS requests and decode the data to gain access.
- If NIS is used for authentication, password hashes are sent around the network in clear text and can be easily captured and cracked, making client systems vulnerable.

Because of these security risks, in most cases, you should plan to replace any legacy NIS environment with Active Directory as the central repository of identity information and the Centrify Agent for *NIX (adclient) as the "client" requesting information. In some cases, however, if may not be practical or desirable to completely replace an existing NIS infrastructure. To handle those cases, Centrify provides its own Network Information Service (adnisd) that enables existing NIS clients to remain in place and co-exist with Active Directory.

Deciding to Maintain NIS in your Environment

Active Directory and the Centrify Agent for *NIX (adclient) provide more secure authentication, authorization, and directory services than provided by traditional NIS client-server communication. Therefore, when you install the Centrify Agent and join a domain, the Name Service Switch configuration file, nsswitch.conf, is normally modified so that account lookup requests are passed to Active Directory through the adclient process. This change to the nsswitch.conf file effectively bypasses the NIS client and server environment.

There are some situations, however, in which maintaining an ongoing or temporary NIS environment may be desirable or necessary. For example:

- If you have a legacy Network Information Server (NIS), you may have configured network information, such as netgroup or automount maps, that you want to make available in response to client requests.
- You may have applications that require access to a NIS server because they send requests directly to the NIS port and expect a NIS process to be listening there.
- You may have computers or devices, such as Network Attached Storage devices or computers with older or unsupported operating systems where you cannot install the Centrify Agent, that need access to information normally stored in NIS maps. Those computers or devices cannot join an Active Directory domain, but are capable of submitting NIS client requests. For those computers or devices, a NIS server may be the only option for providing authentication and look-up services.

If any of these scenarios apply to your organization, you may want to plan a deployment that includes the Centrify Network Information Service to complement the agent.

Using the Network Information Service

To support computers and applications that are capable of submitting NIS client requests to a NIS server, the Server Suite provides its own Network Information Service. The Centrify Network Information Service, adnisd, is an optional process that can be installed on any computer where adclient is installed.

Once installed and running, the Centrify Network Information Service functions like a standard NIS server, but it responds to NIS client requests using the information stored in Active Directory, including any information imported from passwd and group NIS maps or from /etc/passwd and /etc/group files. The Centrify Network Information Service has some of the same security limitations as a standard NIS server, but it does allow you to provide encrypted authentication and directory service to computers where adclient cannot be installed.

The Centrify Network Information Service can be useful in environments where you plan a phased migration from existing NIS servers and clients or when the environment includes legacy systems that you cannot migrate or upgrade to support the Centrify Agent for *NIX.

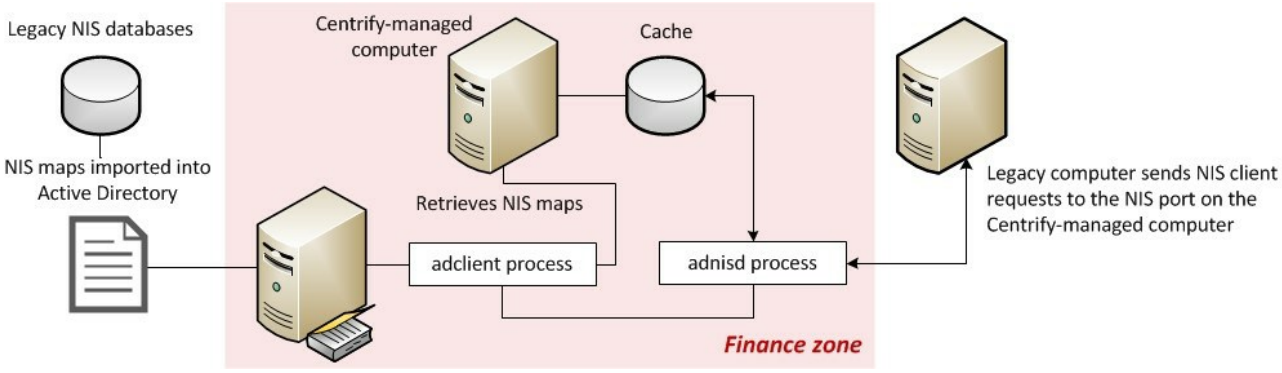
How NIS Client Requests are Processed

If you have decided to maintain a NIS environment, on either an ongoing or temporary basis, you can use the Centrify Network Information Service to replace existing NIS servers and the Access Manager console to migrate NIS map data to Active Directory.

The Centrify Network Information Service (adnisd) can run on any computer that has the adclient agent service installed. Computers that need access to the information stored in Active Directory can then be configured as NIS clients that send their NIS queries to the computer where both the adclient and adnisd service run.

When adnisd receives a request from the NIS client, it checks its local cache of map data, then responds to the client that made the request. The local cache of map data is generated from the map data adnisd receives from Active Directory.

The following figure provides a simplified view of operation.



Derived and Explicitly-defined Maps

Within the local cache, there are two types of maps: **explicitly-defined maps** and **derived maps**. Explicitly-defined maps are NIS maps imported into Active Directory from an existing NIS domain, imported from text files, or created manually using the Centrify Access Manager console. Derived maps are maps that are automatically generated from the information stored in Active Directory. Derived maps access the same data as the explicitly-defined maps using different keys. For example, the user and group maps in the local cache are not retrieved directly from Active Directory, but are generated based on the users and groups that have been enabled for the local computer's zone.

The maps derived from the zone information are passwd.byname, passwd.byuid, group.byname, and group.bygid. These automatically generated maps are placed in the local cache, and can then be used to look up or authenticate users by user name or by UID value, and groups by group name or by GID value. The Centrify Network Information Service also generates derived maps for explicitly-defined network maps that are stored in Active Directory. If adnisd finds a NIS map defined in Active Directory with a name it recognizes, such as netgroup or services, it automatically derives related maps. For example, a netgroup map will automatically generate the netgroup.byhost and netgroup.byuser maps. A services base map will generate the services.byname and services.byservicename maps.

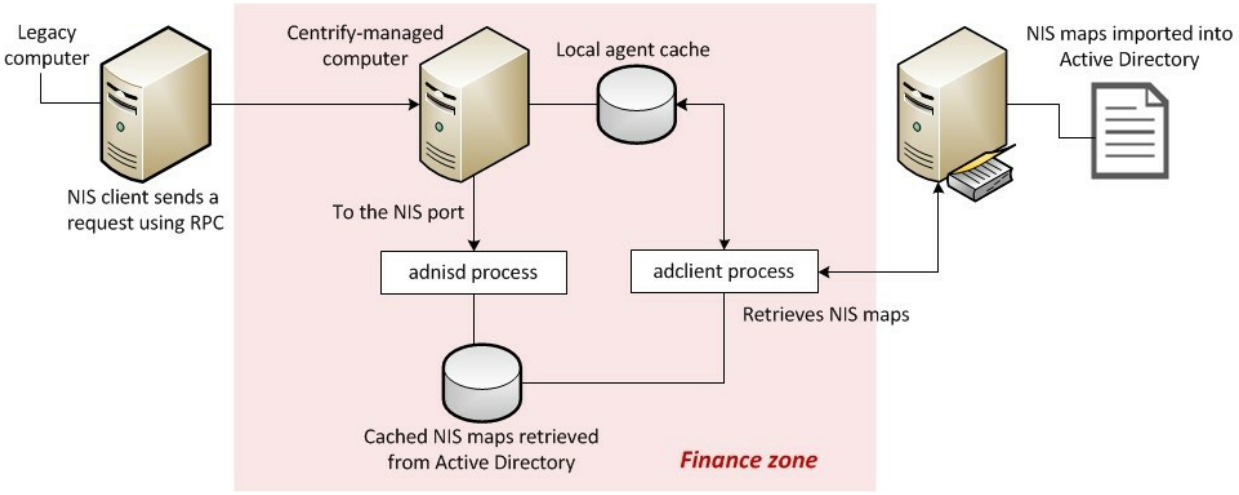
Accessing NIS Maps in the Local Cache

Periodically, theadnisdprocess connects to Active Directory through the adclient process to locate updates to explicitly-defined NIS maps. It then synchronizes the local cache of NIS map data to mirror any changes detected in Active Directory. After polling Active Directory for updates to explicitly-

defined maps, the adnisd process retrieves all users and groups in the current zone from adclient, and generates the derived maps for user and group information.

In essence, the computer where both adclient and adnisd run acts as the NIS server for the local computer's zone. The NIS clients on the network communicate with adnisd using Remote Procedure Calls (RPC) sent to the NIS port on the Centrify-managed computer. The adclient process is responsible for all communication with Active Directory and maintains its own separate cache of data from which adnisd can derive the user and group information for the zone. The adnisd process then stores all of the explicitly-defined and derived maps in its own local cache of map data (in most cases, /var/centrifydc/nis/*). Because adnisd always responds to NIS client requests using the data in its local cache, it can respond even when Active Directory is not available.

The following figure provides a simplified summary of operation.



> **Note**: The adnisd process cannot be used with any legacy NIS servers in a NIS domain. It can only be used in conjunction with Active Directory and the Centrify Agent for *NIX.

Migrating Information from Existing Maps

If you have a legacy NIS environment, you can import user, group, and network information from existing NIS servers and domains. To import the information directly from an existing NIS server, you need to be able to access the NIS server and NIS domain from the Windows computer where the Access Manager console is installed. For example, if you have configured an existing NIS server to be accessible over the Windows network using Samba or a similar program, you can connect directly to that server and NIS domain to import maps. If the NIS server and NIS domain are not accessible from the Windows computer where the Access Manager console is installed, you should export the NIS maps to text files, then import the text files.

> **Note**: Importing existing maps simply provides a mechanism for migrating existing information to the Active Directory. Once the information is imported into Active Directory, the original maps are no longer used and the Centrify Network Information Service uses Active Directory to generate the maps it needs to service authentication requests.

For more information about importing existing user, group, or network information, see Importing and managing NIS maps.

Managing Automounts without Using NIS

If your primary reason for wanting to use NIS is to manage automount information, you have the option of storing the information in Active Directory then retrieving it through the adnisd process or directly through an LDAP request that bypasses the adnisd process.

> **Note**: The automount information must be stored in Active Directory. You can then choose whether to retrieve it using the Centrify Network Information Service (adnisd) or an LDAP query.

As an alternative to using the adnisd process, you can use the optional adauto.pl script located in the /usr/share/centrifydc/etc directory to get automount data. The adauto.pl script gets mount point information directly from Active Directory using LDAP. With the adauto.pl script, you can automount home directories using the information from NIS maps without running the adnisd server process.

The adauto.pl script uses the information you store in the auto.home NIS map for the joined zone and any parent zones up the zone hierarchy from which the local computer inherits NIS map entries. Once you add the script to your automount configuration, the automounter program invokes the script and passes it the user

name of the user logging on. The adauto.pl script then uses the ldapsearch command to retrieve the mount point information from Active Directory and returns the path to the remote home directory for the user logging on. The automounter will then attempt to connect to that home directory.

To use the adauto.pl script:

1. Add the appropriate auto.home mount points to Active Directory by importing or creating automount NIS maps.

   For more information about importing existing auto.home or auto_home NIS maps, see *Importing Network NIS Maps*. For information about creating NIS network maps directly in Active Directory, see Creating new NIS Maps in Active Directory.

   For example:

   - Open Access Manager to navigate to a specific zone.
   - Expand the zone to display NIS Maps.
   - Select NIS Maps, right-click, then click New > Automount.
   - Type auto.home or auto_home as the map name, then click **OK**.
   - Select the new map, right click, then click New to add a new individual map record. For example, create a map record similar to this for all users in a zone:

     Name: * Network Path: lmrh2:/home/&
     Comments: This is the automount path for users in this zone

2. If you are managing mount points on Linux or Solaris, edit the /etc/nsswitch.conf file to change the automount entry from nis to files. For example:

```
vi /etc/nsswitch.conf
...
automount: files
```

For other platforms, such as AIX, you can skip this step.

1. Verify the adauto.pl file is available in the /usr/share/centrifydc/etc/ directory and is executable. For example:

   ls -l /usr/share/centrifydc/etc/adauto.pl
   total 1208
   -rwxr-xr-x 1 root root 1921 Sep 27 10:37 adauto.pl

2. Create a symbolic link for /etc/auto.home or /etc/auto_home to the adauto.pl file. For example, on Linux computers:

   ln -s /usr/share/centrifydc/etc/adauto.pl /etc/auto.home

   On AIX computers, create the link to /etc/auto_home:

   ln -s /usr/share/centrifydc/etc/adauto.pl /etc/auto_home

3. Edit the /etc/auto.master or /etc/auto_master file to call the /etc/auto.home file.

   For example, on Linux computers add the following line to the auto.master file:

   /export/home program:/etc/auto.home

   The specific syntax for the entry is different on different platforms. For example, not all platforms allow you to specify the program keyword in the /etc/auto.master file. For more information about the format of the entry, see the main page for auto.master. For example, on SuSE Linux, the entry should look like this:

   /export/home /etc/auto.home

   On SuSE Linux 10, the corresponding entry is:

   /export/home program /etc/auto.home

   On AIX and Solaris computers, add an entry like this to the /etc/auto_master file:

   /export/home /etc/auto_home

   On some platforms, you can invoke automount from the command line without editing the /etc/auto.master file. For example, you can invoke automount without

editing the /etc/auto.master file by running a command similar to the following on Linux:

```
automount /export/home/ program /etc/auto.home
```

Command line mount points are not supported by automount on AIX.

4. Restart the autofs process. For example, on Linux:

   ```
   service autofs restart
   ```

   On AIX:

   ```
   automount
   ```

   On Solaris 10, the automount service is managed by the service management facility, smf, under the service identifier:

   ```
   svc:/system/filesystem/autofs:default
   ```

   You can use svcadm to perform administrative actions, such as stopping and restarting the service.

Mounting Home Directories with the nosuid Option

To increase security when automatically mounting file systems, you might want to configure the auto_home or auto.home NIS map to prevent users from switching their user or group identity. You can prevent users from mounting file systems with a different user context by specifying the nosuid option.

To set the nosuid option in the auto_home or auto.home NIS map:

1. Open Access Manager to import or create a NIS map to be stored in Active Directory.
2. Expand the appropriate zone and the UNIX Data node to display NIS Maps.
3. Select NIS Maps, right-click, then click New > Automount.
4. Type auto.home or auto_home as the map name, then click **OK**.
5. Right-click the new map.
6. Click **New > Map entry** to add a new individual map record.
7. Set the fields in the map record similar to the following, to enable mounting of home directories with the nosuid option for all users in a zone:

   Name: * Network Path: homeservername:/home/&
   Options: -nosuid

   You can use a similar approach to specify other or additional mount options—such as noexec and nodev—to the map entry.

Using Executable Maps

On some platforms, local maps that have the execute bit set in their file permissions can be executed by the automount program and provided with a key to be looked up as an argument. The executable map is expected to return the content of an automount map entry on its stdout or no output if the entry cannot be determined. Direct maps cannot be made executable.

For more information about executable maps, see the main page forautomount.

Testing the Status of the Automount Service

After restarting the automount service, you can check the status of the service. For example, on Linux run the following command:

```
service autofs status
```

On all platforms, you can run the following command and check the output to verify automount operation:

```
/usr/sbin/automount -V
```

You should see output similar to the following:

```
automount: /export/home mounted automount: no unmounts
```

Running the adauto.pl script

You can run the adauto.pl script with no command-line options to manually refresh the automount NIS maps on demand. Alternatively, you can manually add the adauto.reloadtime configuration parameter to the /etc/centrifydc/centrifydc.conf file to control how frequently automount NIS maps are retrieved for the zone. If you manually add this parameter to the configuration files, you can set the value to specify that maps with a time stamp older than the specified number of minutes should be reloaded.

By default, the adauto.pl script gets automount NIS maps from the zone to which the local computer is joined. If the maps are not found in the joined zone, the script will attempt to get the maps from its parent zone of the joined zone. Alternatively, you can create the file /var/centrifydc/kset.automap and type the common name (CN) of the specific Centrify zone from which you want to load the automount NIS maps.

Testing the adauto.pl script results

After you have configured the auto.home and auto.master maps, you can test that the adauto.pl script is working by entering one of the following commands:

/etc/auto.home userid /etc/auto_home userid

This command should return the path from the auto.home or auto_home NIS map stored in Active Directory. For example:

/server/home/userid

Restarting the Automount Service

If you make any changes to the NIS maps in Active Directory, you should restart the automount service.

Distributing Automount Maps

You can create auto.master and auto.home files as NIS maps in Centrify zones and distribute them using symbolic links to the adauto.pl script. In this scenario, you can take advantage of the capability to support executable maps. Depending on your operating system, however, you might be able to take advantage of the Centrify NSS module to automatically mount home directories instead. If your operating system allows you to use the Centrify NSS module, you can add centrifydc to the automount line in the /etc/nsswitch.conf file.

In most cases, you can use the Centrify NSS module to distribute auto.home maps. You cannot use this approach, however, to distribute the auto.master map on most operating systems. For the auto.master map, your options are typically limited to doing one of the following:

- using NIS.
- using LDAP.
- using a local file.

For information about using LDAP, see "Using the Centrify LDAP proxy service" in the *Administrator's Guide for Linux and UNIX*. If you use a local file, you can use an adedit script to synchronize the auto.master map to a local /etc/auto.master file. The following example illustrates the steps to synchronize the auto.master map to a local /etc/auto.master file.

1. Add the File Copy group policy to a Group Policy Object that applies to Centrify-managed computers.
2. Enable the group policy to copy a script similar to the following to the directory /usr/share/centrifydc/mappers/machine:

```
#!/bin/sh
# Restart adedit using tclsh \
exec adedit "$0" "$@"
# Bind to an Active Directory domain \
bind -machine domain
# Select a zone context \
select_zone zone
catch  {
    select_nis_map auto.master
    set output [open /etc/auto.master w 0644]
    foreach line [gnm] {
    puts $output [regsub ":1" $line ""]
      }
    close $output
    }
}
```

By adding a script similar to this sample script to a GPO, every 90 to 120 minutes the group policy update will execute the script to read the contents of the auto.master map in Active Directory and create a local copy of the /etc/auto.master file.

You can also use this same approach to synchronize all of the maps stored in Active Directory to the local /etc directory. For example:

```
#!/bin/sh
 # Restarts using tclsh \
 exec adedit "$0" "$@"
 bind -machine [adinfo domain]
 slz [adinfo zone]
 foreach map [get_nis_maps] {
    if ([regexp "auto*" $map]) {
       slnm $map
       set output [open /etc/$map w 0644]
          foreach line [gnm] {
          puts $output [regsub ":1" $line ""]
       }
    close $output
    }
}
```

Discontinuing Use of Legacy NIS Servers

If you have existing NIS servers running on your network, you can configure your NIS clients to use the Centrify Network Information Service over time, as needed. Once you have the Network Information Service running, you can also incrementally update the NIS data that's stored in Active Directory using the Access Manager console. Any updates you make are then propagated to all of the `adnisd` servers automatically.

When you are satisfied that you have all of the appropriate NIS information stored in Active Directory and have deployed `adnisd` across the enterprise, as needed, you can then stop any remaining legacy NIS servers and complete the migration to Active Directory for secure, centralized directory service.

> **Note**: Although you can leave the standard NIS servers in place indefinitely, you should plan to migrate all of your data and NIS clients to use the Centrify Network Information Service if you want you to centralize all authentication and directory service in Active Directory. Once you have imported all of the data you need into Active Directory and configured your existing NIS clients to use the Centrify Network Information Service in the appropriate zone, you can decommission any legacy NIS servers and stop any related services.

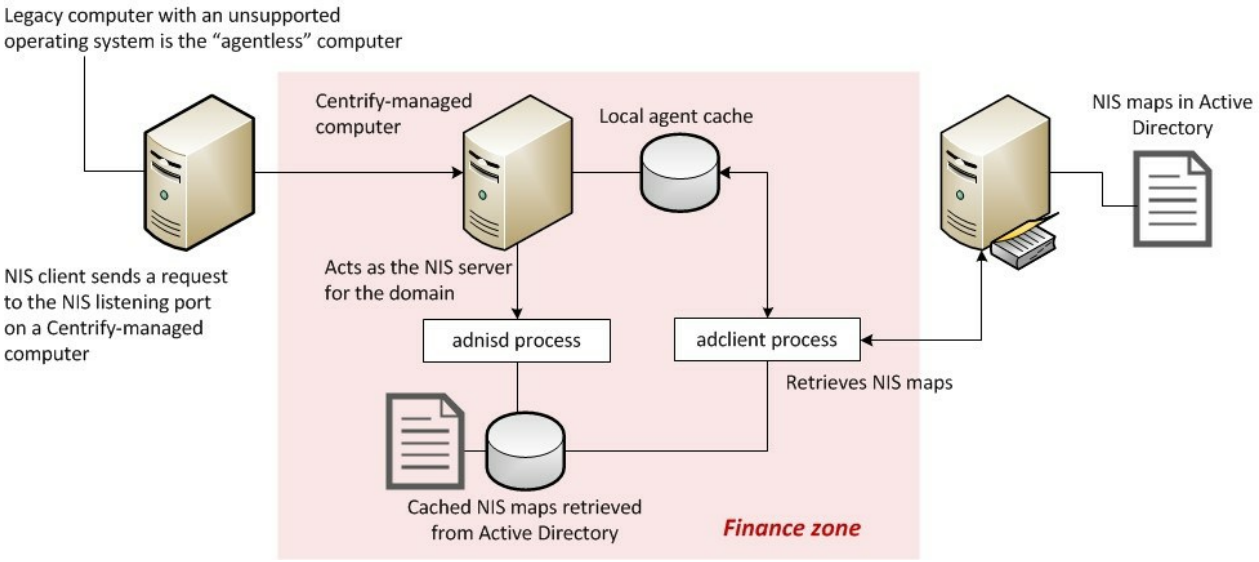
This section describes the activities that are specific to preparing your environment to handle agentless authentication and authorization. If you only plan to use Delinea Network Information Service (adnisd) to publish network information, such as automount mount points, netgroup membership rules, or custom maps, you can skip this chapter.

Deciding to Use Agentless Authentication

Normally, the adclient agent is installed locally on a computer to handle all account authentication and lookup requests that need to be passed to Active Directory. On computers and devices where you cannot install a Delinea Agent locally, you may be able to use the Delinea Network Information Service (adnisd) to provide agentless authentication.

With agentless authentication, computers that have older or unsupported operating systems that can be, or already are, configured as NIS clients can submit NIS requests to the Delinea Network Information Service. The Delinea Network Information Service can then check its cached Active Directory information to verify whether a user or group has valid credentials and is authorized to log on.

The following figure provides a simplified view of this environment.



In this scenario, the Delinea zone acts as the NIS domain for a group of computers or devices that are configured as NIS clients. Those clients submit requests to the Delinea Network Information Service, adnisd, listening on the NIS port.

The Delinea Network Information Service periodically contacts the adclient agent to get updated information from Active Directory and generates a set of "maps" that it stores locally. The Delinea Network Information Service can then use the information in these maps to respond to NIS client requests for authentication or other services.

The user and group "maps" are generated automatically based on the users and groups that have profiles currently enabled in the zone. Network information and custom maps can also be published for a zone, but those maps must be manually imported or created. The maps for agentless authentication only require you to add and enable a profile for each Active Directory user and group who should have access to the zone. In this way, the Delinea Network Information Service can be used to service agentless authentication requests from computers or devices where adclient itself cannot be installed.

Planning for Agentless Authentication

In planning a deployment that supports agentless authentication for NIS clients, you should keep in mind that the zone associated with the computer where adnisd is installed defines the scope of information available to the NIS clients that the adnisd process serves. Each instance of adnisd supports one and only one zone, which is equivalent to a single NIS domain. The adnisd process can only look up information for the computers, groups, and users that exist in the same zone as the local computer account, and all instances of the adnisd in the same zone respond to queries using the same information from Active Directory.

For users and groups to be available for agentless authentication, therefore, they must be enabled for the zone the Delinea Network Information Service serves. In addition, each zone that supports agentless authentication requires an Active Directory attribute for storing the password hash for UNIX-enabled

users. The password hash is not created in Active Directory by default, so it must be generated then maintained using a password synchronization service installed on all of your domain controllers. The Active Directory attribute that holds the password hash must be accessible to the computers you are using as NIS servers in each zone.

> **Note**: If you install the Delinea Network Information Service on multiple computers, whether in the same zone or across multiple zones, all of these instances are zone-specific peers. There are no master/slave instances.

If you decide you want to use the Delinea Network Information Service to support agentless authentication, you should:

- Identify the zones for which you want to publish information. For example, if you want user and group information broadly available to NIS clients across the network and you have a parent zone, you may want to allow agentless authentication for all of the users in that zone. If you want to strictly control which users can be authenticated to NIS clients, you may want to create a separate agentless-authentication child zone that only contains those users and their groups. For each zone that supports agentless authentication, you must specify the Active Directory attribute for storing the password hash.
- Identify the computers that should service NIS client requests in each zone. You can designate any computer that has the Delinea Agent installed to also act as the Delinea Network Information Server in the zone. Any computer you want to use as the NIS server must have the Delinea Agent for *NIX installed and must be joined to an Active Directory domain.
- Install a password synchronization service on all of the domain controllers in the joined domain.
- Install and configure the Delinea Network Information Service (adnisd) on the selected computers in each zone. On the computers that will act as NIS servers in a zone, you must manually install and start the adnisd service. Alternatively, you can modify the startup script on each local computer so that the adnisd process starts whenever the local computer is rebooted. You also may want to customize the configuration parameters that control the operation of the adnisd process.
- Configure computers and devices as NIS clients that bind to the Delinea Network Information Service on the selected computers in each zone. If any existing NIS servers are running, you will need to reconfigure the NIS clients on the network to use the computer where the Delinea Network Information Service is installed as their NIS server.
- Import and enable the users and groups who need to be authenticated to NIS clients for the zone. You can migrate this information from existing NIS servers or local configuration files by importing passwd and group NIS maps or local /etc/passwd and /etc/group files using the **Import from Unix** wizard, or you can manually or programmatically create UNIX profiles for users and groups, as needed. The users and groups must have UNIX profiles stored in Active Directory and enabled for the local computer's zone for the Delinea Network Information Service to generate the maps it needs to service agentless authentication and lookup requests from NIS clients.
- Import and manage any additional NIS maps you want to make available to NIS clients. For example, you can import network maps such as netgroup and automount NIS maps or create custom maps using the Access Manager console.

  > **Note**: Importing existing NIS maps simply provides a mechanism for migrating information to the Active Directory. Once the information is stored in Active Directory, any original NIS maps you imported are no longer used. Instead, the Delinea Network Information Service uses the information stored in Active Directory to automatically generate the maps it needs to service authentication and lookup requests. This local cache of data is updated at a regular interval.

Selecting a Zone to Use for NIS Authentication

A computer's zone is equivalent to a NIS domain for the Delinea Network Information Service. Each instance of the Delinea Network Information Service supports one and only one zone. All instances of the Delinea Network Information Service in the same zone respond to queries using the same information from Active Directory.

If user information from a zone needs to be available to NIS clients for agentless authentication, the Delinea Network Information Service must be able to access the password hash for zone users. However, because Active Directory does not generate a password hash for users by default, there's no default attribute for storing this information.

To enable the password hash to be stored for users in a zone:

1. Start Access Manager.
2. In the console tree, expand the **Zones** node.
3. Select the zone that will service NIS client requests, right-click, then click **Properties**.

   For example, if you want to work with a child zone, sanfrancisco, expand the parent zone and Child Zones nodes, select the sanfrancisco zone right-click, then click **Properties**.

4. On the General tab, select the **Support agentless client** option.
5. Select the Active Directory attribute to use for storing the password hash.

   Depending on the password synchronization service you are using and the Active Directory schema, select one of these attributes:

   - **altSecurityIdentities** if you are using the Delinea Password Synchronization program. Do not select this option if you are using a Microsoft password synchronization service.
   - **msSFU30Password** if you are using the Microsoft Windows Services for UNIX Password Synchronization Service. If you are using the Delinea Password Synchronization program, you can choose this attribute if you have the SFU schema installed.
   - **unixUserPassword** if you are using the Microsoft UNIX Identity Management Service and are using the Delinea Password Synchronization program.

6. Verify the default NIS domain name.

   By default, the zone name is used as the NIS domain name because this makes it easy to identify the scope of the information available to NIS clients. You can type a different name in the zone properties if you choose. Whether you use the default name or another name for the NIS domain, you must use the same name when you configure the NIS clients. For more information about configuring NIS clients, see Configuring NIS clients.

7. Click **OK** to save the changes and close the zone Properties.

Selecting a Computer for NIS Authentication

You can designate any computer in a zone to act as the NIS server for the zone by setting the **Allow this computer to authenticate NIS users** computer property as described in "Adding Support for Agentless Clients" in the *Administrator's Guide for Linux and UNIX*. For example, expand the Computers node in the zone that will service NIS client requests, select the computer account, right-click to select **Properties**, then click the **Delinea Profile** tab to set this option.

The computer account acting as a NIS server for the zone must be able to access the attribute containing the password hash for agentless authentication to be successful.

Selecting **Allow this computer to authenticate NIS users** adds the computer account to the`zone_nis_servers` Active Directory group. Computer accounts that are placed in the `zone_nis_servers` group are automatically granted permission to read the attribute that stores the password hash for users in the zone.

This property setting enables the computer account to access the password hash so that it can authenticate users in response to NIS client requests. However, you must manually install and start the Delinea Network Information Service on the physical computer before the computer can act as a NIS server.

Configuring a Password Synchronization Service

The Delinea Network Information Service must be able to retrieve the current password hash for zone users in order for it to respond to agentless authentication requests from NIS clients. Active Directory, however, does not generate a password hash for users by default. This task is handled by the password synchronization service.Therefore, to generate the password hash for zone users, you first need to install a password synchronization service.

You can install the password synchronization service with the Server Suite or separately using a standalone setup program. Once deployed, it ensures the passwords served by the Delinea Network Information Service are always up-to-date. With a password synchronization service, any time users change their Active Directory password, the corresponding password hash in their user profile is updated to reflect the change. Depending on your environment, you can choose to install one of the following:

- Delinea Password Synchronization program
- Microsoft Windows Services for UNIX Password Synchronization Service
- Microsoft Windows UNIX Identity Management Service

Note: Regardless of the password synchronization service you choose to use, the service must be installed on all domain controllers in the Active Directory domain where you are enabling agentless authentication.

Using Delinea Password Synchronization

You can install the Delinea Password Synchronization program using the Server Suite setup program. Alternatively, you can install Delinea Password Synchronization independent of the the Server Suite using it own setup program. If you install the Delinea Password Synchronization program using the setup program, you can skip this section.

To install the Delinea Password Synchronization program:

1. Copy the CentrifyDC_PasswordSync-n.n.n-win64 package to your Active Directory domain controller.
2. Open the CentrifyDC_PasswordSync-n.n.n-win64 executable or Microsoft software installation (.msi) file to start the setup program.

   Note: You can run the setup program interactively or silently if you use the Microsoft software installation (.msi) file. If you are installing silently using the msiexec program, you can skip the steps in this section.
3. At the Welcome page, click **Next**.
4. Review the terms of the license agreement. If you accept the license agreement, select **I accept the terms of the license agreement**, then click **Next**.
5. Type your name and company, select who should be able to use this application on the computer, then click **Next**.
6. Select a restart option, then click **Finish**.

Once installed, the Delinea Password Synchronization program will generate the initial password hash when users next change their password, then update the password hash at each password change thereafter. The password hashes are created using DES encryption with a two character salt. If the password hash is stored in the altSecurityIdentities attribute, it has a prefix of cdcPasswordHash, for example:

```
cdcPasswordHash:VkievQ69VhYKc
```

If the password hash is stored in one of the other supported attributes, it is stored without a prefix.

When a user changes his Active Directory password, the Delinea Password Synchronization program discovers the zones to which that user has access and updates the appropriate attribute that holds the password hash for that user in each zone.

> **Note**: The initial password hash is only generated when the user changes his password. You may want to force users to change their password at the next logon to get the password set at the earliest opportunity. Client authentication requests may fail for users who do not have a password hash available. If the password hash field in the passwd.byname or passwd.byuid map displays a single exclamation point (!), it indicates that the user's password hash has not been set.

Using Microsoft Password Synchronization Service

If you choose to use one of the password synchronization services provided by Microsoft instead of the Delinea Password Synchronization program, follow the instructions provided with the software to install the service. In general, you need to do the following to use the Microsoft password synchronization services:

- Set the Windows domain to the domain you joined after installing the Delinea Agent for *NIX.
- Set the NIS domain name to the zone name you specified when you joined the domain. For example, if you are using the **default** zone, set the NIS domain to **default**. Although you can set the NIS domain name to something other than the zone name when creating or modifying a zone's properties, you must use the zone name for this setting if you use Microsoft password synchronization.
- Set the NIS Server name to the host name of the computer running both the adclient and adnisd services.
- Give user accounts access to the zone and NIS domain. If you are using the Microsoft Windows Services for UNIX, select the zone name from the list of NIS domains on the **UNIX Attributes** tab.

  The rest of the fields on the UNIX Attributes tab are not used by Server Suite, but you are required to enter information for these fields to enable the NIS domain for the user. Therefore, you should specify a UID, Login shell, Home directory, and Primary group for the user account, then click **OK**.

Locating Zones for Password Synchronization

Only Active Directory users with a UNIX profile created using the Access Manager console include the attribute (parentLink) needed to look up their zone information for password synchronization. You can use the **Orphan Unix data objects** option in the Analyze Wizard to check the forest for accounts missing this attribute setting and attempt to correct the problem.

If the Analysis Results display a **Warning** for the **Orphan Unix data objects** check, you can right-click, then select **Properties** to view additional details. If the profile is missing the parentLink attribute, select the warning, right-click, then select **Populate parentLink** attribute to define this attribute for the user.

For more information about troubleshooting issues for the Delinea Network Information Service, see Troubleshooting and Logging NIS Operations. For more information about using the Analyze wizard in the Access Manager console, see "Analyzing information in Active Directory" in the *Administrator's Guide for Linux and UNIX*.

This section describes how to install and configure the Centrify Network Information Service (adnisd). The adnisd process allows a Centrify-managed computer to act as the NIS server for NIS clients in a joined domain. Using adclient and adnisd together, you can store authentication, authorization and network information in Active Directory, and respond to NIS client requests from computers and devices even where adclient cannot be installed.

Installing the Centrify NIS Server

Whether you want to use the Centrify Network Information Service for agentless authentication, managing network information, or publishing custom maps, you must install and configure adnisd on at least one computer in at least one zone before you can begin responding to NIS client requests.

In most cases, adnisd is installed as part of a custom installation of the Server Suite or as a separate software package, independent of the installation of adclient. The naming convention for the standalone software package is:

```
centrifydc-nis-n.n.n-os-architecture
```

Keep in mind:

- You must install adnisd on a computer where adclient is also installed.
- The Active Directory domain and zone the local computer has joined defines the NIS domain, and therefore the information available to NIS clients.
- You cannot use adnisd to serve NIS maps if your managed computer joined the domain using the --workstation option.
- Using the --workstation option adds a computer to the single Auto Zone where user and group profiles are generated automatically. Computers in the Auto Zone cannot be used as NIS servers or NIS clients.
- You can install adnisd using any installation program appropriate for the local operating environment, such as RPM, SMIT or YAST.
- If you are upgrading from a previous release of Server Suite and have an earlier version of adnisd, stop the existing adnisd service and use install.sh to remove the old packages before installing the new version of adclient and adnisd.

The following steps are only an example of how to install adnisd locally on a computer. The specific steps required depend on the local operating environment and the installation program you choose.

1. As root on the managed computer, use adinfo to verify that adclient is installed, and that the local computer is joined to a domain and can connect to Active Directory:

```
su -
Password:

adinfo

Local host name:     magnolia
Joined to domain:    ajax.org
Joined as:           magnolia.ajax.org
Current DC:          ginger.ajax.org
Preferred site:      Default-First-Site-Name
Zone:                ajax.org/Program Data/Centrify/Zones/default
Last password set:   2006-12-28 14:47:57 PST
CentrifyDC mode:     connected
```

2. Copy the package appropriate to the local computer's operating environment, from the Server Suite CD or a download directory, to a local directory.

   For example, if the operating environment is Solaris 9 SPARC:

   ```
   cp /tmp/centrifydc-nis-n.n.n-sol8-sparc-local.tgz .
   ```

3. If the package is a compressed file, unzip and extract its contents. For example, on Solaris:

```
gunzip -d centrifydc-nis-n.n.n-sol8-local.tgz
tar -xf centrifydc-nis-n.n.n-sol8-sparc-local.tar
```

4. Run the appropriate command for installing the package. For example, on Solaris:

   ```
   pkgadd –d CentrifyDC-nis -a admin
   ```

Adding IP Addresses from Which to Accept Requests

By default, the Network Information Service accepts only local NIS client requests. To accept requests from any other NIS clients in a network, modify nisd.securenets in the /etc/centrifydc/centrifydc.conf file to specify the computer subnets from which to accept NIS requests. This parameter configures adnisd to filter NIS client requests by IP address. It ignores all other NIS client requests.

For example, to restrict NIS requests to the single trusted subnet 172.68.0.0, add a line similar to the following to nisd.securenets:

```
nisd.securenets: 172.68.0.0/255.255.0.0
```

To specify multiple subnets, separate the entries with commas or spaces:

```
nisd.securenets: 172.68.0.0/255.255.0.0,196.48.0.0/0
```

To accept NIS client requests from any computer, use this:

```
nisd.securenets: 0/0
```

On systems with multiple Ethernet interfaces, adnisd configures RPC to the first interface. If an NIS client is trying to communicate on a different interface, adnisd will not receive the request.

Before creating sockets, adnisd reads the centrifydc.conf file to see if an IP address and TCP and UPD ports are specified. If not, it uses localhost and random port numbers assigned by the operating system.

You set the IP address, TCP port and UDP port using the nisd.net_addr, nisd.port.tcp, and nisd.port.udp configuration parameters, respectively in the centrifydc.conf file.

For more information, see the *Configuration and Tuning Reference Guide*.

Starting the adnisd Process

After you have specified the subnets from which to accept NIS client requests, you can either manually start the adnisd process at the command line, or reboot the local computer. By default, the adnisd process starts automatically whenever the computer is rebooted. If you don't want the process started automatically, you should modify the startup script on the local computer to remove adnisd from the processes started.

> **Note**:: The installer adds the adnisd process to a computer's startup script for you. If you are not importing NIS maps right away, you may want to modify the startup script to prevent the adnisd process from starting before you are ready to begin servicing client requests.

To start the adnisd process at the command line:

1. Verify that adclient is running and the local computer is joined to a domain.
2. Verify that RPC is running on the local computer. For example:

   rpcinfo -p localhost

   The adnisd process requires RPC services. If you restart RPC, you also need to restart the adnisd process.
3. Type the appropriate start command. For example, on Red Hat Linux, type:

   ```
   /sbin/service adnisd start
   ```

   On most other platforms, run:

   ```
   /etc/init.d/adnisd start
   ```

   On Solaris 10 or later, the daemon is controlled through the Solaris Service Management Facility. For example:

   svcadm enable nis/centrifydc-server

When the adnisd process starts, it connects to Active Directory through adclient and does the following:

- Retrieves the current user, group, network and custom information stored in Active Directory for its zone.
- Generates additional maps derived from the retrieved information, such as netgroup.byuser, netgroup.byhost, passwd.byuid, passwd.byname, group.byname, and group.bygid.
- Stores the information retrieved or derived from Active Directory in a local cache of NIS map data.

After the initial connection, adnisd periodically connects to Active Directory through adclient to retrieve updated information for its zone. However, adnisd always responds to NIS client requests using the data in its local cache so that it can respond to NIS requests even if Active Directory is unavailable.

Customizing the Update Interval for NIS Maps

By default, every 30 minutes (1800 seconds), adnisd uses adclient to connect to Active Directory. At the update interval, adnisd does the following:

- Checks for network NIS maps explicitly defined in Active Directory to determine whether any records have changed.
- Generates derived maps for any explicitly defined network maps that adnisd recognizes. For example, if the netgroup map is found in Active Directory, adnisd generates the netgroup.byuser and netgroup.byhost maps.
- Updates the local cache with all changes to the network NIS maps.
- Updates the local cache with changes to the derived maps for user and group information in the zone.

Note: In most cases, updating the local cache of NIS data does not require you to restart any services.

In most organizations, the default update interval is adequate. In a more volatile or stable NIS map environment, reduce or increase the time between updates, as appropriate, by modifying the nisd.update.interval parameter in /etc/centrifydc/centrifydc.conf to specify a different number of seconds between updates; for example:

```
nisd.update.interval: 900
```

For more information, see the *Configuration and Tuning Reference Guide*.

Customizing the NIS Maps to PUblish

By default, the adnisd process retrieves all NIS maps stored in Active Directory at each update interval, updates its local cache as needed, and makes all such data available to its NIS clients. In some cases, you may want to prevent NIS clients from accessing data in specific maps or from looking up information using a specific key.

If you want to customize the list of maps to make available to NIS clients, modify the nisd.maps or nisd.exclude.maps parameter in /etc/centrifydc/centrifydc.conf, or apply a group policy.

- With the nisd.maps parameter, you explicitly list the NIS maps, including derived maps, to *include* in the local cache of map data; for example:

  ```
  nisd.maps: hosts.byname,hosts.byaddr,automount
  ```

- With the nisd.exclude.maps parameter, you list the NIS maps to *exclude* from responses to NIS client requests (typically user and group information). When you specify a map, its derived maps are excluded as well. For example:

  ```
  nisd.exclude.maps: group passwd
  ```

For more information, see the *Configuration and Tuning Reference Guide*.

Configuring the Maximum Number of Map Sets

When adnisd receives data for explicitly-defined NIS maps, the data comes from the domain controller selected by the adclient process. If the domain controller the adclient process has changed – for example, if it is unavailable – the adclient process attempts to find another available domain controller.

To ensure the data consistency of the NIS maps retrieved from Active Directory, adnisd keeps a separate set of NIS records from each domain controller. This enables adnisd to switch between domain controllers efficiently, but uses more space in the local cache.

You can control the maximum number of alternate sets of NIS maps to maintain (default is two) by modifying the nisd.maps.max parameter in /etc/centrifydc/centrifydc.conf. For example, to keep up to four sets of NIS maps, specify:

```
nisd.maps.max: 4
```

For more information, see the *Configuration and Tuning Reference Guide*.

Handling Large Active Directory Groups

In most cases, the NIS server cannot send more than 1024 characters of data to NIS clients in response to a query. This limitation can create problems when the NIS client requests information for a large group with a long membership list. By default, the adnisd process automatically truncates the list at 1024 characters.

You can configure adnisd to split large groups into several groups of conforming size and names using nisd.largegroup.suffix and nisd.largegroup.name.length in /etc/centrifydc/centrifydc.conf.

Splitting a single large group into multiple new groups

If you specify any value for the nisd.largegroup.suffix parameter,adnisd splits large groups into multiple new groups automatically, creating a new group whenever a group's data size exceeds 1024-character limit by appending the string you define in nisd.largegroup.suffix plus a sequential number.

For example, if you have a large group named performix-worldwide-corp, and have defined the suffix string as "-all", when the performix-worldwide-corp group membership is split into multiple groups, the groups are named as follows:

```
performix-worldwide-corp-all1
. . .
performix-worldwide-corp-all n
```

All of the new groups have the same group identifier (GID) as the original group.

Setting the maximum length of new group names

If the new group names would exceed the maximum length for group names on a platform, use the nisd.largegroup.name.length parameter. If you do this,adnisd` truncates the original group name so as not to exceed the maximum name length.

For the example above, if you set a maximum name length of 14, the split groups are named:

```
performix-all1
...
performi-all10
...
perform-all100
```

All of the new groups have the same group identifier (GID) as the original group.

For more information, see the *Configuration and Tuning Reference Guide*.

Making the NIS Server Available

After you install and configureadnisd on a computer, you must configure other computers or devices on the network to use the computer runningadnisd for NIS client requests.

In general, configuring NIS clients to use the Centrify Network Information Service involves:

- Stopping any existing legacy NIS server processes.
- Modifying the NIS client's configuration file to identify the zone and computer name of the computer where theadnisd process is installed.
- Sending a bind request from the NIS client to the new Centrify NIS server.

For more information, see Configuring NIS clients.

This section describes how to configure NIS clients to receive authentication, authorization, and network information through the Delinea Network Information Service.

Specifying the Server for NIS Clients to Use

After you install and configure adnisd on a computer, you must configure other computers or devices to send their NIS lookup requests to the computer running adnisd. The specific steps for configuring the NIS client are slightly different in different operating environments. In general, configuring NIS clients involves:

- Stopping the connection to any existing NIS server.
- Identifying the zone and computer name of the computer where adnisd is installed in the client's NIS configuration file.
- Binding to the new Delinea NIS server.
- Restarting services that use NIS, or rebooting the computer.

For information about configuring the NIS client in different operating environments, see the appropriate section below.

> **Note**: The client configuration instructions assume that you are using the zone name as the NIS domain name. If not, substitute the NIS domain name you specified when you created the zone where applicable. For more information about configuring NIS clients on any specific platform and OS version, consult the documentation for that platform.

Configuring NIS Clients on Linux

To configure the NIS client on a Linux computer:

1. Stop any running NIS service and remove all files from the /var/yp/binding directory. For example, run the following commands:

   ```
   /sbin/service ypbind stop
   rm -rf /var/yp/binding/*
   ```

2. Set the NIS domain name for the client to the zone name or NIS domain name of the computer where the adnisd process is running.

   ```
   domainname zone_name
   ```

   For example, if you have installed adnisd on a computer in the corpHQ zone:

   ```
   domainname corpHQ
   ```

3. Edit the NIS configuration file, /etc/yp.conf, to specify the Delinea zone and the name of the computer where adnisd is installed.

   ```
   domain zonename server hostname
   ```

   For example, add a line similar to this to /etc/yp.conf:

   ```
   domain corpHQ server localhost
   ```

   If your NIS clients are configured for broadcast discovery, this step may not be necessary.

4. Start the ypbind service.

   On Red Hat Linux, run:

   ```
   /sbin/service ypbind start
   ```

   On Debian 3.1, run the nis script (controlled using the file /etc/default/nis). By default, the script starts the NIS client, ypbind. For example, run the following command:

   ```
   /etc/init.d/nis start
   ```

   One SuSE Linux 9.3 Professional, run:

   ```
   /etc/init.d/ypbind start
   ```

5. Modify the passwd, group, and shadow lines in /etc/nsswitch.conf file to use compat as the source:

   ```
   passwd: compat
   group: compat
   shadow: compat
   ```

6. Restart services that rely on the NIS domain, or reboot the computer to restart all services. The most common services to restart are autofs, NSCD, cron and sendmail.

Configuring NIS Clients on Solaris

To configure the NIS client on a Solaris computer:

1. Stop any running NIS service and remove all files from the /var/yp/binding directory. For example, run the following commands on Solaris 8 or 9:

   ```
   kill ypbind
   rm -rf /var/yp/binding/*
   ```

   On Solaris 10, stop the service by running:

   ```
   svcadm disable network/nis/client
   ```

2. Set the NIS domain name for the client to the zone name of the computer where adnisd is running.

   ```
   domainname zone_name
   ```

   For example, if you have installed adnisd on a computer in the corpHQ zone:

   ```
   domainname corpHQ
   ```

3. Run the ypinit -c command and enter the name of the computer where adnisd is installed.

This step is not required if you use the broadcast option to locate the server when you run the ypbind command. You must use ypinit, however, if your network topology would prevent a broadcast from reaching the desired servers. For example, if the router does not transmit broadcasts across subnets, use the ypinit -c command to specify a server on a different subnet.

Start the ypbind service. On most versions of Solaris, run:

```
/usr/lib/netsvc/yp/ypbind
```

If you are using the broadcast option to locate the server, start the service with that option. For example:

```
/usr/lib/netsvc/yp/ypbind -broadcast
```

On Solaris 10, run:

```
svcadm enable network/nis/client
```

Modify the passwd, group, and shadow lines in /etc/nsswitch.conf file to use compat as the source:

```
passwd: compat
group: compat
shadow: compat
```

Restart services that rely on the NIS domain or reboot the computer to restart all services. The most common services to restart are autofs, NSCD, cron and sendmail.

Configuring NIS Clients on HP-UX

To configure the NIS client on an HP-UX computer:

1. Stop any running NIS service and remove all files in the /var/yp/binding directory. For example, run the following commands:

   ```
   /sbin/init.d/nis.client stop
   rm -rf /var/yp/binding/*
   ```

2. Edit the NIS configuration file, /etc/rc.config.d/namesvrs, to set the NIS_CLIENT to 1 and the NIS_DOMAIN to the name of the Delinea zone. For example:

   ```
   NIS_CLIENT=1
   NIS_DOMAIN="zone-name"
   ```

3. Add the -ypset option to the YPBIND_OPTIONS variable and set the YPSET_ADDR variable to the IP address of the computer where adnisd is installed. For example:

   ```
   YPBIND_OPTIONS="-ypset"
   YPSET_ADDR="15.13.115.168"
   ```

This step is not required if you want to use the broadcast option to locate the server when you run the ypbind command.

4. Set the NIS domain name for the client to the zone name of the computer where theadnisd process is running.

   domainname zone_name

5. Start the ypbind service. On HP-UX, you can start the service by running:

   ```
   /sbin/init.d/nis.client start
   ```

6. Modify the passwd, group, and shadow lines in /etc/nsswitch.conf file to use compat as the source:

   ```
   passwd: compat
   group: compat
   shadow: compat
   ```

7. Restart services that rely on the NIS domain or reboot the computer to restart all services. The most common services to restart are autofs, pwgrd, cron and sendmail.

Configuring NIS Clients on AIX

To configure the NIS client on an AIX computer:

1. Stop any running NIS service and remove all files from the /var/yp/binding directory. For example, run:

   ```
   stopsrc –s ypbind
   ```

   If the computer is not already a NIS client, you can use the System Management Interface Tool (smit) and the mkclient command to add adnisd to the computer.

2. Open the /etc/rc.nfs file and verify that the startsrc command is configured to start the ypbind daemon:

   ```
   if [ -x /usr/etc/ypbind ]; then
    startsrc -s ypbind
   fi
   ```

3. Set the client's NIS domain name to the zone name of the computer whereadnisd is running. For example:

   ```
   domainname zone_name
   ```

4. Start the ypbind service:

   ```
   startsrc -s ypbind
   ```

5. Restart services that rely on the NIS domain or reboot the computer to restart all services. The most common services to restart are autofs,NSCD, cron and sendmail.

   Note: Theadnisd service is not supported in a workload partitioning (WPAR) environment (Ref: CS-30588c).

Verifying the Client Configuration

Run the domainname command to verify that the client is configured to use the appropriate Delinea zone or NIS domain name. For example, if you have configured a computer to service NIS requests for the sanfrancisco zone and are using the zone name as the NIS domain name:

```
domainname
sanfrancisco
```

To test that the client can connect to the Delinea Network Information Service, run one or more NIS client request commands; for example:

```
ypwhich
ypwhich -m
ypcat -k mapname
```

Checking the Derived passwd and Group Maps

On a computer you have configured as an NIS client, verify that the NIS maps required for agentless authentication are available by running the following command:

```
ypwhich -m
```

At a minimum, you should see the passwd.* and group.* map names, followed by the name of the computer you are using as the NIS server. For example, if the computer running adclient andadnisd is iceberg-hpux, you should see output similar to this:

```
passwd.byuid iceberg-hpux
passwd.byname iceberg-hpux
group.byname iceberg-hpux
group.bygid iceberg-hpux
```

These passwd.* and group.* maps are automatically generated based on the information stored in Active Directory for the zone, including all Active Directory users and groups granted access to the zone. You can view information from any of these maps using a command like ypcat passwd.byname. The output displayed should look similar this:

```
paul:Xq2UvSkNngA:10000:10000:paul:/home/paul:/bin/bash
mlopez:!:10002:10000:Marco Lopez:/home/mlopez:/bin/bash
jsmith:!:10001:10000:John Smith:/home/jsmith:/bin/bash
```

In this example, the user paul has a password hash, but users mlopez and jsmith do not.

If a user account is new, disabled, locked, requires a password change, or is not enabled for a zone, the Delinea NIS server sets the user's hash field to "!"

> **Note**: On some platforms, you may see ABCD!efgh12345$67890 as the password hash for users who need to set their password.

This section describes how to import, create and manage NIS maps and map entries using the Access Manager console.

> **Note**: You can also use ADSI Edit, ADEdit, custom scripts or other tools to add, modify and remove NIS maps and map entries. To import NIS maps, however, you must use the Access Manager console.

Importing and Creating User and Group Profiles

If you want to make user and group information available to NIS clients, whether for agentless authentication or in response to other lookup requests, you must first make sure the appropriate users and groups have zone profiles and role assignments defined in the zone. The zone information is used for automatic generation of the maps passwd.byname, passwd.byuid, group.byname, and group.bygid. If you disable a user profile in the zone, the user's information cannot be retrieved or published in response to NIS client requests, or used to authenticate the user's identity.

You can import existing user and group information directly from existing NIS servers and domains or from properly formatted text files, such as local /etc/passwd and /etc/group files, using the **Import from UNIX** wizard, or you can create new profiles for Active Directory users using the Access Manager console.

Once the appropriate user and group profiles have been added to the zone you are using as a NIS domain, the information is available to NIS clients unless you explicitly restrict the publication of this information.

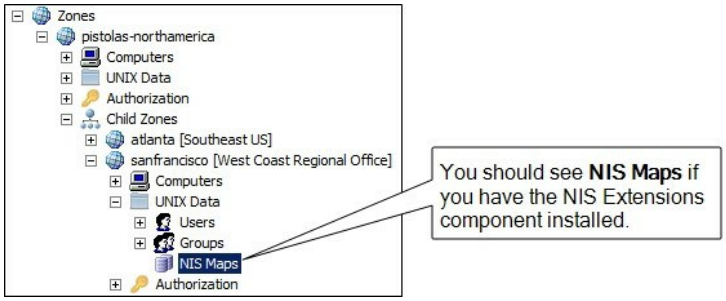
> **Note**: For information about restricting the maps published, see Customizing the NIS maps to publish. For information about importing or creating user and group profiles in a zone, see the *Administrator's Guide for Linux and UNIX*.

Publishing Network or Custom Information

In addition to user and group information, adnisd can publish network information or make custom information available to NIS clients. For example, you can import information from standard NIS maps such as automount, netgroup, and automaster, if these maps exist in your environment. Importing network information or creating custom maps, however, requires you to have the NIS Extensions.

> **Note**: NIS Extensions are installed by default when you run the setup program. If you did not select this option, rerun the setup program and select **NIS Extensions** from the list of Access Manager Administration components.

If you have the NIS Extensions installed, you should see the NIS Maps node under each zone. For example, if you are using hierarchical zones, you can see NIS Maps under the UNIX Data node for the parent or child zone you select:



Importing Network NIS Maps

To use Access Manager to import a standard network NIS map into Active Directory:

1. Open Access Manager.
2. In the console tree, navigate to the specific zone into which you want to import NIS maps.
3. Expand the console tree to display NIS Maps.
4. Select NIS Maps, right-click, then click **Import Maps**.
5. Select whether you want to connect to the NIS server and domain or import the information from a text file, then click **Next**.

- If you are importing maps directly from an existing NIS server, type the name of the **NIS domain** and **NIS server**. Using this option requires network connectivity to the NIS server from the Window computer you are using.
- If you are importing a map from a text file, click **Browse** to navigate to the map file you want to import. If you cannot connect directly to the NIS server, you should export the NIS database to a file; then import the information using this option.

6. Select the NIS maps to import if you are importing directly from an existing NIS server, or type a map name and define the file format if importing from a file, then click **Next**. The Import Maps wizard does not validate the information to be imported. If the map has invalid entries, they are imported as-is.

   If you importing from a text file:

   - Type a **Map name** that describes the type of map being imported. In most cases, you should use the base name that identifies the configuration file used to generate the NIS database. For example, use hosts to identify the map generated from the /etc/hosts file.
   - Type the **Field separator** character used to separate fields in the map file.
   - Type the column number that defines the start of the **Key field**.
   - Specify any additional options as appropriate for the file you are importing. For example, select **Comments are included in the file after** and type the character used to designate comments if the file includes comments.

     For Access Manager to correctly interpret the map file, you need to provide accurate information about the file format, such as the type of separator used between fields.

     Because the Centrify NIS server does not include comments in response to service requests, you must save the map to a text file and import from that file to retrieve comments contained in NIS maps.

7. When the import is complete, click **Finish**.
8. After importing NIS maps, restart the adnisd service.

Creating New NIS Maps in Active Directory

If you cannot import network information from existing NIS maps, you can create new maps by adding the appropriate information directly to Active Directory using Access Manager. Once you add the information to Active Directory, adnisd can use the information to automatically generate a local cache of the map data and make the information in those generated maps available to NIS clients.

> **Note**: If you are creating NIS maps manually, keep in mind that the Network Information Service can return a maximum of 1024 characters of data in response to a query from any NIS map, so make sure all NIS map entries have less than 1024 characters of data.

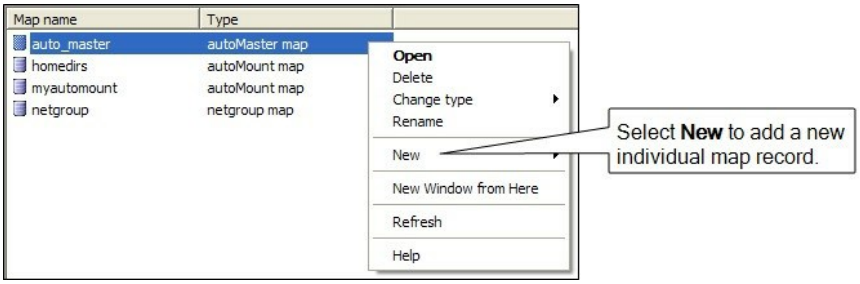
To create a new network NIS map in Active Directory

1. Open Access Manager.
2. Navigate to the specific zone for which you want to create maps.
3. Expand the console tree to display NIS Maps.
4. Select NIS Maps, right-click, then click **New** and select the type of map you want to create.

   For most map types, you can only use the recognized map name for the new map. Recognized map names enable you to use derived maps to retrieve information using different keys. If you are creating a new **Automaster** map, you must choose either auto_master or auto.master as the map name to retrieve the names of the automount maps.

   If you select the **Generic Map** option, you can create a custom NIS map for any key/value pairs that you want to make available to NIS clients. For more information, see Creating generic custom maps.

5. Select the new empty map, right-click, then click **New > Map Entry** or **New > netgroup** to add a new individual map record.



The file format and the specific fields used in individual map records depend on the type of map you are working with.

6. Type the appropriate information for the fields listed, then click **OK** to save a record in the new map.

   For more information about the fields required in any NIS map, see the man page for the type of map you are creating. For example, see the man page for netgroupto see detailed information about required and optional fields and the format of netgroup maps.

   You can use Active Directory groups in netgroup records. Using Active Directory groups in netgrouprecords enables dynamic changes to user and computer pairings based on their Active Directory group membership. If you have existing processes for adding and removing users and computers in Active Directory groups, you can leverage those processes in netgroup records.

Creating Maps for Common Network Services

Centrify uses explicitly-defined NIS maps to generate derived maps automatically. Once a recognized base map is imported or created manually in Active Directory, the agent generates and stores its derived maps so that information can be retrieved searching on different keys.

> **Note**: In most cases, you can import recognized base maps directly from an existing NIS server and domain or from generated text files (for example, files created using the niscat command). Alternatively, you can create the base maps manually using the corresponding map type in Access Manager.

The following table describes the recognized base maps and their derived maps.

aliases

The aliases map is the abbreviated name for the mail.aliases map. The derived maps are mail.aliases and mail.byaddr. In most cases, the NIS map is created from the /etc/aliases or /etc/mail/aliases file. A typical line looks like this:

```
alias: address1 [address2 addressn...] # comment
```

For example:

```
acme: amy.adams@acme.com bill.byrnes@acme.com
widgetco: aaron@widgetco.com,...,zuza@widgetco.com
```

For the mail.alias map, the entries are defined like this:

- Key is the alias name: acme

- Value is the list of addresses for the alias: amy.adams@acme.com bill.byrnes@acme.com

For the mail.byaddr map, the entries are defined like this:

- Key is an address: amy.adams@acme.com
- Value is the corresponding alias: acme

If you create an aliases map in Active Directory, you must include the key as part of the value. For example:

- Key: acme
- Value: acme: someone@acme.com
- Comment: someone@acme.com is the address

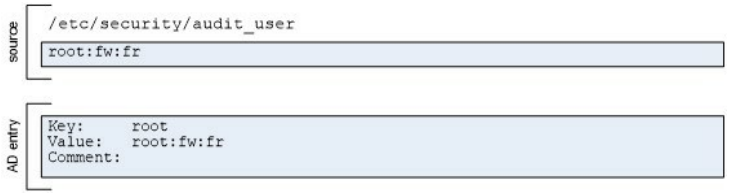
audit_user

In most cases, the audit_user map is created from the /etc/security/audit_user file. A typical line looks like this:

```
user_name:always_audit_flags:never_audit_flags
```

For example:

```
root:lo:no
wily:lo,am:io,cl
kris:lo,ex,+fc,-fr,-fa:io,cl
```



For the audit_user map, entries are defined like this:

- Key is the user name: root
- Value takes the following format: user_name:always_audit_flags:never_audit_flags

If you create an audit_user map in Active Directory, you must include the key as part of the value. For example:

- Key: root
- Value: root:lo:no

This map is only applicable for Solaris.

auth_attr

In most cases, the auth_attr map is created from the /etc/security/auth_attr file. A typical line looks like this:

```
name:res1:res2:short_description:long_description:attr
```

For example:

```
solaris.:::All Solaris Authorization::help=SolarisAuth.html
solaris.user.manage:::Manage Users::help=ManageUsers.html
```

If you create an auth_attr map in Active Directory, you must include the key as part of the value. For example:

- Key: solaris.
- Value: solaris.:::AllSolarisAuthorizations::attribute
- Comment: This map provides authorization attributes for Solaris.

This map is only applicable for Solaris.

bootparams

In most cases, the bootparams map is created from the /etc/bootparams file. A typical line looks like this:

```
client_name key=value:[key=value:...]
```

For example:

```
client root=sr04:/export/client/root domain=nyc.test
engr1 root=smoketest:/export/engr1/root rootopts=:vers=2
```

If you create a bootparams map in Active Directory, the value must consist of key and value pairs. For example:

- Key: client
- Value: root=sr04:/export/client/root domain=nyc.test
- Comment: The value consists of key=value pairs separated by colons (:).

This map is only applicable for Solaris.

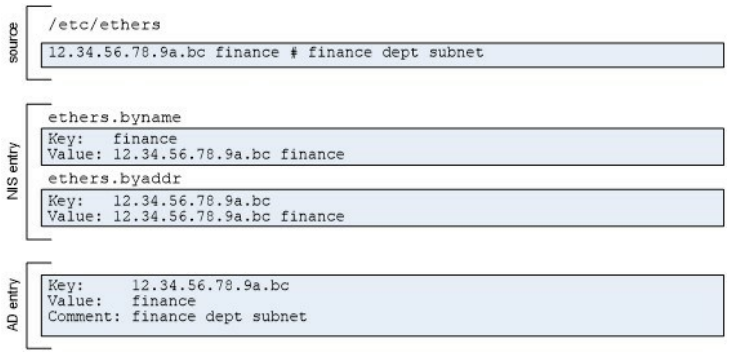
ethers

The ethers map is the abbreviated name for the ethers.by name map. The derived maps are ethers.byname and ethers.byaddr. In most cases, the NIS map is created from the file /etc/ethers file. A typical line looks like this:

```
ethernet_address host_name
```

For example:

```
52:ef:75:72:4e:c8 rhel9
31:ee:c5:72:4e:18 finance
```



For the ethers.byname map, entries are defined like this:

- Key is the host name: rhel9
- Value is the ethernet address for the host name: 52:ef:75:72:4e:c8

For the ethers.byaddr map, entries are defined like this:

- Key is an address: 52:ef:75:72:4e:c8
- Value is the host name: rhel9

If you create an ethers map in Active Directory, you must include the key as part of the value. For example:

- Key: rhel9
- Value: 52:ef:75:72:4e:c8 rhel9
- Comment: The host name for 52:ef:75:72:4e:c8 is rhel9

exec_attr

In most cases, the exec_attr map is created from the /etc/security/exec_attr file. A typical line looks like this:

```
name:policy:type:res1:res2:id:attr
```

For example:

```
Application Server Management:susuer:cmd:::/usr/bin/admin:
DBA:unix-dba:cmd:::/usr/db/bin/dbadmin:
dbuser:unix-dbuser:cmd:RO::/usr/sbin/db/opensql
```

If you create an exec_attr map in Active Directory, you must include the key as part of the value. For example:

- Key: Application Server Management
- Value: execution profile name and properties followed by attributes defined as key and value pairs for the profile:
  Application Server Management:suser:cmd::: \ /usr/appserver/bin/admin:

This map is only applicable for Solaris.

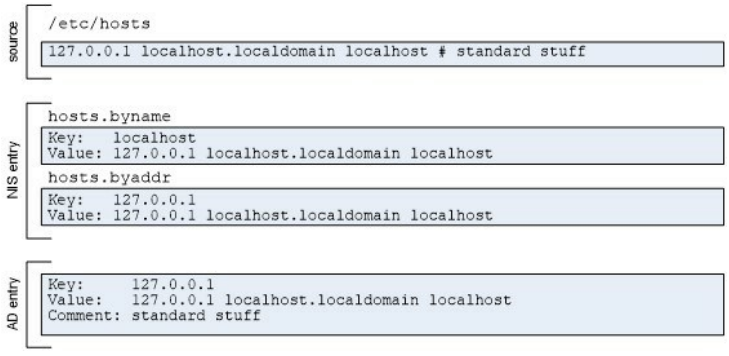
hosts

The hosts map is the the abbreviated name for the hosts.byname map. The derived maps are hosts.byname and hosts.byaddr. In most cases, the NIS map is created from the /etc/hosts file. A typical line looks like this:

```
host_ip_address host_name [alias,...] # comment
```

For example:

```
127.0.0.1 localhost.localdomain localhost
192.168.22.1 arcade.cendura.net arcade arc1 # clustername
```



For the hosts.byname map, entries are defined like this:

- Key is the host name: localhost

- Value is the IP address and any aliases defined for the host: 127.0.0.1 localhost.localdomain localhost

For the hosts.byaddr map, entries are defined like this:

- Key is an address: 127.0.0.1
- Value is the IP address and any aliases defined for the host: 127.0.0.1 localhost.localdomain localhost

If you create a hosts map in Active Directory, you must include the key as part of the value. For example:

- Key: 127.0.0.1
- Value: IP address and any aliases defined for the host: 127.0.0.1 localhost.localdomain localhost
- Comment: The value includes both the host name and IP

netgroup

The netgroup map defines a hierarchy of netgroupgroups and members. The netgroupmap controls access by user name, host name, or NIS domain name. The derived maps are netgnetgroup.byhostroup.byhost and netgroup.byuser. In most cases, the NIS map is created from the /etc/netgroup file. A typical line looks like this:

netgroup_name (host,user,NIS_domain)[,netgroup]...

The keys in a netgroupmap are the names of each netgroup. The values in a netgroupmap are one or more space-separated elements. An element can be:

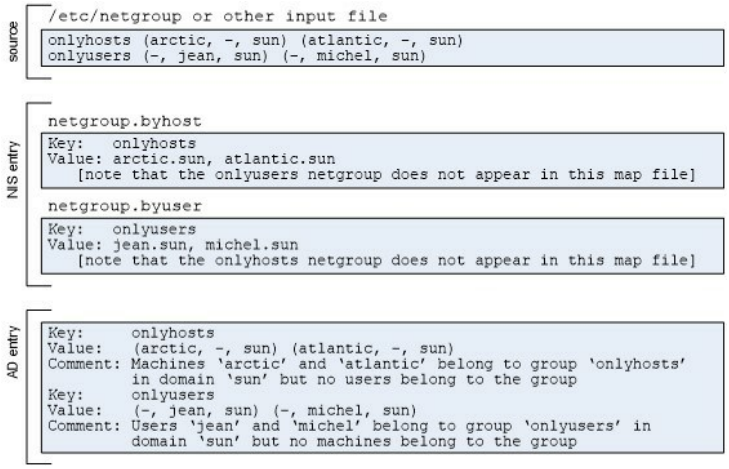
- a set of three comma-separated components.
- a netgroupname.

When specifying an element as a set of three components, you can omit any component to allow any value for that component or specify the special character dash (-) to eliminate a component as a valid value.

The netgroup.byhost map uses the host name as the key and the value is the list of all netgroups that contain the key host somewhere in the hierarchy.

The netgroup.byuser map uses the user name as the key and the value is the list of all netgroups that contain the key user somewhere in the hierarchy.

If you create a netgroupmap in Active Directory, you must not include the key as part of the value. To illustrate, the following example has entries for two netgroups—onlyhosts and onlyusers—and how the groups become key and value entries in the derived NIS maps.



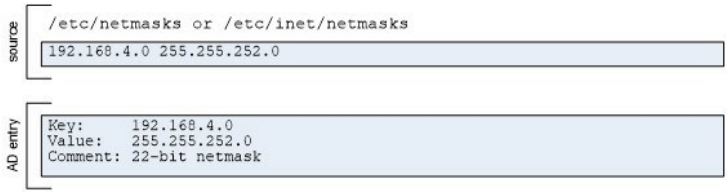
netmasks

In most cases, the netmasks map is created from the /etc/inet/netmasks or /etc/netmasks file. A typical line looks like this:

IP_addressnetmask # comment

For example

192.168.4.0 255.255.252.0
192.168.4.1 255.255.255.0



If you create a netmasks map in Active Directory, you must not include the key as part of the value. For example:

- Key: 192.168.4.0
- Value: 255.255.252.0
- Comment: This is a 22-bit netmask.

This map is only applicable for Solaris.

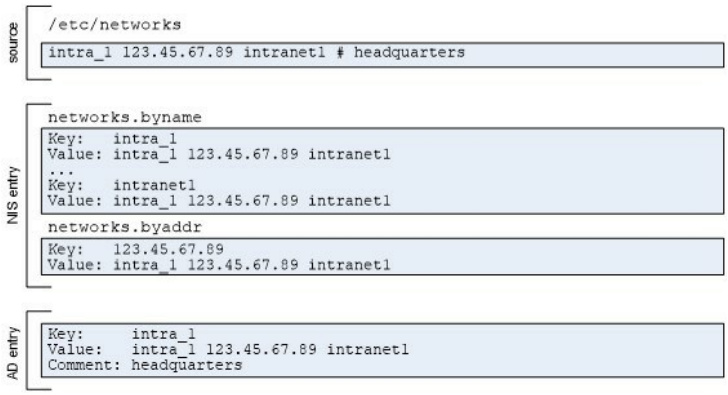
networks

The networks map is the the abbreviated name for the networks.byaddr map. The derived maps are networks.byname and networks.byaddr. In most cases, the networks map is created from the /etc/networks file. A typical line looks like this:

network_name network_address [alias1,...] # comment

For example:

```
arpa 10 arpanet
intra_1 123.45.67.89 intranet # headquarters
sf_site 171.22.0.0 sf1 # san francisco satellite
```



For the networks.byname map, entries are defined like this:

- Key is the network name: intranet
- Value is the network address and any aliases defined for the network: intranet 171.22.0.0 intra

For the networks.byaddr map, entries are defined like this:

- Key is the network address: 171.22.0.0
- Value is the network name and any aliases defined for the network: intranet 171.22.0.0 intra

If you create a networks map in Active Directory, you must include the key as part of the value. For example:

- Key: intranet
- Value: intranet 171.22.0.0 intra
- Comment: The value includes the network name and address

printers

In most cases, the printers map is created from the /etc/printers.conf file. A typical line looks like this:

destination_name key=value[,key=value,...] # comment

For example:

```
buildx:paddr=buildx.acme.com,105004,1,sys,lp,buildxspl,1:
printer3:bsdaddr=server,ps_printer # in copy room
```

source

```
/etc/printers.conf
printer3:bsdaddr=server,ps_printer # in copy room
```

AD entry

```
Key:     printer3
Value:   printer3:bsdaddr=server,ps_printer
Comment: in copy room
```

If you create a printers map in Active Directory, you must include the key as part of the value. For example:

- Key: printer3
- Value: printer name followed by key and value pairs for the printer properties: printer3:bsdaddr=server,ps_printer
- Comment: in copy room

This map is only applicable for Solaris.

prof_attr

In most cases, the prof_attr map is created from the /etc/security/prof_attr file. A typical line looks like this:

```
profile_name:res1:re2,description:attr
```

For example:

```
all:::Execute any command as the user:help=AllRights.html
guest:RO::Allow read-only:audit-flags=all:project=web
```

UNIX file

```
/etc/security/prof_attr
all:::Execute any cmd as user or role :help=U-Rhelp.html
```

NIS entry

```
prof_attr
Key:   <profile_name>
Value: <profile_name>:[res1]:[res2]:<descrip>:<attr>=<attr_value>
```

AD entry

```
Key:     all
Value:   all:::Execute any cmd as user or role :help=U-Rhelp.html
Comment:
```

If you create a prof_attr map in Active Directory, you must include the key as part of the value. For example:

- Key: all
- Value: profile name and properties followed by attributes defined as key and value pairs for the profile: all:::Execute any cmd as user or role:help=All.html

This map is only applicable for Solaris.

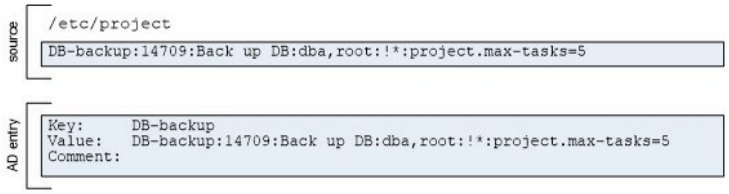
project

In most cases, the project map is created from the/etc/project file. A typical line looks like this:

```
project_name:projectid:comment:user_list:group_list:attr
```

For example:

```
DB-backup:14709:Back up DB:dba,root:!*:project.max-tasks=5
web:101:Web services deployment:root:as-team: \\ task.maxlwps=(privileged,101,signal=SIGTERM)
```



If you create a project map in Active Directory, you must include the key as part of the value. For example:

- Key: DB-backup
- Value: project name and properties followed by attributes defined as key and value pairs: DB-backup:14709:Back up DB:dba,root:!*: \\ project.maxtasks=5

This map is only applicable for Solaris.

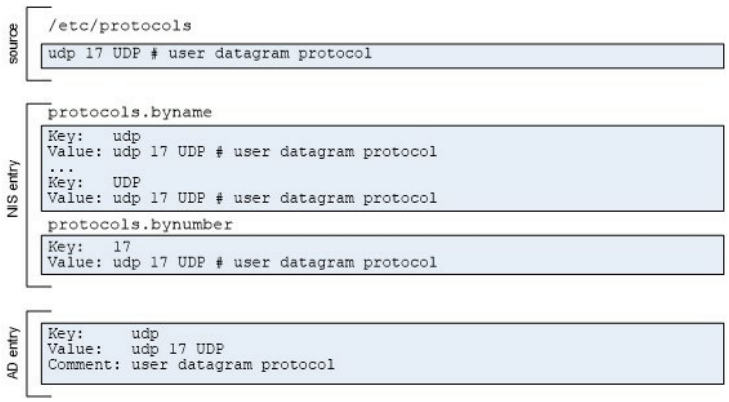
protocols

The protocols map is the the abbreviated name for the protocols.bynumber map. The derived maps are protocols.byname and protocols.bynumber. In most cases, the protocols map is created from the /etc/protocols file. A typical line looks like this:

protocol number alias # comment

For example:

ip 0 IP # internet protocol, pseudo protocol number
udp 17 UDP # user datagram protocol



For the protocols.byname map, entries are defined like this:

- Key is the protocol name: udp
- Value is the protocol name, number, and any aliases defined for the protocol: udp 17 UDP

For the protocols.bynumber map, entries are defined like this:

- Key is the protocol number: 17
- Value is the protocol name, number, and any aliases defined for the protocol: udp 17 UDP

If you create a protocols map in Active Directory, you must include the key as part of the value. For example:

- Key: udp
- Value: udp 17 UDP
- Comment: user datagram protocol

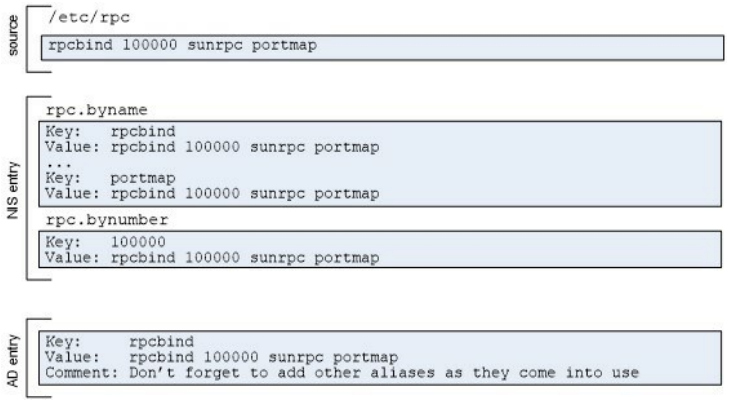
rpc

The rpc map is the the abbreviated name for the rpc.bynumber map. The derived maps are rpc.byname and rpc.bynumber. In most cases, the rpc map is created from the /etc/rpc file. A typical line looks like this:

rpc_name port_number alias1 alias2 ... # comment

For example:

```
portmapper 100000 portmap sunrpc
rpcbind 100001
```



For the rpc.byname map, entries are defined like this:

- Key is the rpc name or alias, so there would be separate entries for: portmapper, portmap, sunrpc, and rpcbind.
- Value for each of the portmapper, portmap, and sunrpc key entries would be the same: portmapper 100000 portmap sunrpc

For the protocols.bynumber map, entries are defined like this:

- Key is the rpc number: 100000
- Value is the rpc name, number, and aliases: portmapper 100000 portmap sunrpc

If you create a rpc map in Active Directory, you must include the key as part of the value. For example:

- Key: portmapper
- Value: portmapper 100000 portmap sunrpc
- Comment: portmap and sunrpc are aliases for portmapper

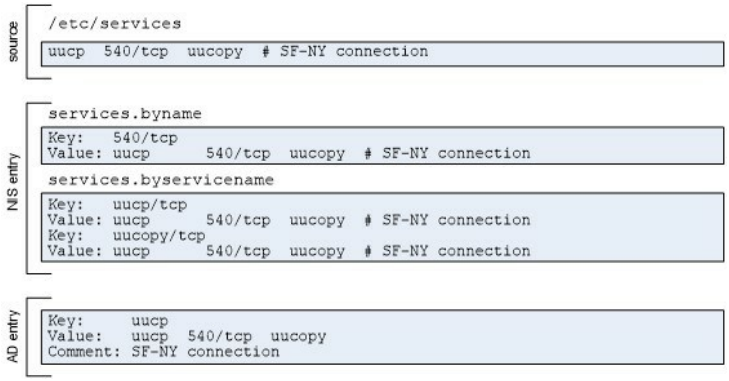
services

The services map is the the abbreviated name for the services.byname map. The derived maps are services.byname and services.byservicename. In most cases, the services map is created from the /etc/services file. A typical line looks like this:

```
service port/protocol alias1 alias2 ... # comment
```

For example:

```
uucp 540/tcp uucopy # this entry is for uucp
```



For the services.byname map, entries are defined like this:

- Key is the service name or alias, so there would be separate entries for: uucp and uucopy.
- Value for each of the uucp and sunrpc key entries would be the same: uucp 540/tcp uucopy

For the service.byservicename map, entries are defined like this:

- Key is the port number and protocol: 540/tcp
- Value contains the same set of fields: uucp 540/tcp uucopy

If you create a services map in Active Directory, you must include the key as part of the value. For example:

- Key: uucp
- Value: uucp 540/tcp uucopy
- Comment: uucopy is an alias for uucp

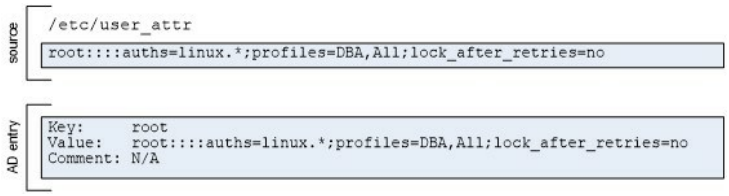
user_attr

In most cases, the user_attr map is created from the /etc/user_attr file. A typical line looks like this:

```
user:qualifier:res1:res2.attr
```

For example:

```
root::::auths=solaris.*,solaris.grant; \\
profiles=Web Console Management,All; \\ lock_after_retries=no; min_label=admin_low; \\ clearance=admin_high
```



If you create a user_attr map in Active Directory, you must include the key as part of the value. For example:

- Key: root
- Value: user name and properties followed by attributes defined as key and value pairs for the profile:

  all::::auths=solaris.*;profiles=DBA,all;lock_after_retries=no

This map is only applicable for Solaris.

Creating Generic Custom Maps

You can create generic maps to publish any type of custom information that you want to make available to NIS clients. Generic custom maps consist of a simple key/value format and optional comments. You can also use generic maps to manually create standar

To add a custom map to Active Directory:

1. Open Access Manager.
2. In the console tree, select **Zones**, and open the specific zone you want to work with.
3. In the console tree, select **NIS Maps** and right-click; then click **New** and select **Generic Map**.
4. Type a name for the new map; then click **OK**.
5. In the details pane, select the new map, right-click; then click **New > Map entry**.
6. Type the appropriate information for the map record you are adding; then click **OK**. For example:
   - Type the **Key** to use in a client request for looking up the corresponding value.
   - Type the **Value** associated with the key.
   - Type any optional **Comments** for the key/value pair.

     For example:

Changing the Map Type

When you import or create NIS maps, the map type determines the fields defined. For example, a Generic map type consists of three fields: the **Key** field (required) the **Value** field (required), and the **Comment** field. If you don't select the correct map type, the Centrify Network Information Service will not be able to interpret the records in the map correctly or respond to client requests with the proper information.

To change the map type of an existing NIS map:

1. Open Access Manager.
2. In the console tree, select **Zones**, and open the specific zone you want to work with.
3. In the console tree, open **NIS Maps**; then the select the map name you want to change. For example, if you have created a map named nethosts, select the nethosts map.
4. Right-click; then click **Change Type** and select the correct map type. For example, if the records in nethosts map should consist of a Key, a Value, and an optional Comment, select **Generic Map** as the map type.

   If records have already been defined for the map using the incorrect map type, in most cases, you will need to modify the fields after changing the map type.

Maintaining Map Records in Active Directory

Once NIS maps are stored in Active Directory, you must maintain the records in Active Directory to ensure changes are reflected in the local map cache that the Centrify Network Information Service uses to respond to NIS client queries. You can use Access Manager to manually add, edit, or delete individual map records for any map. The specific fields available in each record, and which fields are required and which are optional, depend on the type of map you are editing. For example, the fields in an auto.master map entry are different from the fields in a netgroupmap entry. For information about the fields in different types of maps, see Creating new NIS maps in Active Directory.

Modifying Map Records in Active Directory

Specific users and groups can be given the right to add, modify, and delete NIS map entries using the Zone Delegation Wizard. For information about the rights required, see the *Planning and Deployment Guide*.

To edit individual map records:

1. Open Access Manager.
2. In the console tree, select **Zones**, and open the specific zone you want to work with.
3. In the console tree, open **NIS Maps**, the select the map you want to modify. For example, select the auto.master map.
4. Select an individual map record and right-click.
5. Click **Properties** to modify the fields for the selected record or click **Delete** to remove the record from the map.

   If deleting a map record, click **Yes** to confirm the operation.

Deleting a map stored in Active Directory

Specific users and groups can be given the right to delete NIS maps using the Zone Delegation Wizard. For information about the rights required, see the *Planning and Deployment Guide*.

To remove a NIS map from Active Directory:

1. Open Access Manager.
2. In the console tree, select **Zones**, and open the specific zone you want to work with.
3. In the console tree, open **NIS Maps**, the select the map you want to remove.
4. Right-click; then click **Delete** to remove the map from Active Directory.

This section describes how to use diagnostic tools and log files to retrieve information about adnisd operation and correct problems.

Analyzing Zones for Potential Issues

One way to avoid problems with agentless authentication or incomplete information is to periodically analyze the zone in the Active Directory forest using the **Analyze** wizard.

> **Note**: When you run the **Analyze** wizard, it checks only *open* zones in the Active Directory forest. Make sure the zone you are using as a NIS domain is open before analyzing the forest.

To check for potential problems in the Active Directory forest:

1. Open Access Manager.
2. If so prompted, specify the forest domain or domain controller to which to connect.
3. In the console tree, select the Access Manager root node, right-click, and click **Analyze**.
4. At the Welcome page, click **Next**.
5. Select the checks to perform (at least the two in the table below) and click **Next**.

Inconsistency in granting NIS server permissions	Check that a zone_nis_servers group exists in each zone that supports agentless authentication, and that the group contains all NIS servers defined for the zone (to ensure data integrity). This group is required for assigning permissions to Delinea-managed computers that act as NIS servers. Do not delete or modify it manually.
Orphan UNIX data objects	Check for profile objects whose parent objects have been deleted – for example, manually deleted zone objects whose user, group or computer UNIX profile data may be left in Active Directory. This option removes UNIX-specific data from Active Directory.

6. Review the summary report and click **Finish**.
7. If the summary report indicates any issues, select **Analysis Results** in the console tree and view the details listed in the right pane. For example:

   To drill down further, or to resolve the issue, select the warning or error, right-click, and select **Properties**. For example:

Verifying NIS Configuration for Servers and Clients

If you are troubleshooting issues with the Delinea Network Information Service or NIS client look-ups, start by verifying whether the current environment is configured properly by doing the following:

- Check the connectivity between the NIS client and the NIS server with a ping command. If the ping command fails, check the network connection and the DNS configuration for name resolution problems.
- Verify that the nisd.securenets parameter allows responses to NIS clients on other computers. By default, the adnisd process responds only to *local* NIS requests.
- Verify that the adnisd process is running, for example with the ps command. If adnisd is not running, restart it.
- Verify that ypserv is *not* currently running. If ypserv is running, stop it, modify the system initialization files so ypserv does not start when the computer is rebooted, and restart adnisd.
- Verify that adnisd has registered with RPC by running rpcinfo -p localhost on the adnisd server. You should see two entries in the RPC table for the ypserv program (100004):

100004	2	udp	844 ypserv
100004	2	tcp	846 ypserv

If no table is displayed, restart RPC services. If the ypserv process is not listed, restart adnisd.

- Verify RPC connectivity from the NIS client:

  rpcinfo -p server

  You should see the same table and entries as when you listed RPC entries for the adnisd server. For example:

100004	2	udp	844 ypserv
100004	2	tcp	846 ypserv

  If no table is displayed, check the access permissions to the RPC server. For example, on Linux, check /etc/hosts.allow and /etc/hosts.deny files.

- Make sure the correct NIS domain name is configured on the NIS client. The NIS domain name is usually the same name as the name of the zone that the server is joined to. To set the domain name, log on as root run the following command:

  domainname zone_name

- Verify that the ypbind process is running on the NIS client using the ps command. If ypbind is not listed as a running process, configure and start it.
- Verify that ypbind on the NIS client has found the Delinea NIS server by running ypwhich on the NIS client machine.

  If the client is not bound to the correct server name, check the ypbind configuration files and start-up options.

  If you are transitioning from an existing NIS infrastructure to the Delinea Network Information Service, the most common reasons for errors are an incorrect domainname setting or an improper ypbind configuration. For example, if your existing NIS domain names do not match the zone name, some clients may fail because they use the old NIS domain name instead of the domain name you have set up for the Delinea Network Information Service domain.

Updating the Startup Sequence

On some platforms, the adnisd package might prevent the ypbind service from starting properly because of the order in which services are started. For example, if ypbind is configured to start before the adnisd service, the bind will fail. In most cases, this issue does not occur if you are installing new packages because the installation process checks and corrects the startup sequence to ensure that the bind will be successful. However, to prevent unintended changes to the existing startup sequence during an upgrade, upgrading the adnisd package will not modify your existing startup configuration. You can manually correct the startup sequence after an upgrade by running the chkconfig script. For example, run the following command after the adnisd upgrade:

chkconfig adnisd on

Using NIS Command Line Utilities

The Delinea Network Information Service supports common command-line utilities for performing administrative and diagnostic tasks. The following table lists those you may find useful in the Delinea NIS environment.

ypwhich	Display the name of the NIS server the client is connected to.
ypwhich -m	List the maps that are served by the current NIS server.
ypwhich -x	Display the nicknames that are defined for NIS maps.

ypcat -k map	Display the contents of the specified map. This command displays both keys and values.
ypmatch key map	Look-up the specified key in the specified map.
yppoll map	Check the version number of the specified map. This command is only available on Solaris and HP-UX environments. The version number is displayed as an integer. The adnisd process does not use timestamps.

Configuring Logging for adnisd

By default, the adnisd process logs errors, warnings, and informational messages in the syslog and /var/log/messages files, along with other kernel and program messages. You might find it useful to log additional details about the operation of the adnisd process for troubleshooting purposes.

To enable logging for the Delinea Network Information Service:

1. As root, set the logging level for the Delinea Network Information Service by modifying the log.adnisd parameter in the centrifydc.conf file.

   You might also want to suppress log messages from adclient to make it easier to collect and analyze the messages that are specific to adnisd operation. For example, set the log.adnisd parameter to DEBUG to log *all* adnisd operations, and the log parameter for adclient to INFO or WARN to limit messages generated by the adclient process:

   ```
   log: WARN log.adnisd: DEBUG
   ```

   If you only want to collect diagnostic information for netgroup processing, set the log.adnisd.netgroup parameter instead of the log.adnisd parameter. For example:

   ```
   log.adnisd.netgroup: DEBUG
   ```

2. Set the syslog facility to use for logging adnisd operations using the logger.facility.adnisd configuration parameter. This parameter enables you to log adnisd messages using a different syslog facility than the facilities used for logging general adclient messages or adclient audit messages.

   This parameter value can be any valid syslog facility. For example, set this parameter to log messages to auth (default), authpriv, daemon, security, or local0-7 facilities. For example:

   ```
   logger.facility.adnisd: auth
   ```

For performance and security reasons, only enable DEBUG logging when necessary – for example, when requested to do so by Delinea Support, or while diagnosing a problem.

> **Note**: Sensitive information may be written to this file. Evaluate the contents before giving others access to it.

Smart Card for Red Hat Linux

This document explains how to set up smart card authentication for logging on to Red Hat Linux computers.

Why and How to Use a Smart Card to Log On

Smart cards provide an enhanced level of security for Red Hat Linux computers when users log on to Active Directory domains. If you use a smart card to log on, authentication requires a valid and trusted root certificate or intermediate root certificate that can be validated by a known and trusted certification authority (CA).

Because smart cards rely on a public-private key infrastructure (PKI) to sign and encrypt certificates and validate that the certificates were issued by a trusted certification authority and have not expired or been revoked, authentication using a smart card is more secure than a user name and password.

Configuring a smart card for use on a Red Hat Linux computer that is running the Delinea Agent requires that you have already set up a smart card for use in a Windows domain. You do not need to add any smart card infrastructure to the Linux computer, other than a smart card reader and a provisioned smart card.

In a Windows environment, a smart card may be set up either for a single user account or for multiple user accounts. For example, an individual contributor might have access to a single Active Directory account that he uses for all his work. In this case, the card is set up for a single user and the card is linked directly to a UPN. When a user inserts the card to log on, the smart card system looks for the UPN in Active Directory and prompts for a PIN.

Windows 2008 also provides a name-mapping feature that enables configuring a smart card with multiple user accounts. For example, a user might want to log in with a regular account to check mail or perform routine tasks, but log in with an administrator's account to perform privileged tasks. To set up a card for multiple users, an administrator maps a certificate to each user account on the card. When a user inserts the card to log on, the smart card system prompts the user to select which account to use, and prompts for the card's PIN.

If you have set up smart card login for Windows clients in a domain, you can use Access Manager to configure smart card login for Red Hat Linux clients joined to the same domain. If you have provisioned a smart card for use on a Windows computer — either for a single user or multiple users — once you configure smart card support for a Linux computer, you can use the same smart card to log in to a Red Hat Linux computer.

> **Note**: Configuring smart card support in Access Manager is nearly the same for a single-user or multi-user card with the exception that for multi-user cards, you must set an extra configuration parameter as explained in Enabling Support for Multi-User Smart Cards.

Setting up a single user smart card login for Windows computers requires either:

- Microsoft enterprise root certification authority; see the Microsoft TechNet article: Install an enterprise root certification authority.
- A third party certification authority — see the Microsoft KB article: Guidelines for enabling smart card logon with third-party certification authorities.

Setting up a multi-user smart card login for windows requires mapping the certificate on the card to the users who the card is associated with. See the following Microsoft Technet Blog post: Mapping One Smart Card to Multiple Accounts for more information on how to do this.

Configuring Smart Card Authentication

You configure Red Hat Linux computers for smart card authentication primarily through group policy settings. Enabling support for smart cards requires that you set a single policy ("Enable smart card support"). Supporting the use of multi-user smart cards requires that you set a configuration parameter on each Red Hat computer. In addition, Server Suite provides several group policies to control how smart card authentication works after you enable it.

Complete the procedures in the following sections to configure smart card authentication for Red Hat Linux computers:

- Enabling smart card support in which you enable smart card authentication for Active Directory users. This is the only procedure you need to complete to enable smart card authentication. The other procedures allow you to configure different aspects of smart card authentication, such as locking the screen if the smart card is removed, or preventing users from logging in without a smart card.
- Enabling support for multi-user smart cards in which you set the smart card.name.mapping configuration parameter to enable the use of smart cards provisioned with multiple users on a particular computer.
- Enforcing smart card authentication in which you prevent users from logging in with a user name and password on Red Hat Linux computers that have smart card authentication enabled. You can require all users on a computer to use a smart card for logging in or require specific users to use a smart card.
- Configuring certificate validation in which you specify how to use a Certificate Revocation List (CRL) to check the status of certificates stored on a revocation server
- Locking the screen if a smart card is removed in which you require that the computer's screen is locked when a smart card is removed.
- Enabling a certificate without extended key usage in which you enable a Windows group policy setting to allow using certificates without the EKU attribute for smart-card log in.
- Configuring applications for smart card access in which you configure applications such as Firefox and Thunderbird that require smart card authentication to gain access to sensitive sites and data.

Before Configuring Smart Card Authentication

To use a smart card to log on to a Red Hat Linux, CentOS, Debian, or Ubuntu computer, verify that the computers meet these requirements:

- Are running one of the following operating systems:
  - Red Hat Linux (32- or 64-bit) version 5.6 or later
  - CentOS version 5.6 or later
  - Ubuntu 18.04.x LTS, 20.04.x LTS and 21.04 (amd64)
  - Debian 9.x and 10.x (amd64)
  - Rocky Linux (amd64)
  - AlmaLinux (amd64)

    Note: For Debian and Ubuntu systems, be sure to have the opensc-pkcs11, pcscd, and libnss3-tools packages installed.
- Are running the GNOME desktop. The agent does not support use of a smart card with the KDE desktop.
- If a system is running RedHat Linux or CentOS 8.0 or later, the system needs Delinea Agent for *NIX version 5.7.0 or later.
- If a system is running Debian or Ubuntu, the system needs Delinea Agent for *NIX version 5.8.0 or later.
- Are joined to the Windows domain.
- Have a supported smart card reader attached.

Other prerequisites for enabling smart card support differ depending on whether you have configured a single-user or multi-user smart card.

For a single-user card, before enabling smart card support, make sure you do the following:

- Provision a smart card with an NT principal name and PIN. Currently, Access Manager supports Common Access Card (CAC), Personal Identify Verification (PIV), cards with both CAC and PIV profiles (CACNG), and Alternative Logon Token (ALT) smart cards.
- Verify that the Active Directory Zone user's UPN matches the UPN on the smart card.

For a multi-user card, before enabling smart card support, make sure you have the following in place:

- A Windows Server 2008, or later, domain controller for authentication.
- The card is not configured with a UPN. If a card with a UPN is inserted, the computer prompts for a PIN rather than prompting for a user name and password.
- An administrator has added the certificate on the card to the name mapping for the users the card is associated to. See the following Microsoft Technet Blog post: Mapping One Smart Card to Multiple Accounts for more information on how to do this.

For either type of card, verify that the public key infrastructure to support smart card login is operational on the Windows computer running Active Directory and Access Manager. If the user is able to log in to a Windows computer with a smart card, and you have a card reader and a fully-provisioned card for the Linux computer, the user should be able to log in to the Linux computer once you configure it for smart card support.

Although the Linux computer has its own infrastructure for enabling and managing smart card authentication, the Delinea Agent for *NIX and smart card utility (sctool) enable authentication through Active Directory. After you enable smart card support through the Delinea Agent, the Red Hat smart card configuration options have no effect.

Enabling Smart Card Support

Smart card authentication requires configuration changes to certain Red Hat or CentOS Linux files, depending on the version of Red Hat Linux or CentOS you are using.

For example, if you are using Red Hat Linux 5.6 or 6.0, the files affected may include the following:

- /etc/pam.d/gdm
- /etc/pam.d/gnome-screensaver
- /etc/pam.d/password-auth
- /etc/pam.d/smartcard-auth

Smart card authentication also requires configuration changes to certain system Coolkey symbolic links such as the following:

- /usr/lib(64)/libckyapplet.so.1.0.0
- /usr/lib(64)/pkcs11/libcoolkeypk11.so

After you enable smart card authentication, the agent makes the required changes and creates backup copies of the affected files.

The smart card components on the Linux computer are configured by default to use the Delinea Coolkey PKCS #11 module for authentication. Although this is the optimal configuration, if your smart cards are not supported by Coolkey, Delinea allows you to specify a different PKCS #11 module to use for authentication. Delinea does not supply PKCS #11 modules other than the default Coolkey module. If you need to use a third-party module, you must install it yourself.

Some PKCS #11 modules may not work seamlessly with the GDM environment. For example, some card events, such as locking the screen upon card removal, may not work.

To configure a different module, do one of the following:

- If you are enabling smart card support with group policy, you can specify an alternate PKCS #11 module when you enable the group policy; see the procedure: To enable smart card support by using group policy.
- If you are manually enabling smart card support by running sctool, you can set a configuration parameter on each Linux computer to specify the module to use; see the procedure: To manually enable smart card and specify a different PKCS .

Steps

If you are running Red Hat Linux 6.0, you must install some support packages before enabling smart card support; see To install required packages on Red Hat Linux 6.0.

You can enable smart card authentication by either of the following methods:

- Use the "Enable smart card support" group policy, which enables smart card support on all computers to which the Group Policy object applies. Note that configuration changes do not take place until the next group policy update or when you run adgpupdate on the Linux computers.
- Run the sctool -enable utility on each computer that you want to enable for smart card support.

To install required packages on Red Hat Linux 6.0

1. Log on to a Red Hat computer with root privilege and open a terminal window.
2. Run the following command:

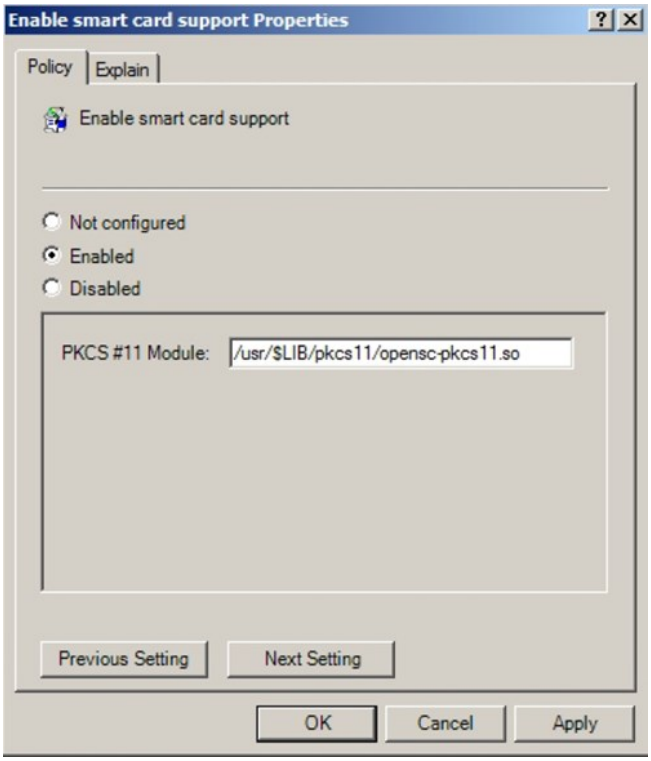
```
[root]#yum groupinstall "Smart card support"
```

To Enable Smart Card Support Using Group Policy

1. On a Windows computer, open Group Policy Management to create or select a Group Policy object that is linked to a site, domain, or organizational unit that includes Red Hat Linux computers; right-click the Group Policy object, then select **Edit**.
2. In the Group Policy Management Editor, expand **Computer Configuration** › **Policies** › **Delinea Settings** › **Linux Settings**, click **Security**, then double-click **Enable smart card support**.
3. Select **Enabled**, then click **OK** to save the policy setting, or go to the next step to change the PKCS #11 module used for authentication.

This group policy modifies Red Hat Enterprise Linux configuration files to look for a smart card user's credentials in Active Directory and verify the identity of the user with the smart card certificate.

4. Optionally, to specify a PKCS #11 module other than the Delinea default module, type the complete path to the module in **PKCS #11 Module**:



> **Note**: Your smart card environment performs optimally when configured to use the default Coolkey module. You should specify a different module only if your smart cards are not supported by Coolkey. Otherwise, skip this step and click **OK** to save the group policy setting.

This field supports the use of the $LIB environment variable in the path to allow a single group policy to work for 32-bit and 64-bit systems. At run time on 32-bit systems$LIBresolves tolib, while on 64-bit systems it resolves to lib64.

For example, the following path specifies the OpenSC PKCS #11 module:

```
/usr/$LIB/pkcs11/opensc-pkcs11.so
```

5. To apply the group policy immediately to any computer you must restart the computer or run the adgpupdate command on it.

   Otherwise, all affected computers will be updated automatically at the next group policy update interval. After computers are restarted or receive the policy update, they are ready for smart card use.

To Manually Enable Smart Card Support Running sctool

1. Log on to a Red Hat computer with root privilege and open a terminal window.
2. Run the sctool utility with the --enable option:

   ```
   [root]$ sctool --enable
   ```

3. Repeat steps 1 and 2 for each computer on which to enable smart card authentication.

To Manually Enable Smart Card and Specify a Different PKCS

1. Open the Delinea configuration file with a text editor, find the rhel.smartcard.pkcs11.module parameter, and set its value to the complete path for your PKCS #11 module.

Be certain to remove the comment for the parameter.

For example, the following parameter value sets PKCS #11 to the OpenSC module:

```
[user]$ vi /etc/centrifydc/centrifydc.conf
...
rhel.smartcard.pkcs11.module: /usr/$LIB/pkcs11/opensc-pkcs11.so
```

This parameter supports the use of the $LIB environment variable in the path to allow a single path specification to work for 32-bit and 64-bit systems. At run time on 32-bit systems $LIB resolves to lib, while on 64-bit systems it resolves to lib64.

2. Save and close the file.
3. Enable, or re-enable smart card support by running the following sctool commands as root:

```
[root]$ sctool --disable
[root]$ sctool --enable
```

4. Refresh the GNOME environment by running the following command as root:

```
[root]$ /usr/sbin/gdm-safe-restart
```

Next Steps

After you enable smart card support, the computer is ready for smart card authentication. You can attach a smart card reader and log in with a valid card and matching Active Directory user.

The next step is to configure one or more of the following smart card authentication options if you wish:

- Enabling support for multi-user smart card which sets the smartcard.name.mapping configuration parameter to enable the use of smart cards provisioned with multiple users on a particular computer.
- Enforcing smart card authentication which prevents users from logging on with just a user name and password.
- Configuring certificate validation which specifies how certificates are validated.
- Locking the screen if a smart card is removed which locks the screen when a smart card is removed to provide enhanced security.

If you have no other options to configure, you can go directly to Verifying smart card authentication to confirm that you can log on to one of the Linux computers that you have configured for smart card authentication.

Enabling Support for Multi-User Smart Cards

If you plan to use multi-user smart cards on a Red Hat Linux computer in your domain, you must set the smartcard.name.mapping parameter to true in the Delinea configuration file for that computer by completing the following the procedure. If your environment exclusively uses single-user smart cards, you can skip this section.

> **Note**: Setting the configuration parameter with this procedure has no effect on single-user smart cards. There is no conflict with using single-user and multi-user on the same computer. However, if a Red Hat Linux computer is accessed through a multi-user card, you must set the configuration parameter by using this procedure.

To enable support for multi-user smart cards

1. On the Red Hat Linux computer, open the Delinea configuration file in a text editor, /etc/centrifydc/centrifydc.conf, with a text editor.
2. Type the following:

   ```
   smartcard.name.mapping: true
   ```

   By default, this parameter is set to false and the configuration file should have a commented line showing this setting. So, alternately, you can find this parameter in the file, remove the comment, and change the value to true.
3. Save and close the file.

Enforcing Smart Card Authentication

By default, enabling smart card support does not force all users to log on using a smart card. If you want to require all Active Directory users to authenticate by using a smart card, you have the option to configure a computer group policy. If you want to require only specific Active Directory users to authenticate by using a smart card, you can configure their user account properties to require a smart card for authentication.

You can enable the "Require smart card login" group policy to ensure that all Active Directory users logging on to a computer must insert a smart card for authentication. If you enable this policy, Active Directory users who forget their smart card will be unable to log on to their computers. However, you add exceptions to this group policy to allow users who forget their smart card to log on using their user name and password on the computers where the policy with exceptions is applied.

> **Note**: If you use this approach to enforce smart card login for all users, be certain that all users have their accounts set with the "Password never expires" option. If a user attempts to log on with a smart card but the password for the account has expired, the smart card login fails with an error message about changing the password. If you use the account option to require smart card for specific users, you can ignore password expiration.

Enforcing smart card authentication applies to all forms of log on, including GUI login, SSH, telnet, and so on. However, it is enforced for Active Directory users only. If a computer is configured with one or more local accounts, those accounts are still able to log on even if you set the group policy to require smart card authentication.

Steps

To require smart card login, complete one of these procedures

- To require smart card login for all users on a computer
- To require smart card login for a specific user

To require smart card login for all users on a computer

1. On a Windows computer, open Group Policy Management and select the Group Policy object where you enabled smart card support for Red Hat Linux computers; right-click the Group Policy object, then click **Edit**.
2. In the Group Policy Management Editor, expand **Computer Configuration** › **Policies** › **Centrify Settings** › **Linux Settings**, click **Security**, then double-click **Require smart card login**.
3. Select **Enabled**.

   Click **Add** if you want to add exceptions to this group policy now, then click Browse to search for and select the Active Directory group allowed to log on using a user name and password if they forget their smart card. If you only want to configure exceptions when they are needed, click **OK** to enable the group policy without exceptions.
4. To apply the group policy immediately to any computer, you must restart the computer or run the adgpupdate command on it.

   Otherwise, all affected computers will be updated automatically at the next group policy update interval.

To require smart card login for a specific user

1. On a Windows computer, open the Access Manager console or Active Directory Users and Computers.
2. Select the user.

   For example, in the Administrator's Console, open *domainName* ___› **Zones** ›** *zoneName* **› **UNIX Data** › **Users**.
3. Right-click the user's name and select **AD Properties**.
4. In the User Properties window for the user, click the **Account** tab.
5. In "Account options", scroll until **Smart card is required for interactive logon** is visible, then select it.

6. Click **OK**.

Configuring Certificate Validation

You can use the **Certificate validation method** group policy to configure how certificates are validated or rejected by using a Certificate Revocation List (CRL) stored on a revocation server.

To Configure How Certificates are Validated

1. On a Windows computer, open Group Policy Management and select the Group Policy object where you enabled smart card support for Red Hat Linux computers; right-click the Group Policy object, then click **Edit**.
2. In the Group Policy Management Editor, expand **Computer Configuration** › **Policies** › **Centrify Settings** › **Linux Settings**, click **Security**, then double-click **Certificate validation method**.
3. Select **Enabled**.
4. Choose one of the following options from **Certificate Revocation List**:
    - **Off:** To disable certificate validation.

      If you select this setting, no revocation checking is performed.
    - **Best attempt:** To check that certificates are not rejected as invalid, untrusted, or revoked by the certificate revocation list (CRL).

      This setting is appropriate for most organizations.
    - **Require if cert indicates:** To check whether there is a successful connection to the revocation server.

      If a URL to the revocation server is provided in the certificate, this setting requires a successful connection to a revocation server, and checks that certificates are not rejected as invalid, untrusted, or revoked by the CRL. You should only use this setting in a tightly controlled environment that guarantees the presence of a CRL server. If a CRL server is not available, certificate validation may prevent furthering processing of an authentication request.
    - **Require for all certs:** To require successful validation of all certificates.

      You should only use this setting in a tightly controlled environment that guarantees the presence of a CRL server. If a CRL server is not available, certificate validation may prevent furthering processing of an authentication request.
5. Click **OK** to save the policy settings.
6. To apply the group policy immediately to any computer, restart the computer or run the `adgpupdate` command on it.

   Otherwise, all affected computers will be updated automatically at the next group policy update interval.

Locking Screen if Smart Card is Removed

Depending on what you consider best practices for using a smart card, you may want the screen to lock whenever a user removes the smart card. If you want to lock the screen when a smart card is removed, you can do so by enabling the **Removing a smart card locks screen** user group policy.

To lock the smart card screen when a smart card is removed

1. On a Windows computer, open Group Policy Management and select the Group Policy object where you enabled smart card support for Red Hat Linux computers; right-click the Group Policy object, then click **Edit**.
2. In the Group Policy Management Editor, expand **Computer Configuration** › **Policies** › **Centrify Settings** › **Linux Settings**, click **Security**, then double-click **Lock Smart Card screen for RHEL**.
3. Select **Enabled**, then click **OK**.

   Note: Policies are turned off by default on Linux systems but can be turned on with a group policy setting. To ensure that the "Removing a smart card locks screen" policy takes effect, verify that the following computer policy is enabled by completing the following two steps.
4. Expand **Computer Configuration** › **Centrify Settings** › **DirectControl Settings**, click **Group Policy Settings**, then double-click **Enable user group policy**.
5. Verify that **Enabled** is selected, and if not, select it, then click **OK**.
6. To apply the group policy "Lock Smart Card screen for RHEL" immediately to any computer you must restart the computer or run the `adgpupdate` command on it.

   Otherwise, all affected computers will be updated automatically at the next group policy update interval. After computers are restarted or receive the policy update, the screen is locked if a smart card is removed.

Enabling a Certificate Without Extended Key Usage

Normally, smart card use requires certificates that contain the extended key usage (EKU) attribute. However, Windows provides a group policy that allows the use of certificates that do not have the EKU attribute.

> **Note**: This group policy is implemented as an administrative template (.adm file), not as an xml file, as are the Delinea group policies.

To use certificates without the EKU attribute with smart cards:

1. Open the group policy editor and edit the GPO that contains the Linux computers enabled for smart-card login.
2. Open **Computer Configuration > Policies > Administrative Templates > Windows Components > Smart Card** and double-click **Allow certificates with no extended key usage certificate attribute**.
3. Click **Enabled** and click **OK**.

   When you enable this policy, it sets the smartcard.allow.noeku parameter to true in the Delinea configuration file. Certificates with the following attributes can also be used to log on with a smart card:

   - Certificates with no EKU
   - Certificates with an All Purpose EKU
   - Certificates with a Client Authentication EKU

4. In a Terminal window, run the sctool command as root with the -E (--no-eku) parameter to re-enable smart card support. You must use either the -a (--altpkinit) or -k (--pkinit) parameter with the -E option; for example:

   ```
   sctool -E -k jsmart@acme.com
   ```

Configuring Applications for Smart Card Access

Many applications, including Firefox and Thunderbird, that require smart card access to sensitive sites or data, create their own NSS database for the user. To give these applications access to the certificates and control revocation lists (CRL) used by the agent for log on, you enable the group policy "Specify applications to import system NSSDB", which synchronizes the system NSSDB file on a computer with each application's NSSDB file.

Each application, such as Firefox, creates a profile file (profile.ini) that specifies the location for its certificates and CRLs. With the "Specify applications to import system NSSDB" policy, you specify the location of the profile file for an application. A Delinea mapper file parses the profile file to determine the location of the application's certificates and CRLs and copies certificates and CRLs to this location.

Steps

If the computers you manage use applications such as Firefox that require smart card access to sensitive sites or data, configure NSS database synchronization to ensure that these applications have access to current certificates and control revocation lists.

To configure NSS database synchronization

1. On a Windows computer, open Group Policy Management and select the Group Policy object where you enabled smart card support for Red Hat Linux computers; right-click the Group Policy object, then select **Edit**.
2. In the Group Policy Management Editor, expand **User Configuration** › **Policies** › **Centrify Settings** › **Linux Settings**, click **Security**, then double-click **Specify applications to import system NSSDB**.
3. Select **Enabled**, then click **Add**.
4. In **Application**, specify the application directory in which to import the system NSS database.

   For each application enter the location of its profiles.ini file. Specify the entry in relation to the home directory of the user by starting the path with ~/. For example, the following entry specifies the default location of the Firefox profiles.ini file

   ~/.mozilla/firefox.
5. Click **Add** to add as many application directories as necessary, then click **OK** to save the settings.

   > **Note**: User policies are turned off by default on Linux systems but can be turned on with a group policy setting. To ensure that the "Specify applications to import system NSSDB" policy takes effect, verify that the following computer policy is enabled:
6. Expand **Computer Configuration** › **Centrify Settings** › **DirectControl Settings**, click **Group Policy Settings**, then double-click **Enable user group policy**.
7. Verify that **Enabled** is selected, and if not, select it, then click **OK**.
8. To apply the group policy immediately to any computer, restart the computer or run the `adgpupdate` command on it.

   Otherwise, all affected computers will be updated automatically at the next group policy update interval. After computers are restarted or receive the policy update, the screen is locked if a smart card is removed.

Configuring Citrix VDA Smart Card Authentication

You can integrate Delinea Agent for *NIX with the Citrix Virtual Delivery Agent (VDA) for Active Directory user authentication. This integration helps users log in to remote Red Hat Linux (RHEL) virtual desktop sessions with a smart card connected to the client device.

The Delinea Authentication Service supports pass-through authentication if the Citrix requirements are met. For details, see https://docs.citrix.com/en-us/linux-virtual-delivery-agent/current-release/system-requirements.html.

Be sure that you have set up smart card authentication already on Windows systems in your domain before continuing.

To configure Citrix VDA smart card authentication:

1. Install the Citrix Linux VDA.

   For details, see the Citrix documentation: https://docs.citrix.com/en-us/linux-virtual-delivery-agent/current-release/installation-overview.html.

   For example, you might run a command that looks like the following:

   ```
   sudo yum -y localinstall XenDesktopVDA-19.9.0.3-1.el7_x.x86_64.rpm
   ```

2. According to the Citrix VDA documentation, install the necessary software and perform the required system integrations.

   NTP isn't required to be configured in an Active Directory environment, but Citrix Linux VDA does require certain software, such as PostgreSQL and openJDK. For details, see https://docs.citrix.com/en-us/linux-virtual-delivery-agent/current-release/configuration.html.

3. Install Delinea Agent for *NIX version 19.9 or later and join the computer to the domain.

   For details, see the **Planning and Deployment Guide**.

4. To configure the agent integrations with the Citrix Linux VDA, add the following setting to the centrifydc.conf file:

   ```
   smartcard.login.service.accounts: ctxsrvr
   ```

   The Citrix smart card login service runs as the ctxsrvr account. This parameter allows you to specify a list of non-root user accounts that use the smart card login services.

5. Configure the Citrix Linux Virtual Delivery Agent (VDA).

   For details, see the Citrix documentation: https://docs.citrix.com/en-us/linux-virtual-delivery-agent/current-release/configuration.html and https://docs.citrix.com/en-us/linux-virtual-delivery-agent/current-release/installation-overview/redhat.html.

   Below is an example of running ctxsetup.sh in interactive mode; be sure to adjust as needed for your environment.

   ```
   $ sudo /opt/Citrix/VDA/sbin/ctxsetup.sh
    Welcome to the Citrix Linux VDA setup script. This script will guide you through the
    configuration of the Linux VDA system services. You can re-run this script at
    any time to reconfigure the system.
    Gathering information...
    Checking CTX_XDL_DOTNET_RUNTIME_PATH... Value not set.
    Dotnet Core runtime environment is needed to run Linux VDA.
    Linux VDA will install it to /opt/dotnet by default.
    If required, please specify an absolute path in valid format here (e.g., /the/path). [\<none\>]:
    Checking CTX_XDL_SUPPORT_DDC_AS_CNAME... Value not set.
    The Virtual Delivery Agent supports specifying a Delivery Controller name using a DNS CNAME record.
    Do you want to enable support for DNS CNAME records? (y/n) [n]: y
    Checking CTX_XDL_DDC_LIST... Value not set.
    The Virtual Delivery Agent requires a space-separated list of Delivery Controller Fully Qualified Domain Names
    (FQDNs) to use for registering with a Delivery Controller. Please provide the FQDN of at least one Delivery
    Controller: CS.CITRIX.TEST
    Checking CTX_XDL_VDA_PORT... Value not set.
    The Virtual Delivery Agent by default communicates with Delivery Controllers using TCP/IP port 80.
    Please provide the TCP/IP port the Virtual Delivery Agent service (ctxvda) should use to communicate with a
    Delivery Controller [80]:
    Checking CTX_XDL_REGISTER_SERVICE... Value not set.
    The Linux VDA services support starting during boot.
    Do you want to register these services to start on boot? (y/n) [y]:
    Checking CTX_XDL_ADD_FIREWALL_RULES... Value not set.
    The Linux VDA services require incoming network connections to be allowed through
    the system firewall. Do you want to automatically open the required ports (by default ports 80, 1494, 2598, 8008 and 6001\~6099) in the
    system firewall for the Linux VDA? (y/n) [y]:
    Checking CTX_XDL_AD_INTEGRATION... Value not set.
    The Virtual Delivery Agent requires Kerberos configuration settings to authenticate with Delivery Controllers. The
    Kerberos configuration is determined from the installed and configured Active Directory integration tool on this
   ```

```
system. Please select the Active Directory integration tool configured on this system:
1: Winbind
2: Quest
3: Centrify 4: SSSD
5: PBIS
Select one of the above options (1-5) [1]: 3
Checking CTX_XDL_HDX_3D_PRO... Value not set.
Linux VDA supports HDX 3D Pro, a set of graphics acceleration technologies designed to optimize the
virtualization of rich graphics applications. HDX 3D Pro requires a compatible NVIDIA Grid graphics card to be
installed. If HDX 3D Pro is selected the Virtual Delivery Agent will be configured for VDI desktops (single-session)
mode. Do you want to enable HDX 3D Pro? (y/n) [n]:
Checking CTX_XDL_VDI_MODE... Value not set.
Linux VDA supports delivery of hosted shared desktops (multi-session) or VDI desktops (single-session).
Do you want to enable VDI desktops (single session) mode? (y/n) [n]: y
Checking CTX_XDL_SITE_NAME... Value not set.
The Virtual Delivery Agent discovers LDAP servers using DNS, querying for LDAP service records. To limit the DNS
search results to a local site, a DNS site name may be specified.
If required, please specify a local DNS site name. [\<none\>]:
Checking CTX_XDL_LDAP_LIST... Value not set.
The Virtual Delivery Agent by default queries DNS to discover LDAP servers, however if DNS is unable to provide
LDAP service records, you may provide a space-separated list of LDAP Fully Qualified Domain Names (FQDNs) with
LDAP port (e.g. ad1.mycompany.com:389).
If required, please provide the FQDN:port of at least one LDAP server. [\<none\>]:
Checking CTX_XDL_SEARCH_BASE... Value not set.
The Virtual Delivery Agent by default queries LDAP using a search base set to the root of the Active Directory
Domain (e.g. DC=mycompany,DC=com), however to improve search performance, a search base may be specified
(e.g. OU=VDI,DC=mycompany,DC=com).
If required, please provide an LDAP search base. [\<none\>]:
Checking CTX_XDL_FAS_LIST... Value not set.
The Federated Authentication Service (FAS) servers are configured through AD Group Policy. But because
the Linux VDA does not support AD Group Policy, you can provide a semicolon-separated list of FAS servers instead.

Caution 1: The sequence must be the same as configured in AD Group Policy.

Caution 2: If any server address is removed, you must fill its blank with the '\<none\>' string and keep the index of server addresses without any changes.
If required, please specify the list of FAS servers (e.g., fasserver.company.com). [\<none\>]:
Checking CTX_XDL_START_SERVICE... Value not set.
The Linux VDA services may be started after configuration is complete.
Do you want to start these services once configuration is complete? (y/n) [y]:
Configuring Citrix Linux VDA ...
Configuration complete.
```

6. In Citrix Virtual Apps or Citrix Virtual Desktops, create the machine catalog and delivery group.

   For details, see https://docs.citrix.com/en-us/linux-virtual-delivery-agent/current-release/installation-overview/redhat.html#step-8-create-the-machine-catalog-in-citrix-virtual-apps-or-citrix-virtual-desktops.

7. (Optional) Enable the group policy entitled "Enable smart card support."

8. Verify that the smart card login is enabled on the Linux computer:

   ```
   $ sudo sctool -s
   ```

   Delinea Smart Card support is enabled.

   If you have not enabled the group policy enabled "Enable smart card support", you may need to run the following command to enable smart card login:

   ```
   $ sctool -e
   ```

   For details about this group policy, see the **Smart Card Configuration Guide**.

9. Reboot the Linux computer.

10. In Citrix StoreFront, enable smart card authentication.

    For details, see https://docs.citrix.com/en-us/storefront/current-release/configure-authentication-and-delegation/configure-authentication-service.html.

Verifying Smart Card Authentication

After you enable smart card support, you should verify that a user is able to authenticate with a smart card on a Red Hat Linux computer.

To verify smart card authentication:

1. On the Red Hat Linux computer, run the following command to check the status of smart card support:

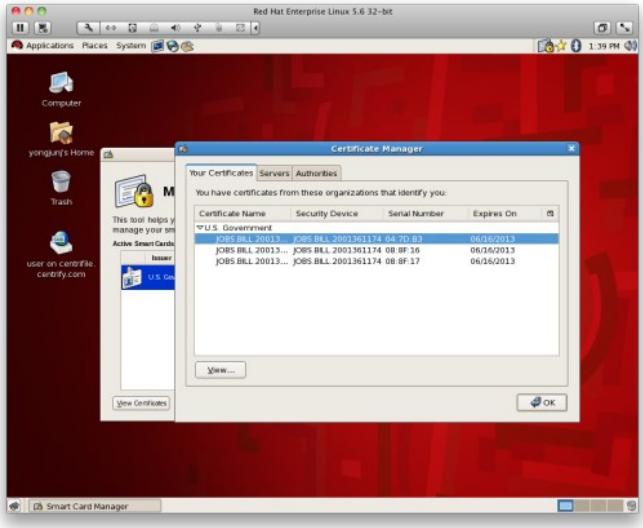
   [root]#sctool --status DirectControl Smart Card support is enabled.

   > **Note**: On Red Hat Linux computers, when enabling smart card support, the agent bypasses the native, Red Hat, smart card infrastructure. Therefore, after you enable smart card with the agent (through the group policy setting or the sctool command), the sctool --status command will show that smart card is enabled but the Red Hat system (GNOME: System > Administration > Authentication > Authentication) might show that it is not enabled. You can ignore the GNOME setting because it is for native smart card authentication, not the authentication used by the agent.

2. Click **System > Administration > Smart Card Manager**.

3. Insert the smart card in the reader and click **View Certificates**.

4. Double-click the certificate for a user account that has a profile in the zone the Red Hat Linux computer has joined, for example, **JOBS.BILL.20013**.



5. Scroll to find the NT Principal name; for example:

NT Principal Name jbill.20013@myDomain.com

6. On a Windows computer, open Activity Directory Users and Computers or the Access Manager console. For example, in the Access Manager console, navigate to the zone that the Red Hat Linux computer has joined and open **UNIX Data > Users**, then double-click the user.

   The NT Principal name in the certificate should match the login name in the Delinea UNIX profile, or in the Active Directory Account tab.

7. Log out of the Red Hat computer.

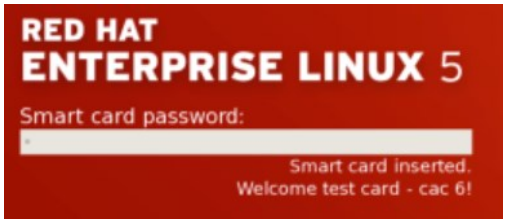
8. Re-insert the smart card in the reader and enter the user's PIN.

Using a Smart Card at Login

When a user inserts a smart card into the card reader attached to a Red Hat Linux computer that is waiting for login, the login dialog is replaced by a smart-card enabled login (if the card is provisioned for an Active Directory user who is enabled for the Delinea zone to which the computer is joined). However, the actual log on screen varies depending on whether the card is provisioned for a single user or for multiple users.

How the Login Screen Appears for a Single-User Card

When a user inserts a single-user card, the smart card login shows the name of the user for whom the card is provisioned, and provides a single text box in which the user can type the PIN associated with the card.



If the user is not enabled for the zone, or is not a valid Active Directory user at all, the smart card login screen is replaced by either a list of local users, or user name and password text entry fields.

The user will be successfully logged in if the following conditions are met:

- The user enters the correct PIN for the smart card.
- The card is trusted by the domain and has not been revoked. The card is checked locally first, online or offline, to ensure that the issuing certificate authority is trusted by the Red Hat Linux computer through the certification authority trust chain, which is set up when the computer joins the domain, and is periodically refreshed.

Checking is performed by the domain controller when the computer is online, and by a local service, based on cached CRLs, when the computer is offline. If the user is not connected to the network but has previously logged on — with a smart card or in some other way — the Delinea Agent gets the UPN from the card and looks up the user in the cached data.

If login fails, no feedback is provided to the user as to why the login is being denied. However, information is logged into various system log files, /var/log/system.log, /var/log/secure.log, and the Delinea log file (/var/log/centrifydc.log) if logging is enabled, that can help determine the reason for a denied login.

How Login Screen Appears for a Multi-User Card

When a user inserts a card that is provisioned for multiple users, the smart card login provides a **Username** box that allows the user to enter the name of the account to use.

When the system finds the user account in Active Directory, it prompts the user to enter the PIN for the card.

If the user is not enabled for the zone, or is not a valid Active Directory user at all, the smart card login dialog is replaced by the previous login screen, either a list of local users or username and password text entry fields.

The user will be successfully logged in if the following conditions are met:

- The user enters the correct PIN for the smart card.
- The card is trusted by the domain and has not been revoked. The card is checked locally first, online or offline, to ensure that the issuing certificate authority is trusted by the Red Hat Linux computer through the certification authority trust chain, which is set up when the computer joins the domain, and is periodically refreshed.

Checking is performed by the domain controller when the computer is online, and by a local service, based on cached CRLs, when the computer is offline. If the user is not connected to the network but has previously logged on — with a smart card or in some other way — the Delinea Agent gets the name from the log on screen and looks up the user in the cached data.

If login fails, no feedback is provided to the user as to why the login is being denied — as is the case when logging in with a password. Information is logged into various system log files that can help determine the reason for a denied login, /var/log/system.log, /var/log/secure.log, and the Delinea log file (/var/log/centrifydc.log) if logging is enabled.

Screen Saver Shows Password Not PIN Prompt

Most smart card users are allowed to log on with a smart card and PIN only — they cannot authenticate with a user name and password. However, it is possible to configure users for both smart card/PIN and user name/password authentication. Generally, this set up works seamlessly: the user either enters a user name and password at the log on prompt, or inserts a smart card and enters a PIN at the prompt.

However, for multi-user cards, it can be problematic when the screen locks and the card is in the reader. When a user attempts to unlock the screen, the system prompts for a password, not for a PIN, although the PIN is required because the card is in the reader. If the user is not aware that the card is still in the reader and enters his password multiple times, the card will lock once the limit for incorrect entries is reached.

What Happens After Login

In general the user experience is the same in both connected and disconnected modes, with the exception of single sign-on (SSO). Because the agent does not cache the smart card's PIN, single sign-on (SSO) is available for smart card authentication only while the computer is connected to the domain.

Of course, certain behaviors and system responses are specific to smart card login:

- If the user removes the smart card after logging on, the response of the system depends on whether the group policy "Lock smart card" screen is enabled in the domain. If it is, the screen locks. Otherwise, the screen does not lock and the user may continue working.

  Note: For a smart card that is provisioned for multiple users, if the screen locks, the system prompts for a Password, not for a PIN, when the user logs back in. However, the user must enter the PIN for the card, *not* the password, when logging back in.

- If the user inserts a smart card while the screen saver is active, the response depends on whether "Lock smart card screen" is enabled in the domain. If it is, the screen saver deactivates. If the policy is not enabled, the screen saver continues running until the user moves the mouse or touches a key.

Disabling Smart Card Support

If you want to disable smart card support, you must disable the group policies you configured to establish smart card authentication.

To Disable Smart Card Support by Using Group Policy

1. Edit the Group Policy object linked to the site, domain, or OU that includes Red Hat Linux computers.
2. Expand **Computer Configuration** › **Policies** › **Centrify Settings** › **Linux Settings**, click **Security**, then double-click **Enable smart card support**.
3. Select **Disabled** and click **OK**.

   When the policy takes effect, smart card strings are removed from /etc/pam.d/system-auth on Red Hat Enterprise Linux 5.6 and /etc/pam.d/smartcard-auth and /etc/pam.d/gnome-screensaver on Red Hat Enterprise Linux 6.0.
4. Expand **Computer Configuration** › **Policies** › **Centrify Settings** › **Linux Settings**, click **Security**, then double-click **Lock Smart Card screen for RHEL**.
5. Select **Disabled** and click **OK**.
6. To apply these group policies immediately to any computer, restart the computer or run the adgpupdate command on it.

   Otherwise, all affected computers will be updated automatically at the next group policy update interval. After computers are restarted or receive the policy updates, they are no longer enabled for smart card use.

To Disable Smart Card Support by Running sctool

1. Log on to a Red Hat computer with root privilege and open a terminal window.
2. Run the sctool utility with the --disable option:

   ```
   [root]$ sctool --disable
   ```
3. Repeat steps 1 and 2 for each computer on which to disable smart card authentication.

> **Note**: If you originally enabled smart card support through group policy by setting "Enable smart card support" you cannot disable it by using sctool --disable. Although this command will temporarily disable smart card support, it will be re-enabled by the policy at the next group policy update interval. To permanently disable smart card support, you must disable **Enable smart card support** as described in the previous procedure, To disable smart card support by using group policy.

Troubleshooting Smart Card Login

If you have problems with smart card login, Server Suiteprovides a command-line tool, sctool, that you can run to configure smart card login, as well as to provide diagnostic information. For example, you can run sctool with the following options:

- sctool --status to show whether smart card support is enabled.
- sctool --dump to display information about the smart card system setup as well as any smart cards that are attached to the computer.
- sctool --pkinit *userPrincipalName* to obtain Kerberos credentials on a single-user smart card for troubleshooting purposes.

  During login with a smart card, the agent calls sctool --pkinit to obtain Kerberos credentials from the smart card currently in the reader. Because this option simulates a good portion of the smart card login process, if you are having trouble logging in you can run sctool --pkinit to obtain useful troubleshooting information. If the command executes successfully, the name of the user will be displayed. If the command fails, you will receive an error message that may help you troubleshoot the issue.
- sctool --altpkinit *unixName* to obtain Kerberos credentials on a multi-user smart card for troubleshooting purposes.

  During login with a multi-user smart card, the agent calls sctool --altpkinit to obtain Kerberos credentials from the smart card currently in the reader (because the card is configured for multiple accounts, the user is prompted to provide a username, which the command uses to obtain the Kerberos credentials). Because this option simulates a good portion of the smart card login process, if you are having trouble logging in you can run sctool --altpkinit unixName to obtain useful troubleshooting information. If the command executes successfully, the name of the user will be displayed. If the command fails, you will receive an error message that may help you troubleshoot the issue.
- sctool --check-kdc-eku to enable checking of the KDC certificate for the Extended Key Usage (EKU) extension "Kerberos Authentication". Do not use this option if you have not updated your KDC to include the required EKU. Enable EKU checking after updating your KDC certificate.

  EKU checking is disabled by default.

  This parameter must be used with the -k (--pkinit) parameter or the -a (--altpkinit) parameter

For more information about using sctool, see the sctool man page.

Administration Guides

The following administrator guides are available

- Linux/Unix Administrator Guide
- Windows Administrator Guide
- macOS Administrator Guide
- Unix/Linux Quick Start
- MFA Guide
- Auto-Enrollment Guide

Refer to the following topics:

- Server Suite for Linux / Unix
- Managing Zones and Delegating Admin Tasks
- Managing Account Profiles and Identity Attributes
- Authorizing Basic Access
- Defining Rights to Use Commands
- Defining Rights to Use PAM Applications
- Using Secure Shell Sessions-based Rights
- Creating and Assigning Custom Role Definitions
- Working with Computer Roles
- Working with Managed Computers
- Importing sudoers Configuration Files
- Using Centrify OpenLDAP Proxy Service
- Using Workstation Mode and Auto Zone
- Troubleshooting Authentication and Authorization
- Using Centrify Commands for Administrative Tasks
- Using Python with Centrify Objects

Server Suite for Linux and UNIX

Server Suite is an IT management solution that provides key services for managing user and group profiles, role-based access rights, elevated privileges for administrative activity, and auditing-based regulatory compliance. These services can be used together or independently, depending on the requirements of your organization. The topics in this section introduce the key Server Suite that enable you to centrally manage Linux and UNIX computers. It includes an overview of how Centrify enables your organization to manage identity attributes, role-based access rights, and administrative activity through an integrated set of services.

Why Securing Access is Crucial

For most organizations, it is critical to control access to computer and application resources to prevent disruptions of service, data tampering, or security breaches. For many organizations, it is also critical to monitor and report on user activity to ensure regulatory compliance with government or industry standards. However, managing who has access to sensitive data, core business services, and the computers and applications that perform vital functions is especially difficult in data centers that include a mix of virtual and physical computers running different operating systems and platform versions.

Why Managing User Account Information Might be a Problem

In a cross-platform environment, you are likely to have multiple identity stores that might have overlapping or conflicting information about the user population. You might also have several different authentication methods—with varying degrees of security—that you are required to manage. For example, in a typical environment with a mix of Linux and UNIX computers, you might have to maintain any combination of the following authentication methods:

- Local configuration files on individual UNIX servers and workstations to identify local users and groups.
- NIS or NIS+ servers and maps to store account and network information for groups of UNIX servers and workstations.
- Kerberos realms and a Key Distribution Center to provide authentication for some users and services.
- Lightweight Directory Access Protocol services to support LDAP queries and responses.

Managing all of these services separately can be costly and inefficient. In addition, users who have access to more than one application or computer platform often have to remember multiple login accounts with conflicting user name or password policy requirements. Individual applications might also require the use of a specific authentication method. For example, a database application or a web service might require users to have a database- or application-specific account.

If you have an environment where user and group account information is stored in multiple locations rather than in a single repository, it is likely that you have overlapping, conflicting, or out-of-date information about who should have access to the computers in your organization. You might also be using less secure authentication and authorization services than required, if you are relying on local configuration files or NIS servers and maps. For example, if you are in an organization that is subject to regulatory compliance, an audit might require you to improve the security of the authentication and authorization services you use.

Why Managing Access and Privileges Might be a Problem

Most organizations require some groups of users to be allowed to use administrative accounts and passwords. For example, you might want to grant these permissions to allow some users to log on to computers that host administrative applications or data center services, but restrict access so that users can only log on when appropriate.

In many cases, the primary way you secure access to computers is by granting a limited number of users or groups root administrative privileges or configuring sudoers rights locally. These common practices leave computers vulnerable to insider threats and present a security risk that might be exploited by an external attack. As common as it is, granting administrative access rights is likely to violate the principal of least privilege, which is intended to minimize your exposure to these types of risks.

In other cases, users who need administrative privileges to perform specific tasks might use a shared administrator and service account password. However, shared passwords reduce accountability, leave computers vulnerable to insider threats, and are also often flagged by auditors as a security issue. If you are in an industry that has compliance requirements, shared passwords might present a significant business risk.

How Centrify can Reduce Security Risks

To reduce the overhead of managing account information and access rights across your organization, Centrify provides the following key features:

Secure Authentication and Identity Management

Centrify enables you to define and manage the identity attributes in user profiles, consolidate and simplify the management of account information, improve the security of authentication and directory services, and enforce consistent password and account policies.

Role-based Access Rights

Centrify enables you to define and manage access rights and role definitions, restrict which users can do what on specific sets of computers or during specific periods of time, and control and restrict access to administrative privileges.

Delegation of Authority

Centrify enables you to delegate administrative activity on a task-by-task basis. By delegating individual tasks to specific users or groups, you can establish a separation of duties at the level of granularity you require.

Auditing of Activity

Centrify enables you to collect and store an audit trail of user activity when and where you want it. With the auditing service, you can selectively capture and analyze only audit trail events or all user and computer activity.

These features can be used together or independently, depending on the type of licenses you purchase and the specific requirements of your organization. For example, some licenses for Server Suite might enable identity management, access control, and privilege management. Other licenses might enable auditing of user activity and reporting services.

How Zones Help you Organize Information

One of the most important aspects of managing computers with Centrify software is the ability to organize computers, users, groups, and other information about your organization into **Centrify zones**. A Centrify zone is a logical object that you create to organize computers, rights, roles, security policies, and other information into logical groups. These logical groups can be based on any organizing principle you find useful. For example, you can use zones to describe natural administrative boundaries within your organization, such as different lines of business, functional departments, or geographic locations. You can also use zones to isolate computers that share a common attribute, such the same operating system.

Zones provide the first level of refinement for access control, privilege management, and the delegation of administrative authority. For example, you can use zones to create logical groups of computers to achieve the following goals:

- Control who can log on to specific computers.
- Grant elevated rights or restrict what users can do on specific computers.
- Manage role definitions, including availability and auditing rules, and role assignments on specific computers.
- Delegate administrative tasks to implement “separation of duties” management policies.

You can also create zones in a hierarchical structure of parent and child zones to enable the inheritance of profile attributes, rights, roles, and role assignments from one zone to another or to restrict local or remote access to specific computers for specific users or groups.

Because zones enable you to grant specific rights to users in specific roles on specific computers, you can use zones as the first level of refinement for controlling who has access to which computers, where administrative privileges are granted, and when administrative privileges can be used.

You can also use zones to establish an appropriate separation of duties by delegating specific administrative tasks to specific users or groups on a zone-by-zone basis. With zones, administrators can be given the authority to manage a given set of computers and users without granting them permission to perform actions on computers in other zones or giving them access to other Active Directory objects.

Improving Security: Access and Privilege Management

Centrify provides its identity management, access control, and privilege management features for Linux and UNIX computers through a combination of features provided by Access Manager and by the Centrify Agent on the computers you want to manage.

You can install Access Manager and related management tools on one or more Windows computers. For example, the central console for performing most identity management, access control, and privilege management tasks is Access Manager. From Access Manager, you can perform all of the following common administrative tasks:

- Define and manage identity attributes for the Active Directory users who need access to Linux and UNIX computers.
- Import and migrate UNIX users, groups, and network information from local configuration files and NIS maps.
- Define and manage rights that allow users to run command-line programs, PAM applications, and secure shell operations.
- Select rights to create role-based access control role definitions and assign those roles to the appropriate users and groups.
- Delegate administrative tasks and control the specific permissions granted to users who are managing the computers in your organization.

For example, you can use Access Manager to delegate specific administrative tasks—such as the ability to add and remove users or assign roles—to a particular user or group. As an administrator, you can also use Access Manager to configure roles that have specific start and expiration dates or that limit the availability of a role to specific days of the week or hours of the day. You can use zones in combination with rights and roles to restrict or grant access to specific Linux and UNIX computers in your organization.

Through the use of zones and roles, Centrify provides granular control over **who** can do **what**, and control over **where** and **when** those users should be granted elevated privileges.

Consolidating User Account Information

Centrify enables you to consolidate all of your user and group account information in a single repository. By consolidating user account information, you can improve IT efficiency and overall operational security. For example, you can automate the provisioning of new accounts and the elimination of accounts that are no longer used without changes to your existing infrastructure or processes.

A single repository also enables you to establish consistent password policies for all of the computers you manage. For example, you can enforce consistent rules for password complexity and minimum length for all users on all computers. A single repository also benefits users, who only have to remember one password, regardless of the computer they use.

By using Centrify zones and override controls, you can migrate your entire user population without modifying any existing account attributes. For example, you can map multiple UNIX profiles with different identity attributes to a single user account, or resolve conflicts if the profiles for different users have the same identity attributes. This flexibility ensures that you can migrate legacy user accounts without changing any existing profile attributes, so that all of the existing directory and file ownership remains unchanged.

Over time, you can then continue to improve organizational security by eliminating legacy identity stores, directories, and databases, including all locally managed /etc/passwd files and local user accounts.

Defining Role-based Access Rights

Role-based access rights are more flexible than UNIX group membership rights and easier to define than user specifications in a sudoers configuration file. Role-based access rights can be narrowly applied or broadly inherited across any number of computers. You can restrict when role-based rights can be used by defining roles that are available only on certain days of the week or only during specific hours of the day. You can also make role assignments temporary by setting a date and time for the assignment to start or expire. For example, you might given the user Jonah elevated privileges to run administrative commands in the Backup Operators role for a period of two weeks while the primary backup administrator is on vacation.

Role-based access rights also prevent password sharing for privileged accounts, helping to ensure accountability. Users who need to run privileged commands can either temporarily elevate their privileges in an unrestricted login shell or be required to run the commands in a tightly controlled restricted shell without being prompted to provide the administrative password. All of their privileged or restricted shell activity can be traced to the account they used to log on.

Improving Accountability: Auditing User Activity

Centrify provides its auditing and analysis features through a combination of auditing components on Windows computers and the auditing features of the Centrify Agent on the computers you manage. The auditing service includes several components to support the multitier architecture of the auditing infrastructure. These components are installed on Windows computers to enable you to collect and store detailed information about user activity.

The central console for configuring the auditing infrastructure and managing audit-related features is Audit Manager. From Audit Manager, you can perform the following common administrative tasks:

- View the status of all audited computers and the other components of the auditing infrastructure.
- Manage the scope and security for auditing-related activity.
- Set permissions for the tasks granted to specific auditors.

There is also a separate Audit Analyzer console for searching and replaying captured activity.

Why auditing User Activity is Important

Just as it is important to protect assets and resources from unauthorized access, it is equally important to track what the users who have permission to access those resources have done. For the users who have privileged access to computers and applications with sensitive information, auditing helps ensure accountability and improve regulatory compliance. With the audit and monitoring service, you can capture detailed information about user activity and all of the events that occurred while a user was logged on to an audited computer.

If you choose to enable auditing on Linux or UNIX computers, the Centrify Agent on that computer starts recording user activity as soon as a user logs on. The agent continues recording until the user logs out or the computer is locked because of inactivity. The user activity captured includes an audit trail of the actions a user has taken and a keystroke record of the text that was entered (stdin) and the results that were displayed (stdout and stderr). The information recorded while a user is logged on—which is called a **session**—is collected as it happens, so you can monitor computers for suspicious activity or troubleshoot problems immediately after they occur.

Reviewing User Activity

When you audit user activity on a computer, the information is transferred to a Microsoft SQL Server database so that it is available for review and follow-up. Because sessions and audit trail events are stored in the database, you can create queries and reports to find information of interest. For example, you can search the stored user sessions to look for policy violations, command-line execution errors, or malicious activity that may have led to a service degradation or an outage.

In addition to saving the input and output recorded, sessions provide a summary of actions taken so that you can scan for potentially interesting or damaging actions without playing back a complete session. After you select a session of interest in Audit Analyzer, the console displays a list of commands in the order in which the user executed them. You can then select any command in the list to start viewing the session beginning with that action. For example, if the user ran a command that reports credit card information, you can scan the list of commands for the command that accesses credit card information and begin reviewing what happened in the session from that time on.

Using Access and Auditing Features Together

You can use access-related features and components without auditing if you aren't interested in collecting and storing information about session activities. You can also deploy auditing-related features and components without access control and privilege management features if you are only interested in auditing user activity on Linux and UNIX computers. However, you can recognize the most value from Server Suite by using all of the services as an integrated solution for managing elevated privileges and ensuring accountability and regulatory compliance across all platforms in your organization.

Enabling Access Control without Auditing on a Managed Computer

If you only enable access control features, the agent enforces the role-based privileges that enable users to log on, access PAM-based application, and run administrative or restricted shell commands. All of the role-based activity is traceable to the user's own account credentials. However, the audit trail of user activity is only recorded in the computer's local system log (syslog) facility. Information that is only stored in a computer's syslog facility can be more difficult to monitor and query than information stored in a central repository such as Microsoft SQL Server database.

Enabling Auditing without Access Control on a Managed Computer

If you only enable auditing, the agent captures detailed information about the command input and output in the login shell of the managed computer. All of the activity is stored in the Microsoft SQL Server database and available to you for queries and reports. However, there's no role-based enforcement of what activity is allowed on the audited computer.

Enabling Access Control and Auditing on a Managed Computer

If you use the infrastructure access management and auditing services together, you can define role-based access rights, restrict when and where roles are available, identify roles that should be audited, trace activity when roles with elevated permissions are selected and used, and play back session activity based on the criteria you choose.

By combining access management and auditing on the same computer, you can have an audit trail and, optionally, a video record of all actions performed with elevated privileges. For example, when you deploy access management, users must be assigned to a role with permission to log on. If they are allowed to log on and auditing is deployed, the agent begins auditing their activity. If a user accesses a PAM-based application or executes a privileged command, the action is recorded and can be traced back to the account used to log on.

The following illustration provides a simplified view of the architecture and flow of data when you deploy components for access control, privilege management, and auditing on a Linux or UNIX computer.

However, auditing requires database storage for the audited sessions audit trail events. Auditing also requires additional management of the network connections used to collect and transfer audit-related information from computers being audited to one or more databases where the sessions and audit trail events are stored. If you plan to use the infrastructure access management and auditing services together, you also need to decide which roles should require auditing and which features to enable on each computer you want to manage. In most cases, you choose whether to enable access control features, auditing features, or both feature sets when you install the agent on a computer.

Although it is not depicted in the illustration, you do not have to enable the auditing service to record audit trail events locally for successful or failed operations. By using the auditing service, however, you can store the audited sessions and audit trail events in a database and report on specific types of activity, such as the execution of privileged commands or access to applications and information that must be kept secure. With auditing enabled, the audit trail and the user activity are available for display, querying, and analysis from any computer where you install Audit Analyzer. Through rights and roles you can restrict access to sensitive information and control who can run commands with elevated privileges or perform administrative tasks. Through queries and reports, you can track all of the activity taking place—by user, computer, the time the activity took place, the role that was used, the command that was executed, or other criteria—to verify that only authorized users are performing authorized tasks and to investigate and correct any unauthorized access anywhere in your organization.

For complete information about setting up and managing an audit installation, see the *Auditing Administrator's Guide*.

Managing Zones and Delegating Administrative Tasks

Zones are the key component for organizing account profiles, identity attributes, role-based access rights, and role assignments. Zones also enable you to establish logical administrative boundaries and delegate specific administrative tasks to the appropriate users and groups for Linux and UNIX computers. This chapter describes the different types of zones and how to use Access Manager to create and manage zones, modify zone properties, and delegate administrative tasks to other users and groups in your organization.

Starting Access Manager for the First Time

The first time you start Access Manager, you can use the Setup Wizard to prepare the Active Directory forest with organizational units and containers for Centrify objects. From the Setup Wizard, you can create either the recommended deployment structure or a custom deployment structure and set all of the appropriate permissions for the objects automatically. If you skip this initial configuration, you can rerun the Setup Wizard at a later time or create organizational units and containers manually. At a minimum, however, you need to select a location in Active Directory for license keys and zones. For more information about the recommended organizational units and permissions, see the *Planning and Deployment Guide*.

What to do Before Updating Active Directory

Before you use Access Manager the first time, you should contact the Active Directory administrator to determine the appropriate location for the deployment structure and whether you have the appropriate rights for completing this task. The specific administrative rights required for this task depend on the policies of your organization and who has permission to create classStore and parent and child container objects in Active Directory.

Rights Required for this Task

If you don't have administrative rights to create container objects in Active Directory, a domain administrator in the forest root domain can run the Setup Wizard or manually create the container objects and set the rights on those objects to allow other users to complete the initial configuration without being members of an administrative group.

The following table describes the minimum rights that must be granted on manually created container objects for other users to successfully complete the configuration with the Setup Wizard.

Licenses container	Read all properties Create classStore objects Modify permissions	This object only
	Write Description property Write displayName property	This object and all child objects
	By default, all Authenticated Users have read and list contents permission for the Licenses container and all of its child objects.	
Zones container	Read all properties Create classStore objects Create Container objects	This object only
	Write displayName property	This object and all child objects

If you are a domain administrator and manually creating the container objects, you should add a security group for Zone Administrators to Active Directory. Set the following permissions on the parent Zones container to allow other users to manage zones.

Zones container	Read all properties Create Container objects Delete Container objects	This object only
	Write displayName property	This object and all child objects

Who Should Perform this Task

A Windows Active Directory administrator performs this task, depending on your organization's policies, by running the Setup Wizard or by manually creating container objects and notifying another user of the location of the container objects. The user who runs the Setup Wizard must be granted the rights required to create classStore objects.

How often you Should Perform this Task

In most organizations, you only do this once for an Active Directory forest. However, if you want to create more than one administrative boundary, you can create additional parent containers as needed.

Steps for Completing this Task

The following instructions illustrate how to run the Setup Wizard from Access Manager.

To update Active Directory using Access Manager:

1. Open Access Manager.
2. Verify the name of the domain controller and the user credentials for connecting to the forest, then click **OK**.
3. At the Welcome page, click **Next**.
4. Select **Use currently connected user credentials** to use your current log on account or select **Specify alternate user credentials** and type a user name and password, then click **Next**.
5. Select **Generate the Centrify recommended deployment structure** if you want to create all of the containers for the recommended deployment structure automatically.

   If you select this option, select whether you want to generate the default deployment structure or generate a custom structure, then click **Next**.

   - If you are generating the default structure, clicking Next enables you to select or create the location for the deployment structure in Active Directory. For example, if you want to create the top of the default deployment structure at the domain level, click **Next**, then click **Browse** to select the domain name. After you have selected a location, click **OK**. then click **Next** to create the deployment structure.
   - If you are generating a custom structure, clicking Next enables you to export the script that creates the default structure or run a script you have previously written.

     If you are generating a default or custom deployment structure, verify the successful execution of the script that creates the structure, then click **Next** to continue.
6. Verify the parent container for licenses is in the top-level Centrify container if you are using the default deployment structure or the container of your choice, then click **Next**.

   You can add other Licenses containers in other locations later using the Manage Licenses dialog box.
7. Review the permission requirements for the container, then click **Yes** to continue.
8. Type or copy and paste the license key you received, then click **Add**.

   If you received multiple license keys, add each key to the list of installed licenses, then click **Next**. If you received license keys in a text file, click **Import** to import the keys directly from the file instead of adding the keys individually, then click **Next**.
9. Verify the **Create default zone container** option is selected and the parent container for zones is in the top-level Centrify container or the container of your choice, then click **Next**.

   If you run the Setup Wizard at any time after the initial creation of the Zones container, this step displays the **Change default zone container** option and the current container location. Select this option and click Browse to change the default container for zones, then click **Next**.
10. If you are using the recommended deployment structure, click **Next** to continue.

    This option allows "self-service" join operations for computers in the Computers container. It is only applicable if you are not using the recommended deployment structure. If you want to support "self-service" join operations and are not using the recommended deployment structure, select **Grant computer accounts in the Computers container permission to update their own account information**, then click **Next**.
11. If you plan to use Access Manager to manage information stored in Active Directory and maintain data integrity, click **Next** to continue.

    You should select **Register administrative notification handler for Microsoft Active Directory Users and Computers snap-in** if you want to automatically maintain the integrity of the information in Centrify profiles.

    This option prevents Centrify profile information from being left "orphaned" when changes are made to Active Directory objects such as users and groups. This option is not selected by default because it requires you to be a member of Enterprise Admins or Domain Admins group for the forest root

domain.

12. Select **Activate Centrify profile property pages** if you want to be able to display Centrify profiles in any Active Directory context, then click **Next**.

    Setting this option ensures that displaying the properties for a user, group, or computer always displays the Centrify Profile tab regardless of how you navigate to the Properties dialog box.

13. Review and confirm your configuration settings, click **Next**, then click **Finish**.

What to Do Next

Create at least one parent zone.

Where you can Find Additional Information

If you want to learn more about the importance and benefits of using zones, see the following topics for additional information:

- How zones help you organize information
- Improving security: access and privilege management
- Improving accountability: auditing user activity

Preparing to Create Zones

As discussed in How zones help you organize information, Centrify zones help you organize computers, users, groups, access rights and other information into logical groups similar to Active Directory organizational units or Network Information Service (NIS) domains. You have several options when choosing the type of zone to create, and the type of zone you select depends entirely on what your organization needs. The first decision to make is the type of zone to create:

- Hierarchical, which is the default and supports inheritance and overrides.
- Classic, which is backward-compatible to support older versions of the Centrify Agent.
- SFU, which supports the Microsoft Services for UNIX schema and rarely used.
- Auto Zone, which is a simplified "zone" for computers to join when you don't need any control over profiles, access rights, or roles and role assignments.

With the exception of SFU zones, you can mix and match any combination of zone types in the same Active Directory forest, as needed. For example, you can create one or more classic zones to support legacy agents, an Auto Zone for a group of computers that don't require the management of identity attributes or access rights, and hierarchical zones for the computers for which you want to actively manage access rights and privileges.

Creating Hierarchical Zones

Hierarchical zones enable you to establish parent-child zone relationships, allowing profile attributes, rights, role definitions, and role assignments to be inherited down the zone hierarchy. In most cases, you define information in a parent zone so that is available in one or more child zones, as needed. At any point in the zone hierarchy, you can choose to use or override information from a parent zone.

You should use hierarchical zones if your organization has any of the following requirements:

- You have existing user and group profiles that must be migrated with legacy identity attributes to maintain existing file ownership.
- You have user and group profiles that have conflicting identity attributes on different computers.
- You have users and groups that require different role-based access rights, privileges, and role assignments on different sets of computers.

If you are using hierarchical zones, you can use the local account management feature as described in Managing account profiles and identity attributes

You can configure multi-factor authentication for login access to Centrify-managed Linux and UNIX computers and for privileged command execution in hierarchical zones, classic zones, and Auto Zone. However, some of the steps differ depending on the type of zone where you want to use multi-factor authentication. For details about configuring multifactor authentication, see "Preparing to use multi-factor authentication" and the *Multi-factor Authentication Quick Start Guide*.

Creating Classic Zones

Classic zones do not support inheritance or overrides and have other limitations in how they support role-based access rights. For example, in classic zones, authorization is disabled by default, and must be consciously enabled on a zone-by-zone basis before any role-based access rights or privileges can be configured or assigned.

You should only create new classic zones if your organization has any of the following requirements:

- You must support older versions of the Centrify Agent for *NIX.
- You have a user population with very few or no identity attribute conflicts.
- You have little or no need to centrally manage access rights and privileges.

If you are using classic zones, you cannot use the local account management feature as described in Managing account profiles and identity attributes

You can configure multi-factor authentication for access to Centrify-managed Linux and UNIX computers and for privileged command execution in classic zones. However, the implementation is slightly different than in hierarchical zones, so some of the steps differ depending on the type of zone where you want to use multi-factor authentication. For details about configuring multifactor authentication, see "Preparing to use multi-factor authentication" and the *Multi-factor Authentication Quick Start Guide*.

Creating an Auto Zone

Most organizations that deploy the Centrify Agent on Linux or UNIX computers have an existing user population to migrate to Active Directory, and hierarchical zones make the most sense. However, multiple zones are not required for all situations. You can greatly reduce the time required and complexity of your deployment if a single zone suits your organization's needs. This type of zone is created automatically when computers join the domain using the --workstation option.

An Auto Zone automatically enables all of the users and groups in an Active Directory forest to become valid users and groups on the Linux and UNIX computers that join the Auto Zone.Their profiles are generated automatically and there's no need to manage account profiles, access rights, privileges, or delegated administrative tasks.

You should only use the Auto Zone option if your organization meets the following requirements:

- You are not migrating an existing user population.
- You want to automatically generate profiles for all or most Active Directory users and groups without managing identity attributes.
- You don't want to configure and manage role-based access rights and privileges or role assignments.

If you are using an Auto Zone, you cannot use the local account management feature as described in Managing account profiles and identity attributes

You can configure multi-factor authentication for both licensed and Express agents to control access to Centrify-managed Linux and UNIX computers. For licensed agents, you can also require multi-factor authentication to run privileged commands in an Auto Zone. However, the implementation is slightly different than in hierarchical zones, so some of the steps differ depending on the type of zone where you want to use multi-factor authentication. For details about configuring multi-factor authentication, see the *Multi-factor Authentication Quick Start Guide*.

Creating a New Parent Zone

In most cases, you design a basic zone structure as part of the deployment process. After the initial deployment, you can create new hierarchical zones any time you have new administrative boundaries. For example, if you acquire another organization, add offices that are managed by a different group, or restructure the organization along different functional lines, you are likely to need new zones.

You can create as many parent zones as you need. You must create at least one new zone before you begin adding Linux and UNIX computers to the Active Directory domain, unless you are joining with the --workstation option.

What to do before creating a new parent zone

Before you can create parent zones, you must have installed Access Manager and run the Setup Wizard. You should also have a basic zone design that describes how you are organizing information, for example, whether you are using one top-level parent zone or more than one parent zone. You should also decide whether to create the new zone in the default Zones container object or in another container or organizational units within Active Directory. There are no other prerequisites for performing this task.

Rights required for this task

Only the user who creates a zone has full control over the zone and can delegate administrative tasks to other users and groups through the Zone Delegation Wizard. To create new zones, your user account must be a domain user with the following permissions:

Parent container for new zones, for example: domain/Acme/Zones	On the **Object** tab, select **Allow** to apply the following permission to this object and all child objects: Create Container Objects Create Organizational Unit Objects **Note** Both permissions are required if you want to allow zones to be created as either container objects or organizational unit objects.
Parent container for Computers in the zone	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create group objects Write Description property

Note: If the Active Directory administrator manually sets the permissions required to create zones, you should verify that the account also has permission to add an authorization store, define rights and roles, and manage role assignments.

Who should perform this task

A Windows domain administrator performs this task, depending on your organization's policies. The user who creates the zone is responsible for delegating administrative tasks to other users or groups, if necessary. In most organizations, this task is done using an account with domain administrator privileges.

How often you should perform this task

After you are fully deployed, you create new zones infrequently to address changes to your organization.

Steps for completing this task

The following instructions illustrate how to create a new parent zone using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To create a new parent zone using Access Manager:

1. Open Access Manager.
2. Select Zones, right-click, then click **Create New Zone**.
3. Type the zone name and, optionally, a longer description of the zone.

   In most cases, you should use the default parent container and container type that you created when you configured the Active Directory forest and use the default zone type, which creates the new parent zone as a hierarchical zone, then click **Next**.

The only reasons for changing the default settings would be if you want to:

- Create a zone in a new location to separate administrative activity for different groups of administrators.
- Create a zone as an organizational unit because you want to assign a Group Policy Object to the zone.
- Create a classic or SFU zone to support legacy Centrify Agents or to store data using the Microsoft Services for UNIX schema.

  For additional information about any field in the new zone wizard, you can press F1 to view the context-sensitive help.

4. Review information about the zone you are creating, then click **Finish**.

What to do next

After you create a new parent zone, you might want to create its child zones.

Where you can find additional information

If you want to learn more about the importance and benefits of using zones, see the following topics for additional information:

- How zones help you organize information
- Preparing to create zones

Creating Child Zones

The primary reason for creating child zones is to inherit profile attributes, role definitions, and role assignments from a parent zone. You can then use the child zone to override the specific profile attributes that might be different on a given set of Linux and UNIX computers than you have defined in the parent zone. Less often, you might want to use a child zone to override specific access rights, role definitions, or roles assignments that you have made in a parent zone. For example, if you have created a role definitions that allows a user to run a specific application with administrative privileges in a parent zone, you can use child zones to limit the scope of that right to specific subsets of computers.

What to do before creating child zones

Before you create child zones, you must have installed Access Manager, run the Setup Wizard to create the Zones container, and created at least one parent zone. You should also have a basic zone design that describes the zone hierarchy for the child zone. There are no other prerequisites for performing this task.

Rights required for this task

Only the user who creates a zone has full control over the zone and can delegate administrative tasks to other users and groups through the Zone Delegation Wizard. To create new child zones, your user account must be a domain user with the following permissions:

Container for the parent zone, for example if the parent zone is berlin: domain/MyOU/Zones/berlin	On the **Object** tab, select **Allow** to apply the following permission to this object and all child objects: Create Container Objects Create Organizational Unit Objects **Note** Both permissions are required if you want to allow zones to be created as either container objects or organizational unit objects.
Parent container for Computers in the zone	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create group objects Write Description property These permissions are only needed if you are supporting “agentless” authentication in the new zone.

Note: If the Active Directory administrator manually sets the permissions required to create zones, you should verify that the account also has permission to add an authorization store, define rights and roles, and manage role assignments.

Who should perform this task

A Windows administrator performs this task, depending on your organization’s policies. The user who creates the zone is responsible for delegating administrative tasks to other users or groups, if necessary. In most organizations, this task is done using an account with domain administrator privileges.

How often you should perform this task

After you are fully deployed, you create new child zones infrequently to address changes to the scope of ownership and administrative tasks.

Steps for completing this task

The following instructions illustrate how to create a new child zone using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer’s Kit*, or in community forums on the Centrify website.

To create a new child zone using Access Manager:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name that will contain the new child zone.
3. Right-click, then click **Create Child Zone**.
4. Type the zone name and, optionally, a longer description of the zone.

   Because this is a child zone, you should use the default parent container and container type, then click **Next**.
5. Review information about the child zone, then click **Finish**.

Opening and Closing Zones

Because properties and objects are organized into zones, you must open a zone to work with its contents. If you open a parent zone, its child zones are also available for you to use by default. If you open a child zone, you can choose whether to open its parent zone.

To open an individual parent or child zone:

1. Open Access Manager.
2. Select Zones, right-click, then click **Open Zone**.
3. Type all or part of the name of the zone you want to open, then click **Find Now**.
4. Select the zone to open from the list of results, then click **OK**. You can use the **CTRL** and **SHIFT** keys to select multiple zones.

Loading all zones

As an alternative to opening individual or parent and child zones manually, you can automatically load all zones in a forest or all zones in a specific container at startup time. If you choose to load all zones, you cannot manually close zones.

To load all zones automatically:

1. Open Access Manager.
2. Select Access Manager, right-click, then click **Options**.
3. On the **Filter Settings** tab, select **Load all zones**, then select **connected forest** to automatically load all zones in the forest or click **Browse** to navigate to specific container.

You should not select the Load all zones option if you want to manually open and close zones for performance reasons.

Closing individual zones

After you open a zone, it stays open during your current sessions unless you close it. If you have a large number of zones, however, you should close any zones you aren't actively working with for better performance.

To close an open zone:

1. Open Access Manager.
2. Expand Zones and select an open parent zone, right-click, then click **Close**.
3. Click **Yes** to confirm that you want to close the zone.

Delegating administrative tasks

If you have created at least one zone, you can give other users and groups permission to perform specific types of administrative tasks within that zone. For example, assume you have created a new zone called Finance and you want to give the users who access computers in this zone the permissions required to perform certain kinds of tasks based on their role. You can accomplish this goal by selecting a group or users, then assigning that group or user one or more tasks. For example, in the Finance zone, you might want to delegate administrative tasks like this:

- The members of the Active Directory group FinanceITStaff are allowed to perform all administrative tasks in the Finance zone.
- The members of the Active Directory group FinanceManagers are allowed to add, modify, and remove user and group profiles in the Finance zone.
- The members of the Active Directory group FinanceUsers are allowed to join computers to the Finance zone, but perform no other tasks.
- The Active Directory users jason.ellison and noah.stone are granted permission to manage role assignments in the Finance zone.

In most cases, each zone should have at least one Active Directory group that can be delegated to perform all administrative tasks, so that members of that group can manage their own zone. You are not required to create or use a zone administrator group for every zone. However, assigning the management of each zone to a specific user or group creates a natural separation of duties for administrative tasks.

If you delegate control for individual tasks—for example, by assigning only the join computers task to one group and only the add and remove users tasks to

another—you should ensure the members of each group know the tasks they are assigned.

You can delegate administrative tasks for parent zones, for child zones, and for individual computers. Because computer-level overrides are essentially single computer zones, you can assign administrative tasks to users and groups at the computer level.

What to do before delegating administrative tasks

Before you delegate administrative tasks for a zone, you must have created at least one zone. For each zone you create, you should also identify at least one user or group that can be delegated to perform all administrative tasks. For example, if you have a Finance zone, you might want to create a Finance Admins group in Active Directory, then delegate **All** tasks to that group so that members of that group can manage their own zone.

There are no other prerequisites for performing this task.

Rights required for this task

Only the user who creates a zone has full control over the zone and can delegate administrative tasks to other users and groups.

For information about the permissions set when you select different administrative tasks in the Zone Delegation Wizard, see the *Planning and Deployment Guide*.

Who should perform this task

The domain administrator who creates the zone is responsible for delegating administrative tasks to other users or groups, if necessary. Only the account used to create a zone has full control over the zone's properties and permission to delegate administrative tasks to other users. The user who creates a zone is also the only user who can add NIS maps to the zone. The right to create NIS maps is exclusive to the creator of a zone because it requires permission to create containers in Active Directory. The zone creator can, however, grant other users permission to add, remove, or modify NIS map entries.

How often you should perform this task

In most organizations, you delegate administrative tasks any time you create a new zone. You also might change the delegation to change the either tasks assigned or the users and groups that have been assigned specific tasks periodically to address changes to your organization. For example, if an existing zone administrator takes over new responsibilities or leaves the organization, you might need to delegate additional tasks or select a different user or group to perform administrative tasks.

Steps for completing this task

The following instructions illustrate how to delegate zone administration tasks to a user, group, or computer using Access Manager. Examples of scripts that use the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To delegate administrative tasks to specific users and groups in a zone:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones required to select the zone name for which you want to delegate administrative tasks.
3. Right-click, then click **Delegate Zone Control**.
4. Click **Add** to find the users, groups, or computer accounts to which you want to delegate specific tasks.
5. Select the type of account—**User**, **Group**, or **Computer**—to search for, type all or part of the account name, then click **Find Now**.
6. Select one or more accounts from the list of results, then click **OK**.
7. When you are finished adding users and groups to which you want to assign administrative tasks, click **Next**.
8. Select the tasks you want to delegate to the user or group, then click **Next**.

   For example, if you want all of the members of the group you selected in the previous step to be able perform all administrative tasks for a zone, check the **All** task. To restrict the administrative tasks a user or group can perform, select only those specific tasks.

   restrict the administrative tasks

9. If you are delegating the task of joining computers to a zone, you can specify the scope of computers you can join to the zone; you pick a container in Active Directory to grant access to.

   If you leave the scope blank, the scope is the domain root. Be aware that the postalAddress field is used for information about joining computers to a zone; if you lookup the permissions for people you've delegated the task of joining computers to a zone, they'll have permissions to the postalAddress field for the affected computers.

10. Review your selections, then click **Finish**.

If you have delegate administrative tasks to one or more groups that have members logged on, you should notify the group members to log out and log back on before they attempt to perform the administrative tasks assigned to the group.

Changing Zone Properties

After you create a zone, you can change its zone properties at any time. For example, if you want to change the parent zone for a child zone, you can do so by modifying the child zone's properties. Depending on whether you are viewing a classic, hierarchical, or SFU zone and the components you have installed, you might see and be able to set different zone properties.

To display the properties for a zone:

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties**.

   If the zone you have selected is a hierarchical zone, the properties are organized on the following tabs.

General	View and set general information about the selected zone, including the location of the zone in Active Directory, the zone type, and the zone description. For additional details about general properties, see the following topics:
	Changing the zone description
	Changing the parent zone or location of a zone
	Setting the master domain controller for a zone
	Selecting a license container for a zone
	Adding support for agentless clients
	Setting custom permissions for a zone
Platform	View and set the identity platform instance to use for the selected zone. For additional details about setting identity platform properties, see the following topic: Selecting a identity platform instance for a zone
User Defaults	Set default values for user profile attributes in the selected zone. For additional details about user default properties, see the following topic: Setting user defaults
Group Defaults	Set default values for group profile attributes in the selected zone. For additional details about group default properties, see the following topic: Setting group defaults
Variables	Add or edit user-defined variables or override the default values of predefined variables in the selected zone. For additional details about zone variables, see the following topic: Configuring variables for a zone
Provisioning	Configure automated provisioning for user and group profiles if you have the Zone Provisioning Agent installed on the local computer. For additional details about provisioning properties, see the following topic: Configuring automated provisioning The Provisioning tab is only displayed if the Zone Provisioning Agent is installed. For detailed information about configuring automated provisioning, see the *Planning and Deployment Guide*.

Changing the zone description

You can set or change the optional description for a zone at any time. For example, if you didn't specify a description when you created the zone or if there have been changes in your organization that warrant a change in the description of a zone, you can modify the Description field to make the change.

To change the zone description

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties** to display the General tab.
4. Type a description for the zone in the Description field, then click **OK**.

Changing the parent zone or location of a zone

From Access Manager, you can make any existing hierarchical zone the child of another zone or make any child zone a new parent zone by dragging and dropping the zone into a new location or by changing the Parent zone field on the zone's General properties tab.

Selecting the default location when moving a zone

If you make changes to the zone hierarchy, Access Manager prompts you to specify the new Active Directory location for the zone. In most cases, you should accept the default location for the zone you are moving. The default Active Directory location will be either:

- The **new parent zone** container if you are moving a child zone from one parent to another or if you moving a parent zone to become a child zone.
- The default **Zones** container you created the first time you started Access Manager if you are making a child zone a new top-level parent zone.

You are not required to accept the default Active Directory location when changing the zone hierarchy. If you select a different Active Directory location for the zone, however, you should note the location and whether the zone you are moving is now a parent or a child zone. If the zone structure displayed in Access Manager is different from the zone container structure you are using in Active Directory, you might find unexpected problems with inheritance and overrides, with modifying zone properties, or with deleting zones.

Moving a zone without changing its Active Directory location

When you are prompted to specify the Active Directory location for a zone you are moving, you have the option to select **No** and leave the current Active Directory location unchanged. If you change the parent zone without changing the Active Directory location for a zone, you should note that the location does not reflect the zone hierarchy. In rare cases, you might find it useful to leave the Active Directory location unchanged but doing so might make it more difficult to locate the zone object at a later time.

Restarting the agent after moving a zone

If you change the location for a zone in Active Directory, you must restart the Centrify Agent for *NIX on the computers in that zone so that they recognize the new zone location.

After you move the ZoneName object to a new parent container or organizational unit, run the following command to restart the Centrify Agent for *NIX on the computers in the zone:

/usr/share/centrifydc/bin/centrifydc restart

To move a zone to a new parent by changing properties

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties** to display the General tab.
4. For the Parent zone field, click **Browse** to find and select the zone to use as the parent, then click **OK**.
5. Click **OK** to save the new zone properties.
6. In the Move Zone dialog, verify the location selected for the **Yes, move to** option to accept the default location, then click **OK**.

   In rare cases, you might want to click **Browse** to select a different Active Directory location for the zone you are moving, or select **No**, then click **OK** to keep the zone in its original location.

Setting the master domain controller for a zone

In most cases, computers connect to the first available Active Directory domain controller and it is not necessary to specify the master domain controller to use for a zone. In some cases, however, you might want to identify a specific domain controller to use for a zone to prevent connections from other domain controllers from adding or removing users and groups in that zone.

To prevent connections from other domain controllers, you can set the Master domain controller field to the fully-qualified name of the domain controller you want to use. After you identify a master domain controller, administrators who connect to the zone using any other domain controller will not be able to make changes to the zone.

If you have multiple administrators managing any zones, you should notify them before setting or changing the master domain controller. You should also make this change while all other administrators are logged off. Depending how long it takes for replication to complete for all of the domain controllers in the Active Directory forest, you might want to schedule this change for a time when no administrators need access to zone information.

To change the master domain controller

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to change the master domain controller.

   You can use Shift-Click or Ctrl-Click to select multiple zone names.
3. Right-click, then click **Change Master Domain Controller**.
4. Type the fully-qualified domain name for the new domain controller, then click **OK**.
5. Click **Yes** to confirm that you want to change the master domain controller for the zone.

You should avoid changing from one master domain controller to another, if possible. Changing the master domain controller requires you to wait for replication to complete to see up-to-date zone information or modify information in the selected zone. In some cases, however, changing the master domain controller might be unavoidable. For example, if there are zones connecting to a master domain controller that has a hardware failure or must be taken offline for maintenance, you will need to configure a new master domain controller for the zones to use.

If you change the master domain controller, you should run the Analyze command afterwards to check the Active Directory forest and verify that no duplicate UIDs or GIDs have been introduced.

Selecting a license container for a zone

By default, zones are configured to use any available license container in the forest. In most cases, the container used is the default **Licenses** container you created the first time you started Access Manager. If you have more than one Licenses container, you might want to select a specific license container for a set of computers in the one zone and a different license container for a set of computers in another zone. For example, you might want to select separate Licenses containers for the zones associated with two different business units.

To use a specific license container for a zone, you can type the path to a new container object in the License container field.

To use a specific license container for a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties** to display the General tab.
4. Select a specific license container from the list of available License container, then click **OK**.

For more information about licenses keys and using multiple license containers, see the *License Management Administrator's Guide*.

Adding support for agentless clients

If you are using the Centrify Network Information Service (adnisd) on a managed computer to respond to NIS client requests from computers where the Centrify Agent cannot be installed, you can configure one or more zones to act as the NIS domain for those client requests.

To add support for agentless NIS clients in a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties** to display the General tab.
4. Select the **Support agentless client** option.
5. Select the Active Directory attribute you want to use to store the password hash and verify the zone name is the NIS domain name you want to use or type a new name, then click **OK**.

For more information about installing and using the Centrify Network Information Service (adnisd) to respond to NIS client requests and configuring agentless clients, see the Network Information Service Administrator's Guide.

Setting custom permissions for a zone

For convenience, you can access Permissions for a zone directly from the zone properties General tab. You can then allow or deny basic permissions—such as Read and Write permissions—to specific users and groups or click **Advanced** to set more granular permissions on a zone.

Selecting a identity platform instance for a zone

In most cases, the identity platform instance property is set automatically when you register a connector for Privileged Access Service. If you have access to more than one identity platform instance—for example, if you have more than one customer identifier, you can select the URL for a specific instance from the zone properties.

To select a identity platform instance for a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties**.
4. Click the **Platform** tab.
5. Verify the identity platform instance URL is the customer-specific URL you want to use, or click **Browse** to select the URL for a different customer-specific identity platform instance.

   Child zones inherit the identity platform instance property from their parent zone. If you are viewing properties for a child zone, you can select **Override trusted identity platform instance** then click **Browse** to select a different identity platform instance for the child zone.

   For details about installing and configuring a connector, see "Preparing to use multi-factor authentication."
6. Click **OK** to confirm the identity platform instance selected.

Configuring default values for a zone

You can configure default settings for user and group profiles that are added to the zone. The user and group defaults you configure can include predefined variables that populate the user or group profile by using Active Directory attributes or settings configured on individual managed computers.

By specifying user default and group default settings, you can simplify the process of adding user and group profiles to child zones. For example, you can define a default user profile that uses the sAMAccountName attribute for a user's UNIX login name. All users who are added to the zone are then automatically assigned a UNIX login name based on their sAMAccountName. If you define the default attributes in a parent zone, they can also be inherited in all of the child zones under that parent and only overridden where other values are explicitly required.

Setting user defaults

When you create a zone, it includes a default set of user profile attributes. In most cases, there's no need to modify any of the default settings unless you want to define partial profiles in a parent zone that will be manually completed in child zones. For example, the default setting for the numeric user identifier (UID) is an automatically generated UID based on the user's globally unique security identifier (SID). This setting ensures all users who are added to the zone are assigned a unique UID for the entire forest.

If you define a default value for any user profile attribute, that value is used to populate the user profile displayed when you add users to the selected zone. When you add a user to the zone, you can accept the default profile attributes or override any of the default attributes displayed.

To view or modify the default user profile in a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties**.
4. Click the **User Defaults** tab.
5. Review the default settings and modify any of the defaults, if needed.

   For most organizations, the default settings are appropriate. For example, the Active Directory sAMAccountName attribute most closely resembles the most common format for the UNIX login name and an automatically generated UID ensures that all new users have a unique UID in the forest. For more information about the attribute fields or the default values, press F1 to view the context-sensitive help.
6. Click **OK**.

For more information about using default values, see Creating user profiles for Active Directory users. For more information about using predefined or custom variables in user profiles, see Setting runtime variables in user profiles.

Setting group defaults

When you create a zone, it includes a default set of group profile attributes. In most cases, there's no need to modify the default settings for groups unless you are manually assigning numeric group identifiers (GID) or using the Apple algorithm for generating the GID.

If you define a default value for a group attribute, that value is used to populate the group profile displayed when you add groups to the selected zone. When you add a group to the zone, you can accept the default profile attributes or override any of the default attributes displayed.

To view or modify the default group profile in a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties**.
4. Click the **Group Defaults** tab.
5. Review the default settings and modify any of the defaults, if needed.

   For most organizations, the default settings are appropriate. For example, the Active Directory sAMAccountName attribute most closely resembles the most common format for the group name and an automatically generated GID ensures that all new group have a unique GID in the forest. For more information about the attribute fields or the default values, press F1 to view the context-sensitive help.
6. Click **OK**.

For more information about using default values, see Creating group profiles for Active Directory groups. For more information about using predefined or custom variables in user profiles, see Setting runtime variables in user profiles.

Configuring variables for a zone

Predefined and custom variables enable you to generate user profiles and group profiles using Active Directory properties or properties defined on managed computers.

You can add custom runtime variables, or override the definition for predefined variables, in a zone by modifying the zone properties. Runtime variables are resolved by the agent when a computer joins a zone. The default user profile settings use predefined runtime variables in place of specific values for the GECOS, Home directory, and Shell attributes.

Zone variables and their definitions are inherited down the zone hierarchy, and can be overridden in a child zone or on individual computers. You can also use configuration parameters to control the value for any variables locally on particular computers. If a value is set in the configuration file, it overrides any values

that you set for the zone.

Adding custom runtime variable

In most cases, you don't need to add custom variables to a zone. However, if you have modified the Active Directory schema or want to use custom attributes in user or group profiles, you can add custom variables to the zone to accommodate your changes.

To add a custom variable to a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties**.
4. Click the **Variables** tab.
5. Click **Add**.
6. Type a variable name and a value, then click **OK**.

   For example, you might want to define a custom variable named gecos and set its value to a static string, such as Engineering-Nova Scotia-Q22, for a zone.

   Similarly, you might want to add custom variables for different operating systems you support, such as mac-home or aix-shell for a zone that includes computers with different operating systems. For example, if a zone includes Linux, AIX, and Mac OS X computers, you might have a default profile that uses the predefined variables, but a subset of accounts that use the mac-home or aix-shell custom variables.
7. Click **OK** to save the properties.

Modifying predefined variable values

In most cases, you don't need to override predefined variable values for a zone. However, if you have created different zones for different operating systems, you might find it useful to modify predefined variable values for those zones to address different operating system requirements.

To modify a predefined variable value in a zone

1. Open Access Manager.
2. Expand Zones and the individual parent or child zones, as required, to locate and select the zone name for which you want to display properties.
3. Right-click, then click **Properties**.
4. Click the **Variables** tab.
5. Click **Add**.
6. Type the name of a predefined variable and a value, then click **OK**.

   For example, you might want to change the predefined variable named home and set its value to an appropriate home directory for the zone, such as /export/home for a zone where all of the computers are Solaris computers, or /Users for a zone with only Mac OS X computers. Similarly, you might want to change the predefined variable shell to set its value to /usr/bin/ksh for a zone with IBM AIX computers.
7. Click **OK** to save the properties.

Editing or removing variables

After you have added custom variables or modified predefined variable values in a zone, you can later select those variables to edit or remove them.

Configuring automated provisioning

The Centrify Zone Provisioning Agent is a separate service that enables automated provisioning and de-provisioning of user and group accounts on a zone-by-zone basis. You can configure the Zone Provisioning Agent to monitor specific Active Directory groups for a zone. If you add or remove Active Directory users or groups in the monitored groups, the Zone Provisioning Agent automatically adds or removes the corresponding user or group profiles in the zone. If

you have the Centrify Zone Provisioning Agent installed, you can use the zone properties Provisioning tab to do the following:

- Enable provisioning for users, groups, or both.
- Specify the Active Directory group to base provisioning on.
- Select the method for automatically generating profile attributes for users, groups, or both.

For more detailed information about automated provisioning and using the Zone Provisioning Agent, see the *Planning and Deployment Guide*. For more information about the attribute fields or the options for generating profile attributes, press F1 to view the contextsensitive help.

Renaming a Zone

You can rename a zone at any time. For example, if your organization changes how business units are aligned, moves to a new location, or merges with another organization, you might want to update zone names and descriptions to reflect these changes. You might also want to rename zones if your initial deployment did not use a naming convention for new zones, and you want to implement one after you have agents deployed.

What to do before renaming a zone

Before you rename zones, you might want to define and document a naming convention to use for future zones or the reasons for changing the zone name. You should also identify the computers in the zone to be renamed. You must restart the agent on those computers for the new zone name to be recognized. There are no other prerequisites for performing this task.

Rights required for this task

To rename a zone, your user account must be set with the following permissions:

Parent container for an individual zone For example, a ZoneName container object, such as: domain/Zones/arcade	Write Description Write name Write Name These are the minimum permissions required to rename a zone and not allow a user or group to modify any other zone properties. You can set permissions manually, or automatically grant these and other permissions to specific users or groups by selecting the **Change zone properties** task in the Zone Delegation Wizard.

Who should perform this task

A Windows administrator performs this task, depending on your organization's policies. The user who creates the zone is responsible for delegating administrative tasks to other users or groups, if necessary. In most organizations, this task is done using an account with domain administrator privileges.

How often you should perform this task

After you are deployed, you rename zones only when you need to address organizational changes or to implement or improve the naming conventions you use.

Steps for completing this task

The following instructions illustrate how to rename a zone using Access Manager.

To rename a zone using Access Manager:

1. Open Access Manager.
2. Expand **Zones** to display the list of zones, then expand any child zones in the zone hierarchy until you see the specific zone you want to modify.
3. Select the zone to change, right-click, then click **Rename**.
4. Type the new name and, if needed, any changes to the zone description.
5. Restart all of the Centrify UNIX agents on the computers in the zone you have renamed.

   You do not have to leave and rejoin after changing a zone name. However, you must restart the agent for the name change to take effect on a managed computer.centrifydc In a terminal window on each managed computer, run the following command:

   /usr/share/centrifydc/bin/centrifydc restart
6. You can verify the updated zone name on a local computer by using the adinfo command, which includes the joined zone name in its output.

Adding Computers to a Zone

You can only join a domain by creating a computer account that is either a "zone computer" profile or a "workstation" account that uses Auto Zone. Depending on the tool and operating system you prefer to use, there are several ways you can add a computer account to a zone. For example, if you prefer to create the "zone computer" account from a Linux or UNIX computer:

- You can run the adjoin command interactively or in a script and specify the zone as a command line option while joining the Active Directory domain.
- You can use ADEdit commands interactively or in a script to add a computer account to a zone before joining the domain.

If you prefer to create the "zone computer" account from a Windows computer:

- You can prepare a computer account in Access Manager before joining the domain.
- You can use the Centrify Access Module for PowerShell cmdlets interactively or in a script to add a computer account to a zone.

Precreating computer accounts using ADEdit or the Centrify Access Module for PowerShell cmdlets is particularly useful if you want to join multiple computers with minimal command line options and if you want to allow the computer account to be used to perform a "self-service" join. For more information about preparing a computer account before joining a domain, see Preparing computer accounts before joining.

For more information about specifying the zone, joining the domain, and modifying computer properties, see Working with managed computers. For information about using Auto Zone, see Using workstation mode and Auto Zone.

Managing Licenses

The first time you start Access Manager, you are prompted to create a Licenses container and add or import license keys. You can also add and remove license containers and keys after the initial configuration.

To modify license information

1. Open Access Manager
2. Select Access Manager, right-click, then select **Manage Licenses**.
3. Click Add to add a new license container or license key.
4. Select an existing license container or license key, then click **Remove** to remove that container or key.

For details about licensing, including how to request new license keys after deployment, check license usage and compliance, and how license counts are determined, see the *License Management Administrator's Guide*.

Reporting Zone Information

You can access legacy reports from within Access Manager by selecting Access Manager, right-clicking, then selecting **Report Center**. You can also use command-line programs, PowerShell scripts, or ADEdit scripts to report zone information. In most cases, however, you should install and configure Report Services to generate and access reports about the Active Directory domain and your zones.

For details about installing and configuring Report Services, and how to customize and access the reports that generated, see the *Report Administrator's Guide*.

Migrating from Classic to Hierarchical Zones

Classic zones are primarily intended for backward compatibility with older versions of the Centrify Agent. If you upgrade the agent to version 5.x or later, you can migrate any or all of your classic zone information into one or more hierarchical zones.

Migrating a classic zone to a hierarchical zone is a multi-step process that requires some initial planning. For example, the first step in the migration changes the zone type but does not change any existing zone information, including the computer accounts that are joined to the zone. To take full advantage of the hierarchical zone after migration, however, it is likely that you will need to modify some of your existing zone information and move computer accounts into different zones.

Preparing for migration

To prepare for the migration of any classic zones, you should first review the existing zone information for "dominant" user and group profiles—that is, profiles with attributes that are common to multiple classic zones. Dominant profiles will help you to identify one or more classic zones that you can use as potential parent zones. A parent zone provides a baseline for the user and group profiles that can be inherited in child zones. The parent zone also enables you to manage rights and role definitions that can be inherited in the child zones you create. If you are able to identify dominant profiles, most of your classic zones will become child zones that inherit information from the parent zone, with specific attribute overrides on a zone-by-zone or computer-by-computer basis, as necessary.

To illustrate how you should analyze your existing environment, assume you have several classic zones to address different profile requirements on different computers, but only two administrative groups that have different policies and procedures for adding users or granting privileges. In this scenario, you might create two parent zones—one for each administrative team—and use child zones or computer overrides to address specific profile attribute differences. If your organization has a single account fulfillment desk that handles all provisioning and access privileges, you might create a single parent zone for managing all or most user and group profiles, then use child zones to manage more granular account privileges.

If you have a "master" classic zone where the most commonly-used profile attributes for most of your users and groups are defined, that zone is a likely candidate to become a hierarchical parent zone. If none of your existing classic zones is suitable to become a parent zone, you should create a new parent zone as described in Creating a new parent zone. The parent zone must exist before you can use the migration utility.

Verifying you have upgraded Access Manager

You can use Access Manager to view and manage any combination of zones. However, the console must be version5.x or later to work with hierarchical zones. You can check the version of the console you have installed by opening Access Manager, clicking Help, then selecting About Access Manager.

Verifying you have upgraded UNIX agents

The migration utility is a command-line program installed with the Centrify Agent for *NIX. You must upgrade the agent to version 5.1, or later, on at least one UNIX computer to do any migration. You can verify the agent version by running the adinfo command with the --version (-v) option.

What the migration utility does

After you have identified at least one classic zone as potential parent zones, you can use the migration utility to convert the classic zone into a hierarchical parent zone. After you make the classic zone a hierarchical zone, you can run the migration utility to make other classic zones into child zones of the parent zone.

During the migration, all of the user and group profiles in the source zone are copied to the specified parent zone. If identical profiles exist in multiple classic zones, the identical profiles become a single profile in the parent zone. If there are user or group profiles in multiple zones with different attribute values—for example, a UID of 10001 in one classic zone, but 10003 in another classic zone, the migration utility creates a single profile for the user in the parent zone, and creates a profile override with the distinct attribute values in each target child zone. Each child zone inherits the base profile from the parent zone but applies the overrides for any attributes that are different in different zones.

The migration utility copies everything else—including rights, roles, role assignments, groups, and NIS maps—into the new child zone for each classic zone being migrated.

Using the migration utility

Centrify provides the command-line program admigrate to simplify the process of migrating profiles, rights, roles, role assignments, and NIS maps from a classic zone to a hierarchical zone.

The admigrate program is installed by default in the following directory:

/usr/share/centrifydc/adedit/admigrate

Note that the first zone you migrate becomes the primary source of profile information for the other zones you migrate. You should start with the zone that it contains the most consistent profile attributes.

Note: Admigrate does not migrate classic SFU zones (Ref: CS-28289a) nor zone delegation rights (Ref: IN-90002).

To migrate zone information from a classic to hierarchical zone:

1. Log on to a Linux or UNIX computer running adclient and open a terminal window.
2. Open a text editor to create a file with bind information for each domain to which admigrate must connect.

   Specify the Active Directory credentials for an account with permission to create child zones, rights, roles, user profiles, and group profiles in the parent zone with one line per domain in the format:

   bind domain_account_password

   For example, create a file named migrate.conf with information similar to the following:

   bind finance.acme.com administrator {1234abcepassword}
   bind eng.acme.com engadmin {1234abcepassword}
3. Save and close the file.
4. Run the admigrate command.

   admigrate -in classicZone -z targetZone -hz parentZone -config configFile

classicZone	The distinguished name of the classic zone to migrate. For example: “cn=finance,cn=zones,ou=unix,dc=acme,dc=com”
targetZone	The distinguished name of the new zone. It can be the same as the existing classic zone name, however the new zone will be a child zone of the specified parent zone, so the distinguished name is different. For example: “cn=finance,cn=global,cn=zones,ou=unix,dc=acme,dc=com”
parentZone	The parent zone for the migration. The specified zone must be an existing zone. The target zone becomes a child zone of this zone. You can run admigrate multiple times and specify the same parent zone and different source and target zones each time to migrate multiple zones to different child zones of this parent. For example: “cn=global,cn=zones,ou=unix,dc=acme,dc=com”
configFile	The configuration file to use with the migration. The configuration file is primarily useful to specify bind information if you are migrating zones from domains that are different from the target zone's domain. The file is a simple text file, for example: -config admigrate.txt

For more information about other options you can use when running admigrate, see the man page for admigrate.

The first time you run admigrate, the command copies all of the user profiles from the source zone to the parent zone. Everything else defined in the source zone—including groups, rights, role definitions, role assignments, and NIS maps—is copied from the source zone to a new target child zone.

1. Repeat Step 4 for each classic zone you want to migrate as a child of the parent zone.

Sample migration

To illustrate how to use the admigrate command, assume you are migrating two classic zones—finance and engineering—into a new empty parent zone named global. For this example, the distinguished name of the classic finance zone (the source zone) is this:

“cn=finance,cn=zones,ou=unix,dc=test,dc=org”

After migration, the distinguished name of the finance child zone (the target zone) is this:

“cn=finance,cn=global,cn=zones,ou=unix,dc=test,dc=org”

To migrate the classic finance zone, you would run a command similar to the following:

```
/usr/share/centrifydc/adedit/admigrate \
-in "cn=finance,cn=zones,ou=unix,dc=test,dc=org" \
-z "cn=finance,cn=global,cn=zones,ou=unix,dc=test,dc=org" \
-hz "cn=global,cn=zones,ou=unix,dc=test,dc=org" \
-config ~/migrate.conf \
-v > migrate_finance.txt
```

In this example, the target zone name is the same as that of the input classic zone, except its distinguished name is different because it is a child zone of the *global* zone. The -config parameter specifies the file that contains bind information, in this cases ~/migrate.conf. The -v option directs verbose output to a text file.

You would then run admigrate for the next zone to migrate. For example:

```
/usr/share/centrifydc/adedit/admigrate \
-in "cn=engineering,cn=zones,ou=unix,dc=test,dc=org" \
-z "cn=engineering,cn=global,cn=zones,ou=unix,dc=test,dc=org" \
-hz "cn=global,cn=zones,ou=unix,dc=test,dc=org" \
-config ~/admigrate.txt \
-f -v > migrate_eng.txt
```

To simplify the migration process for multiple zones, you could put admigrate in a shell script and specify the source zone as an input variable or read it from a file with a listing of all your zones.

Inheritance and overrides

Each time you run admigrate with the same parent zone and a different source and target zone, the admigrate utility does the following:

- If a user profile from the source zone does not exist in the parent zone, the utility creates a profile for the user in the parent zone.
- If a user profile exists in the parent zone and matches the user profile from the source zone, the new child zone will inherit the user profile attributes as they are defined in the parent zone.
- If a user profile already exists in the parent zone and has attribute values that differ from those for the user from the source zone, the utility creates a user profile in the child zone with overrides for the differing attribute values. For example, if a user profile exists for oscar.romero in the parent zone, but has a different numeric identifier (UID) in the engineering zone, the UID attribute value would be different in the engineering child zones. The other attributes would be inherited from the parent zone.
- Copies the groups, rights, role definitions, role assignments, and NIS maps from the source zone to the target child zone.

The admigrate utility does not copy delegated permissions from the existing classic zones to the new child zones. In addition, delegated permissions are *not* automatically inherited from parent zones to the child zones. After migrating classic zones, you must explicitly delegate administrative permissions on a zone-by-zone basis.

Roles and rights for migrated users

The admigrate utility adds the following role definitions for migrated users:

- **login_at_roles** assigns the UNIX system rights **Password login...** and **Nonpassword login**. It does not assign **Login with non-Restricted Shell** because the user may be assigned to a restricted shell.
- **login_all_apps** assigns the login-all PAM right, which grants access to all PAM applications. It does not assign any UNIX system rights.

By default, all users are added to the **login_all_apps** role so that if they are granted login rights, they have access to all PAM applications, which is the default for users in classic zones. If PAM access rights are restricted by another role assignment, the restricted role assignment will override the rights granted by login_all_apps.

Access uses the following role-assignment rules when migrating roles and rights from a classic zone to a hierarchical zone:

User assigned to role	Enabled	Assign to the following roles: **login_at_roles**, which grants **Password login and Nonpassword login** UNIX system rights. **login_all_apps**, which grants access to all PAM applications. Corresponding user-created roles, which are migrated.
User assigned to role	Disabled	Assign to corresponding user-created roles, which are migrated. No login roles are assigned because the user is disabled in the classic zone.
User not assigned to role	Enabled	Assign to the default **UNIX Login** role, which grants all UNIX system login rights and access to all PAM applications.
User not assigned to role	Disabled	Assign to the default **listed** role, which makes the user visible in the zone but does not assign any UNIX system rights or PAM access rights.

In classic zones, users who are added to a zone are enabled for login access by default. As an administrator, you can leave a user profile defined in a zone but disable login access.

All the roles and rights you defined in the source zone, as well as any role assignments to user-created roles, are added, as-is, to the child zone each time you run admigrate. For example, if you defined a privileged mount command in 20 classic zones, admigrate will copy that mount command to 20 new hierarchical zones. Therefore, after migration you should analyze your role definitions and access right definitions to see if some of them can be moved up to the parent zone to take advantage of inheritance.

Assigning the audit level when migrating

In hierarchical zones, role definition can be assigned an auditing level. This setting is not applicable in classic zones.During migration from classic zones to hierarchical zone, the default "Audit if possible" auditing level, is assigned to all migrated role definitions. After you have migrated, you can change the auditing level in any role definition. For more information about changing the auditing level for a role definition, see Changing the audit level for role definitions.

Moving joined computers to hierarchical zones

After you have migrated data from classic zones to new hierarchical zones, you can move the computers to the new zones using the adchzone command-line program.

When you use adchzone to change the zone for a computer, the command copies the UNIX profile from the old zone to the new zone, deletes computer profile from the old zone, then stops and restarts adclient to flush the cache and update the zone information. The advantage of this approach over leaving the old zone (adleave) and then joining (adjoin) the new zone is that it is very quick and preserves all the join information without you having to specify join options.

For example, run a command similar to the following to move a computer joined to the classic finance zone to the new child finance zone:

```
/usr/share/centrifydc/adedit/adchzone \
-z "cn=finance,cn=global,cn=zones,ou=unix,dc=acme,dc=com"
-u finance-adm
```

You will be prompted to supply a password for the specified user.

After changing the zone, you can open Access Manager to see the computer in the Computers node of the new zone, or you can run adinfo on the computer to verify the new zone information.

What to do after the migration

The admigrate utility migrates most zone information automatically. After using the utility, however, you might want to perform the following tasks to complete the migration:

- Delete unnecessary copies of right and role definitions.

  You should analyze the right and role definitions to see how many of them have been copied into multiple zones. Rights and roles that are defined in the parent zone are available for use in all child zones. By moving role and right definitions to the parent zone you simplify your zone structure making it easier to understand the rights and roles that are available for your organization.

- Review provisioning rules.

  In many cases, hierarchical zones simplify automated provisioning by enabling you to define a baseline profile in a parent zone and only override specific attributes when necessary. If you are using automated provisioning, you should check whether you are defining the provisioning rules in parent zones or in child zones.

- Delegate permissions on a zone-by-zone basis.

  Use the Zone Delegation Wizard to delegate administrative tasks and the assign the corresponding permissions to the appropriate users and groups in your new child zones.

Managing Account Profiles and Identity Attributes

This chapter describes how to create user and group profiles that grant access to Centrify managed Linux and UNIX computers and how to manage identity attributes using Access Manager. No matter what type of zone your environment uses—classic, hierarchical, or auto zone—you can use Access Manager to create and maintain profiles for Active Directory users and groups.

If your environment uses hierarchical zones, you can also use Access Manager to create and maintain profiles for local Linux and UNIX users and groups.

For Active Directory users and groups, you can also perform the tasks described here using ADEdit or Windows PowerShell commands and scripts or other tools, such as Active Directory Users and Computers.

For local users and groups, you can also perform the tasks described here using adedit and other command line utilities. See Using Centrify commands for administrative tasks for details about using commands to configure local users and groups.

For additional information about planning the migration of an existing user population, see the *Planning and Deployment Guide.*

Creating Group Profiles

You can create group profiles for Active Directory groups and—in hierarchical zone environments—local groups. A group profile consists of two attributes and a list of group members. The attributes that must be defined for the group profile to be complete are the following:

- A unique numeric identifier (GID).
- A group name.

A group must have a complete profile with all of these attributes defined to be recognized as a valid group in a zone or on a specific computer. These are the same attributes you define locally for Linux and UNIX groups in the /etc/group file.

For details about creating profiles for Active Directory groups, see Creating group profiles for Active Directory groups. For details about creating profiles for local Linux and UNIX groups, see Creating, modifying, and deleting group profiles for local groups.

Creating group profiles for Active Directory groups

You can create a group profile for any domain local, global, or universal security groups you have defined in the Active Directory forest. Associating a group profile with an Active Directory group also enables you to take advantage of any nested group membership you have defined and any group policies you have applied to a domain or organizational unit.

Although associating a group profile with an Active Directory group can be convenient, there is no predetermined requirement to create group profiles for Active Directory groups. Creating a group profile does not create profiles for any members of the group. User accounts must be explicitly given their own profiles.

Note: You can automate the provisioning of account profiles through the use of Active Directory groups. For information about configuring your environment for automated provisioning, see the *Planning and Deployment Guide*.

What to do before creating a new Active Directory group profile

Before you can create Active Directory group profiles, you must have created one or more Active Directory security groups, installed Access Manager, and run the Setup Wizard. You should also identify the specific Active Directory groups for which a group profile is required. In most organizations, only a limited number of Active Directory groups require a zone profile. There are no other prerequisites for performing this task.

Rights required for this task

You must have permission to add groups to a zone. Zone administrators can grant this permission through the Zone Delegation Wizard. If the Active Directory administrator manually sets the permissions, your user account must be a domain user with the following permissions to create group profiles in a zone:

Parent container object for the group profile within the zone	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint objects Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectClass
Group account object in Active Directory For example: domain/Users/group_name	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read groupType Read objectCategory Read objectClass Read objectGUID Read objectSid
Parent container object for the individual zone For example, if you are adding a group to the Finance zone: domain/UNIX/Zones/Finance	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectGUID Write Description

Who should perform this task

A Windows domain administrator performs this task, depending on your organization's policies. In most organizations, this task is delegated to a specific user or group with administrative authority in the selected zone.

How often you should perform this task

In most cases, you only create new group profiles infrequently to address changes to your organization.

Steps for completing this task

If you choose to create group profiles for Active Directory groups, you can use Access Manager, Active Directory Users and Computers, the Access Module for Windows PowerShell, ADEdit, or the Centrify Windows API.

The following instructions illustrate how to create a new group profile using Access Manager. Examples of scripts that use ADEdit, Windows PowerShell, or the Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To create a group profile for an Active Directory group using Access Manager:

1. Open Access Manager.
2. Expand Zones and any parent or child zones required to select the zone name to which you want to add the Active Directory group.
3. Expand UNIX Data and select Groups, right-click, then click **Create UNIX Group**.
4. Type a search string to locate the Active Directory group for which you want to create a profile, then click **Find Now**.

   For example, type "fin" to display the Finance Users and Finance Admins groups.
5. Select one or more groups in the results, then click **OK**.
6. Review the default zone profile settings for the group and make changes if needed, then click **OK**.

   You can deselect an attribute to change the default value or to create a partial group profile in the current zone. You can complete the profile by providing a value for an attribute in a child zone of the current zone. For example, if you use the same group name but different numeric identifiers on two set of computers, you can inherit the group name from a parent zone and set the different numeric identifiers in the child zones.

   In the **AIX Extended Attributes** tab, you can view and set AIX attributes for the group's zone profile. Click **Add** to add an attribute and a value, click **Edit** to change an attribute, or click **Remove** to remove an attribute from the group's zone profile.

   If you selected more than one group, review the profile settings for the each group and modify the default settings, if necessary, then click **OK**.

   If you are adding groups with similar names, you might want to modify the default group name to distinguish the groups. For example, if you are adding both the Finance Admins and Finance Users groups to the same zone, you can change the default group name to finadmin and finuser to make it easier to tell the groups apart. Keep in mind that in some operating environments group names cannot be more than 8 characters and special characters might not be supported.

Creating, modifying, and deleting group profiles for local groups

When you create a local group profile in Access Manager, it is saved in /etc/group on each computer in each zone where the profile is defined. You can create local profiles at the zone level (for example, under **Zones** › *Zonename* › **UNIX Data**) and at the computer level (for example, under **Zones** › *Zonename* › **Computers** › *Computername* › **UNIX Data**). Local group profiles that you create at the zone level are available for local and Active Directory users in the zone and child zones to join.

What to do before creating a new local group profile

You should perform the following tasks before creating local group profiles:

- Ensure that local account management is enabled and configured through configuration parameters or group policies. See Enabling and configuring local account management for more information.
- It is suggested that you review the existing group names in etc/group on the computers where the local group profile will be implemented so that you do not attempt to create a group profile with a name that is already used. Access Manager performs a name validation check against etc/group in the current zone when you create a new local group. If the group name already exists in etc/group somewhere in the current zone, you are prompted to provide a different name for the group that you are creating.

Rights required for this task

The rights required to create local group profiles are the same as the rights required to create Active Directory group profiles. See Rights required for this

task for details about those rights.

Using partial profiles and child zones to fine tune group attributes

Access Manager allows you to create a partial profile by leaving any of the attributes blank. Partial profiles can be useful for defining a common set of attributes that are used in multiple zones, then defining specific attributes that vary from one child zone to another or that require different settings on specific computers. For example, you could define the Members attribute in a parent zone, and then override the parent zone attribute settings by defining the Members attribute differently in different child zones.

If you intend to leave an attribute blank, deselect the attribute check box. However, you must provide a value for at least one attribute to create the group profile.

Groups can have an incomplete profile in a parent zone as long as any missing attributes are defined in a child zone. If a group profile is still partial at the computer level, the profile is ignored by the agent, and it is not added to /etc/group on the local computer. Group profiles must contain the attributes listed in Creating group profiles to be complete.

Specifying profile states

The *profile state* lets you control whether a local group account is in place in etc/group and is enabled for use locally. When you create a local group account, you specify the initial profile state. You can change the profile state afterwards to control availability of the local group account. A local group account can have one of the following states:

- **Enable**: If the local group profile is complete, it will be installed or updated in /etc/group at the next local account refresh interval.
- **Remove from /etc/group**: The group profile will be removed from etc/group at the next local account refresh interval.

You can also choose not to define the profile state by deselecting the **State** check box in the Set Local Group Profile dialog. Deselecting the **State** check box results in one of the following scenarios:

- If a local group profile with the same name exists in the parent zone, the state from the parent group profile is inherited.
- If the parent zone does not contain a group profile with the same name, or if a parent group profile exists but does not define the state, the group profile that you are currently defining is considered incomplete.

Roles and local group account visibility

You use role assignments to control whether local users are visible in a zone. A predefined role definition, local listed, is available for use with local user and local group profiles. As with the listed predefined role, the local listed role does not grant any system rights, PAM rights, or command rights. It is a specialized role that can be used when a local user or local group profile must exist for computers in a zone, but no local user or local group access should be granted.

You can optionally define other roles in the zone to grant visibility to local users and local groups.

By default, all local groups having a complete profile are visible in a zone. You do not have to assign a role to a local group to make the local group visible. However, it is often useful to assign a role (such as local listed) to a local group so that all local users in the local group inherit the role assignment, and are visible in the zone.

See Creating, modifying, and deleting user profiles for local users for more information about how roles are used to control visibility of local user accounts.

How often Access Manager and local group accounts are synchronized

The /etc/group file on local computers is updated periodically based on the information that you define for local group profiles in Access Manager. The /etc/group update interval is controlled by the following group policy and configuration parameter:

- **Group Policy: Set refresh interval for access control cache**, located in Computer Configuration > Centrify Settings > DirectControl Settings > Network and Cache Settings.
- **Configuration parameter:** adclient.refresh.interval.dz, located in the /etc/centrifydc/centrifydc.conf configuration file.

The same group policy and parameter control how often the authorization store cache is updated. Local account information is updated immediately after authorization store information is refreshed in the authorization cache.

For more information, see the *Group Policy Guide*, the *Configuration and Tuning Reference Guide*, and Enabling and configuring local account management.

Steps for completing this task

To create a group profile for a local group using Access Manager

1. Open Access Manager.
2. Expand Zones and any parent zones, child zones, or computers required to select the zone or computer to which you want to add the local group.
3. Expand UNIX Data and select Local Groups.

   You can create a new local group in these ways:

   - **By dragging and dropping an existing local group from another location.** Expand zones or computers to the location of the original local group, and drag it to the location of the new local group. The local group is moved to the new location. To copy (instead of move) the original group, press <Ctrl> while you drag the group.
   - **By cutting or copying an existing local group from another location, and then pasting it into the current location.** Expand zones or computers to the zone where the original local group exists, right-click a local group and select **Cut** or **Copy**, return to the zone where you are creating the new local group, right-click, and select **Paste**.
   - **By creating an entirely new local group.** Perform Step 4 through Step 8 of this procedure.
4. In Local Groups, right-click, then click **Create UNIX Group**.
5. Type a name for the new local group and click **OK**.
6. In the Set UNIX Group Profile dialog, select or deselect check boxes to specify which attributes to set. You must specify at least one attribute to be able to save the profile.

   - **GID:** Type a numeric group ID of your choice.
   - **Members:** Click **Add** to launch the Add Members dialog. In a comma-separated list, type the UNIX names of the users who will be in the group.

     Access Manager does not check the validity of the user names that you provide. You should ensure that all of the names that you provide are UNIX names that currently exist.

     Note that the group profile is considered complete even if this attribute has an empty value.
   - **State:** Specify whether the group account is added to, and enabled in, etc/group. Possible values are:

     Enable: The group profile will be installed or updated in /etc/group at the next local account refresh interval.

     Remove from /etc/group: The group profile will be removed from etc/group at the next local account refresh interval.

     Note: To modify permissions for a local group, you must first
     create and save the local group as described in this procedure, and then
     modify permissions as described in Step 4 in the section(To modify group
     profile attributes and permissions for a local group](https://docs.centrify.com/Content/auth-admin-unix/ProfilesGroupLocal.htm#modify_permissions_local_group).

     For the profile to be complete, it must contain settings for group name (specified in Step 5 of the procedure To create a group profile for a local group using Access Manager), GID, and state. You can save the profile now even if it is partial, although it will not be implemented in /etc/group until you update it in the current zone, or with settings in child zones, so that it is complete, and you set the state to **Enable**. For example, if you use the same group name but different numeric identifiers on two set of computers, you can inherit the group name from a parent zone and set the different numeric identifiers in the child zones.

     In the **AIX Extended Attributes** tab, you can view and set AIX attributes for the local group's zone profile. Click **Add** to add an attribute and a value, click **Edit** to change an attribute, or click **Remove** to remove an attribute from the group's zone profile.
7. Review your local group profile settings and click **OK**.

   If the profile is complete, it is added to /etc/group at the next local account refresh interval.
8. To optionally assign the local listed role to the local group, so that all local users in the local group are visible in the zone:

   1. At the level where you created the local group, right-click **Role Assignments**, and then select **Assign Role**.

2. In the Select Role dialog, select **local listed** and click **OK**.
3. In the Assign Role dialog, ensure that **Accounts below** is selected, and click **Add Local Account**.
4. In the **Add Local Account** dialog, select **Local UNIX Group** in the **Type** field, type the local group name in the **Account** field, and click **OK**.
5. In the Assign Role dialog **Accounts below** area, highlight the local group account and click **OK**. The local group is now listed as an assignee of the local listed role.

To modify group profile attributes and permissions for a local group:

1. In Access Manager, expand UNIX Data for the zone or computer containing the local group that you want to modify.
2. In the Local Groups details pane, right-click the local group to modify and select **Zone Profile**.

   The Properties dialog for the profile is displayed.
3. Modify attribute selections and settings as described in Step 6 in the procedure To create a group profile for a local group using Access Manager. Keep in mind the following considerations when you change attributes.

   If there is no parent profile for the same local group name:

   - You can edit profile fields to customize the value.
   - You can deselect profile fields to define a partial profile.

     If a parent profile for the same local group name already exists in a parent zone:
   - You can edit profile fields to customize the value.
   - You can deselect profile fields to inherit attribute values from the parent profile.
4. To optionally modify group permissions (such as read, write, create or delete child object, and so on), click **Permissions**. Refer to the "Active Directory permissions required for administrative tasks" chapter in the *Planning and Deployment Guide* for details about using the Permissions dialog to modify zone-level user and group permissions.
5. Review your changes to the local group profile and click **OK**.

   Your changes are applied to the local group profile in /etc/group at the next local account refresh interval.

To delete a group profile for a local group from a zone or computer:

Note: This procedure does not remove a local group profile from /etc/group. To remove a local group profile from /etc/group, perform the procedure described in [To remove a group profile for a local group from /etc/group](https://docs.centrify.com/Content/auth-admin-unix/ProfilesGroupLocal.htm#remove_group_profile).

1. In Access Manager, expand UNIX Data for the zone or computer containing the local group that you want to delete.
2. In the Local Groups details pane, right-click the local group to modify and select **Delete**.
3. At the warning prompt, select **Yes**.

   The local group is deleted from Access Manager. The group profile still exists in /etc/group, but it is ignored.

To remove a group profile for a local group from /etc/group

1. In Access Manager, expand UNIX Data for the zone or computer containing the local group that you want to remove from /etc/group.
2. Perform one of the following procedures:

   - Right-click a local group, select **Change Profile State**, then select **Remove from /etc/group**.
   - Right-click a local group, select **Zone Profile**, change the value of the **State** field to **Remove from /etc/group**, and click **OK.**

     At the next local account refresh interval, the local group's profile is removed from /etc/group.

Delegating control of local group management tasks

You can use the Zone Delegation Wizard and Computer Delegation Wizard as described in the *Planning and Deployment Guide* to delegate control of local group management tasks.

Delinea

Migrating Local Group Profiles to Active Directory

In most cases, you get more operational benefits by using Active Directory groups to manage UNIX and Linux user accounts than you would get from migrating your local group profiles into Active Directory. For example, by using Active Directory groups to manage both Windows and UNIX users, you can use your existing provisioning and access control policies across multiple platforms and automate the provisioning and de-provisioning of accounts and access rules.

In some cases, however, you might find it useful to migrate some or all of your existing local groups to Active Directory. If you want to move local group profiles into Active Directory, you have the option to import local groups on a zone-by-zone basis. As part of the import process, you can choose to how each local group should be handled. For example, you can:

- Create a new Active Directory group for each imported group.
- Extend an existing Active Directory group to include an imported group.
- Merge an imported group into an existing UNIX group profile.

Making Group Membership a Requirement

On most Linux and UNIX computers, users can only be members of a limited number of groups at once. Because of this limitation, it is useful to be able to change a user's effective group membership to add and remove groups when necessary. You can use the adsetgroups command to dynamically manage the set of Active Directory groups that are available to a user account. You also have the option to specify that membership in a specific group is required in a zone. If you specify that a group is required, users who are members of the group cannot remove the required group profile from their currently active set of groups.

To make membership in a specific group profile required:

1. Open Access Manager.
2. Expand Zones and any parent or child zones required to select the zone name for which you want to add a required group.
3. Expand Groups, then select the group name you want to make required.
4. Right-click, then select **Zone Profile** to display the Centrify UNIX Profile for the group.
5. Select the **Users are required to be members of this group** option.
6. Click **Permissions** to set specific permissions for this group, if needed, then click **OK**.

For more information about using the adsetgroups command, see the adsetgroups man page.

Creating User Profiles

You can create user profiles for Active Directory users and—in hierarchical zone environments—local users. A user profile consists of the attributes required by the name service switch (NSS) facility on Linux and UNIX computers. User attributes that must be defined for the user profile to be complete are the following:

- A user name (the UNIX login name).
- A unique numeric user identifier (UID).
- The user's primary group profile numeric identifier (GID).
- The default home directory for the user.
- The default login shell for the user.
- General information about the user account (GECOS). (This attribute is required for Active Directory user profiles, but not for local user profiles.)

A user must have a complete profile with all of these attributes defined to be recognized as a valid user in a zone or on a specific computer. You can optionally define other attributes that are not required for the user profile to be complete.

These are the same attributes you define locally for Linux and UNIX users in the /etc/passwd file.

For details about creating profiles for Active Directory users, see Creating user profiles for Active Directory users. For details about creating profiles for local Linux and UNIX groups, see Creating, modifying, and deleting user profiles for local users.

Creating user profiles for Active Directory users

You can create a user profile for any domain user you have defined in the Active Directory forest by adding the user to a zone, or by adding the user to a specific computer in a zone. Associating a user profile with an Active Directory user determines how the Active Directory user is identified on Linux and UNIX computers.

Note: You can automate the provisioning of user profiles through the use of Active Directory groups. For information about configuring your environment for automated provisioning, see the *Planning and Deployment Guide*.

What to do before creating a new Active Directory user profile

Before you can create Active Directory user profiles, you must have created one or more Active Directory users, installed Access Manager, and run the Setup Wizard. You should also identify the computers where Active Directory users might require different profile attributes. For example, you might have some Active Directory users that require the default home directory attribute to be set the to /home for access to most computers, but require the attribute to be set to /Users when they log on to Mac OS X computers.

In most organizations, Active Directory users have one “dominant” profile with consistent attributes across multiple computers, but require “override” settings to some profile attributes on specific computers or groups of computers. Therefore, most user profiles are only added to parent zones and inherited in child zones.

Rights required for this task

You must have permission to add users to a zone. Zone administrators can grant this permission through the Zone Delegation Wizard. If the Active Directory administrator manually sets the permissions, your user account must be a domain user with the following permissions to create user profiles in a zone:

Parent container object for the user profile	On the **Object** tab, select **Allow** to apply the following permission to this object only: Create serviceConnectionPoint Objects This permission is required for both standard zones and RFC 2307compliant zones. For standard zones, you need to apply additional permissions. Click the **Properties** tab and select **serviceConnectionPoint objects** from the object list, then select **Allow** to apply the following properties to this object: Read Name Read name Read displayName
User account object in Active Directory For example: domain/Users/user_name	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectCategory Read objectClass Read objectGUID Read objectSid Read userAccountControl

Parent container object for the individual zone For example, if you are adding a user to the Finance zone: domain/UNIX/Zones/Finance	Click the **Properties** tab and select **Allow** to apply the following properties to this object only: Read objectGUID Write Description

Who should perform this task

A Windows domain administrator performs this task, depending on your organization's policies. In most organizations, this task is delegated to a specific user or group with administrative authority in the selected zone.

How often you should perform this task

In most cases, you create and remove user profiles frequently to address changes to your user population.

Steps for completing this task

The following instructions illustrate one way to create a new user profile using Access Manager. You can also add a user profile and assign a role to an Active Directory user with the Add User wizard. Examples of scripts that use ADEdit, Windows PowerShell, or the Windows API are available in other guides, the *Centrify Software Developer's Kit*, or in community forums on the Centrify website.

To create a user profile for an Active Directory user using Access Manager:

1. Open Access Manager.
2. Expand Zones and any parent or child zones required to select the zone name to which you want to add the Active Directory group.

   In most cases, you should add user profiles to a parent zone.
3. Expand UNIX Data and select **Users**, right-click, then click **Add User to Zone**.
4. Type a search string to locate the user account, then click **Find Now**.

   For example, type "qa" to display the qa-lab, qa-hk and qaVenice1x users.
5. Select one or more users in the results, then click **OK**.
6. Review the default zone profile settings for the user and make any changes if needed, then click **OK**.

   You can deselect an attribute to change the default value or to create a partial user profile in the current zone. You can then complete the profile by providing a value for an attribute in a child zone of the current zone. For example, if you use the same login name but different numeric identifiers on two set of computers, you can inherit the login name from a parent zone and set the different numeric identifiers in the child zones.

   In the **AIX Extended Attributes** tab, you can view and set AIX attributes for the user's zone profile. Click **Add** to add an attribute and a value, click **Edit** to change an attribute, or click **Remove** to remove an attribute from the user's zone profile.

   If you selected more than one user, review the profile settings for the each user and modify the default settings, if necessary, then click **OK**.

Changing the default profile attributes

When you add Active Directory users to a zone, Access Manager displays a default new user profile. You can accept or change the default values for any of the profile attributes, as needed. The default attribute values are automatically generated based on a few simple rules and, in most cases, you can accept them as-is. The following table describes how the default values are populated.

Login name	The Active Directory user logon name associated with the Active Directory account.

UID	A unique number automatically generated by an algorithm based on the security identifier (SID) for the Active Directory user.
Primary group	A unique numeric identifier that represents a private primary group and is the same as the user's default UID. Private groups are not stored or managed in Active Directory.
GECOS	A runtime variable that resolves to the Active Directory displayName attribute associated with the Active Directory account.
Home directory	A runtime variable that specifies the default home directory when resolved locally on a computer.
Shell	A runtime variable that specifies the default login shell when resolved locally on a computer. To set the user's shell to the default shell defined for this computer in this zone.

Defining partial UNIX profiles

Access Manager allows you to create a partial profile by leaving any of the attributes blank. Partial profiles can be useful for defining a common set of attributes that are used in multiple zones, then defining specific attributes that vary from one child zone to another or that require different settings on specific computers. For example, you could leave the Shell attribute blank in a parent zone, define it as /bin/bash in a child zone, but override it with /usr/bin/ksh in a grandchild zone that only contains AIX computers. You could also leave the Home directory attribute blank in a parent zone, then set it to /home in one child zone and to /Users on an individual Mac OS X computer that joins the child zone.

If you intend to leave an attribute blank, deselect the attribute check box. However, you must provide a value for at least one attribute to add the user profile. Users must have a complete profile in a zone for any role assignments to be effective. Keep in mind, however, that users can have an incomplete profile in a parent zone as long as any missing attributes are defined in a child zone to allow role assignments in the child zone.

Defining valid login names

User profile login names can consist of letters, numbers, hyphens, underscores, periods and dashes. Some operating environments may have additional restrictions. For example, some operating environments do not support user names that are longer than 8 characters or require that the first character of the user name be alphabetic. Because UNIX user names typically use only lowercase characters, the default user profile name displayed follows this convention. If you modify the default profile name and include uppercase characters, keep in mind that the proper case must be used when entering the user name. For compatibility with Samba, the dollar sign ($) can also be used at the end of the user name. In general, other special characters, such as ! and &, are not supported.

If the Windows logon name includes unsupported special characters, Access Manager replaces them with underscores for the UNIX login name. For example, Access Manager converts a Windows logon name with special characters, such as qa:user2 into a valid UNIX login name of qa_user2.

Identifying a primary group

In most UNIX environments, a user's primary group identifier (GID) is a “private” group that exists solely for that user. The user is not included as a “member” of the private primary group. You can follow this convention by using a UNIX-only “private” group that is not linked to an Active Directory group, which is the default when you create a new user profile.

If you keep the default private primary group, the primary group identifier (GID) setting in the user profile does not affect the user's actual Active Directory group membership in any way, and there's no need to manage primary groups for UNIX users through Active Directory.

In some cases, however, you might want to assign an Active Directory group that has a corresponding group profile as a user's primary group. If you specify an Active Directory group as a user's primary group, keep in mind that you must manage the membership of that group using Active Directory Users and Computers and that if you identify a group with a large number of members—such as Domain Users—it is likely to affect performance.

For more information about defining primary groups for users, see the *Planning and Deployment Guide*.

Creating, modifying, and deleting user profiles for local users

When you create a local user profile in Access Manager, it is saved in /etc/passwd on each computer in each zone where the profile is defined. You can create local profiles at the zone level (for example, under **Zones** › *Zonename* › **UNIX Data**) and at the computer level (for example, under **Zones** › *Zonename* ›

Computers > *Computername* > **UNIX Data**).

After you create local user profiles, you perform a separate set of tasks to create and manage local user passwords. For detailed information about local user passwords, see Creating and managing local user passwords.

What to do before creating a new local user profile

You should perform the following tasks before creating local user profiles:

- Ensure that local account management is enabled and configured through configuration parameters or group policies. See Enabling and configuring local account management for more information.
- It is suggested that you review the existing user names in etc/passwd on the computers where the local user profile will be implemented so that you do not attempt to create a user profile with a name that is already used. Access Manager performs a name validation check against etc/passwd in the current zone when you create a new local user. If the user name already exists in etc/passwd somewhere in the current zone, you are prompted to provide a different name for the user that you are creating.

Rights required for this task

The rights required to create local user profiles are the same as the rights required to create Active Directory user profiles. See Rights required for this task for details about those rights.

Using partial profiles and child zones to fine tune user attributes

Access Manager allows you to create a partial profile by leaving some user attributes blank. Partial profiles can be useful for defining a common set of attributes that are used in multiple zones, then defining specific attributes that vary from one child zone to another or that require different settings on specific computers. For example, you could leave the Shell attribute blank in a parent zone, define it as /bin/bash in a child zone, but override it with /usr/bin/ksh in a grandchild zone that only contains AIX computers.

If you intend to leave an attribute blank, deselect the attribute check box. However, you must provide a value for at least one attribute to create the user profile.

Users can have an incomplete profile in a parent zone as long as any missing attributes are defined in a child zone. If a user profile is still partial at the computer level, the profile is ignored by the agent, and it is not added to /etc/passwd on the local computer. User profiles must contain the attributes listed in Creating user profiles to be complete.

Specifying profile states

The *profile state* lets you control whether a local user account is in place in etc/passwd and is enabled for use locally. When you create a local user account, you specify the initial profile state. You can change the profile state afterwards to control availability of the local user account. A local user account can have one of the following states:

- **Enable**: If the user profile is complete, it will be installed or updated in /etc/passwd at the next local account refresh interval. The user can log into the local computer, and is visible in Access Manager if a role with the visible right (such as local listed) is granted to the user. See Roles and local user account visibility for more information about how roles affect local user visibility.
- **Disable**: If the user profile is complete, it will be installed or updated in /etc/passwd at the next local account refresh interval. However, the user will not be able to log into the local computer. This state results in what is typically called a "locked account." UNIX and Linux service accounts and system accounts are typically set up as locked accounts.
- **Remove from /etc/passwd**: The user profile will be removed from etc/passwd at the next local account refresh interval.

You can also choose not to define the profile state by deselecting the **State** check box in the Set Local User Profile dialog. Deselecting the **State** check box results in one of the following scenarios:

- If a local user profile with the same name exists in the parent zone, the state from the parent user profile is inherited.
- If the parent zone does not contain a user profile with the same name, or if a parent user profile exists but does not define the state, the user profile that you are currently defining is considered incomplete.

Roles and local user account visibility

You use role assignments to control whether local users are visible in a zone. A predefined role definition, local listed, is available for use with local user and local group profiles. As with the listed predefined role, the local listed role does not grant any system rights, PAM rights, or command rights. It is a specialized role that can be used when a local user profile must exist for computers in a zone, but no local user access should be granted.

You can optionally define other roles in the zone to grant visibility to local users.

As with role assignments for Active Directory users, local user role assignments can be made at the zone level, computer level, or computer role level. Use the following guidelines to establish where local users are visible in Access Manager:

- To make a local user visible to all computers in a zone, assign the local listed role to the local user account (or to all local UNIX accounts) in the zone (for example, assign local listed to users located in **Zones** › *Zonename* › **UNIX Data** › **Local Users**).
- To make a local user visible only to a specific computer, assign the local listed role to the local user account (or to all local UNIX accounts) located in the computer zone (for example, assign local listed to users located in **Zones** › *Zonename* › **Computers** › *Computername* › **UNIX Data** › **Local Users**).
- To make a local user visible only to a group of computers, create a computer role and assign the local listed role to the local user account (or to all local UNIX accounts) in the computer role.

How often Access Manager and local user accounts are synchronized

The /etc/passwd file on local computers is updated periodically based on the information that you define for local user profiles in Access Manager. The /etc/passwd update interval is controlled by the following group policy and configuration parameter:

- **Group Policy: Set refresh interval for access control cache**, located in Computer Configuration › Centrify Settings › DirectControl Settings › Network and Cache Settings.
- **Configuration parameter:** adclient.refresh.interval.dz, located in the /etc/centrifydc/centrifydc.conf configuration file.

These are the same group policy and parameter that control how often the authorization store cache is updated. Local account information is updated immediately after authorization store information is refreshed in the authorization cache.

For more information, see Enabling and configuring local account management of this guide. For additional group policy and configuration parameter information, see the *Group Policy Guide*, and the *Configuration and Tuning Reference Guide*.

Steps for completing this task

To create a user profile for a local user using Access Manager, Method 1

Note: This method begins from the Local Users node, and allows you to assign just one role, local listed, to the local user. To use the Add User to Zone wizard, which lets you assign other roles to the local user, see [To create a user profile for a local user using Access Manager, Method 2](https://docs.centrify.com/Content/auth-admin-unix/ProfilesCreatingLocal.htm#user_profile_method_2).

1. Open Access Manager.
2. Expand Zones and any parent zones, child zones, or computers required to select the zone or computer to which you want to add the local user.
3. Expand UNIX Data and select Local Users.

   You can create a new local user in these ways:

   - **By dragging and dropping an existing local user from another location.** Expand zones or computers to the location of the original local user, and drag it to the location of the new local user. The local user is moved to the new location, and no longer exists in the original location. To copy the original user to the new location and also retain it in the original location, press <Ctrl> while you drag the user.
   - **By cutting or copying an existing local user from another location, and then pasting it into the current location.** Expand zones or computers to the zone where the original local user exists, right-click a local user and select **Cut** or **Copy**, return to the zone where you are creating the new local user, right-click, and select **Paste**.
   - **By creating an entirely new local user.** Perform Step 4 through Step 8 of this procedure.
4. In Local Users, right-click, then click **Add User to Zone**.

5. Type a name for the new local user and click **OK**.
6. In the Set UNIX User Profile dialog, select or deselect check boxes to specify which attributes to set. You must specify at least one attribute to be able to save the profile.

   If a parent profile for the same local user name already exists in a parent zone, some attribute fields will be filled in already with inherited values. You can edit profile fields to customize inherited values, and you can deselect other profile fields to inherit attribute values from the parent profile.

   - **UID:** Type a numeric user ID of your choice.
   - **Primary group:** From the drop-down list, select an existing group, or select **<Not defined>** to leave the PGID attribute undefined, or select **<...>** to see additional group choices or to create a new local group.

     To create a new local group after clicking **<...>**, click **Add** in the Select a Group dialog, and follow the procedure for creating a new local group starting with Step 5 in the section To create a group profile for a local group using Access Manager.
   - **GECOS:** Optionally type general information of your choice about the local user account. This attribute is not required for the profile to be complete.
   - **Home directory**: Type the default local computer home directory for the local user.
   - **Shell**: Select the default shell for the local user. Choices are /bin/bash, /bin/csh, /bin/ksh, /bin/sh, /bin/tcsh, %.
   - **State:** Specify whether the local user account is added and enabled in /etc/passwd. Choices are as follows.
     - **Enable**: If the user profile is complete, it will be installed or updated in /etc/passwd at the next local account refresh interval. The user will be able to log into the local computer, and the user is visible in Access Manager.
     - **Disable**: If the user profile is complete, it will be installed or updated in /etc/passwd at the next local account refresh interval. However, the password field in /etc/passwd will be set to !!, and the user will not be able to log into the local computer. This state results in what is typically called a "locked account." The user is still visible in the zone as long as the local listed role is assigned to the user.
     - **Remove from /etc/passwd**: The user profile will be removed from etc/passwd at the next local account refresh interval.

     For the profile to be complete, it must contain the attributes listed in Creating user profiles. You can save the profile even if it is partial, although it will not be implemented in /etc/passwd until you update it in the current zone, or with settings in child zones, so that it is complete, and you set the state to enabled. For example, if you use the same user name but different numeric identifiers on two set of computers, you can inherit the user name from a parent zone and set the different numeric identifiers in the child zones.

     In the **AIX Extended Attributes** tab, you can view and set AIX attributes for the local user's zone profile. Click **Add** to add an attribute and a value, click **Edit** to change an attribute, or click **Remove** to remove an attribute from the user's zone profile.

     Note: To modify permissions for a local user, you must first create and save the local user as described in this procedure, and then modify permissions as described in [To modify user profile attributes and permissions for a local user](https://docs.centrify.com/Content/auth-admin-unix/ProfilesCreatingLocal.htm#modify_profile_attributes).
7. By default, new local users are assigned the local listed role so that local users are visible in Access Manager. This assignment is specified in the **Assign local listed role to make this user visible** check box. To keep this default assignment, ensure that the check box remains selected.

   To give the local user a different role assignment, deselect the check box. If you deselect the check box, you will need to manually assign a role with visible rights to the local user after completing this procedure.
8. Review your attribute selections and settings, and click **OK**. If the user profile is complete, it is added to /etc/passwd at the next local account refresh interval.

To create a user profile for a local user using Access Manager, Method 2

Note: This method describes how to create a local user profile using the Add User to Zone wizard, which lets you assign roles other than just local listed to the local user.

1. Open Access Manager.
2. Expand Zones and any parent zones, child zones, or computers required to select the zone to which you want to add the local user.
3. Right-click the zone, and select **Add User**.

The Add User to Zone wizard launches.

4. In the Select User Type dialog, select **Local UNIX user**, and click **Next**.
5. In the Specify Local UNIX User dialog, type a name for the local user, and click **Next**.
6. In the Add User to Zone dialog, select the **Define user UNIX profile** and **Assign roles** check boxes. Click **Next**.
7. Fill in the local users profile attribute settings in the Define User UNIX Profile dialog as described in Step 6 in the section To create a user profile for a local user using Access Manager, Method 1, and click **Next**.
8. In the Assign Roles dialog, the local listed role is included by default. To optionally add different roles as choices, click **Add** and select one or more roles to add to the list.
9. In The Assign Roles dialog, select one or more roles, and click **Next**.
10. In the Confirm Your Selections dialog, review your choices and click **Next**.
11. In the final wizard screen, click **Finish**.
12. Confirm that the new local user was created by expanding UNIX Data in the zone and clicking **Local Users**. The new local user should be listed in the user details pane.

To modify user profile attributes and permissions for a local user:

1. In Access Manager, expand UNIX Data for the zone or computer containing the local user that you want to modify.
2. In the Local User details pane, right-click the local user to modify and select **Zone Profile**.

   The Properties dialog for the profile is displayed.
3. Modify attribute selections and settings as described in Step 6 in the section To create a user profile for a local user using Access Manager, Method 1. Keep in mind the following considerations when you change attributes.

   If there is no parent profile for the same local user name:

   - You can edit profile fields to customize the value.
   - You can deselect profile fields to define a partial profile.

     If a parent profile for the same local user name already exists in a parent zone:
   - You can edit profile fields to customize the value.
   - You can deselect profile fields to inherit attribute values from the parent profile.
4. To optionally modify user permissions (such as read, write, create or delete child object, and so on), click **Permissions**. Refer to the "Active Directory permissions required for administrative tasks" chapter in the *Planning and Deployment Guide* for details about using the Permissions dialog to modify zone-level user and group permissions.
5. Review your changes to the local user profile and click **OK**.

   Your changes are applied to the local user profile in /etc/passwd at the next local account refresh interval.

To disable a user profile for a local user:

Note: This procedure does not remove a local user profile from /etc/passwd. To remove a local user profile from /etc/passwd, perform the procedure described in To remove a user profile for a local user from /etc/passwd.

1. In Access Manager, expand UNIX Data for the zone or computer containing the local user that you want to disable.
2. In the Local Users details pane, right-click the local user and select **Change Profile State**.
3. Select **Disable**.

The local user remains visible in Access Manager. At the next local account refresh interval, the local user's profile in /etc/passwd is modified so that the password field contains !!, and the user cannot log into the local computer.

To delete a local user from a zone

Note: This procedure does not remove a local user profile from /etc/passwd. To remove a local user profile from /etc/passwd, perform the procedure described in "To remove a user profile for a local user from /etc/passwd before you delete the local user from the zone.

1. In Access Manager, expand UNIX Data for the zone or computer containing the local user that you want to delete from the zone.
2. In the Local Users details pane, right-click the local user and select **Delete**.
3. In the confirmation dialog, select **Yes** to delete the user from the zone. To prevent the confirmation dialog from displaying in the future, select **Do not warn me again**.
4. In the next confirmation dialog, select **Yes**.

   The user is removed from zone, and is no longer controlled through Access Manager. However, the user profile remains in /etc/passwd on local computers.

To remove a user profile for a local user from /etc/passwd

1. In Access Manager, expand UNIX Data for the zone or computer containing the local user that you want to remove.
2. In the Local Users details pane, right-click the local user and select **Change Profile State**.
3. Perform one of the following procedures:
   - Right-click the local user, select **Change Profile State**, then select **Remove from /etc/passwd**.
   - Right-click the local user, select **Zone Profile**, change the value of the **State** field to **Remove from /etc/passwd**, and click **OK.**

At the next local account refresh interval, the local user's profile is removed from /etc/passwd.

Delegating control of local user management tasks

You can use the Zone Delegation Wizard and Computer Delegation Wizard as described in the *Planning and Deployment Guide* to delegate control of local user management tasks.

Creating and managing local user passwords

After you create local user profiles as described in the preceding sections, you still need to assign a password to each user. You can create local user passwords in one of these ways:

- By creating a shell script to execute the passwd command on each local computer, giving each local user the password that you specify in the script. The shell script can be executed manually, or by enabling adclient.local.account.notification.cli to run the script automatically when local accounts are refreshed. This is the least secure way to assign passwords to local users, because the same password is assigned to each user when the script runs. After the script runs, you must change passwords locally so that each password is unique.

  This guide does not include detailed instructions for implementing this method of creating local user passwords.

- If your environment contains a third-party password management product, you can create a shell script that executes on each local computer, giving each local user a random password. The shell script can include a section that submits the passwords to the password management product for storage and maintenance. The shell script can be executed manually, or by enabling adclient.local.account.notification.cli to run the script automatically when local accounts are refreshed.

  A sample shell script, handle_local_accts.sh, is provided in /usr/share/centrifydc/samples/localacctmgmt for you to use as a reference when you create your own shell script. Typically, the shell script that you create should perform the following tasks:

  - Assign a random password to newly provisioned local users, and to local users whose accounts were recently unlocked (that is, re-enabled after having been disabled).
  - Optionally create a home directory for each new local user.

- Provide the user account information, including the generated passwords, to a third-party password management solution.

  For syntax details about the notification CLI, execute the sample script with the -h option:

  handle_local_accts.sh -h

- If your environment does not contain a third-party password management product and you want to create and maintain unique passwords for each local user, you can use Server Suite to manage local user passwords.

  Using Server Suite to manage local user passwords involves these tasks:

  - Register for Server Suite.
  - Download the Centrify Agent for Linux software package.
  - On each UNIX and Linux computer where you will assign passwords to local users, execute the cenroll command to register the computer as a managed resource.
  - Create a shell script that executes on each local computer, giving each local user a random password. The shell script should include commands to manage generated passwords. The agent package includes a sample shell script that you can use as a reference when you create your own shell script.
  - Enable the adclient.local.account.notification.cli configuration parameter to run the shell script automatically when local accounts are refreshed.

Setting Runtime Variables in User Profiles

Access Manager maintains a set of predefined runtime variables that you can use in place of specific values in Active Directory user profiles and local user profiles. Using the variables simplifies the process of defining profile attributes. The Centrify Agent for *NIX resolves the runtime variables defined in a profile with appropriate values when a computer joins a domain and zone.

The predefined runtime variables you can use in profiles are:

%	The domain to which the computer is joined.
%	The root home directory. By default, this directory is /home on most Linux and UNIX computers. For Mac OS X computers, the default home directory is /Users. On Solaris computers, the default home directory is /export/home).
%	The host name of the joined computer.
%	The default login shell for the user. By default, the shell is /bin/bash on most Linux and UNIX computers. On Solaris and HP computers, the default shell is /bin/sh. On AIX computers, the default shell is /usr/bin/ksh.
%	The Active Directory site of the joined computer.
%	The user's UNIX login name. **Note:** This variable is supported only for Active Directory users. It is not supported for local users.
%	The zone to which the computer is joined.

You can use these predefined runtime variables or custom variables at any point in the zone hierarchy, including a parent zone, a child zone, or on individual computers. At runtime, the adclient process resolves the variables based on how the following configuration parameters are set and where the variables are defined in the zone hierarchy:

- nss.runtime.defaultvalue.var.variableName

  These parameters — one for each predefined variable — defines the default value for each parameter as shown in the table. These are the values are used if the variable is not explicitly defined in the zone or by the nss.runtime.var.variableName parameter in the configuration file. For example:

  nss.runtime.defaultvalue.var.home: /home

  nss.runtime.defaultvalue.var.shell: /bin/bash

- nss.runtime.var.variableName

  These parameters allow you to specify a specific value for any of the predefined variables in the configuration file. The value in the configuration file is essentially a computerspecific override because it applies only to the computer on which it is defined and overrides any other setting for the variable, including the default value, or a specific value in a zone Properties page. For example:

  nss.runtime.var.home: /Users

  nss.runtime.var.shell: /bin/sh

To override the default definition for any predefined variable in a zone, you can simply add a variable with the same name to the zone by using the zone Properties page or by using ADEdit. Zone variables and zone variable definitions are inherited down the profile tree, which means that a variable could have one definition at the top of the tree and a different definition at the bottom. The value that is applied depends at which level of the zone hierarchy a computer joins the domain.

To define values for predefined variables in a parent or child zone:

1. Open Access Manager.
2. Expand Zones and any parent or child zones required to select the zone name in which you want to override a profile attribute.

For example, if you want to override the default login shell in the child zone that only AIX computers join, you might expand Child Zones to view and select the IBM AIX Only zone.

3. Select the zone, right-click, then click **Properties**.
4. Click the **Variables** tab, then click **Add**.
5. Type the name of the predefined variable and the custom value you want to use, then click **OK** to save the variable definition.

   For example, type shell and set the value to /usr/bin/ksh to modify the default shell definition.
6. Click **OK** to close the zone properties.

Using Active Directory attributes as variables

You can also use any Active Directory user attributes as variables by specifying the attribute name in the following format:

%

For example, if you want to populate the GECOS field of a user's zone profile with the information from the user's department attribute, you could specify the variable as follows:

%

By default, only a subset of common user object attributes can be retrieved and resolved by the adclient process. The default set of attributes you can use in a user profile are:

- mail
- department
- description
- mobile
- title
- telephoneNumber

The most common format for the GECOS field in a user profile contains the user's full name, building number, and office phone number separated by commas. Depending on the operating system and desktop manager you are using, the information from the GECOS field might also be used to display the user name when logging on. If you specify an attribute for the GECOS field that includes a comma, you might see the first part of the attribute treated as the user's full name and displayed in the login screen. For example, if you are using the department attribute in the GECOS field and the attribute is defined as "Cendura, San Francisco, Engineering, 25th floor, office 202", you might see Cendura listed as a user on the login screen.

Using other attributes in a profile

The default user attributes are recognized by adclient without requiring any modification to the managed computer or Active Directory. If you want to use any other attribute, whether it is a standard schema attribute like company or homePhone or a custom attribute that you have added to the Active Directory schema such as supervisorId, you must add an entry for the attribute to the adclient.custom.attributes.user parameter in centrifydc.conf file, then restart adclient and flush the cache.

For example, you might add the following attributes to the centrifydc.conf file:

adclient.custom.attributes.user: company supervisorId

After modifying the file, you would run the following commands to restart the agent and clear the cache:

/usr/share/centrifydc/bin/centrifydcrestart

adflush -f

For more information about defining custom attributes, see the *Configuration and Tuning Reference Guide*.

Attributes for users in a forest with a one-way trust

Keep in mind when using attribute variables that if you add users to a zone from a oneway trusted forest, the Centrify Agent will only be able to retrieve values for the userPrincipalName and samAccountName attributes. Therefore, at runtime, when the adclient process resolves variable definitions, fields that contain any other variables will be blank for a user from a one-way trusted forest.

Adding custom variables to a zone

You can also create your own variables at any point in the zone hierarchy, including a parent zone, a child zone, or on individual computers. You can add custom variable names and values in exactly the same way you define new values for the predefined runtime variables, except that you type a custom variable name and value.

Importing Local Account Profiles

Most organizations have at least some local user and group profiles that must be migrated to Active Directory. Access Manager provides an Import from UNIX wizard that enables you to import user and group profiles from local /etc/passwd and /etc/group files or from NIS servers and domains.

If you are not migrating any local account profiles, you can skip this section. However, if you have a large or complex user population to migrate, you should use the information in this section along with the *Planning and Deployment Guide* for a more complete view of the migration process and analysis requirement.

Collecting account information

Before using the Import from UNIX wizard, you should do the following to prepare:

- Identify each source of user information and analyze the information to determine your zone requirements.
- Run appropriate commands—such as getent passwd, getent group, or niscat—to export user and group information and save it in properly-formatted text files.

  Copy the text files to a location that is accessible from the Windows network. If you want to import information directly from NIS maps instead of text files, you should verify that you can access NIS servers and domains from the Windows network.
- Review the text files entries to remove account entries that don't need to be mapped to Active Directory accounts.

  You can automatically exclude system accounts with UID or GID values from 0 to 99 during the import process, but you might want to remove other accounts prior to the import. As part of the review process, determine which entries should map to existing Active Directory accounts or which entries require new Active Directory objects.

Using variables when importing UNIX users

When you import UNIX user accounts, you can use a variable in the GECOS field so that Active Directory will automatically populate that information. The variable you can use is as follows:

%

For example: In your /etc/passwd file, you have the following information for a user:

ron:x:10061:10061:%:/home/ron:/bin/bash

After you import the user with the UNIX import user wizard, the following user is in the pending import area:

UID: 10061

Login name: ron

Shell: /bin/bash

Home directory: /home/ron

Primary Group: 10061

GECOS: %

After you map this pending user to a user account in Active Directory, the % text is converted to the user's display name at runtime by adclient. When you view the user profile in Active Directory or Access Manager, you'll see the % text in the GECOS field; when you query the user from a UNIX computer using something such as adquery or getpwent, you'll see the actual user display name in the GECOS field.

Using the Import from UNIX wizard

After you have created text files with user and group information or verified access to a NIS server and domain, you are ready to perform the first step in the migration process using the Import from UNIX wizard.

To import user and group information:

1. Open Access Manager.

2. Expand Zones and any parent or child zones required to select the zone name into which you want to import users and groups.
3. Select UNIX Data, right-click, then click **Import from UNIX**.
4. Select the import source, then click **Next**.
    - If you select Network Information Service (NIS), type the name of the NIS domain and the host name of the NIS server. The NIS domain and server must be accessible from the Windows network for information to be imported successfully.
    - If you select UNIX configuration files, click **Browse** to locate the text files to import.

    If you selected **Network Information Service** or **UNIX configuration files** in Step 4, go to Step 5.
5. Select the import options you want to use, then click **Next**.

    The import options displayed depend on the import source. For example, if you selected UNIX configuration files and specified a text file containing user accounts and a text file containing group accounts, the import options are:
    - **Include system accounts** to include accounts with UID or GID values from 0 to 99.

      On most computers, accounts with UID or GID values from 0 to 99 are reserved for accounts, such as root, tty, and ftp that you don't need to import or manage using Active Directory. Select the **Include system accounts** option to include these accounts. This option is only displayed if importing from UNIX configuration files.
    - **Automatically shorten the UNIX name to 8 characters** to limit UNIX user and group names to a maximum of 8 characters.

      On some computers, user and group names cannot be longer than 8 characters. If you are importing users and groups that might need access to computers that do not support names longer than 8 characters, you can select **Automatically shorten the Unix name to 8 characters** to automatically truncate the names imported.

      If you are importing from NIS, you can choose to import users, groups, or both.
6. Select a location for storing pending import data, then click **Next**.

    For example, to store pending data for the current zone in an XML file, select **Store in XML file** and specify the location for the file. If the file does not already exist in the default location, you are prompted to create it. To select another location for the XML file, click **Browse**.
7. Review the summary of information to be imported, and select the **Check data conflicts while importing** option if you want to check for conflicts and potential matching candidates during the import process, then click **Finish**.

    If you are importing a large number of users or groups, selecting **Check data conflicts while importing** can cause the import process to take some time to complete. If you don't select this option, you must check the status of users or groups after importing.

After you close the Import from UNIX wizard, users and groups are placed in Active Directory or in an XML file with the status of Pending Import. You must then decide how each user and group should be mapped to accounts in Active Directory.

Checking for conflicts and matching candidates

To move a user or group from Pending Import to a UNIX profile attached to an Active Directory user or group, you must first check for potential conflicts and for potential matching user or group candidates in Active Directory. If you selected the **Check data conflicts while importing** option in the Import from UNIX wizard, you have already completed this step and can continue to Mapping UNIX profiles to Active Directory accounts.

To check the status of pending information:

1. Open Access Manager.
2. Expand Zones and any parent or child zones required to select the zone name into which you imported users and groups.
3. Expand UNIX Data, then expand Groups and Users to see the Pending Import nodes.

    For example, if you imported information for the "Finance" zone, open that zone, expand UNIX Data, then expand Groups and Users.
4. Select Pending Import to display the list of users or groups to be imported.

For example:

Pending import
